PDF Navigation Tips

Find

To find a word or term in the PDF:

1. Select Find under the Edit menu or use the keyboard shortcut: CTRL + F for PC; COMMAND + F for Mac.
2. Type a word or term in the Find box. To specify Whole words only or Case-sensitive, use the drop-down arrow to the right of the Find box and toggle these criteria on or off.

The found term will be highlighted in the text. To go to other occurrences of the term, use the previous and next buttons that appear beside the Find box.

Advanced Search

Use the drop-down arrow to the right of the Find box and select Open Full Search. Additional search options are available by selecting Show More Options at the bottom of the pane. Options in the advanced search window include matching the exact word or phrase, matching only some of the words, and stemming (see below).

> **Stemming** finds words that contain part (the stem) of a specified search word. For example, a search for the word *opening* would find instances of *open, opened, opens*, and *openly.* Wildcard characters (* or ?) are not permitted in stemming searches. Stemming isn't available if either Whole words only or Case-sensitive is selected.

Links

Links to other sections of the document are colored red. When you click on a link and are directed to another page, use the following keyboard shortcut to return to the original page: ALT + <left arrow> for PC; COMMAND + <left arrow> for Mac.

A Guide to Using the *NFPA® 1 Fire Code Handbook*

This eighth edition of the *NFPA 1 Fire Code Handbook* contains the complete text of the 2018 edition of NFPA® 1, *Fire Code,* and the nonmandatory annex material. Commentary is provided in this handbook to explain the reasoning behind the *Code*'s requirements.

176 Chapter 10 • General Safety Requirements

Exhibit 10.7

Stair sign placement.

Exhibit 10.8

Stairway identification sign with tactile floor level designator.

Exhibit 10.7 illustrates the placement required to ensure that the sign is readily visible, whether the door leaf is open or closed.

The indication of the direction to the level of exit discharge can be extremely useful to occupants of a building, especially if the occupants are below the level of exit discharge. The natural tendency of occupants is to attempt egress by traveling downward in a stair; this is counterproductive where the exit discharge is located on an upper level. Also, many buildings have multiple levels of entrance, which create confusion with respect to travel direction in a given stair.

The requirements of 10.11.3 are not exempted for existing buildings, because it is feasible and cost effective to install signs providing the required information. Because stair enclosures are usually not as aesthetically well finished as occupied portions of a building, the requirement for the signage (other than for the tactile floor level designator) is often met by stenciling the information directly onto the walls.

The provision of 10.11.3.1.13 was revised for the 2009 edition of the *Code*. In prior editions, roof access or lack of roof access was required to be designated by a sign. In many cases, roof access was provided for emergency responders only, and a sign reading "Roof Access" was misleading to building occupants. The current provision requires that only the lack of roof access be designated by a sign.

The provision of 10.11.3.1.7 was new to the 2015 edition of the *Code*. It replaced a provision that required the signage to be located approximately 60 in. (1525 mm) above the floor landing. The *Code* user now has a definitive height range for placement of the sign above the floor landing. Other criteria were moved or combined for clarification.

The provision of 10.11.3.1.16 is needed so that signs installed prior to 2009, when subitems (L) through (O) were added, are not unfairly reclassified as noncompliant.

The provision of 10.11.3.1.8 was revised for the 2018 edition of the *Code* to add the words "from within the stair enclosure," because misinterpretations were being made that occupants must be able to see the sign before entering the exit stair enclosure.

Exhibit 10.8 shows a stairway identification sign with the information required by 10.11.3.1. The element reading *Level 2* was provided for compliance with 10.11.3.1.2, which requires that the signage indicate the floor level, and for compliance with 10.11.3.1.10, which requires that the floor level designation also be tactile in accordance with ICC/ANSI A117.1, *Accessible and Usable Buildings and Facilities*. The minimum 5 in. (125 mm) high floor level number — the large *2* in this case — that was provided for compliance with 10.11.3.1.14 cannot serve as the tactile floor level designation because ICC/ANSI A117.1 limits raised characters to being not more than 2 in. (51 mm) in height. Further, the floor level designation is provided in braille below the tactile element, because ICC/ANSI A117.1 requires that raised letters be duplicated in braille.

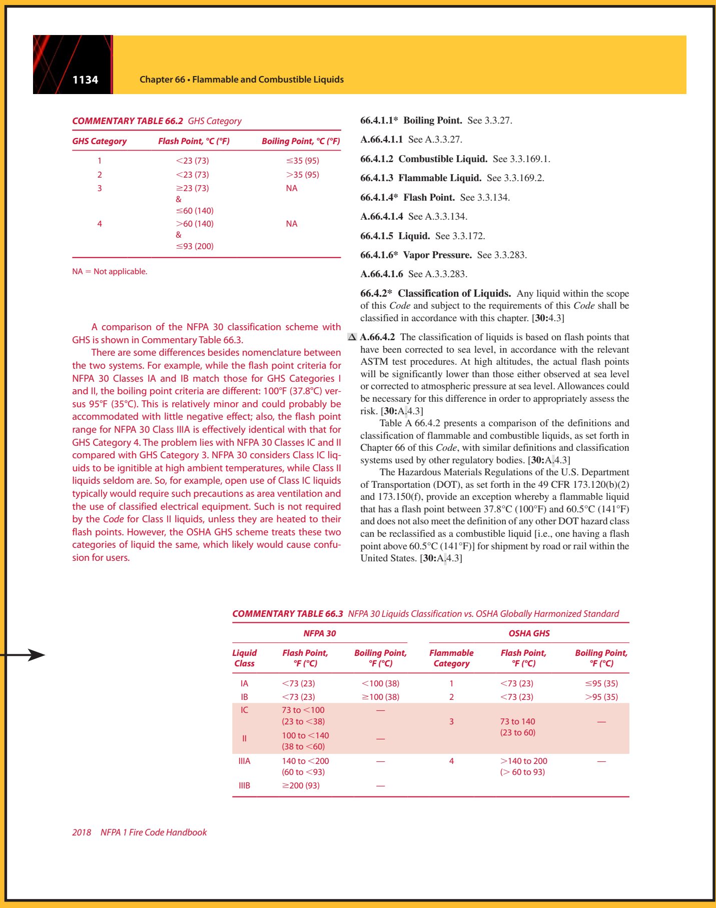
Δ **10.11.3.2** Wherever an enclosed stair requires travel in an upward direction to reach the level of exit discharge, special signs with directional indicators showing the direction to the level of exit discharge shall be provided at each floor level landing from which upward direction of travel is required, unless otherwise provided in 10.11.3.2.1 and 10.11.3.2.2, and both of the following also shall apply:

(1) Such signage shall comply with 14.14.8.1 and 14.14.8.2.
(2) Such signage shall be visible when the door leaf is in the open or closed position.

[***101:***7.2.2.5.4.2]

2018 NFPA 1 Fire Code Handbook

Commentary exhibits, including both illustrations and photographs, are set off in red frames.



1134 Chapter 66 • Flammable and Combustible Liquids

COMMENTARY TABLE 66.2 *GHS Category*

GHS Category	Flash Point, °C (°F)	Boiling Point, °C (°F)
1	<23 (73)	≤35 (95)
2	<23 (73)	>35 (95)
3	≥23 (73) & ≤60 (140)	NA
4	>60 (140) & ≤93 (200)	NA

NA = Not applicable.

A comparison of the NFPA 30 classification scheme with GHS is shown in Commentary Table 66.3.

There are some differences besides nomenclature between the two systems. For example, while the flash point criteria for NFPA 30 Classes IA and IB match those for GHS Categories I and II, the boiling point criteria are different: 100°F (37.8°C) versus 95°F (35°C). This is relatively minor and could probably be accommodated with little negative effect; also, the flash point range for NFPA 30 Class IIIA is effectively identical with that for GHS Category 4. The problem lies with NFPA 30 Classes IC and II compared with GHS Category 3. NFPA 30 considers Class IC liquids to be ignitible at high ambient temperatures, while Class II liquids seldom are. So, for example, open use of Class IC liquids typically would require such precautions as area ventilation and the use of classified electrical equipment. Such is not required by the *Code* for Class II liquids, unless they are heated to their flash points. However, the OSHA GHS scheme treats these two categories of liquid the same, which likely would cause confusion for users.

66.4.1.1* Boiling Point. See 3.3.27.

A.66.4.1.1 See A.3.3.27.

66.4.1.2 Combustible Liquid. See 3.3.169.1.

66.4.1.3 Flammable Liquid. See 3.3.169.2.

66.4.1.4* Flash Point. See 3.3.134.

A.66.4.1.4 See A.3.3.134.

66.4.1.5 Liquid. See 3.3.172.

66.4.1.6* Vapor Pressure. See 3.3.283.

A.66.4.1.6 See A.3.3.283.

66.4.2* Classification of Liquids. Any liquid within the scope of this *Code* and subject to the requirements of this *Code* shall be classified in accordance with this chapter. [**30:**4.3]

Δ **A.66.4.2** The classification of liquids is based on flash points that have been corrected to sea level, in accordance with the relevant ASTM test procedures. At high altitudes, the actual flash points will be significantly lower than those either observed at sea level or corrected to atmospheric pressure at sea level. Allowances could be necessary for this difference in order to appropriately assess the risk. [**30:**A.4.3]

Table A 66.4.2 presents a comparison of the definitions and classification of flammable and combustible liquids, as set forth in Chapter 66 of this *Code*, with similar definitions and classification systems used by other regulatory bodies. [**30:**A.4.3]

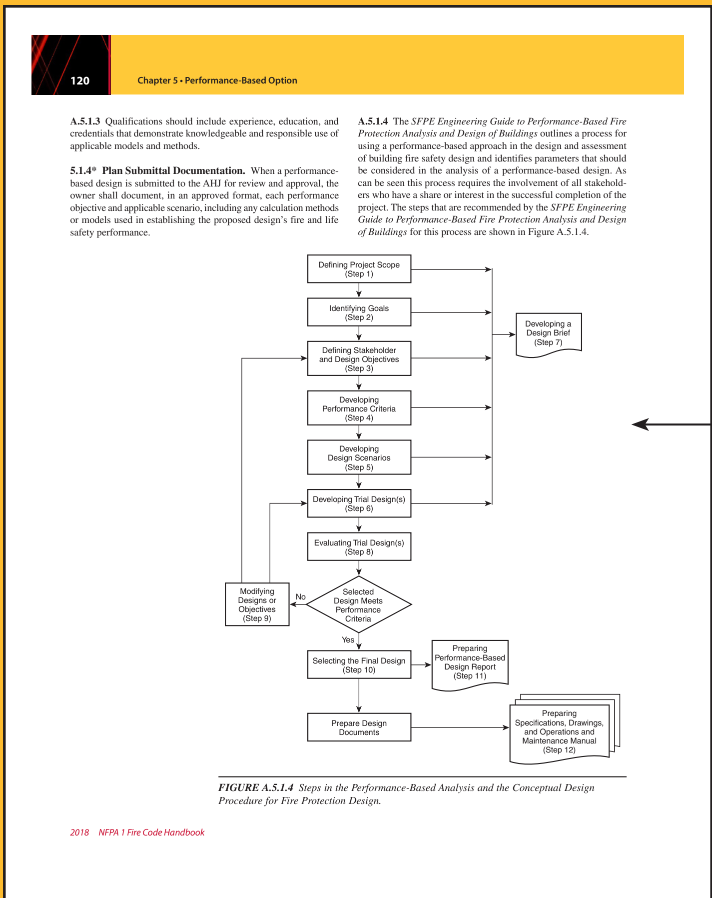
The Hazardous Materials Regulations of the U.S. Department of Transportation (DOT), as set forth in the 49 CFR 173.120(b)(2) and 173.150(f), provide an exception whereby a flammable liquid that has a flash point between 37.8°C (100°F) and 60.5°C (141°F) and does not also meet the definition of any other DOT hazard class can be reclassified as a combustible liquid [i.e., one having a flash point above 60.5°C (141°F)] for shipment by road or rail within the United States. [**30:**A.4.3]

COMMENTARY TABLE 66.3 *NFPA 30 Liquids Classification vs. OSHA Globally Harmonized Standard*

NFPA 30			OSHA GHS		
Liquid Class	Flash Point, °F (°C)	Boiling Point, °F (°C)	Flammable Category	Flash Point, °F (°C)	Boiling Point, °F (°C)
IA	<73 (23)	<100 (38)	1	<73 (23)	≤95 (35)
IB	<73 (23)	≥100 (38)	2	<73 (23)	>95 (35)
IC	73 to <100 (23 to <38)	—	3	73 to 140 (23 to 60)	—
II	100 to <140 (38 to <60)	—			
IIIA	140 to <200 (60 to <93)	—	4	>140 to 200 (> 60 to 93)	—
IIIB	≥200 (93)	—			

2018 NFPA 1 Fire Code Handbook

Commentary tables are printed in red to distinguish them from the *Code* tables.



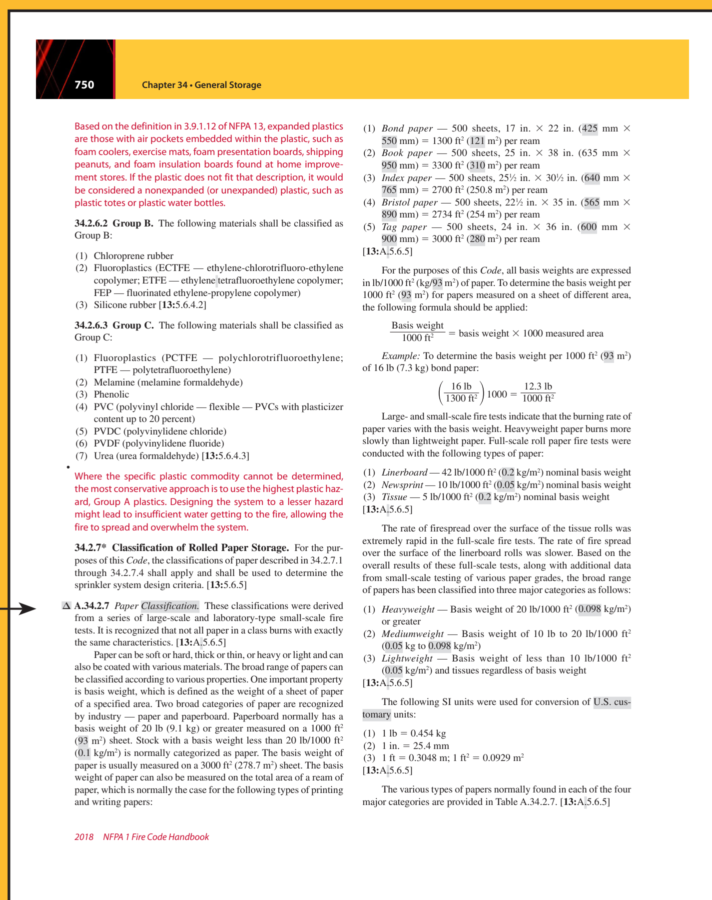
A.5.1.3 Qualifications should include experience, education, and credentials that demonstrate knowledgeable and responsible use of applicable models and methods.

5.1.4* Plan Submittal Documentation. When a performance-based design is submitted to the AHJ for review and approval, the owner shall document, in an approved format, each performance objective and applicable scenario, including any calculation methods or models used in establishing the proposed design's fire and life safety performance.

A.5.1.4 The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* outlines a process for using a performance-based approach in the design and assessment of building fire safety design and identifies parameters that should be considered in the analysis of a performance-based design. As can be seen this process requires the involvement of all stakeholders who have a share or interest in the successful completion of the project. The steps that are recommended by the *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* for this process are shown in Figure A.5.1.4.

FIGURE A.5.1.4 Steps in the Performance-Based Analysis and the Conceptual Design Procedure for Fire Protection Design.

Code figures and tables are printed in black.



Based on the definition in 3.9.1.12 of NFPA 13, expanded plastics are those with air pockets embedded within the plastic, such as foam coolers, exercise mats, foam presentation boards, shipping peanuts, and foam insulation boards found at home improvement stores. If the plastic does not fit that description, it would be considered a nonexpanded (or unexpanded) plastic, such as plastic totes or plastic water bottles.

34.2.6.2 Group B. The following materials shall be classified as Group B:

(1) Chloroprene rubber
(2) Fluoroplastics (ECTFE — ethylene-chlorotrifluoro-ethylene copolymer; ETFE — ethylene tetrafluoroethylene copolymer; FEP — fluorinated ethylene-propylene copolymer)
(3) Silicone rubber [**13:**5.6.4.2]

34.2.6.3 Group C. The following materials shall be classified as Group C:

(1) Fluoroplastics (PCTFE — polychlorotrifluoroethylene; PTFE — polytetrafluoroethylene)
(2) Melamine (melamine formaldehyde)
(3) Phenolic
(4) PVC (polyvinyl chloride — flexible — PVCs with plasticizer content up to 20 percent)
(5) PVDC (polyvinylidene chloride)
(6) PVDF (polyvinylidene fluoride)
(7) Urea (urea formaldehyde) [**13:**5.6.4.3]

Where the specific plastic commodity cannot be determined, the most conservative approach is to use the highest plastic hazard, Group A plastics. Designing the system to a lesser hazard might lead to insufficient water getting to the fire, allowing the fire to spread and overwhelm the system.

34.2.7* Classification of Rolled Paper Storage. For the purposes of this *Code*, the classifications of paper described in 34.2.7.1 through 34.2.7.4 shall apply and shall be used to determine the sprinkler system design criteria. [**13:**5.6.5]

Δ **A.34.2.7** *Paper Classification.* These classifications were derived from a series of large-scale and laboratory-type small-scale fire tests. It is recognized that not all paper in a class burns with exactly the same characteristics. [**13:**A.5.6.5]

Paper can be soft or hard, thick or thin, or heavy or light and can also be coated with various materials. The broad range of papers can be classified according to various properties. One important property is basis weight, which is defined as the weight of a sheet of paper of a specified area. Two broad categories of paper are recognized by industry — paper and paperboard. Paperboard normally has a basis weight of 20 lb (9.1 kg) or greater measured on a 1000 ft² (93 m²) sheet. Stock with a basis weight less than 20 lb/1000 ft² (0.1 kg/m²) is normally categorized as paper. The basis weight of paper is usually measured on a 3000 ft² (278.7 m²) sheet. The basis weight of paper can also be measured on the total area of a ream of paper, which is normally the case for the following types of printing and writing papers:

(1) *Bond paper* — 500 sheets, 17 in. × 22 in. (425 mm × 550 mm) = 1300 ft² (121 m²) per ream
(2) *Book paper* — 500 sheets, 25 in. × 38 in. (635 mm × 950 mm) = 3300 ft² (310 m²) per ream
(3) *Index paper* — 500 sheets, 25½ in. × 30½ in. (640 mm × 765 mm) = 2700 ft² (250.8 m²) per ream
(4) *Bristol paper* — 500 sheets, 22½ in. × 35 in. (565 mm × 890 mm) = 2734 ft² (254 m²) per ream
(5) *Tag paper* — 500 sheets, 24 in. × 36 in. (600 mm × 900 mm) = 3000 ft² (280 m²) per ream

[**13:**A.5.6.5]

For the purposes of this *Code*, all basis weights are expressed in lb/1000 ft² (kg/93 m²) of paper. To determine the basis weight per 1000 ft² (93 m²) for papers measured on a sheet of different area, the following formula should be applied:

$$\frac{\text{Basis weight}}{1000\ \text{ft}^2} = \text{basis weight} \times 1000\ \text{measured area}$$

Example: To determine the basis weight per 1000 ft² (93 m²) of 16 lb (7.3 kg) bond paper:

$$\left(\frac{16\ \text{lb}}{1300\ \text{ft}^2}\right)1000 = \frac{12.3\ \text{lb}}{1000\ \text{ft}^2}$$

Large- and small-scale fire tests indicate that the burning rate of paper varies with the basis weight. Heavyweight paper burns more slowly than lightweight paper. Full-scale roll paper fire tests were conducted with the following types of paper:

(1) *Linerboard* — 42 lb/1000 ft² (0.2 kg/m²) nominal basis weight
(2) *Newsprint* — 10 lb/1000 ft² (0.05 kg/m²) nominal basis weight
(3) *Tissue* — 5 lb/1000 ft² (0.2 kg/m²) nominal basis weight

[**13:**A.5.6.5]

The rate of firespread over the surface of the tissue rolls was extremely rapid in the full-scale fire tests. The rate of fire spread over the surface of the linerboard rolls was slower. Based on the overall results of these full-scale tests, along with additional data from small-scale testing of various paper grades, the broad range of papers has been classified into three major categories as follows:

(1) *Heavyweight* — Basis weight of 20 lb/1000 ft² (0.098 kg/m²) or greater
(2) *Mediumweight* — Basis weight of 10 lb to 20 lb/1000 ft² (0.05 kg to 0.098 kg/m²)
(3) *Lightweight* — Basis weight of less than 10 lb/1000 ft² (0.05 kg/m²) and tissues regardless of basis weight

[**13:**A.5.6.5]

The following SI units were used for conversion of U.S. customary units:

(1) 1 lb = 0.454 kg
(2) 1 in. = 25.4 mm
(3) 1 ft = 0.3048 m; 1 ft² = 0.0929 m²

[**13:**A.5.6.5]

The various types of papers normally found in each of the four major categories are provided in Table A.34.2.7. [**13:**A.5.6.5]

Specific icons and shading within *Code* text indicate where text has changed from the previous edition.

A Guide to Using the *NFPA® 1 Fire Code Handbook*

This eighth edition of the *NFPA 1 Fire Code Handbook* contains the complete text of the 2018 edition of NFPA® 1, *Fire Code,* and the nonmandatory annex material. Commentary is provided in this handbook to explain the reasoning behind the *Code*'s requirements.

off the worker's view of the exterior doors. The placement of temporary directional signs that point to exits throughout the building is important, as well as the rearrangement of such signs as the building interior changes during construction.

16.1.4 Fire department access roads provided in accordance with 18.2.3 shall be provided at the start of a project and shall be maintained throughout construction.

Fire department access roads are required throughout the construction process. The minimum 20 ft (6.1 m) of required clear width must be maintained at all times for access to the building and the building site. Maintenance of fire department access roads should be a key component of the fire protection plan (where required; see 16.1.2) and fire safety program (see 16.3.1).

Large construction sites might require two or more fire department access roads to be provided for access to within 150 ft (46 m) of all exterior first floor walls. (See 7.5.5.7 of NFPA 241.)

16.1.5 Permanent fire department access road markings shall not be required until the building is complete or occupied for use.

Signs marking the fire department access road might be required, in accordance with 18.2.3.5. Permanent signs are not required until after construction is completed. Temporary signs might be required to ensure that fire department access roads are kept clear during construction, alteration, or demolition operations. (Also see 7.5.5.6 of NFPA 241.)

16.2 Processes and Hazards

This section covers specific operations that represent likely ignition sources and lists specific combustible, flammable, or explosive materials that are generated or used in the course of construction. If not handled correctly, these materials can cause a disastrous situation.

16.2.1 Temporary Heating Equipment.

16.2.1.1* Temporary heating equipment shall be listed. [**241:**5.2.1]

A.16.2.1.1 Examples of relevant test standards include, but are not limited to, the following:

(1) UL 647, *Standard for Unvented Kerosene-Fired Room Heaters and Portable Heaters*
(2) ANSI/UL 1278, *Standard for Moveable and Wall- or Ceiling-Hung Electric Room Heaters*

[**241:**A.5.2.1]

16.2.1.2 Temporary heating equipment shall be installed in accordance with its listing, including clearance to combustible material, equipment, or construction. [**241:**5.2.2]

16.2.1.3 Temporary heating equipment shall be installed, used, and maintained in accordance with the manufacturer's instructions, except as otherwise provided in 16.2.1.4. [**241:**5.2.3]

16.2.1.4 Where instructions, as addressed in 16.2.1.3, are not available, temporary heating equipment shall be used in accordance with recognized safe practices. [**241:**5.2.4]

16.2.1.5 Temporary heating equipment shall be situated so that it is secured. [**241:**5.2.5]

Paragraph 16.2.1.5 requires temporary heating devices to be secured to prevent them from being tipped over or accidentally moved. Any associated tanks should also be secured. Heaters that tip over or are easily moved can come into contact with combustible materials or spilled fuel. Special care should be taken with the movement of cylinders and the connection of hoses to heating appliances. (See Chapter 69 for requirements pertaining to liquefied petroleum gas and liquefied natural gas.)

16.2.1.6 Only personnel familiar with the operation of the temporary heating equipment shall be allowed to operate such devices. [**241:**5.2.6]

16.2.1.7* Temporary heating equipment, where utilized, shall be monitored for safe operation and maintained by properly trained personnel. [**241:**5.2.7]

A.16.2.1.7 Misuse of temporary heating devices has resulted in numerous fires and millions of dollars in property loss. Temporary heating equipment, while operating, should be visually inspected every hour to ensure that combustibles have not blown or fallen over near the temporary heating device. During windy periods, it might be necessary to reduce the interval between inspections. Any object near the temporary heating device that is hot to the touch should be moved, or the temporary heating device should be relocated. The visual inspection also should ensure that the appliance is operating properly. Any appliance that is not operating properly should be turned off until repairs have been made. [**241:**A.5.2.7]

Where plastic films are used for temporary enclosures, they must comply with Test Method 2 of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*. Plastic film used for temporary enclosure of buildings should be adequately fastened to ensure that it does not rip off and get blown against a heater or other heat-producing device. Storage of combustible construction materials should be kept a safe distance from any heating appliance.

16.2.1.8 Temporary heating equipment and devices noted to be damaged or considered to be a potential safety hazard shall not be used. [**241:**5.2.8]

16.2.1.9 Temporary heating equipment using exposed radiant heating wires shall not be used. [**241:**5.2.9]

16.2.1.10 Temporary electrical heating equipment shall be equipped with tip-over protection and overheat cutoffs. [**241:**5.2.10]

Δ **16.2.1.11** Chimney or vent connectors, where required from direct-fired heaters, shall be maintained at least 18 in. (460 mm) from combustibles and shall be installed in accordance with NFPA 211. [**241:**5.2.11]

Mandatory *Code* text is printed in black.

Nonmandatory Annex A material is printed in black and follows the *Code* text it references.

Compliance with this *Code* can be achieved in more than one way, as indicated in 1.4.4. A building either complies with the *Code's* prescriptive requirements or achieves equivalency through documentation of AHJ-approved alternatives or modifications. If an alternate approach to compliance is implemented, and the AHJ has judged that the alternative provides equivalency, the building is considered *Code* compliant. Compliance achieved by means of equivalency differs from a waiver that permits continued use of a noncompliant building, which should never be permitted. Documentation of equivalencies should be maintained by both the building owner and the AHJ for the life of the building. In addition, such documentation should specify whether changes to the building, such as removal of an otherwise nonrequired smoke detection system, will render the equivalency void.

1.4.5 Each application for an equivalent, alternative, or modified fire protection feature shall be filed with the AHJ and shall be accompanied by such evidence, letters, statements, results of tests, or other supporting information as required to justify the request. The AHJ shall keep a record of actions on such applications, and a signed copy of the AHJ's decision shall be provided for the applicant.

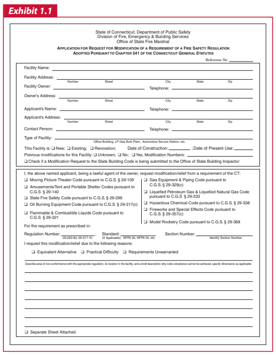
An applicant filing a request for an equivalency, alternative, or modification should be provided with a form by the AHJ. Exhibit 1.1 shows the first page of one such form for requesting a modification to a *Code* requirement. The form ensures that each applicant provides the AHJ with the appropriate information in an acceptable manner.

The AHJ should also require information, as necessary, to assist in determining whether the alternative level of protection is equivalent to the intent of this *Code*. The information required might include testing data, listing or labeling reports, engineering reports, and other supporting details that allow the AHJ to make an informed decision. The information must be maintained in an appropriate file so that a record on which the decision was based is available. This information is also important if the applicant files an appeal on the AHJ's decision to the Board of Appeals, as outlined in Section 1.10.

Δ **1.4.6 Approval.** The AHJ shall approve such equivalent, alternative, or modified construction systems, materials, or methods of design when it is substantiated that the standards of this *Code* are at least equaled. If, in the opinion of the AHJ, the standards of this *Code* are not equaled by the alternative requested, approval for permanent work shall be refused. Consideration shall be given to test or prototype installations.

The AHJ has the discretionary authority to approve or refuse an equivalency, alternatives, or modifications. However, that approval or refusal needs to be based on the ability of the applicant to justify that the equivalent level of life safety and protection has been provided.

Exhibit 1.1



Sample application form for an equivalency, alteration, or modification. (Courtesy of State of Connecticut, Department of Public Safety)

1.4.7 Tests.

1.4.7.1 Whenever evidence of compliance with the requirements of this *Code* is insufficient or evidence that any material or method of construction does not conform to the requirements of this *Code*, or to substantiate claims for alternative construction systems, materials, or methods of construction, the AHJ shall be permitted to require tests for proof of compliance to be made by an approved agency at the expense of the owner or his/her agent.

1.4.7.2 Test methods shall be as specified by this *Code* for the material in question. If appropriate test methods are not specified in this *Code*, the AHJ is authorized to accept an applicable test procedure from another recognized source.

The question of "What is an appropriate test?" is one that needs careful consideration by the AHJ. If an incorrect type of test is submitted to the AHJ or if the AHJ specifies an incorrect test method, the code specified level of safety may not be achieved. If there is a question about the appropriate test method to be used, the AHJ should consult subject experts and testing laboratories with expertise in the area.

1.4.7.3 Copies of the results of all such tests shall be retained in accordance with Section 1.11.

Commentary is printed in red to distinguish it from *Code* text.

948 Chapter 50 • Commercial Cooking

Simultaneous operation provides for common actuation of all fire suppression systems protecting the hazards in the single hazard area. The goal of this requirement is to cover all the components of the cooking operation to suppress a fire.

Arguments have been made against the simultaneous operation approach, especially with respect to chemical systems, which provide a limited supply of extinguishing agent. Some believe it is safer to discharge the chemical only in the areas where the fire is burning. If the fire then spreads to other areas, some remaining chemical is still available. When chemical is prematurely discharged, dry chemical tends to be carried out of the system by fan action, while wet chemical tends to drain out of the system; therefore, if a fire subsequently spreads, no agent remains to extinguish the spreading fire.

The concern regarding premature discharge of extinguishing agent led to the sequential or separate component fire suppression approach as an alternative to simultaneous discharge. This approach is especially effective and practical in the case of a manifold exhaust system in a large restaurant or when manifolding multiple types of restaurant exhaust systems in a food court of a shopping mall. In either case, simultaneous actuation of all systems is messy and expensive, especially in the case of a food court, where a real or an accidental discharge in one restaurant can result in multiple lawsuits from the affected restaurants due to premature actuation of adjacent fire protection systems.

NFPA 17 contains requirements for fixed pipe extinguishing systems using dry chemical agents for protection of restaurant hood, duct, and cooking appliance systems. Additionally, NFPA 17A contains requirements for fixed pipe extinguishing systems using wet chemical agents for protection of cooking equipment.

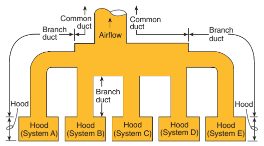
Alternative designs to simultaneous discharge are found in the annexes of NFPA 17 and NFPA 17A. These alternative systems segment the total manifold exhaust in different ways, all of which provide some backup protection in the common duct areas that permits some of the hoods or restaurants to continue operating while shutting down those that have experienced fire or those without a backup system in their common duct. These systems are a necessity for common design solutions for food courts with manifold exhaust systems and can be economical in large restaurants with multiple hoods on manifold exhaust systems. Exhibit 50.6 through Exhibit 50.9 illustrate various system configurations.

Example 1

A fire is detected by System A; its hood and branch duct are operated. Simultaneously, Systems B, C, D, and E are also actuated. All fuel or power to all protected appliances served by the common exhaust duct is shut off.

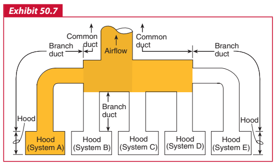
Upon operation of the common exhaust duct systems, the fuel or power to all protected appliances served by the common exhaust duct is shut off. The cooking appliance, hood, and branch duct systems provide protection in accordance with NFPA 17 and NFPA 17A. (See Exhibit 50.6.)

Exhibit 50.6



Simultaneous operation of all systems.

Exhibit 50.7



Simultaneous operation of a single cooking appliance, hood, or branch duct system and the system protecting the common duct.

Example 2

System 1, protecting the entire common exhaust duct, is separate from Systems A, B, C, D, and E. A fire is detected in System A. System A and System 1 operate simultaneously. Shutdown of all appliances protected by Systems A, B, C, D, and E is in accordance with NFPA 17. (See Exhibit 50.7.)

Example 3

System E also provides protection for the entire common exhaust duct. A fire is detected in System C. System C and System E operate simultaneously. Shutdown of all appliances protected by Systems A, B, C, D, and E is in accordance with NFPA 17. (See Exhibit 50.8.)

Example 4

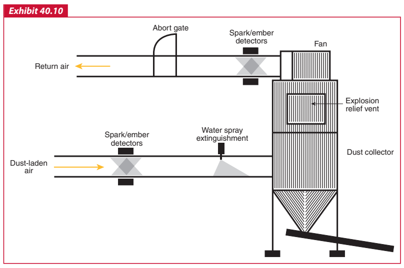
System E also provides protection for the entire common exhaust duct. A fire detected in System E will result in the actuation of System E only. Shutdown of all appliances protected by Systems A, B, C, D, and E is in accordance with NFPA 17. (See Exhibit 50.9.)

2018 NFPA 1 Fire Code Handbook

Examples help illustrate how the *Code* is applied in real-world situations.

794 Chapter 40 • Dust Explosion and Fire Prevention

Exhibit 40.10



Basic spark detection and extinguishment system for a single air-material separator.

Case Studies illustrate the importance of implementing NFPA 1 requirements.

Case Study

On February 7, 2008, a series of sugar dust explosions at the Imperial Sugar Company manufacturing facility in Port Wentworth, Georgia, resulted in 14 worker fatalities. In addition to the 14 fatalities, 36 workers were treated for serious burns and injuries, some of which caused permanent, life altering conditions. The explosions and subsequent fires destroyed the sugar packing buildings, palletizer room, and silos and severely damaged the bulk train car loading area and parts of the sugar refining process areas. The Imperial Sugar manufacturing facility housed a refinery for converting raw cane sugar into granulated sugar. Through a system of conveyors and elevators, the raw sugar was transported from grain silos to sugar processing machines, and the final sugar products were stored in buildings surrounding the silos.

In its investigation report released in September 2009, the U.S. Chemical Safety Board (CSB) found that an initial dust explosion originated in the enclosed steel belt conveyor located below the sugar silos where high concentrations of sugar dust had accumulated inside the enclosure. The initial explosion stirred up sugar dust that had built up on the floors and other surfaces, causing a chain reaction of additional dust explosions through the buildings. Fires resulting from the explosions destroyed the packing buildings, silos, and palletizer building and severely damaged parts of the refinery and sugar loading area.

Many contributing factors to the explosions were identified, including the following:

- Equipment that was not designed or maintained to minimize the release of sugar and sugar dust into the work area
- Inadequate housekeeping practices, which resulted in accumulations of combustible sugar and sugar dust on the floors and other elevated surfaces throughout the packing buildings
- Accumulation of airborne combustible sugar dust above the maximum explosible concentration
- Inadequate evacuation plans

The investigation conducted by the CSB highlighted many safety concerns regarding buildings where dust explosions are a risk and resulted in a list of recommendations to ensure that buildings at risk for dust explosions reduce that risk and even prevent such explosions from occurring. Additional information on the Imperial Sugar Company explosion and fire, as well as the CSB investigation report, in its entirety, can be found online at http://www.csb.gov/investigations/detail.aspx?SID=6.

Contents

Preface

The 2018 edition of NFPA 1, *Fire Code*, contains updated requirements from text extracted from other NFPA codes and standards. Because the *Code* relies so heavily on extracted text from other documents, the *Code* has the advantage of reflecting the technical knowledge and expertise of the many committees responsible for the codes and standards from which the text is extracted. This *Code* is intended to provide local and state jurisdictions with an effective fire code. This edition of the handbook is based on the 2018 edition of NFPA 1. The *Code* consists of 75 chapters (13 of which are reserved for future topics). The 2018 edition contains a new Chapter 35 (formerly reserved) on Animal Housing Facilities, a new Chapter 38 (formerly reserved) on Marijuana Growing, Processing, or Extraction Facilities, and a new Chapter 55 (formerly reserved) on Cleaning and Purging of Flammable Gas Piping Systems.

The editors developed new explanatory material in this handbook, and revised commentary from the previous edition, which relied on the expertise of NFPA technical committees, many independent subject matter specialists, and NFPA technical staff. Much of the commentary text clarifies the *Code* requirements as well as the annex material in the various codes and standards from which the requirements were extracted. The *Code* has changed significantly since the first issuance in 1925 of NFPA 1L, *Fire Prevention Bureau Ordinance*. That first edition provided fire departments with regulations for establishing a fire prevention bureau and a means for staffing the bureau. NFPA 1L also defined the bureau's powers and duties. With the *Ordinance* in place, a fire department was responsible for enforcing all laws and ordinances covering the prevention of fires, the storage and use of explosives and flammables, the installation and maintenance of fire alarm systems and fire-extinguishing equipment, the maintenance and regulation of fire escapes, and the means and adequacy of exits in case of fire. The fire department was also given responsibility for the investigation of the cause, origin, and circumstances of fires. NFPA 1L remained as an NFPA document until 1973.

NFPA 1, *Fire Prevention Code*, was developed as a result of NFPA members' requests for a document that would cover all aspects of fire protection and prevention and support the adoption and utilization of other NFPA codes and standards. The NFPA Board of Directors requested that staff initiate work in 1971 to develop such a document. The result of that work was then given to a newly formed technical committee that assumed responsibility for the draft and processed the proposed *Code* following the NFPA Regulations Governing Committee Projects. The first edition of NFPA 1, *Fire Prevention Code*, was adopted and published in 1975.

The original 1975 *Code* served as a guide for the development of a local fire prevention code. The appendixes could be incorporated into the local code as desired by the local officials. Appendix A listed NFPA codes and standards that were suitable for inclusion in a fire prevention code and a recommendation that the codes and standards be adopted in their entirety as a supplement to the code text of NFPA 1.

In the late 1980s, the Fire Marshals Association of North America (FMANA), now known as the International Fire Marshals Association (IFMA), undertook the task of developing a more self-contained code. FMANA added administrative sections, extracted text from many of those codes and standards that fire inspectors would need to use in the field, and incorporated appropriate NFPA codes and standards by reference. That draft was submitted as a proposal to the NFPA Technical Committee on Fire Prevention Code.

The committee examined changes affecting the built environment and used input from FMANA to change the scope and content of the *Code* to provide a comprehensive document for the protection of life and property. A special task group on hazardous materials examined technological changes in the use, handling, and storage of flammable and combustible materials. In chapters in which extracted hazardous materials requirements appeared, greater emphasis was placed on protection of life and property from chemical products made and used in industry. This major rewrite resulted in the 1992 edition of NFPA 1, *Fire Prevention Code.*

NFPA and the Western Fire Chiefs Association (WFCA) subsequently formed an alliance to jointly develop a comprehensive fire code. NFPA and WFCA appointed an Ad Hoc Task Group of ten fire code enforcement officials to review the provisions of the *Uniform Fire Code* (UFC) and NFPA 1 to identify requirements to be included in the draft of the new code in accordance with the agreement between the organizations. Over the course of nine months, the Ad Hoc Task Group volunteered hundreds of hours of time and expertise to create the draft, which evolved into the 2003 edition of NFPA 1, *Uniform Fire Code*. The title of NFPA 1 remained *Uniform Fire Code* until the 2009 edition, which was renamed NFPA 1, *Fire Code*.

The 2018 edition of the handbook provides discussions of the provisions of NFPA 1, *Fire Code*. The commentary is not a substitute for the actual requirements in the *Code* or in the text of the many codes and standards that are incorporated by reference in this *Code*. NFPA's other code handbooks are also valuable sources of information on requirements in this *Code*.

Kristin C. Bigda, P.E.
Principal Fire Protection Engineer

Acknowledgments

The editor thanks and acknowledges the contributions of the following individuals who have contributed to commentary in this edition of the Handbook or to commentary for previous editions of the handbook, which remains in place in this edition, or on which revised commentary was based.

NFPA staff who contributed to this edition of the handbook include the following:

- Allan Fraser (Chapter 16)
- Thomas McGowan (Chapter 17)
- Steven Sawyer (Chapter 18)
- Barry Chase, Senior Fire Alarm Engineer (Chapter 21, Section 42.10)
- Lawrence Russell, Principal Chemical and Marine Specialist (Chapter 28)
- Val Boutin, Fire Protection Engineer (Chapter 32)
- Susan Bershad, Chemical Engineer (Chapter 40, Chapter 63)
- Laura Moreno, Engineer (Chapter 41)
- Eric Nette, Engineer (Chapter 51)
- Robert Benedetti, *retired* (Chapter 43 and Chapter 60)

NFPA staff who contributed to previous editions of the handbook: Michele Steinberg, Division Manager, Wildland Fire Protection.

Outside authors who contributed to this edition of the handbook include the following:

- Tony Apfelbeck, Fire Marshal/Building Official/Division Chief, Altamonte Springs, FL (Chapters 1, 15, and 18)
- Kelly Nicolello, UL, LLC, Fort Worth, TX (Chapter 52)

Outside authors who contributed to previous editions of the handbook include the following:

- Scott Adams, Assistant Fire Chief/District Fire Marshal, Park City, UT
- Tony Apfelbeck, Fire Marshal/Building Official/Division Chief, Altamonte Springs, FL
- Shane Clary, Bay Alarm Company, Pacheco, CA
- Ed Comeau, writer-tech.com, Belchertown, MA
- Bradford T. Cronin, Strategic Code Solutions, Kingston, MA
- Tom DeMint, Fire Chief, Poudre Fire Authority, CO
- Ryan Depew, Depew Services, MA
- Ron Farr, Underwriters Laboratories Inc. (retired) and State Fire Marshal (retired), MI
- Robert Fash, Deputy Fire Marshal, Las Vegas Fire & Rescue, Las Vegas, NV
- Dan Hodge, North Haines Fire Department, Rapid City, SD
- Robert James, Underwriters Laboratories Inc., Chicago, IL
- Richard Kraus, API/Petroleum Safety Consultants, Falls Church, VA
- R.T. Leicht, Delaware State Fire Marshal's Office, Wilmington, DE
- Michael Madden, AMEC Environment & Infrastructure, San Diego, CA
- Chris Schiehl, NBC Universal Studios, Universal City, CA
- Richard Schiehl, R.B. Schiehl & Associates, Palm Desert, CA
- Catherine Stashak, Office of the Illinois State Fire Marshal, Chicago, IL
- Steven Younis, Steven E. Younis PE, Inc., Franklin, MA.

Editors of other NFPA handbooks and annotated standards, portions of which are incorporated in this handbook, include: Gregory Harrington, Matthew Klaus, Chad Duffy, Richard Roux, Christopher Coache, Robert Benedetti, Janna Shapiro, Jacqueline Wilmot, Barry Chase, and Eric Nette. The editors of the previous editions of this handbook, Gregory Harrington, Carl Peterson, Steven Sawyer, and Martha Curtis, provided a solid foundation on which to build.

Our Product Manager, Debra Rose, and our Production Editors, Tracy Gaudet and Ken Ritchie, supervised the development and production of this handbook.

Many other individuals supported the development of this handbook. They include members of the NFPA Building Fire Protection Department, namely, Division Manager Robert E. Solomon, P.E., and Val Boutin. A special thank you goes to Val, a Fire Protection Engineer, who contributed significantly to the review of edits, commentary placement, and review of the document pages.

About the Editor

Kristin C. Bigda, P.E., Principal Fire Protection Engineer in the Building Fire Protection and Life Safety Department at NFPA. She serves as Staff Liaison to the Fire Code Technical Committee, Fire Doors and Windows Technical Committee, as well as several safety to life and building code technical committees responsible for the development of NFPA *101*® and *NFPA 5000*®. Kristin is the editor of the NFPA 80 Handbook. Prior to joining the NFPA staff in 2007, Kristin attended Worcester Polytechnic Institute where she received degrees of Bachelor of Science in Civil Engineering and Master of Science in Fire Protection Engineering. Kristin is also a registered professional engineer in the discipline of fire protection in the Commonwealth of Massachusetts.

Introduction

NFPA® 1, *Fire Code,* and Commentary

This handbook includes the complete text of the 2018 edition of NFPA 1, *Fire Code,* which comprises 75 chapters of requirements. The handbook contains requirements in Chapters 1 through 75, followed by seven supporting annexes (three of which are adoptable by jurisdictions).

The Technical Committee on Fire Code prepared the mandatory provisions found in Chapters 1 through 75 within the framework of NFPA's consensus codes- and standards-making system. Many of the requirements in this *Code* have been extracted from other NFPA codes and standards, and others come from the former NFPA 1, *Uniform Fire Code,* to provide a comprehensive fire code. Because these provisions are designed to be suitable for adoption into law, the text is concise, without extended explanation.

The Technical Committee on Fire Code also developed the annexes of the *Code* within NFPA's codes- and standards-making system. The annex material is designed to assist users in interpreting the mandatory *Code* provisions. It is not considered part of the requirements of the *Code*; this material is advisory or informational. Annexes D, E, and F are written in mandatory language so they can be adopted by a jurisdiction where needed. An asterisk (*) following a *Code* paragraph number indicates that advisory annex material pertaining to that paragraph appears in Annex A. For the reader's convenience, in this handbook, Annex A material has been repositioned to appear immediately following its corresponding *Code* text.

The explanatory commentary in this handbook was prepared by the handbook editors, with the assistance of those individuals mentioned in the acknowledgments, and is intended to provide the reader with an understanding of the provisions of the *Code* and to serve as a resource and reference for implementing the provisions of or enforcing the *Code*. The commentary is not a substitute for the actual wording of the *Code* or the text of the many codes and standards that are incorporated by reference. The commentary immediately follows the *Code* text it discusses and is set in red type for easy identification.

The explanatory material in this handbook is influenced heavily by the various codes and standards from which the requirements of NFPA 1, *Fire Code,* were extracted and, where available, by other NFPA handbooks on specific codes and standards. For the full content of such handbooks, the reader is referred to the following publications:

Nette, Eric, P.E., ed., *LP-Gas Code Handbook,* 2017 edition, NFPA, Quincy, MA.

Benedetti, Robert, CSP, P.E., and Janna Shapiro, eds., *Flammable and Combustible Liquids Code Handbook,* 2018 edition, NFPA, Quincy, MA.

Bigda, Kristin C., P.E., and Gregory E. Harrington, P.E., eds., *Life Safety Code® Handbook,* 2018 edition, NFPA, Quincy, MA.

Chase, Barry, ed., *Standard for Portable Fire Extinguishers Handbook,* 2010 edition, NFPA, Quincy, MA.

Duffy, Chad R. W., ed., *Stationary Fire Pumps Handbook,* 2016 edition, NFPA, Quincy, MA.

Klaus, Matthew J., ed., *Automatic Sprinkler Systems Handbook,* 2016 edition, NFPA, Quincy, MA.

Hart, Jonathan R., and Matthew J. Klaus, eds., *Water-Based Fire Protection Systems Handbook,* 2017 edition, NFPA, Quincy, MA.
Coache, Christopher D., and Richard J. Roux, eds., *National Fire Alarm and Signaling Code® Handbook,* 2016 edition, NFPA, Quincy, MA.
Solomon, Robert E., P.E., and Gregory E. Harrington, P.E., eds., *Building Construction and Safety Code® Handbook*, 2003 edition, NFPA, Quincy, MA.
Wilmot, Jacqueline R., ed., *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations Handbook,* 2017 edition, NFPA, Quincy, MA.

NFPA 1 Summary of Technical Changes: 2015 to 2018

This table provides an overview of major code changes from the 2015 edition to the 2018 edition of NFPA 1, *Fire Code*. Changes to extracted documents are not included in the table, nor are purely editorial and formatting changes. For more information about the reason(s) for each change, visit www.nfpa.org/1. The first revision (FR) numbers, second revision (SR) numbers, and CAM (certified amending motion) numbers given in the third column of this table are for reference to the official documentation of the technical committee's actions.

Section Number	***Comments***	***FR/SR Reference***
Chapter 1 Administration		
1.3.2.2 **A.1.3.2.2**	Revised text provides users with another compliance strategy for items not addressed by the *Code*. The text clarifies the intent that, for occupancies or hazards not specifically regulated by NFPA 1 or its referenced standards, performance-based design approach is an option. New annex text supports the text added to 1.3.2.2	**FR-95**
1.4.1.1 Compliance with Subsequent Editions of Referenced Publications. **1.4.1.1.1** **1.4.1.1.2** **A.1.4.1.1** **A.1.4.1.1.1** **A.1.4.1.1.2**	New paragraphs permit the use of newer editions of the codes and standards than those referenced by the adopted edition of NFPA 1. Where the adoption of NFPA 1 is delayed and newer editions of the referenced publications are available, the new paragraphs specifically give the AHJ the authority to utilize those newer publications. Where newer editions of referenced publications are used, the entire edition must be referenced, because the new paragraphs do not permit picking specific sections from multiple editions of a referenced publication unless technical documentation is submitted and approved by the AHJ via equivalency. New annex section provides additional information on the application of the new *Code* section.	**FR-114**
1.4.5	This subsection has been revised to include equivalent and modified fire protection features that may be approved by the AHJ. The addition of the terms *equivalent* and *modified* ensures that an applicant attempting to utilize these approaches has to meet the same application criteria as for an "alternative."	**FR-6**
1.4.6 Approval	This subsection has been revised to include equivalent and modified fire protection features that may be approved by the AHJ. The addition of the terms *equivalent* and *modified* ensures that an applicant attempting to utilize these approaches has to meet the same application criteria as for an "alternative."	**FR-7**
1.7.2 Minimum Qualifications to Enforce this *Code* **1.7.2.1** **1.7.2.2** **1.7.2.3** **1.7.2.4**	New subsection and paragraphs mandate the required minimum qualifications and competencies as referenced in NFPA 1031 and NFPA 1037 for individuals enforcing the *Code*. If AHJs choose to modify those minimum qualifications and competencies, they can do so at time of adoption. However, the model provisions in the fire code should expect that fire inspectors, plans examiners, and fire marshals are technically competent to perform their job functions.	**FR-115**

Section Number	Comments	FR/SR Reference
A.1.7.7.1	The newly promulgated NFPA 1730 provides a national standard as to how risk assessment and fire protection resources should be allocated in order to accomplish the purpose of the fire code. As a model code, NFPA 1 should specify compliance with the NFPA national standard in this area. If a local jurisdiction chooses to delete it, they have that option during the adoption process.	
1.10.5.6	Current paragraph 1.10.1.1.2 states that the board shall consist of five or seven members. Based on the current language, either 100 percent or 71 percent of the members would have to be in attendance. A quorum of 100 percent is unrealistic, and the typical standard for establishing a quorum is at least 50%. This *Code* change establishes 50 percent as the quorum.	**FR-9**
Table 1.12.8(a) Permit Requirements	The permitting requirements added to Table 1.12.8(a) coordinate with new provisions for mobile cooking operations in Chapter 50, energy storage systems in Chapter 52, and marijuana processing and extraction facilities in new Chapter 38.	**FR-10, SR-66**
1.14.5	This change updates the subsection to reference approved construction documents rather than plans. NFPA 1 uses the terms *construction documents* and *shop drawings*. Previous editions of the *Code* used the term *plans,* which was not inclusive of everything that the revised term catches.	**SR-67**
1.14.6 A.1.14.6	This revision requires that plans and design documents be prepared by a registered design professional. Certain scopes of design work warrant and/or require individuals who prepare such plans to demonstrate that they have specific qualifications to practice that ensure the quality and safety of the design. Annex A text provides guidance to the AHJ as to when the documents should be prepared by such a design professional.	**FR-117**
1.16.4.2 1.16.4.3	The new paragraphs clarify an unintended consequence of existing text that appeared to require a $250 fine when a jurisdiction has not otherwise adopted a separate fee schedule. Requiring a $100 penalty per day for each violation provides a reasonable penalty amount and necessary guidance for how to apply the penalty (per day, per violation.) The text clarifies that the intent is for a jurisdiction to adopt the model code and have a violation provision that could then be applied without having to adopt a separate fees schedule.	**FR-118, SR-11**
1.17 Permit Fees A.1.17	New section provides a basic authorization for the AHJ to adopt a fee schedule. New Annex A text provides direction on how to establish service levels and how fees/revenues should be allocated to cover the cost of services provided under this *Code*.	**FR-116**
Chapter 2 Referenced Publications		
2.1.1 Compliance with Subsequent Editions of the Referenced Publications 2.1.1.1 2.1.1.2 A.2.1.1 A.2.1.1.1 A.2.1.1.2	New subsection permits the use of newer editions of the codes and standards than those referenced by the adopted edition of NFPA 1. Where the adoption of NFPA 1 is delayed and newer editions of the referenced publications are available, the new subsection specifically gives the AHJ the authority to utilize those newer publications. Where newer editions of referenced publications are used, the entire edition must be referenced, because the new text does not permit picking specific sections from multiple editions of a referenced publication unless technical documentation is submitted to and approved by the AHJ via equivalency. New Annex A material provides additional information on the application of the new *Code* requirements.	**FR-119**

Section Number	*Comments*	*FR/SR Reference*
Chapter 3 Definitions		
3.3.20 Barricade (Explosives or Fireworks)	New definitions have been added to Chapter 3 from NFPA 1124, which has been reissued, for terms used within NFPA 1.	**FR-138**
3.3.20.1 *Artificial Barricade*		
3.3.20.2 *Natural Barricade*		
3.3.42 Chemical Fume Hood	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter. This definition is extracted from NFPA 45.	**SR-85**
3.3.84 Deficiency	New definitions extracted from NFPA 25 coordinate with the new provisions from 13.1.9.	**FR-136**
3.3.84.1 *Critical Deficiency*		
3.3.84.2 *Noncritical Deficiency*		
3.3.86 Desolventizing	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
3.3.111 Extraction Room (Marijuana)	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
3.3.112.1 Animal Housing Facility	New definition has been added to clarify the application of new Chapter 35 for animal housing facilities.	**CAM 1-5**
3.3.130 Fireworks	New definitions have been added to Chapter 3 from NFPA 1124, which has been reissued, for terms used within NFPA 1.	**FR-139**
3.3.130.1 *Display Fireworks*		
A.3.3.130 Fireworks		
A.3.3.130.1 Display Fireworks		
3.3.176 Marijuana Extraction Equipment	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
3.3.177 Marijuana Extraction Facility	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
3.3.185 Miscella	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
3.3.187 Mobile or Temporary Cooking	New definition and annex language support the application of new provisions in Section 50.7 for mobile and temporary cooking operations.	**FR-143**
A.3.3.187 Mobile or Temporary Cooking		
3.3.191 Observation	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
3.3.192.12 *High-Risk Occupancy*	New definition extracted from NFPA 1730 and added to Chapter 3 coordinates with new provisions of 10.2.7 on minimum fire prevention inspection frequencies for existing occupancies.	**FR-122**
A.3.3.192.12 High-Risk Occupancy		
3.3.192.18 *Low-Risk Occupancy*	New definition extracted from NFPA 1730 and added to Chapter 3 coordinates with new provisions of 10.2.7 on minimum fire prevention inspection frequencies for existing occupancies.	**FR-123**
A.3.3.192.18 Low-Risk Occupancy		

Section Number	Comments	FR/SR Reference
3.3.192.21 ***Moderate-Risk Occupancy*** **A.3.3.192.21 Moderate-Risk Occupancy**	New definition extracted from NFPA 1730 and added to Chapter 3 coordinates with new provisions of 10.2.7 on minimum fire prevention inspection frequencies for existing occupancies.	**FR-124**
3.3.231 Rubberized Asphalt Melter (Melter)	New definition supports the application of new 16.7.3 on rubberized asphalt melters for roof deck systems.	**FR-141**
3.3.232 Rural	New definition provides direction to the AHJ as to what is a "rural" environment and what is a "suburban" environment. Specific exceptions are provided in Chapter 18 for structures that fall within those definitions. Without clear criteria, the AHJ is left with no guidance as to when the exceptions should apply. See also new definition of *suburb or suburban*.	**SR-68**
3.3.265 Suburb or Suburban **A.3.3.265 Suburb or Suburban**	New definition provides direction to the AHJ as to what is a "rural" environment and what is a "suburban" environment. Specific exceptions are provided in Chapter 18 for structures that fall within those definitions. Without clear criteria, the AHJ is left with no guidance as to when the exceptions should apply. See also new definition of *rural*.	**SR-69**
3.3.274 Transfilling **A.3.3.274 Transfilling**	New definition added in conjunction with new Chapter 38 on marijuana growing, processing, and extraction facilities supports the application of requirements in that chapter.	**SR-85**
Chapter 10 General Safety Requirements		
10.2.7 Minimum Fire Prevention Inspection Frequencies for Existing Occupancies **10.2.7.1** **10.2.7.2** **10.2.7.3** **10.2.7.4**	New subsection extracted from NFPA 1730 addresses the minimum fire prevention inspection frequencies for existing occupancies. To ensure that existing occupancies comply with the fire prevention code, a fire prevention inspection is required as part of the standard of care as specified in NFPA 1730. This new text incorporates that standard of care into NFPA 1.	**FR-121**
10.10.10 Discontinuance **A.10.10.10**	Bonfires in densely populated urban areas can create nuisance issues to neighboring properties where smoke from the bonfires is wind driven into other homes and businesses. The AHJ should have the authority to have the fire discontinued until more appropriate and safer conditions are available. The new Annex A text provides additional clarity as to what constitutes a potential hazardous condition under this subsection as well as also confirming that these determinations will need to be made on a case-by-case basis.	**SR-14**
A.10.11.1	New A.10.11.1 provides guidance on alternative means for identifying the locations of new and existing buildings	**FR-163**
10.11.1.2	The new text provides a minimum height and width for address numbers to ensure a reasonable level of visibility to emergency responders. The current 10.11.1.1 states that addresses shall be plainly legible and visible. However, this created a source for conflict and differences of opinion. The 4 in. minimum is a reasonable standard.	**FR-15**

Section Number	Comments	FR/SR Reference
10.11.1.3 **A.10.11.1.3**	New text that addresses the proper programing of telecommunications equipment to convey correct address information in the event of an E911 call is imperative. Incorrect information can result in a delayed response to a fire, EMS, or other emergency. The code should require the owners/occupants to ensure that their chain in the E911 communication is correct and maintained.	**FR-125**
10.11.1.4 **10.11.1.5**	New text requires that the assignment of addresses to buildings be in accordance with a method approved by the AHJ. Assignment of addressing buildings and changes of addresses to existing buildings can create significant difficulties to emergency responders if a consistent approach is not utilized. Maintaining a current addressing methodology is becoming increasingly important as addressing databases, such as GIS, are being used in new technology application during a response.	**FR-17**
10.11.1.6	The existing language in 10.11.1 did not provide any provision for the addressing of individual suites in a multiple tenant environment. A shopping center could have one single address, displayed at the street in accordance with 10.11.1.1, but numerous suites could go unidentified but be in compliance with the current provision of NFPA 1. The new text helps to reduce the potential for delays in response times of emergency responders when trying to locate a particular suite within a multi-suite complex.	**FR-16**
10.19.1	Revision clarifies that the structures required to comply with the provisions of 10.19.1.1 through 10.19.1.4 should be those that exceed either the threshold for height or area.	**FR-126**
Chapter 11 Building Services		
11.1.4.1	The existing code language required relocatable power taps to be listed but did not specify the standard to be used. The change to this paragraph adds references to specific standards for listing, which clarifies which relocatable power taps are suitable for specific occupancies and uses.	**SR-15**
11.5.2.3 **(1)** **(2)** **(3)** **(4)** **(5)**	Revised text references UL 647, *Standard for Safety for Unvented Kerosene-Fired Room Heaters and Portable Heaters*, which provides requirements for unvented kerosene-fired room heaters, including requirements for automatic primary safety controls or for inherent construction that prevents abnormal discharge of fuel at the burner in case of ignition failure or premature flame extinguishment. This change adds the specific UL standard to be used for the certification and listing of kerosene heaters.	**FR-128**
11.9.3 **11.9.3.1**	This revision modifies the size of emergency command center rooms from a minimum of 96 ft^2 (8.9 m^2) to 200 ft^2 (19 m^2). New 11.9.3.1 provides an exemption for existing emergency command center rooms so that they are not inadvertently required to be expanded in size to meet the new provisions of 11.9.3.	**FR-2, SR-16**
11.10.2	Requirements for two-way radio communication enhancement systems are now located in NFPA 1221.	**FR-108**
11.12.2.1.1 Rapid Shutdown Marking through 11.12.2.2.2.3.4 Minimizing Obstructions in Pathways	New text incorporates the provisions for PV system marking requirements and extracts text from *NFPA 70*.	**FR-129**

Section Number	Comments	FR/SR Reference
11.12.3.2 Vegetation Management Plan	Revised text provides flexibility for the AHJ to enforce provisions appropriate to the scale of a project. For example, it would be overly restrictive to assume a project would import gravel to cover a 500 acre photovoltaic power plant, and it would be environmentally insensitive to do so. Revised text provides AHJs with the resource and guidance to properly evaluate large-scale ground-mount PV installations and also addresses the environmental aspect of large installations.	**FR-132**
Chapter 12 Features of Fire Protection		
12.3.3 Maintenance of Fire-Resistive Construction, Draft-Stop Partitions, and Roof Coverings **12.3.3.3**	Revised text requires visual inspections of fire-resistance rated assemblies in high-rise buildings every 3 years, revised from 5 years. Waiting 5 years to do an inspection, with the various changes that occur with respect to tenant improvements and facility upgrades could result in this critical fire protection feature being compromised for an unacceptable period of time.	**FR-1**
A.12.3.3	The new text added to A.12.3.3 provides useful information to assist with the periodic inspection and maintenance process for firestop systems.	**FR-160**
Chapter 13 Fire Protection Systems		
13.1.9	Revision permits AHJ to approve the time for corrections of deficiencies. The definitions for *deficiency*, *critical deficiency*, and *noncritical deficiency* have been added to Chapter 3 to support the application of 13.1.9.	**FR-135**
13.1.10	Existing 13.1.10 was deleted to eliminate a conflict with 13.3.3.6.5.2, which requires impairments to water-based fire protection systems to comply with NFPA 25. Also, 13.7.1.4.3 requires fire alarm system impairment procedures to comply with NFPA 72.	**FR-110**
13.1.3 Integrated Fire Protection and Life Safety System Test **A.13.1.3**	When fire protection and life safety systems are integrated with other building systems, they should be tested end-to-end. Referencing NFPA 4 provides guidance since no other document addresses end-to-end testing of integrated systems. New text is extracted from NFPA *101*.	**FR-134**
A.13.2.2.2(3)	New Annex A text provides guidance on determining building height.	**FR-111**
Chapter 16 Safeguarding Construction, Alteration, and Demolition Operations		
16.7 Tar Kettles and Rubberized Asphalt Melters through 16.7.3.10.3	New section on rubberized asphalt melters distinguishes the differences between safe use of torches or tar kettles and rubberized asphalt melters on roof decks. Both operations need safeguards against the potential for fire, but with different constraints. The new text, which separates out rubberized asphalt melters for use on roof decks, brings with it recognition of fire safety as a part of that process. Rubberized asphalt melters operate and perform differently from tar kettles. It is important to note that the fuel used to provide indirect heating to the rubberized asphalt melter is diesel, so there are temperature controls inherent in melters in part due to the need to maintain the roofing material at 350°F to 380°F. Overheating into the temperature range of ordinary combustibles makes the rubberized asphalt product unsuitable for roof deck application. Because of the lower application temperature on noncombustible roof decks, the opportunity for fire with this method is greatly decreased compared to tar kettles and torches.	

Section Number	Comments	FR/SR Reference
	The new text for rubberized asphalt melters is consistent with the intent of the code while providing important differentiations from the more hazardous operations involving open flames and tar kettles.	
Chapter 18 Fire Department Access and Water Supply		
18.1.3.1 Fire Apparatus Access **18.1.3.2 Fire Hydrant Systems**	"AHJ" is the proper term for the regulatory body within NFPA codes and standards that is empowered to enforce the code. The term "AHJ" is utilized throughout the remainder of Chapter 18. The fire department might or might not be the AHJ.	**FR-20**
18.2.3.2.1.1	Section 13.3 points the user to the appropriate section in NFPA 1 that addresses sprinkler options.	**FR-22**
18.2.3.3 **A.18.2.3.3**	New Annex A text addresses questions that frequently come up regarding how an AHJ should determine when multiple fire apparatus roads are required under this paragraph. This annex material provides guidance to the common situations of flood, rail traffic, and congestion.	**FR-21**
18.2.3.4 Traffic Signal Pre-emption	Traffic signal pre-emption improves response times and provides for safer fire fighter responses by halting conflicting traffic movements. When fire department units are equipped with such devices, newly installed traffic signals should also be equipped to ensure that the new intersections don't increase response times or contribute to a dangerous response condition.	**FR-140**
A.18.2.3.5.1.1 **18.2.3.5.1.1.1** **A.18.2.3.5.1.1.1** **18.2.3.5.1.1.2** **18.2.3.5.1.3.1** **18.2.3.5.1.2.2** **A.18.2.3.5.2** **18.2.3.5.6.3**	Revisions to these paragraphs and associated Annex A material on specifications of fire department access roads intend to provide flexibility to the AHJ to evaluate and approve reduced access road widths where conditions warrant.	**FR-152, SR-18**
18.2.3.5.6.1	This revision clarifies the permitted gradient for a fire department access road. The revised text reminds users that the gradient cannot exceed the limitations of the apparatus and must also be approved by the AHJ.	**SR-19**
18.2.4.2.6 **18.2.4.2.6.1** **18.2.4.2.6.2**	New paragraph provides required standards with which electric gate systems and gates intended for automatic operation must comply. Maintenance of the gate system in the same condition as it was installed is imperative to ensure the long-term safe operation of the gate. Otherwise, gate components could fail or be disabled, and there would be no mechanism for the AHJ to address repairs or safety.	**FR-154, SR-20, SR-21**
Chapter 19 Combustible Waste and Refuse		
19.2.1.4 Rubbish Within Dumpsters **19.2.1.4.1** **19.2.1.4.2** **(1)** **(2)** **(3)**	Revision is editorial in nature. The paragraphs have been rewritten to comply with the formatting of exceptions within NFPA codes and standards.	**FR-3**

Section Number	Comments	FR/SR Reference
Chapter 27 Manufactured Home and Recreational Vehicle Sites		
27.1.2	Referenced publication title has been updated.	**FR-52**
Chapter 29 Parking Garages		
29.1.3	New text provides a pointer to NFPA 2 for the storage of self-propelled vehicles powered by GH_2 or LH_2.	**FR-103**
Chapter 30 Motor Fuel Dispensing Facilities and Repair Garages		
30.1.1.1	NFPA 2 contains two chapters on hydrogen fueling facilities. In lieu of extracting two chapters' worth of material, a simple reference to NFPA 2 points the user to those requirements.	**FR-99**
30.2.1.1	NFPA 2 contains a chapter on repair garages servicing hydrogen-fueled vehicles. In lieu of extracting an entire chapter's worth of material, a simple reference to NFPA 2 points the user to those requirements. Furthermore, requirements for repair garages servicing self-propelled vehicles powered by GH_2 or LH_2 are contained only in NFPA 2 and nowhere else. Previous text in NFPA 52 has been removed.	**FR-100**
Chapter 31 Forest Products and Biomass Feedstocks		
Chapter 31 Forest Products and Biomass Feedstocks	The modification of the chapter title is to provide for material covered by new 31.3.10 addressing biomass feedstock utilized at biomass to ethanol industrial facilities.	**SR-60**
31.1 General	This revision adds biomass feedstock as an item that must comply with Chapter 31 and NFPA 664 for consistency with new 31.3.10.	**SR-61**
31.3.1.1 **(1)** **(2)** **(3)** **(4)** **(5)** **(6)**	This revision adds the outside storage of biomass feedstocks as being included in the application of Chapter 31. This revision is necessary to correlate with the addition of new 31.3.10.	**SR-62**
31.3.10 Outside Storage of Biomass Feedstock through 31.3.10.12	This new subsection provides requirements for the safe storage of biomass feedstock at biomass to ethanol manufacturing facilities. Previous general requirements for the storage of agricultural products was not sufficient for these types of operations. The storage arrangement dimensions are based upon current operations after shorter separation distances were found to be insufficient to retard fire spread. The requirements for securing the site in an approved manner and for the provision of lightning protection is in recognition of the two main causes of fires in this type of storage, arson and lightning strikes.	**SR-64**
Chapter 34 General Storage		
34.10.3.1 **34.10.4 Outside Storage at Pallet Manufacturing and Pallet Recycling Facilities through 34.10.4.12**	This change adds a new paragraph (34.10.3.1) and a new subsection (34.10.4) to the *Code*. Subsection 34.10.4 addresses the outdoor storage of wood and wood composite pallets or listed pallets equivalent to wood on the same site as a pallet manufacturing or pallet recycling facility. Outdoor pallet storage areas for manufacturing and recyclers of pallets were not adequately addressed by the requirements previously in NFPA 1 because pallets are not idle nor managed in an idle fashion at these types of facilities. Pallet manufacturers and recyclers have intimate knowledge of their pallet inventory, which is considered an asset. The storage areas are fluid environments where pallets are being moved and replaced on a daily basis.	**FR-159, SR-71, SR-73**

Section Number	*Comments*	*FR/SR Reference*
	The outdoor storage area of pallet manufacturing and recycling facilities is an active management environment. Because personnel are a constant presence within the storage area, fire hazards can be identified and reported and immediate corrective action taken. Storage yards are organized by pallet type and into recycle streams for high operational efficiency, kept sufficiently free of waste and debris, and perimeters are well maintained. The intent of the new subsection is to reduce the likelihood of fire at pallet manufacturing and recycling facilities through best practices. In the event that a fire does occur, measures are described that will mitigate the spread of fire to adjoining structures and properties through the establishment of pallet pile spacing between buildings and property lines.	
Chapter 35 Animal Housing Facilities		
Chapter 35 Animal Housing Facilities **35.1 General** **35.2 Permits**	This revision adds a new Chapter 35, which references NFPA 150 for animal housing facilities. A definition of *animal housing facility* has also been added to Chapter 3.	**CAM 1-4**
Chapter 38 Marijuana Growing, Processing, or Extraction Facilities		
Chapter 38 Marijuana Growing, Processing, or Extraction Facilities	New Chapter 38 provides safety requirements for marijuana growing, processing, and extraction facilities. The Committee provided language for a new chapter as a Committee Input during the First Draft stage. After the First Draft meeting a task group was formed consisting of both Technical Committee members and industry experts who volunteered their time over the year to further develop and refine the chapter. This new chapter is a direct result of requests from the industry for guidance in the *Code* on the requirements necessary to protect marijuana growing, processing, and extraction facilities. Several hazards make these facilities unique (e.g., use of hazardous materials as solvents, fumigation, special systems and equipment, staff training, transfilling LPG), and this new chapter focuses on those hazards while pointing users to other sections in the *Code* for provisions that can be applied generically (fire protection systems, means of egress, occupancy classification, hazardous materials.)	**SR-84**
Chapter 40 Dust Explosion and Fire Prevention		
40.1 Application **40.1.1** **40.2 Permits**	This revision replaces requirements in Chapter 40 that were extracted from NFPA 654 with the equivalent provisions from NFPA 652. NFPA 652 provides the basic principles of and requirements for identifying and managing the fire and explosion hazards of combustible dusts and particulate solids. NFPA 652 is now the umbrella standard that governs the series of other standards related to dust and explosion hazards.	**FR-142, SR-23**
40.7.1.4	A key portion of the new standard NFPA 652, *Standard on the Fundamentals of Combustible Dust*, is Chapter 7 and its requirement for existing operations to perform a dust hazards analysis to evaluate fire, deflagration, and explosion hazards and provide recommendations to manage those hazards. This is an important step to address in existing facilities that may or may not have been established utilizing appropriate dust hazard safety precautions.	**FR-102**

Section Number	Comments	FR/SR Reference
Chapter 41 Welding, Cutting, and Other Hot Work		
41.1.4	NFPA 51A has been withdrawn and incorporated into NFPA 55.	**FR-105**
Chapter 45 Combustible Fibers		
45.1.3	This new text clarifies the application of Chapter 45 with regard to the new subsection added to Chapter 31 (31.3.10) on the outside storage of biomass feedstocks.	**SR-63**
Chapter 50 Commercial Cooking		
50.1.1	Revision addresses new text on temporary and mobile cooking equipment in 50.7.1.	**FR-104**
50.7 Mobile and Temporary Cooking Operations	New Section 50.7 provides requirements for mobile and temporary cooking operations to provide guidance on these type of operations after recent events involving such operations along with a lack of regulation for the increasing number of temporary and mobile cooking units. There was no one place to find all the requirements for mobile and temporary cooking operations. The requirements include common provisions for operation (e.g., permits, portable fire extinguishers, training, fire department access) appropriate to NFPA 1. The remaining text brings together requirements from NFPA 96 and NFPA 58 to address specifics on cooking equipment, LP-Gas systems, storage, leak detection, installation and use of containers, and vehicle maintenance and protection. A definition of *mobile or temporary cooking* was added to Chapter 3 to assist in the application of this new section	**FR-98, SR-29, SR-26, SR-27, SR-25, SR-28, SR-24**
Chapter 52 Energy Storage Systems		
Chapter 52 Energy Storage Systems **52.1 General through 52.3**	Chapter 52 has been both updated and also completely rewritten in sections to appropriately address both recognized battery technologies as well as new technologies and applications of energy storage systems. The title of the chapter has been updated to Energy Storage Systems, which more accurately reflects the chapter being inclusive of both battery technologies as well as other energy storage technologies.	**SR-65**
Chapter 53 Mechanical Refrigeration		
53.2.3.1.1 Alarm Threshold	This change correlates NFPA 1 with ANSI/IIAR 2-2014, which revises the detection threshold for ammonia alarms to 25 ppm.	**FR-150**
53.2.3.3.3	This change correlates NFPA 1 with ANSI/IIAR 2-2014, which revises the detection threshold for activation of ventilation systems in ammonia machinery rooms to 150 ppm ($^1/_2$ IDLH). This is a fraction of the 160,000 ppm LFL for ammonia.	**FR-151**
53.3.3 Decommissioning of Ammonia Refrigeration Systems	This revision adds a reference to ANSI/IIAR 8, which is a new standard that provides regulations for the decommissioning of closed-circuit ammonia refrigeration systems.	**FR-147**
Chapter 55 Cleaning and Purging of Flammable Gas Piping Systems		
Chapter 55 Cleaning and Purging of Flammable Gas Piping Systems **55.1 Application**	This revision adds a reference to NFPA 56 for cleaning and purging activities for new and existing flammable gas piping applications. Inclusion of NFPA 56 as a referenced document in NFPA 1 provides AHJs and owners with clear direction to ensure compliance with NFPA standards on the hazard.	**SR-22**

Section Number	Comments	FR/SR Reference
Chapter 61 Aerosol Products		
A.61.1.1.1	The new Annex A text clarifies the application of Chapter 60 and Chapter 61 to aerosol products in storage and mercantile occupancies.	**FR-106**
Chapter 63 Compressed Gases and Cryogenic Fluids		
63.9.1 General **63.9.2 Permits** **63.9.2.1** **63.9.2.2** **63.9.2.3**	This revision adds requirements for insulated liquid carbon dioxide systems. Specifically, 63.9.2 addresses the permitting requirements for these systems and applications. 63.9.3 through 63.9.14.3.4 are new to the 2018 edition of the *Code* and have been added as part of this revision. The text is extracted from NFPA 55.	**SR-31**
Chapter 65 Explosives, Fireworks, and Model Rocketry		
A.65.1.1	This new Annex A text clarifies the scope and application of Chapter 65. The text is related to 1.3.2.2, which notes consumer fireworks sale and use as being one of the conditions where the AHJ needs to turn to other resources.	**FR-96**
65.2.2	This revision adds back into the *Code* a reference to NFPA 1124, which has been reissued.	**FR-97**
65.5.1	This revision adds back into the *Code* a reference to NFPA 1124, which has been reissued.	**FR-107**
Annex F Fire Fighter Breathing-Air Replenishment Systems		
Annex F Fire Fighter Breathing-Air Replenishment Systems **F.1 General**	New Annex F provides guidance for those jurisdictions using fire fighter air replenishment systems. The systems are not mandated by the *Code*; rather, the annex is provided solely to assist those AHJs needing to enforce such requirements.	**SR-59**

1

Administration

Chapter 1 addresses the administrative and enforcement requirements of NFPA 1. It covers the scope, purpose, and application of the *Code* within the adopting jurisdiction's legal enforcement boundaries. The authority to enforce the *Code*, enforcement power given to the authority having jurisdiction (AHJ), permitting requirements, liability, and qualifications of individuals practicing contracting are also covered. The importance of Chapter 1 is critical to the AHJ; the powers specified in this chapter are the basis for enforcing all other chapters and references contained in this *Code*. Frequently, when a legal challenge arises to the AHJ during attempts to enforce the *Code*, a failure by the AHJ to comply properly with the administrative procedures of the *Code* is almost always one of the accusations. A failure of the AHJ to comply with the administrative provisions has the potential to invalidate any needed enforcement action.

While Chapter 1 provides comprehensive provisions and direction on how the *Code* should be administered and enforced, these administrative procedures and requirements are frequently customized by the jurisdiction as part of the code adoption process. To ensure that unintended conflicts are not created, the adopting AHJ should consult other state or local ordinance, laws, and administrative rules that affect this chapter before adopting this *Code*.

If the AHJ adopts its own local administrative provisions as part of a Chapter 1 revision, the AHJ should ensure that all topics specified in Chapter 1 are covered in the locally adopted administrative provisions. If topics are deleted without appropriate replacement, the deletion may result in the AHJ being unable to enforce the *Code* appropriately or to enforce a reasonable level of safety.

1.1 Scope

1.1.1 The scope includes, but is not limited to, the following:

(1) Inspection of permanent and temporary buildings, processes, equipment, systems, and other fire and related life safety situations
(2) Investigation of fires, explosions, hazardous materials incidents, and other related emergency incidents
(3) Review of construction plans, drawings, and specifications for life safety systems, fire protection systems, access, water supplies, processes, hazardous materials, and other fire and life safety issues
(4) Fire and life safety education of fire brigades, employees, responsible parties, and the general public
(5) Existing occupancies and conditions, the design and construction of new buildings, remodeling of existing buildings, and additions to existing buildings
(6) Design, installation, alteration, modification, construction, maintenance, repairs, servicing, and testing of fire protection systems and equipment
(7) Installation, use, storage, and handling of medical gas systems
(8) Access requirements for fire department operations
(9) Hazards from outside fires in vegetation, trash, building debris, and other materials
(10) Regulation and control of special events including, but not limited to, assemblage of people, exhibits, trade shows, amusement parks, haunted houses, outdoor events, and other similar special temporary and permanent occupancies
(11) Interior finish, decorations, furnishings, and other combustibles that contribute to fire spread, fire load, and smoke production
(12) Storage, use, processing, handling, and on-site transportation of flammable and combustible gases, liquids, and solids
(13) Storage, use, processing, handling, and on-site transportation of hazardous materials
(14) Control of emergency operations and scenes
(15) Conditions affecting fire fighter safety
(16) Arrangement, design, construction, and alteration of new and existing means of egress

While it is intuitive to owners, occupants, contractors, design professionals, and the public that the *Code* is intended to protect occupants of the building, it is not always understood by these stakeholders that the *Code* is intended to protect fire fighters. There are many specific NFPA 1 *Fire Code* provisions in place to address fire fighter safety. Many of the provisions to protect occupants, such as fire sprinkler protection, also protect fire fighters.

1.1.2 Title. The title of this *Code* shall be NFPA 1, *Fire Code*, of the National Fire Protection Association (NFPA).

1.2* Purpose

The purpose of this *Code* is to prescribe minimum requirements necessary to establish a reasonable level of fire and life safety and property protection from the hazards created by fire, explosion, and dangerous conditions.

Provisions of NFPA 1 represent the minimum levels of protection needed to provide life safety from fire to building occupants, property protection, and enhanced emergency responder safety. Building owners, tenants, and design professionals should carefully consider whether additional safeguards might be needed based on their specific loss tolerability. For example, meeting the requirements of NFPA 1 alone might not provide sufficient protection from fire to a highly valued risk, such as rare artwork that might be destroyed by exposure to smoke. Such determination needs to be made based on a complete risk assessment of the property. The protection requirements of this *Code* can always be supplemented, but they should never be reduced.

A.1.2 Consideration for life safety could include occupants, fire department personnel, fire brigade members, employees, responsible parties, and the general public.

1.3 Application

1.3.1 This *Code* shall apply to both new and existing conditions.

The *Code* addresses requirements for both new and existing conditions. It recognizes that, in most cases, existing conditions or structures are unable to meet the requirements for new structures, occupancies, or conditions without considerable hardship and that sometimes only minimal gains in safety might be achieved. The *Code* also recognizes that a minimum level of fire and life safety must be provided for all structures and conditions. The requirements for existing buildings are intended to be reasonable and limit the resulting disruption and financial impact, while still providing a minimum, acceptable level of fire and life safety.

In some cases, requirements for existing buildings or conditions are less restrictive than those for new buildings or conditions because it is sometimes impractical to apply the requirements for new construction to an existing situation. In other cases, however, the requirements for new and existing occupancies or conditions might be identical. It is the intent of the *Code* that its requirements apply to existing buildings and that conditions are applied retroactively unless specifically stated otherwise to provide a minimum, reasonable level of protection to all buildings.

Frequently, AHJs are approached by an owner or a tenant to questions that an existing code compliance issue is "grandfathered in" with approval because the violation existed for a long time or that the violation existed before adoption of the *Code*. It is important to note that there is no grandfathering of existing violations. As indicated above, the *Code* will differentiate between new and existing conditions within the text when such differentiation is appropriate.

1.3.2* Referenced Standards.

A.1.3.2 This *Code* is partially composed of limited text references extracted from other NFPA codes and standards in an effort to bring together information useful during field inspections.

With respect to hazardous materials, provisions in Chapters 60, 61, 63, 65, 66, and 69, are partial extracts of materials from NFPA standards referenced in each of these chapters. These extracts are included in NFPA 1 to assist users of the document by providing ready access to provisions that could be routinely referenced by fire code enforcers. However, through their adoption by reference in NFPA 1, the NFPA standards identified in these chapters apply in their entirety.

1.3.2.1 Details regarding processes, methods, specifications, equipment testing and maintenance, design standards, performance, installation, or other pertinent criteria contained in those codes and standards listed in Chapter 2 of this *Code* shall be considered a part of this *Code*.

The codes and standards referenced in Chapter 2 are mandatory requirements of this *Code* and should be enforced as part of this *Code* to the extent they are referenced. In certain instances, this *Code* references the complete code or standard; in other instances, a specific section of the code or standard is referenced. All references to the codes and standards listed in Chapter 2 should be taken in the context of the *Code* requirements of Chapters 1 through 75.

1.3.2.2* Where no applicable codes, standards, or requirements are set forth in this *Code* or contained within other laws, codes, regulations, ordinances, or bylaws adopted by the authority having jurisdiction (AHJ), compliance with applicable codes and standards of NFPA or other nationally recognized standards, as are approved, or approved performance-based options in accordance with Chapter 5, shall be deemed as prima facie evidence of compliance with the intent of this *Code*.

NFPA publishes about 300 codes and standards that can assist the AHJ with topics not addressed by this *Code* specifically and offer guidance in determining equivalent levels of protection, as provided in Section 1.4. Even if an NFPA code or standard is not referenced in Chapter 2, or if the NFPA document is a guide or recommended practice, the AHJ can use such NFPA documents for guidance to determine evidence of compliance with the intent of this *Code*. Where no NFPA code or standard exists to address a particular situation, the AHJ can use any nationally recognized standard for guidance, including industry standards from organizations such as the American Petroleum Institute (API), FM Global, ASTM International (ASTM), Underwriters Laboratories (UL), or the Compressed Gas Association (CGA).

N **A.1.3.2.2** This section provides a basis for regulating an occupancy or hazard not specifically regulated by NFPA 1 or its referenced standards (e.g., retail sales and associated storage of consumer fireworks; wind turbines; amusement structures not defined as special amusement buildings, such as outdoor roller coasters and water slides). The AHJ has the authority to use any available resource and its own discretion to develop an appropriate protection scheme, including use of the provisions of Chapter 1, Administration; Chapter 4, Goals and Objectives; Chapter 5, Performance-Based Option; or other nationally recognized standards as indicated in 1.3.2.2 to regulate such occupancies or hazards.

1.3.2.3 Nothing herein shall diminish the authority of the AHJ to determine compliance with codes or standards for those activities or installations within the AHJ's responsibility.

1.3.2.4 Retroactivity of Referenced Standards to Existing Conditions. Unless otherwise specified by 1.3.2.4.1 through 1.3.2.4.3, the current provisions of the referenced standards shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of this *Code*.

1.3.2.4.1 Where specified by a reference standard for existing occupancies, conditions, or systems, the provisions of the referenced standards shall be retroactive.

1.3.2.4.2 Facilities, equipment, structures, and installations, installed in accordance with a reference standard, shall be maintained in accordance with the edition of the standard in effect at the time of installation.

1.3.2.4.3 In those cases where the AHJ determines that the existing situation constitutes an imminent danger, the AHJ shall be permitted to apply retroactively any portions of the current referenced standards deemed appropriate.

The intent of 1.3.2.4 is to clarify the application of referenced codes and standards to existing conditions. For example, it is not the *Code's* intent to require that a sprinkler system installed when the building was constructed be brought up to the latest edition of NFPA 13, *Standard for the Installation of Sprinkler Systems,* every time that standard is updated, unless the AHJ determines that the existing installation is no longer adequate for the hazard or that an imminent danger exists, as described in 1.3.2.4.3.

1.3.3 Conflicts.

1.3.3.1 When a requirement differs between this *Code* and a referenced document, the requirement of this *Code* shall apply.

NFPA codes and standards are updated periodically. The editions of the codes and standards referenced in Chapter 2 are the current editions available when this *Code* was issued on August 17, 2017, and became effective on September 6, 2017.

With the adoption of the 2018 edition of NFPA 1 by a jurisdiction, the specific editions of the various codes and standards referenced in Chapter 2 are the enforceable editions of those codes and standards, unless the adopting legislation specifies that a different edition be used. For example, this *Code* references the 2016 edition of NFPA 13. However, the AHJ's adoption process for NFPA 1 might require a more current edition of NFPA 13. If a different edition of a referenced code or standard is specified, the text of the most recent edition might differ from extracted text in this edition of the *Code*. The AHJ should be aware of this during the code adoption process.

There might be instances where NFPA 1 contains requirements beyond those addressed in the referenced codes and standards. In such instances, where the requirements in the *Code* differ from those of the referenced code or standard, the requirements in this *Code* take precedence.

1.3.3.2 When a conflict between a general requirement and a specific requirement occurs, the specific requirement shall apply.

Examples of a general requirement versus a specific requirement can be found in Section 10.9 and 60.5.1.5.1. Section 10.9 has a general provision dealing with smoking, while 60.5.1.5.1 contains specific requirements on how to address smoking in areas where hazardous materials are used, stored, or handled. In this case, the specific requirements of 60.5.1.5.1 apply.

1.3.4 Multiple Occupancies. Where two or more classes of occupancy occur in the same building or structure and are so intermingled that separate safeguards are impractical, means of egress facilities, construction, protection, and other safeguards shall comply with the most restrictive fire safety requirements of the occupancies involved.

See 6.1.14 for additional guidance on multiple occupancies. An example of a multiple occupancy in which the uses are mixed (intermingled) might be a school (educational occupancy) with an auditorium (assembly occupancy) within it. If the classrooms and auditorium are not separated and share exit access components, the most restrictive requirements of the occupancies involved apply throughout the building. Each requirement for each occupancy involved must be evaluated individually; it should not be assumed that all requirements for one occupancy are more restrictive than requirements for another.

Δ **1.3.5 Vehicles and Vessels.** Vehicles, vessels, or other similar conveyances, when in fixed locations and occupied as buildings, as described by Section 11.6 of NFPA *101* shall be treated as buildings and comply with this *Code*.

Conversions such as railroad cars converted to dining or drinking establishments, ships or barges converted to hotels or restaurants, or transportation trailers used for storage or mercantile sales are not uncommon. Where these vehicles, vessels, or other mobile structures are in a fixed location and occupied as a building, the *Code* intends that they be regulated as a building. Although these vehicles and vessels are existing structures, the AHJ may require that they be reviewed for code compliance as new buildings under the provision of this *Code* unless specifically exempted from such application in the *Code*. In cases where it is unclear whether a vehicle or vessel is being used as a building, the AHJ should determine whether the vehicle or vessel meets the criteria described in 1.3.5 and Section 11.6 of NFPA *101*®, *Life Safety Code*®, or whether it is regulated by another agency, such as the U.S. Coast Guard or U.S. Department of Transportation. If the vehicle or vessel does not meet the criteria of 1.3.5 and Section 11.6 of NFPA *101*, it should be exempt from the requirements of this *Code*.

1.3.6 Buildings.

1.3.6.1 Buildings permitted for construction after the adoption of this *Code* shall comply with the provisions stated herein for new buildings.

1.3.6.2* Buildings in existence or permitted for construction prior to the adoption of this *Code* shall comply with the provisions stated herein or referenced for existing buildings *(see 10.3.2)*.

A.1.3.6.2 A limited but reasonable time should be allowed for compliance with any part of this *Code* for existing buildings, commensurate with the magnitude of expenditure, disruption of services, and degree of hazard. Occupied existing buildings should comply with 10.3.3.

The term *existing building* is defined in 3.3.29.5 as "a building erected or officially authorized prior to the effective date of the adoption of this edition of the *Code* by the agency or jurisdiction." Existing installations, such as fire alarm systems, sprinkler systems, and electrical installations, are not required to be brought into compliance with the latest edition of the applicable code or standard unless the AHJ determines that not doing so creates an imminent danger. See 1.3.2.4.3.

Existing buildings that do not comply with the *Code* are required to be brought into compliance. Based on the number and extent of the violations, a reasonable time should be given to correct the violations. When determining reasonable time, the AHJ should evaluate the degree of hazard with respect to fire and life safety, magnitude of work required, and, to a lesser extent, expenditure and disruption to the building occupants. The cost of correcting *Code* deficiencies should not be the only or the final basis for determining the time allowed for compliance. It is worth restating that the *Code* represents the minimum level of protection required for a reasonable level of fire and life safety — it does not represent the ultimate protection package.

1.3.6.3 Repairs, renovations, alterations, reconstruction, change of occupancy, and additions to buildings shall conform to this *Code*, NFPA *101*, and the building code.

In jurisdictions where a building code has been adopted, the building code, in addition to NFPA *101*, should be used to determine requirements for repairs, renovations, alterations, reconstruction, additions, and changes of occupancy classification. Where a building code has not been adopted, NFPA *101* should be used as the basis for fire and life safety provisions.

1.3.6.4 Newly introduced equipment, materials, and operations regulated by this *Code* shall comply with the requirements for new construction or processes.

1.3.7 Severability. If any provision of this *Code* or the application thereof to any person or circumstance is held invalid, the remainder of the *Code* and the application of such provision to other persons or circumstances shall not be affected thereby.

1.4 Equivalencies, Alternatives, and Modifications

Section 1.4 provides limited latitude to the AHJ in applying the *Code* to new and existing buildings. The AHJ should determine the granting of equivalencies, alternatives, or modifications by reviewing technical data provided with the applications for such requests. Chapter 5 provides a method or system to assist the AHJ in reviewing these requests. However, such requests do not need to be limited to the performance-based options outlined in Chapter 5. If a request is granted, the equivalency, alternative, or modification must provide at least the same level of protection as the original *Code* requirement and meet the goals and objectives of this *Code*.

NFPA 1 recognizes that in some situations applying its requirements to existing situations might not be practical. In such cases, the AHJ is permitted to modify the *Code* requirements. However, a reasonable degree of safety must be provided.

1.4.1 Equivalencies. Nothing in this *Code* is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety to those prescribed by this *Code*, provided technical documentation is submitted to the AHJ to demonstrate equivalency and the system, method, or device is approved for the intended purpose.

N **1.4.1.1* Compliance with Subsequent Editions of Referenced Publications.** The AHJ shall be authorized to accept subsequent editions of publications referenced in this *Code* as evidence of compliance with the specified edition. When the AHJ accepts compliance with a subsequent edition of a referenced publication, compliance with subsequent edition shall be considered evidence of compliance with this *Code's* specified edition.

N **A.1.4.1.1** New editions of referenced publications incorporate advances in knowledge, best practices, and technology. Therefore, if an owner or contractor provides compliance with a new edition of a referenced publication that is specified by this *Code*, the AHJ should accept the new edition as evidence of full compliance with the *Code*.

For various reasons, jurisdictions may not be able to adopt the most recent edition of this *Code* when it is published. Frequently, these delays involve many years between adoptions resulting in editions of referenced standards that are no longer the most current. This section of the *Code* anticipates the problems that AHJs confront on a recurring basis. Rather than a designer or contractor being forced to use an older edition of a standard just because it is the edition referenced in this *Code*, the AHJ is authorized to approve designs using subsequent editions of the standards referenced in Chapter 2.

For example, this *Code* references the 2016 edition of NFPA 13 in Chapter 2. In some jurisdictions, this *Code* will likely be in effect well beyond the date NFPA produces the 2019 edition of NFPA 13. Once the 2019 edition of NFPA 13 is published, subparagraph 1.4.1.1 of this *Code* would authorize the AHJ to accept the 2019 edition of NFPA 13 as clear evidence of compliance with the 2016 edition of NFPA 13 referenced in Chapter 2. See 1.4.1.1.1.

N **1.4.1.1.1*** Compliance with subsequent editions of reference publications shall be achieved by complying with the entire subsequent edition of the referenced publication.

N **A.1.4.1.1.1** The intent of 1.4.1.1 and 1.4.1.1.1 is that an AHJ should approve the use of subsequent editions of referenced publications only when the entire new edition of the referenced standard is used. This paragraph is not intended to permit the use of "cherry-picking" specific sections of one edition of a referenced standard but to use the entire subsequent edition of the referenced standard.

Designers and contractors may approach AHJs for approval to use a section in a future edition of a code or standard that will add design flexibility. Although permitted under subparagraph 1.4.1.1.2, the AHJ should be cautious about granting approvals that "cherry pick" certain sections of subsequent codes or standards. Frequently, modifications to codes and standards from one edition to another are not made as stand-alone changes. They are parts of a package that, to provide the appropriate protection, must be applied in their entirety. Other sections of the code or standard may also have been modified at the same time as the section the AHJ is being asked to approve. A.1.4.1.1.1 informs AHJs that when they approve for use subsequent editions of a code or standard, and not a current edition, the new edition should be used in its entirety.

N **1.4.1.1.2*** Compliance with individual specific sections contained in subsequent editions of referenced publications, and not the entire reference publication, shall only be approved by the AHJ through technical documentation submitted in compliance with 1.4.1 or 1.4.2.

N **A.1.4.1.1.2** In circumstances where the AHJ is requested to use a specific section in a subsequent edition of a referenced publication and not the entire subsequent edition, the AHJ should require technical documentation submitted in compliance with 1.4.1 or 1.4.2. Before approving the use of specific sections of subsequent editions of referenced documents and not the entire edition of the subsequent edition, the AHJ should ensure that other changes did not occur to the subsequent edition that might affect the overall level of fire and life safety protection.

1.4.2 Alternatives. The specific requirements of this *Code* shall be permitted to be altered by the AHJ to allow alternative methods that will secure equivalent fire safety, but in no case shall the alternative afford less fire safety than, in the judgment of the AHJ, that which would be provided by compliance with the provisions contained in this *Code*.

Paragraph 1.4.2 allows the AHJ flexibility in dealing with existing buildings, including those that are deemed historic. Also see 4.5.2 and Section 20.17.

Historic buildings might have numerous *Code* deficiencies, such as open stairs (unprotected vertical openings) or highly combustible interior finishes. Rather than waiving requirements, the AHJ might require that a facility attain a level of safety equivalent to that required by the *Code*. For example, the use of sprinkler systems, smoke detection systems, voice alarm systems for staged evacuation, smoke control systems, or other features and systems might be required to overcome the existing deficiencies. Such an approach might be applied when bringing the building into strict compliance with the *Code* would destroy its historic fabric or character. Alternate approaches might increase safety to a level well above what existed in the building.

Before an inspection takes place, records should be reviewed carefully to determine whether equivalencies or alternate levels of protection have already been approved. It is important to note that the alternate level of protection must be at least equal to that specified by the *Code*; waivers are not permitted.

1.4.3 Modifications. The AHJ is authorized to modify any of the provisions of this *Code* upon application in writing by the owner, a lessee, or a duly authorized representative where there are practical difficulties in the way of carrying out the provisions of the *Code*, provided that the intent of the *Code* shall be complied with, public safety secured, and substantial justice done.

1.4.4 Buildings with equivalency, alternatives, or modifications approved by the AHJ shall be considered as conforming with this *Code*.

Compliance with this *Code* can be achieved in more than one way, as indicated in 1.4.4. A building either complies with the *Code's* prescriptive requirements or achieves equivalency through documentation of AHJ-approved alternatives or modifications. If an alternate approach to compliance is implemented, and the AHJ has judged that the alternative provides equivalency, the building is considered *Code* compliant. Compliance achieved by means of equivalency differs from a waiver that permits continued use of a noncompliant building, which should never be permitted. Documentation of equivalencies should be maintained by both the building owner and the AHJ for the life of the building. In addition, such documentation should specify whether changes to the building, such as removal of an otherwise nonrequired smoke detection system, will render the equivalency void.

1.4.5 Each application for an equivalent, alternative, or modified fire protection feature shall be filed with the AHJ and shall be accompanied by such evidence, letters, statements, results of tests, or other supporting information as required to justify the request. The AHJ shall keep a record of actions on such applications, and a signed copy of the AHJ's decision shall be provided for the applicant.

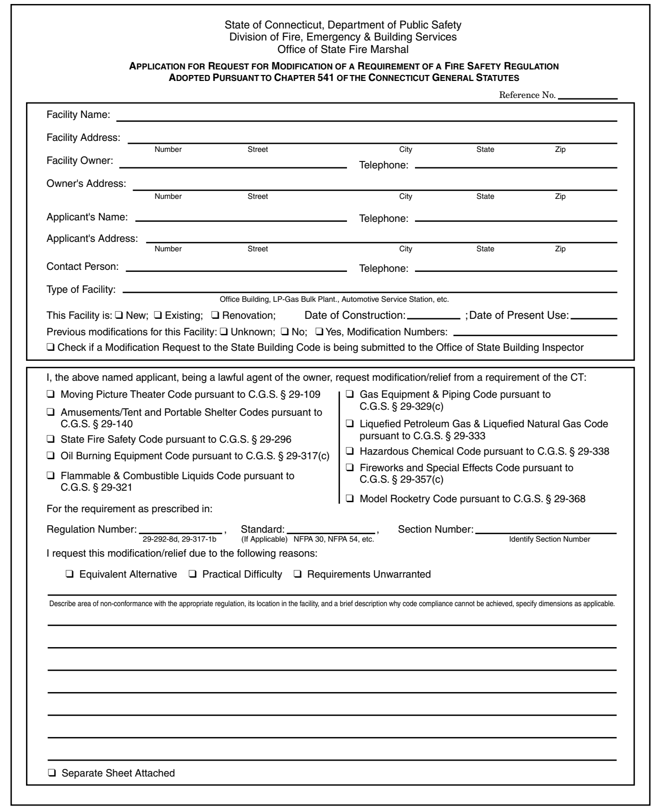
An applicant filing a request for an equivalency, alternative, or modification should be provided with a form by the AHJ. Exhibit 1.1 shows the first page of one such form for requesting a modification to a *Code* requirement. The form ensures that each applicant provides the AHJ with the appropriate information in an acceptable manner.

The AHJ should also require information, as necessary, to assist in determining whether the alternative level of protection is equivalent to the intent of this *Code*. The information required might include testing data, listing or labeling reports, engineering reports, and other supporting details that allow the AHJ to make an informed decision. The information must be maintained in an appropriate file so that a record on which the decision was based is available. This information is also important if the applicant files an appeal on the AHJ's decision to the Board of Appeals, as outlined in Section 1.10.

Δ **1.4.6 Approval.** The AHJ shall approve such equivalent, alternative, or modified construction systems, materials, or methods of design when it is substantiated that the standards of this *Code* are at least equaled. If, in the opinion of the AHJ, the standards of this *Code* are not equaled by the alternative requested, approval for permanent work shall be refused. Consideration shall be given to test or prototype installations.

The AHJ has the discretionary authority to approve or refuse an equivalency, alternatives, or modifications. However, that approval or refusal needs to be based on the ability of the applicant to justify that the equivalent level of life safety and protection has been provided.

Exhibit 1.1



State of Connecticut, Department of Public Safety
Division of Fire, Emergency & Building Services
Office of State Fire Marshal

APPLICATION FOR REQUEST FOR MODIFICATION OF A REQUIREMENT OF A FIRE SAFETY REGULATION
ADOPTED PURSUANT TO CHAPTER 541 OF THE CONNECTICUT GENERAL STATUTES

Reference No. ______

Facility Name: ______
Facility Address: ______ (Number, Street, City, State, Zip)
Facility Owner: ______ Telephone: ______
Owner's Address: ______ (Number, Street, City, State, Zip)
Applicant's Name: ______ Telephone: ______
Applicant's Address: ______ (Number, Street, City, State, Zip)
Contact Person: ______ Telephone: ______
Type of Facility: ______ (Office Building, LP-Gas Bulk Plant., Automotive Service Station, etc.)
This Facility is: ❑ New; ❑ Existing; ❑ Renovation; Date of Construction: ______ ; Date of Present Use: ______
Previous modifications for this Facility: ❑ Unknown; ❑ No; ❑ Yes, Modification Numbers: ______
❑ Check if a Modification Request to the State Building Code is being submitted to the Office of State Building Inspector

I, the above named applicant, being a lawful agent of the owner, request modification/relief from a requirement of the CT:
- ❑ Moving Picture Theater Code pursuant to C.G.S. § 29-109
- ❑ Amusements/Tent and Portable Shelter Codes pursuant to C.G.S. § 29-140
- ❑ State Fire Safety Code pursuant to C.G.S. § 29-296
- ❑ Oil Burning Equipment Code pursuant to C.G.S. § 29-317(c)
- ❑ Flammable & Combustible Liquids Code pursuant to C.G.S. § 29-321
- ❑ Gas Equipment & Piping Code pursuant to C.G.S. § 29-329(c)
- ❑ Liquefied Petroleum Gas & Liquefied Natural Gas Code pursuant to C.G.S. § 29-333
- ❑ Hazardous Chemical Code pursuant to C.G.S. § 29-338
- ❑ Fireworks and Special Effects Code pursuant to C.G.S. § 29-357(c)
- ❑ Model Rocketry Code pursuant to C.G.S. § 29-368

For the requirement as prescribed in:
Regulation Number: ______ (29-292-8d, 29-317-1b), Standard: ______ (If Applicable) (NFPA 30, NFPA 54, etc.), Section Number: ______ (Identify Section Number)
I request this modification/relief due to the following reasons:
❑ Equivalent Alternative ❑ Practical Difficulty ❑ Requirements Unwarranted

Describe area of non-conformance with the appropriate regulation, its location in the facility, and a brief description why code compliance cannot be achieved, specify dimensions as applicable.

❑ Separate Sheet Attached

Sample application form for an equivalency, alteration, or modification. (Courtesy of State of Connecticut, Department of Public Safety)

1.4.7 Tests.

1.4.7.1 Whenever evidence of compliance with the requirements of this *Code* is insufficient or evidence that any material or method of construction does not conform to the requirements of this *Code*, or to substantiate claims for alternative construction systems, materials, or methods of construction, the AHJ shall be permitted to require tests for proof of compliance to be made by an approved agency at the expense of the owner or his/her agent.

1.4.7.2 Test methods shall be as specified by this *Code* for the material in question. If appropriate test methods are not specified in this *Code*, the AHJ is authorized to accept an applicable test procedure from another recognized source.

The question of "What is an appropriate test?" is one that needs careful consideration by the AHJ. If an incorrect type of test is submitted to the AHJ or if the AHJ specifies an incorrect test method, the code specified level of safety may not be achieved. If there is a question about the appropriate test method to be used, the AHJ should consult subject experts and testing laboratories with expertise in the area.

1.4.7.3 Copies of the results of all such tests shall be retained in accordance with Section 1.11.

1.5 Units

1.5.1 International System of Units. Metric units of measurement in this *Code* are in accordance with the modernized metric system known as the International System of Units (SI).

1.5.2 Primary and Equivalent Values. If a value for a measurement as given in this *Code* is followed by an equivalent value in other units, the first stated value shall be regarded as the requirement. A given equivalent value could be approximate.

1.6 Enforcement

This *Code* shall be administered and enforced by the AHJ designated by the governing authority. *(See Annex C for sample wording for enabling legislation.)*

NFPA 1 might be enforced by different agencies in different jurisdictions. Depending how the *Code* is adopted, enforcement responsibilities might be divided between state and local agencies or between different agencies at either the state or local level. If the enforcement responsibility is divided, each agency must be aware of the portions of NFPA 1 for which it has enforcement responsibility and must understand the source of its authority to enforce those portions.

The agency needs to confirm their ability to legally adopt and enforce this *Code* with the proper legal procedures to use during a code adoption process. Frequently, an individual or company contesting the need to comply with this *Code* will challenge the agency's authority to adopt this *Code* and the mechanism used to adopt this *Code*. If the *Code* was not legally or properly adopted, the ability to enforce this *Code* will be brought into question and may not be upheld.

1.7 Authority

1.7.1 Administration. The provisions of this *Code* shall apply without restriction, unless specifically exempted.

The governing authority might choose to supplement or alter the *Code*. The authority might, for example, mandate that specific annex material be adopted or that certain sections of the *Code* cannot apply within the jurisdiction. Annexes are provided for informational purposes only and are not part of the requirements of this *Code*. However, two annexes in NFPA 1 are adoptable: Annex D, Hazardous Materials Management Plans and Hazardous Materials Inventory Statements; and Annex E, Fire Fighter Safety Building Marking System. Governing authorities choosing to adopt either or both of these annexes must include them by name in the ordinance adopting this *Code*. The annexes then become an enforceable part of the *Code*. See Annex C for a sample ordinance to adopt NFPA 1.

1.7.2* Minimum Qualifications to Enforce this *Code*. The AHJ shall establish minimum qualifications for all persons assigned the responsibility of enforcing this *Code*.

Δ **A.1.7.2** For additional information on qualifications of code enforcement personnel, see NFPA 1031, NFPA 1033, NFPA 1035 and NFPA 1037.

N **1.7.2.1** Fire inspectors and plans examiners shall meet the minimum professional qualifications established in NFPA 1031.

NFPA 1031, *Standard for Professional Qualifications for Fire Inspector and Plan Examiner*, provides a list of job performance requirements with matching knowledge areas and skills that a fire inspector or plans examiner should possess when performing specific job functions. NFPA 1031 has three levels of progression for fire inspectors and two plans examiners. The *Code* requires that fire inspectors and plans examiners be assigned only to roles that match their NFPA 1031 fire inspector or plans examiner levels.

The primary method to ensure that fire inspectors and plans examiners are trained appropriately to their job functions is via an accredited certification program. ProBoard and IFSAC, International Fire Service Accreditation Congress, are two examples of such fire service accrediting bodies that evaluate fire service certifying entities. Certifying entities will then provide certification to NFPA 1031 for fire inspectors and plans examiners.

N **1.7.2.2** The AHJ shall be authorized to approve alternative qualifications for personnel conducting fire inspections and plan examination if the AHJ determines the individual possesses the knowledge, skills, and abilities to perform the job performance requirements of the position.

N **1.7.2.3** Fire marshals shall meet the minimum professional qualifications established in NFPA 1037.

NFPA 1037, *Standard on Fire Marshal Professional Qualifications*, specifies minimum job performance requirements, knowledge, and skills expected of a fire marshal. Before placing an individual in the position of a fire marshal, NFPA 1037 requires that the agency must ensure that the individual meets the requirements of NFPA 1031.

N **1.7.2.4** The AHJ shall be authorized to approve alternative qualifications for personnel performing the position of fire marshal if the AHJ determines the individual possesses the knowledge, skills, and abilities to perform the job performance requirements of the position.

1.7.3 Interpretations.

1.7.3.1 The AHJ is authorized to render interpretations of this *Code* and to make and enforce rules and supplemental regulations in order to carry out the application and intent of its provisions.

The AHJ is authorized to clarify or supplement *Code* requirements based on its interpretation for ease of use and enforcement. The granting of this authority includes the power to adopt rules, polices, and regulations to effectively implement the intent of this *Code*. Because AHJs are charged with enforcing this *Code*, they must also provide interpretations of its intent and application. AHJs requiring assistance in determining the application or intent of a requirement might consider contacting other area AHJs or NFPA technical staff for assistance.

1.7.3.2 Such interpretations, rules, and regulations shall be in conformance with the intent and purpose of this *Code* and shall be available to the public during normal business hours.

1.7.4 Enforcement Assistance. Police and other enforcement agencies shall have authority to render necessary assistance in the enforcement of this *Code* when requested to do so by the AHJ.

The enforcement power given to the AHJ varies. Assistance from another agency, such as a police department, building department, or public works department, might be required when carrying out the responsibilities assigned by the *Code*. The AHJ should maintain a close working relationship with other enforcement agencies whose assistance is needed to enforce the *Code* properly.

If regular assistance is needed, having the same person(s) from the assisting enforcement agency work with the AHJ each time enables that person(s) to become familiar with the issues and provide better continuity and support. At times, personnel from other enforcement agencies might be assigned to the office of the AHJ.

1.7.5 Delegation of Authority. The AHJ shall be permitted to delegate to other qualified individuals such powers as necessary for the administration and enforcement of this *Code*.

The AHJ might have staff assigned to assist with enforcement duties. Staff members might have specific or specialized assignments, such as plan review or flammable and combustible liquid inspection responsibilities, or they could perform a variety of duties. In either case, the organizational structure should be clear. In addition, AHJ designated staff members might be assigned to roles outside of the traditional fire prevention bureau, such as to fire department operations units in fire stations. Staff members and others should be able to identify a clear chain of command to the AHJ, the duties and responsibilities of the various command and staff positions, and the procedures for all staff to follow. This information should be provided as part of staff training, and a written copy should be available for reference and review as needed.

1.7.6 Reliance on Other Enforcement Officials.

1.7.6.1* The AHJ shall be authorized to rely on plan reviews, inspections, opinions, and approvals rendered by other enforcement officials in determining compliance with this *Code*.

Δ **A.1.7.6.1** The AHJ enforcing NFPA 1 may not have the technical expertise, required certifications, licensure, or legal authority to enforce all of the provisions and subject matter contained therein. As an example, Chapter 11 contains references to codes and standards that regulate specific building subsystems. These subsystems could be regulated by electrical, mechanical, plumbing, or other specialty enforcement officials with technical expertise or legal authority in the specific area of the subsystem. This paragraph authorizes the AHJ enforcing NFPA 1 to rely on the opinion and authority of these specialty enforcement officials in order to determine compliance.

The AHJ for NFPA 1 should have an understanding with other AHJs, such as building, mechanical, plumbing, and electrical codes, on issues that may cross over each other's scope of authority. As an example, systems such as medical gas and liquefied petroleum gas might be regulated by multiple codes or authorities. Developing an understanding as to scope of plans review and inspections for those systems that might be jointly regulated will go a long way to ensuring quality customer service and that hazards are not missed by multiple AHJs.

1.7.6.2 When the AHJ relies on inspections, plan reviews, opinions, and approvals rendered by other enforcement officials in determining compliance with this *Code*, the other enforcement officials shall be deemed to be acting as agents under their own authority and not as agents of the AHJ enforcing this *Code*.

The provisions of paragraph 1.7.6 clarify that the AHJ responsible for its enforcement likely has neither the authority nor the expertise to enforce the plumbing, mechanical, or electrical code, among others, as referenced by other sections of this *Code*. The AHJ can rely on the approvals of other applicable enforcement officials to determine compliance with such other codes.

1.7.7 Inspection.

1.7.7.1* The AHJ shall be authorized to inspect, at all reasonable times, any building or premises for dangerous or hazardous conditions or materials as set forth in this *Code*.

N **A.1.7.7.1** New construction and existing occupancy inspection services should comply with NFPA 1730.

1.7.7.2 The AHJ shall have authority to order any person(s) to remove or remedy such dangerous or hazardous condition or material. Any person(s) failing to comply with such order shall be in violation of this *Code*.

If a dangerous or hazardous condition is found during an inspection, the AHJ is required to order the owner to correct the violation. Owners who fail to correct or abate such deficiencies are in violation of the *Code*. See Section 1.16 and Section 10.2.

1.7.7.3 To the full extent permitted by law, any AHJ engaged in fire prevention and inspection work shall be authorized at all reasonable times to enter and examine any building, structure, marine vessel, vehicle, or premises for the purpose of making fire safety inspections.

The phrase *all reasonable times,* which is used in subparagraph 1.7.7.3, usually corresponds to the operating or business hours of a building or property. In most cases, performing a fire inspection at midnight in a business occupancy that is open from 8 a.m. to 5 p.m. is not reasonable. However, it may be reasonable to conduct an inspection of a bar or nightclub at midnight. AHJs should confer with their jurisdiction's legal counsel for further guidance.

1.7.7.4 Before entering, the AHJ shall obtain the consent of the occupant thereof or obtain a court warrant authorizing entry for the purpose of inspection except in those instances where an emergency exists.

The ability to perform an inspection is an important part of a jurisdiction's fire and life safety program. To perform an inspection, the inspector needs to obtain permission from the property owner, as stated in 1.7.7.4. In some jurisdictions, an occupant can allow entry for the inspection. In many jurisdictions, the AHJ can apply for and receive an administrative warrant to perform inspections if entry is not granted. In jurisdictions where an administrative warrant is not available, the acquisition of a search warrant might be required. The inspector should be familiar with state and local laws regarding the right to enter property and the appropriate procedures to take when consent is not granted.

Basic search and seizure guidelines require that the person granting permission for an inspection has control over the area(s) to be entered. In most cases, determining who has the authority to allow access to an occupancy or an area for inspection is relatively easy. However, in multi-tenant arrangements, such as apartments with more than one tenant in a single dwelling unit, determining the right of an individual to grant inspection access to all areas is more difficult. In the case of multiple tenants, any tenant can allow access to common spaces, such as the living room, kitchen, and bathroom (if they share the bathroom). However, bedroom areas are usually under the separate control of each tenant, and each can allow access only to his or her own bedroom. Another important factor is the age of the person granting permission. Minors do not have the authority to grant permission to enter or inspect a premises.

The AHJ needs to exercise caution when entering a property without permission or a warrant on the grounds that an emergency exists. The AHJ's determination of the presence of an emergency may be subject to challenge and overturned if the evidence for such a determination is not deemed reasonable by a court. If the AHJ has any uncertainty about their legal authority to conduct an inspection, the AHJ should confer with their jurisdiction's legal counsel for guidance before conducting the inspection.

1.7.7.5 As used in 1.7.7.4, emergency shall mean circumstances that the AHJ knows, or has reason to believe, exist and that can constitute imminent danger.

An example of the application of 1.7.7.5 would be where the AHJ or the fire department sees smoke coming from an apartment window. In such a situation, the owner or occupant's permission would not be required to enter the premises and extinguish the fire. In fact, according to 1.7.8, 1.8.2, and 1.8.3, any person(s) interfering with the duties of those involved would be in violation of this *Code*. Other examples of emergencies could include situations such as reports of a gas leak, a building that is potentially structurally unsafe, improper storage of hazardous materials, fire protection systems that are out of service, or locked means of egress. If challenged whether a search was legal under this section, the burden will be on the AHJ to demonstrate that the information the AHJ had met the standard of an emergency.

1.7.7.6 Persons authorized to enter and inspect buildings, structures, marine vessels, vehicles, and premises as herein set forth shall be identified by credentials issued by the governing authority.

Identification credentials for a fire code inspector might include a photo identification card that carries the inspector's name, title, and affiliation, as well as the name and address of the issuing agency. The photo should show the inspector's face and should be current. For example, if the inspector has a beard or mustache, the card photo should not show him as clean-shaven. The printing on the card should be legible in poor lighting conditions and large enough for those with poor eyesight to read easily.

The AHJ should willingly demonstrate to any member of the public their proper credentials if questioned.

1.7.8 Where conditions exist and are deemed hazardous to life or property by the AHJ, the AHJ shall have the authority to summarily abate such hazardous conditions that are in violation of this *Code*.

Abatement of a hazard means to correct the hazard. Whether the hazard exists on public or private property, the AHJ has the authority to correct that condition when the condition is hazardous to life or property. The AHJ needs to use discretion in exercising this authority. The more imminent the danger, the greater the justification exists for the AHJ to take abatement action.

See Section 1.16 for requirements on serving notice of violations and penalties.

1.7.9 Interference with Enforcement. Persons shall not interfere or cause conditions that would interfere with an AHJ carrying out any duties or functions prescribed by this *Code*.

1.7.10 Impersonation. Persons shall not use a badge, uniform, or other credentials to impersonate the AHJ.

1.7.11 Investigation.

A complete investigation of the origin, cause, and circumstances of fire incidents assists the AHJ in determining the fire and life safety risks in its jurisdiction and can help in planning fire prevention activities. In addition, professionally conducted fire investigations to ascertain the origins and causes of fires are necessary to determine if a crime has been committed. Fire investigators should follow NFPA 921, *Guide for Fire and Explosion Investigations,* when conducting fire investigations. Individuals assigned the role of a fire investigator should also meet the professional qualification standards contained in NFPA 1033, *Standard for Professional Qualifications for Fire Investigator.*

1.7.11.1 Authority. The AHJ shall have the authority to investigate the cause, origin, and circumstances of any fire, explosion, release of hazardous materials, or other hazardous condition.

1.7.11.2 Evidence. The AHJ shall have the authority to take custody of all physical evidence relating to the cause of the fire, explosion, release of hazardous materials, or other hazardous condition.

With regards to the application of 1.7.11.1 and 1.7.11.2, the AHJ should ensure that they have a legal right to search a property and/or take physical evidence under their state laws and federal limitations.

1.7.11.3 Limiting Access. The AHJ shall have the authority to limit access to emergencies or other similar situations.

1.7.11.4 Trade Secret. Information that could be related to trade secrets or processes shall not be made part of the public record except as could be directed by a court of law.

Freedom of information laws and local legal counsel should be consulted for guidance about the proper handling of records, reports, and other documents that might involve proprietary industry information. State freedom of information laws may supersede this provision.

1.7.12 Plans and Specifications.

The review of plans by an AHJ ensures compliance with the *Code*. In jurisdictions where other departments or AHJs also review plans, the requirements of 1.7.12 provide for an additional review by the AHJ responsible to enforce this *Code* and referenced standards. Cooperation among the fire official, the building official, and other code officials is key to the success of any code enforcement program. With good cooperation and coordination from plan review up to and including final approval, both the jurisdiction and the community benefit by ensuring compliance with all applicable codes and standards.

1.7.12.1 The AHJ shall have the authority to require plans and specifications to ensure compliance with applicable codes and standards.

The AHJ is granted broad discretionary power to determine when and what plans and specifications are required to be reviewed. Usually, the requirement to submit plans and specifications is tied to the permit approval process.

1.7.12.2 Plans shall be submitted to the AHJ prior to construction unless otherwise permitted by 1.7.12.4.

1.7.12.3 The construction documents for each phase shall be complete in themselves, so that review and inspection can properly be made. Preliminary plans of the total building shall be submitted with the construction documents, and with sufficient detail, so that proper evaluation can be made. Areas and items not included in the phase to be permitted shall be shown as not included. [**5000:**1.7.6.3.3.3]

1.7.12.4 The AHJ is authorized to exempt detached one- and two-family dwellings and accessory structures from the submittal of plans.

Frequently, one- and two-family dwelling plans are reviewed and approved for compliance with an adopted building code by the building department. In this circumstance, the AHJ may determine that there is limited value for the AHJ enforcing this *Code* to conduct an additional review. However, the AHJ should ensure that fire department access and water supply provisions have been addressed adequately because those topics are typically not addressed in a building code. It is important to note that even if a one- or two-family dwelling is exempt from a plan review for the architectural design, the AHJ would still be warranted in requiring a plan review for a fire sprinkler system design. Exemption from permit requirements is covered under 1.7.12.9.

1.7.12.5 Plans shall be submitted to the AHJ prior to the change of occupancy of any existing building.

In some cases, a change of occupancy classification might not involve physical alterations to the building. For example, an open retail space (mercantile occupancy) might be converted to a travel agency (business occupancy) with no construction required except for the replacement of fixtures and furnishings. In such a case, notification must be provided to the AHJ so that compliance with the *Code* requirements applicable to the new occupancy can be verified. In most cases, this will also require that the building's or lease space's occupancy classification be clearly stated on its certificate of occupancy; changes to the building's or lease space's occupancy classification should render the certificate of occupancy invalid.

1.7.12.6 Plans shall be submitted to the AHJ prior to the alteration of the means of egress or fire protection systems of any existing building.

1.7.12.7 Plans shall be submitted to the AHJ for other conditions as deemed necessary by the AHJ to determine compliance with the applicable codes and standards.

1.7.12.8 The AHJ shall be authorized to require permits for conditions listed in 1.7.12.2, 1.7.12.5, and 1.7.12.6, unless otherwise permitted by 1.7.12.9.

1.7.12.9 The AHJ is authorized to exempt detached one- and two-family dwellings and accessory structures from the permit requirement of 1.7.12.8.

See commentary to 1.7.12.4.

1.7.12.10 No construction work shall proceed until the AHJ has reviewed the plans for compliance with the applicable codes and standards and the applicable permits have been issued.

Construction work on buildings and the installation or modification of fire protection systems must not commence until plans are approved and the appropriate permits are issued by the AHJ. Contractors who start work without permits do so at their own risk and are in violation of the *Code*. Many jurisdictions discourage work without a permit by adopting a permit fee schedule that provides a penalty of double or triple the normal permit fee for work occurring without a permit. Other regulatory methods to discourage work without a permit are to provide disciplinary action to contractors in jurisdictions that require certificates of fitness or licenses. Some jurisdictions provide contractors with flexibility by issuing permit types that allow for early start of work before the full permit is issued. These permits only allow work to occur up to the point of the fire inspection and at the contractor's risk.

1.7.13 Inspection of Construction and Installation.

1.7.13.1 The AHJ shall be notified by the person performing the work when the installation is ready for a required inspection.

Persons performing work subject to inspection should be notified how much lead time is required for scheduling inspections. For example, it might be reasonable to require inspections to be scheduled at least 24 hours in advance. Requiring inspections to be scheduled two weeks in advance is probably unreasonable and not conducive to beneficial relationships between the AHJ and the development community.

1.7.13.2 Whenever any installation subject to inspection prior to use is covered or concealed without having first been inspected, the AHJ shall have the authority to require that such work be exposed for inspection.

At times, an inspector might discover that items subject to inspection are intentionally or unintentionally covered or concealed. To confirm that an installation of wiring, ductwork, or other similar building system was made in accordance with the appropriate standards or prior approvals, the AHJ can require that the area be exposed for inspection. The installer should notify the AHJ, in advance and when work is visible, that an installation is in need of an inspection. The AHJ should establish guidelines for the inspections types that are required for each permit type and the notification time frames.

1.7.13.3 When any construction or installation work is being performed in violation of the plans and specifications as approved by the AHJ, a written notice shall be issued to the responsible party to stop work on that portion of the work that is in violation.

1.7.13.4 The notice shall state the nature of the violation, and no work shall be continued on that portion until the violation has been corrected.

During the construction or the installation of systems or equipment, the work performed might be found to differ from the approved plans or specifications. The change might be necessary because of unexpected features or conditions in a building or an area. If changes are noted during an inspection, the AHJ can issue a stop work order to suspend the work until proper corrective action or approval has been obtained. See Exhibit 1.2 for an example of a form that an AHJ can use to issue a stop work order. (See 1.7.15 for details on stop work orders.)

If approval for modification of the approved plans or specifications, or both, has not been obtained, the stop work order protects the building owner, the community, and the AHJ from problems that could result from the unapproved work.

Exhibit 1.2

LEGAL NOTICE

Date ________________

WHEREAS, VIOLATIONS OF { Article ________, Section ________ of the Zoning Ordinance / Article ________, Section ________ of the Building Code / Article ________, Section ________ of the ____________ Code } have been found on these premises, IT IS HEREBY ORDERED in accordance with the above Code that all persons cease, desist from, and

STOP WORK

at once pertaining to construction, alterations or repairs on these premises known as________________________________

All persons acting contrary to this order or removing or mutilating this notice are liable to arrest unless such action is aurhorized by the Department.

____
CODE OFFICIAL

Sample form for a stop work order.

The inspector can allow work to resume when the appropriate approvals, the corrections, or an explanation for the variation from the approved plans or specifications is obtained.

A stop work order issued under this section should be reserved only for circumstances where there is a significant divergence from the plans. In most other cases, the AHJ can issue a rejection on an inspection and direct the contractor to correct the plans to match the field conditions or to correct the field condition to match the plans.

1.7.14 Certificate of Occupancy. When the building code requires a certificate of occupancy, the certificate of occupancy shall not be issued until approved by the AHJ for fire code enforcement.

The building code typically empowers the building official to issue a certificate of occupancy once the use is determined to be compliant with the approved plans and the adopted building code. The issuance of a certificate of occupancy is usually the final authorization for the start of the building's intended use by the occupants and public. In most jurisdictions, that authorization involves final approved inspections by building, mechanical, plumbing, and electrical inspectors. The AHJ for fire code enforcement should have the same standing as the other trade inspectors for co-approval.

1.7.15 Stop Work Order. The AHJ shall have the authority to order an operation, construction, or use stopped when any of the following conditions exists:

(1) Work is being done contrary to provision of this *Code*.
(2) Work is occurring without a permit required by Section 1.12.
(3) An imminent danger has been created.

The AHJ has the authority to order the cessation of work where any of the conditions cited under 1.7.15 are encountered. The most serious of these relates to the creation of *imminent danger,* which is defined in 3.3.159 as "a condition or practice in an occupancy or structure that poses a danger that could reasonably be expected to cause death, serious physical harm, or serious property loss." An example of imminent danger might be unauthorized handling of explosives by untrained personnel without proper precautions. The AHJ might reasonably expect that such activity has a relatively high probability of causing death, serious physical harm, or serious property loss. The issuance of a stop work order in such a case would be most appropriate. In addition, if work is occurring without a permit or if the work is contrary to the code, the AHJ can issue a stop work order. Similar language is cited in 1.17.13.3 that allows a stop work order to be issued when conditions in the field do not match the plans.

1.7.16 Imminent Dangers and Evacuation.

1.7.16.1 When, in the opinion of the AHJ, an imminent danger exists, the AHJ shall be authorized to order the occupants to vacate, or temporarily close for use or occupancy, a building, the right-of-way, sidewalks, streets, or adjacent buildings or nearby areas.

1.7.16.2 The AHJ shall be authorized to employ the necessary resources to perform the required work in order to mitigate the imminent danger.

1.7.16.3 Costs incurred by the AHJ in the performance of emergency work shall be the responsibility of the property owner or other responsible party creating such imminent danger.

The AHJ might evacuate a building or an area, or stop a use or an operation, when danger is imminent. One common reason for evacuation, other than fire or a similar emergency, is overcrowding.

Care should be taken when evacuating an overcrowded building, especially where alcohol is served and occupants might become disorderly or even violent. The inspector should be certain that he or she has the appropriate authority to order the evacuation under the specific circumstances present. The inspector should also be careful to follow all department guidelines before initiating the evacuation. As a safety precaution for the inspector and the evacuees, adequate police presence should be in place before an evacuation begins.

1.7.17 Standby and Fire Watch Personnel.

1.7.17.1 The AHJ shall have the authority to require standby fire personnel or an approved fire watch when potentially hazardous conditions or a reduction in a life safety feature exist due to the type of performance, display, exhibit, occupancy, contest, or activity; an impairment to a fire protection feature; or the number of persons present.

1.7.17.2 The owner, agent, or lessee shall employ one or more qualified persons, as required and approved, to be on duty.

The term *qualified persons,* as used in 1.7.17.2, is left to the discretion of the AHJ. The term *fire personnel* also includes emergency medical service (EMS) personnel who may be required as part of a standby for an activity that may generate a need for EMS services for participants or spectators. Depending on the circumstances, qualified persons might be building personnel, security personnel, emergency medical technicians, paramedics, fire inspectors, or fire fighters. The number of qualified persons is also subject to determination of the AHJ.

1.7.17.2.1 The cost of standby fire personnel shall be at no cost to the AHJ.

The building owner or building owner's representative is responsible for the cost of standby and fire watch personnel. In determining the cost to provide such services, the AHJ may include salaries, benefits, equipment use, overhead to plan and manage the standby, and any other costs that are created to the jurisdiction as a result of the standby. In cases of anticipated events where the jurisdiction will provided the standby personnel, the jurisdiction may consider collecting the estimated cost of the standby fire personnel at the time the permit or other authorization is provided for the activity requiring standby fire personnel.

1.7.17.3* Such standby fire personnel or fire watch personnel shall be subject to the AHJ's orders at all times and shall be identifiable and remain on duty during the times such places are open to the public, when such activity is being conducted, or as required by the AHJ.

A.1.7.17.3 Before each performance or the start of such activity, such individuals should inspect the required fire appliances provided to see that they are properly located and in good working order, and should keep diligent watch for fires during the time such place is open to the public or such activity is being conducted and take prompt measures for extinguishment of fires that can occur.

Standby fire personnel are subject to the orders of the AHJ and should not serve other unrelated functions unless specifically permitted by the AHJ. They should be readily identifiable and available during the times specified by the AHJ. These times could be short term, such as during a performance, or long term, such as while a sprinkler system is impaired or out of service.

1.7.18 Public Fire Education.

1.7.18.1 The AHJ shall have the authority to develop and implement a public fire safety education program as deemed necessary for the general welfare with respect to the potential fire hazards within the jurisdiction.

Public fire and life safety education programs should be a major part of any fire prevention program. Community outreach, education, and awareness programs should start as early as possible in preschool and/or elementary school and continue through high school. Adult programs should also be available to increase fire and life safety awareness in the community. A review of the community's fire records can help to identify high-risk problems or areas in the community that require extra fire and life safety efforts.

Fire education programs in schools should be a year-round endeavor and not merely a special program conducted during an annual Fire Prevention Week. School systems can incorporate fire safety programs into their existing curricula. The fire prevention authority can help by advising schools on the proper training of presenters and by identifying appropriate materials to reinforce the fire safety message. NFPA's *Learn Not to Burn*® and *Remembering When*™ programs provide training and materials needed for such a fire safety effort.

The media can be a useful partner in fire safety awareness initiatives for adults and children. Television and radio stations might run public safety messages free of charge as part of their licensing requirements. In addition, many cable companies offer public access as part of their contract to provide service to the community. These programs are excellent opportunities to provide fire safety education messages on a regular basis. The fire department, police department, and other public service agencies can pool their resources to use these public access avenues more effectively. Collaboration relieves a single agency from the burden of providing a complete program every week and gives the audience a broader spectrum of programming to maintain their interest.

There are situations where education of a specific segment of the public is a required activity under the *Code*, for example, in crowd management training programs, assembly occupancies, and emergency action plans.

1.7.18.2 The AHJ shall have the authority to ensure duly authorized public fire safety education programs or public fire safety messages are disseminated to the general public.

1.8 Duties and Powers of the Incident Commander

1.8.1 Authority. The incident commander conducting operations in connection with the extinguishment and control of any fire, explosion, hazardous materials incident, natural disaster, rescue, and/or other emergency shall have authority to direct all operations of fire extinguishment, mitigation of a hazardous materials incident, natural disaster, rescue, and/or control and to take necessary precautions to save life, protect property, and prevent further injury or damage.

The incident commander of an emergency operation must have the authority to do what is necessary to mitigate a hazard. Paragraph 1.8.1 gives the incident commander broad authority to perform the duties required. As such, state statutes, local ordinances, and department policies related to the duties and powers of an incident commander should also be considered when determining the scope of an incident commander's duties and powers.

1.8.2 Controlling Scene. During any emergency described in 1.8.1, including the investigation of the cause of such emergency, the incident commander or authorized representative shall be permitted to control or prohibit the approach to the scene of such emergency by any vehicle, vessel, or person.

Paragraph 1.8.2 authorizes the incident commander to prevent people from entering the scene of an emergency and to evacuate areas in a danger zone. Areas in a danger zone include areas in the path of a fire and downwind of a hazardous materials spill or release.

1.8.3 Obstruction of Operations. Persons shall not obstruct the operations of the fire department or disobey any command of the incident commander or authorized representative or any part thereof, or any order of a police officer assisting the fire department.

State statutes should also be consulted because those documents typically contain provisions that make the obstruction of fire department operations a criminal offense.

1.8.4 Scene Barrier. The incident commander or authorized representative in charge of an emergency scene shall have the authority to establish barriers to control access in the vicinity of such emergency and to place, or cause to be placed, ropes, guards, barricades, or other obstructions across any street or alley to delineate such emergency scene barrier.

During emergency operations, the incident commander should establish safe areas and keep the public within those areas. Physical barriers, barrier tape, or other means appropriate for the situation and the duration of the emergency can accomplish the requirement of 1.8.4. Exhibit 1.3 shows an example of barrier tape blocking access to a fire scene.

Some emergency scenes are more controllable than others. For example, controlling access to an incident on a limited-access highway is less complicated than controlling access to a fire in a downtown area close to traffic and pedestrians. At all emergencies, the incident commander should ensure that the area controlled is large enough for adequate expansion of the emergency, as warranted. The area should be large enough to accommodate the personnel and equipment required for mitigation of the incident, as well as to ensure the public's safety.

Exhibit 1.3

Barrier tape blocking access to a fire scene. (©Rodehi, Dreamstime .com)

Reducing the size of the area under control is easier than increasing it. Special provisions for the media should be in place, including a system for providing the media with special passes and access to specific areas when necessary and appropriate.

1.8.5 Persons, except as authorized by the incident commander in charge of the emergency, shall not be permitted to cross barriers established in accordance with 1.8.4.

1.9 Liability

While the provision of Section 1.9 provides appropriate liability protections to the AHJ professionally and personally, the AHJ should check with the jurisdiction's legal counsel for any additional liability laws. If the AHJ is involved in litigation, Section 1.9 should be brought to the attention of the AHJ's legal counsel.

1.9.1 The AHJ, and other individuals charged by the AHJ, or the incident commander of emergency operations, charged with the enforcement of this *Code* or any other official duties, acting in good faith and without malice in the discharge of their duties, shall not thereby be rendered personally liable for any damage that could accrue to persons or property as a result of any act or by reason of any act or omission in the discharge of their duties.

Subsection 1.9.1 addresses a situation in which a plaintiff may attempt to hold an AHJ personally liable for damages. As long as the AHJ is acting in good faith and without malice in their official actions, the intent of this section is to shield the AHJ from any personal liability associated with their official job function.

1.9.2 The fire department and AHJ, acting in good faith and without malice in the discharge of the organizations' public duty, shall not thereby be rendered liable for any damage that could accrue to persons or property as a result of any act or by reason of any act or omission in the discharge of such duties.

Subsection 1.9.2 addresses a situation in which a plaintiff may attempt to hold an AHJ or the fire department professionally liable for damages. As long as the AHJ or the fire department is acting in good faith and without malice in their official actions, the intent of this section is to shield the AHJ and fire department from professional liability associated with their official job function.

1.9.3 Any suit brought against the AHJ, the incident commander, or such individuals because of such act or omission performed in the enforcement of any provision of such codes or other pertinent laws or ordinances implemented through the enforcement of this *Code* or enforced by the code enforcement agency shall be defended by this jurisdiction until final termination of such proceedings, and any judgment resulting therefrom shall be assumed by this jurisdiction.

1.9.4 This *Code* shall not be construed to relieve from or lessen the responsibility of any person owning, operating, or controlling any building or structure for any damages to persons or property caused by defects, nor shall the code enforcement agency or its parent jurisdiction be held as assuming any such liability by reason of the inspections authorized by this *Code* or any permits or certificates issued under this *Code*.

1.10 Fire Code Board of Appeals

The AHJ should consult state statutes and local ordinances for additional guidance that may further direct the AHJ as to the composition, authority, and function of the Fire Code Board of Appeals.

1.10.1 Establishment of Fire Code Board of Appeals. A Board of Appeals shall be established to rule on matters relating to the fire code and its enforcement.

1.10.1.1 Membership.

1.10.1.1.1 The members of the Board of Appeals shall be appointed by the governing body of the jurisdiction.

1.10.1.1.2 The Board of Appeals shall consist of five or seven principal members and one ex officio member representative of the AHJ. Each principal member shall be permitted to have an alternate with similar experience to serve in his or her stead when necessary.

1.10.1.1.2.1 The jurisdiction governing body shall have the authority to appoint alternates who shall serve when a principal member is unable to fulfill their obligations. Alternates shall have the full authority and responsibility of principal members when serving in place of a principal member.

The purpose of appointing alternates is to assist in ensuring that a quorum is reached for meetings. For local boards, it can sometimes be a challenge to assemble board members in a timely manner to meet and reach decisions. If principal members are unavailable, alternate members can step in to ensure the quorum is reached and the meeting can proceed.

1.10.1.1.3 Members and alternate members shall be appointed based on their education, experience, and knowledge.

1.10.1.1.4 Members and alternates shall be appointed to a 3-year term.

1.10.1.1.5 Members and alternates shall be composed of individuals experienced in the following fields or professions:

(1) Engineering or architectural design
(2) General contracting
(3) Fire protection contracting
(4) Fire department operations or fire code enforcement
(5) Building code enforcement
(6) Legal
(7) General public

1.10.1.1.5.1 Members and alternates shall not be employees, agents, or officers of the jurisdiction.

1.10.1.1.5.2 Members and alternates shall be residents of the jurisdiction.

1.10.1.1.5.3 No more than one member shall represent the same field or provision listed in 1.10.1.1.5.

Diversity in the Board of Appeals membership is important to ensure a fair and impartial hearing. To achieve fairness, no more than one member of the same profession should be appointed to the board, except as an alternate. A range of professional representation ensures issues that come before the board are analyzed effectively and quality, evidence-based decisions are reached.

1.10.1.1.6 The representative of the AHJ shall be an ex officio member and shall be entitled to participate in all discussions. The ex officio member shall not be entitled to a vote.

1.10.1.1.7 No member of the Board of Appeals shall sit in judgment on any case in which the member holds a direct or indirect property or financial interest in the case.

If a board member, the company a board member represents, or that company's constituent or customer has applied to the board for an appeal, the board member should recuse himself or herself from all discussions and findings of the board in relation to that appeal.

1.10.1.1.8 The board shall select one of its members to serve as chair and one member to serve as vice chair.

1.10.2 Rules and Procedures of the Board of Appeals. The Board of Appeals shall have the authority to establish rules and regulations for conducting its business that are consistent with the provisions of this *Code*.

1.10.3 Authority of the Board of Appeals.

1.10.3.1 The Board of Appeals shall provide for the reasonable interpretation of the provisions of this *Code* and issue rulings on appeals of the decisions of the AHJ.

The Board of Appeals is charged with ensuring that the intent of the *Code* and public safety are met. The board is not permitted to grant variances or waivers that allow noncompliance with the *Code*. (See 1.10.3.4.) Board of Appeals members should receive training on the limitations of their authority, intent of the code, and the process to be used in rendering a decision.

1.10.3.2 The ruling of the Board of Appeals shall be consistent with the letter of the *Code* or when involving issues of clarity, ensuring that the intent of the *Code* is met with due consideration for public safety and fire fighter safety.

1.10.3.3 The Board of Appeals shall have the authority to grant alternatives or modifications through procedures outlined in Section 1.4 of the *Code*.

It is important to differentiate alternatives and modifications from waivers. Alternatives and modifications allow for differing approaches than what the prescriptive provisions of this *Code* may require while still providing for an equivalent level of property and life safety protection. The granting of a waiver would allow a petitioner to the board to disregard the protection provisions of the *Code* and is not allowed under 1.10.3.4.

1.10.3.4 The Board of Appeals shall not have the authority to waive the requirements of the *Code*.

The Board of Appeals is prohibited from waiving any requirement of the *Code*. AHJs and board members should be careful to ensure that a waiver is not being misrepresented as an alternative or modification. Any alternatives or modifications must be proven to ensure the intent of the *Code* is met for property protection, building safety, and fire fighter safety.

If a waiver request is submitted to the Board of Appeals, the request should be dismissed by the board's legal counsel without the board considering the request. When an appeal is rejected by the board's legal counsel, the applicant should be informed in writing by the board legal counsel that the appeal has been rejected as the board has no jurisdiction to rule on waivers.

1.10.3.5 The Board of Appeals decisions shall not be precedent setting.

Previous rulings by a board are not intended to set a precedent for future rulings. Each appeal should be made based on the circumstances relating to each individual appeal.

1.10.4 Means of Appeals.

1.10.4.1 Any person with standing shall be permitted to appeal a decision of the AHJ to the Board of Appeals when it is claimed that any one or more of the following conditions exist:

(1) The true intent of the *Code* has been incorrectly interpreted.
(2) The provisions of the *Code* do not fully apply.
(3) A decision is unreasonable or arbitrary as it applies to alternatives or new materials.

The board must review each application before accepting an appeal to determine whether one of the conditions in 1.10.4.1 exists. Where none of the conditions exist, the application for a hearing should be rejected, and the applicant must be sent a letter stating why the application was rejected. The letter should outline what further action, if any, the applicant can take within the appeals process of the jurisdiction.

1.10.4.2 An appeal shall be submitted to the AHJ in writing within 30 calendar days of notification of violation. The appeal shall outline all of the following:

(1) The *Code* provision(s) from which relief is sought
(2) A statement indicating which provisions of 1.10.4.1 apply
(3) Justification as to the applicability of the provision(s) cited in 1.10.4.1
(4) A requested remedy
(5) Justification for the requested remedy stating specifically how the *Code* is complied with, public safety is secured, and fire fighter safety is secured

If the application is insufficient, it should be rejected by the board legal counsel and the applicant should be notified of such reasons for rejection. Incomplete or deficient appeal applications that do not meet the criteria of 1.10.4.2 should not be allowed to reach the board for a hearing.

The appeals process should not be allowed to be used as a tactic to delay the correction of violations. Typically, the property owner or tenant is given a period of time to abate a violation found during an inspection. The expectation is that work will commence as soon as practicable after the violations are reported to the owner or tenant. If the owner or tenant disagrees with the AHJ or its representative, an appeal must be made in a timely manner so that the issue can be resolved and the appropriate correction made. Any notice of violation should carry a prominent notice with wording that states: "If you intend to appeal any of the findings of this inspection or the need for corrective action, that appeal must be filed with (name of agency) within 30 days of the date of this inspection, as shown above."

1.10.4.3* Documentation supporting an appeal shall be submitted to the AHJ at least 7 calendar days prior to the Board of Appeals hearing.

A.1.10.4.3 No additional information should be submitted to review by the Board of Appeals without the information submitted to the AHJ for their review prior to the hearing date. Additional information submitted after the filing of the appeal to the Board and AHJ should be made available to the Board and AHJ in a time frame that permits adequate review before the hearing date.

To ensure a fair review of the appeal, the AHJ should have access to all documentation that will be presented to support the appeal. This disclosure will provide the AHJ with an opportunity to review the evidence and supporting documents and then develop a recommendation to the board. Neither the AHJ nor the board should be surprised with new evidence presented at the board hearing that has not been either available to the AHJ or part of the informational package presented to the board.

1.10.5 Meetings and Records.

1.10.5.1 Meetings of the Board of Appeals shall be held at the call of the chair, at such other times as the board determines, and within 30 calendar days of the filing of a notice of appeal.

The number of appeals received by the jurisdiction determines how often the board needs to meet. The importance of a timely hearing prevents unnecessary added expense due to a delay in the projects of appellants.

An initial hearing must be held not more than 30 days after submittal of the appeal. This limit does not mean a judgment must be issued at that time; the board might require additional information to make a decision. The *Code* does not specifically address timely notification of the board's decision. Generally, the board's written decision should be sent to all affected parties as soon as possible after it rules on the appeal and the AHJ is notified.

1.10.5.2 All hearings before the Board of Appeals shall be open to the public.

All meetings must be open to the public. The rules and regulations for conducting business should define the procedures for allowing the public to speak or to be given copies of the material under discussion. The procedures for many Board of Appeals is that only the individuals with some significant connection to the case (standing) are be permitted to speak. The board can set time limits on speakers, even at public hearings. In addition, copies of correspondence submitted to the board, while they must be available for public inspection, do not have to be provided to members of the public attending the meeting. If interested parties want to obtain copies of relevant documents, they can be obtained or purchased according to the local regulations governing public-record documents. The local legal counsel should be consulted for information on open meeting law requirements.

1.10.5.3 The Board of Appeals shall keep minutes of its proceedings showing the vote of each member on every question or, if the member is absent or fails to vote, these actions shall be recorded.

1.10.5.4 The Board of Appeals shall keep records of its examinations and other official actions.

1.10.5.5 Minutes and records of the Board of Appeals shall be public record.

1.10.5.6 A quorum shall consist of not less than a simple majority of appointed members or alternates.

1.10.5.7 In varying the application of any provision of this *Code*, or in modifying an order of the AHJ, a two-thirds vote of the quorum shall be required.

When the Board of Appeals is requested to modify an order of the AHJ or to vary the application of the *Code*, the board is required to obtain a two-thirds super majority of the quorum. This super majority requirement ensures that a consensus exists within the board that public safety, fire fighter safety, and property protection is secured by the board's action to vary the application of the *Code* or modifying an order of the AHJ. If the board cannot obtain a two-thirds majority vote, then the motion fails, and the AHJ's order is upheld.

1.10.6 Decisions.

1.10.6.1 Every decision of the Board of Appeals shall be entered in the minutes of the board meeting.

1.10.6.2 A decision of the Board of Appeals to modify an order of the AHJ shall be in writing and shall specify the manner in which such modification is made, the conditions upon which it is made, the reasons therefore, and justification linked to specific code sections.

Frequently, board decisions are rendered with conditions tied to the decision. These conditions are often key components in establishing life safety, fire fighter safety, and property protection. Therefore, it is imperative that these conditions are captured as part of the board decision.

As part of the board's decision, the board must present the evidence it is using to justify its decisions. Those decisions must provide for life safety, fire fighter safety, and property protection that is equivalent to the levels of safety the *Code* provides.

1.10.6.3 Every decision shall be promptly filed in the office of the AHJ and shall be open for public inspection.

1.10.6.4 A certified copy shall be sent by mail or delivered in person to the appellant, and a copy shall be publicly posted in the office of the AHJ for 2 weeks after filing.

1.10.6.5 The decision of the Board of Appeals shall be final, subject to such remedy as any aggrieved party might have through legal, equity, or other avenues of appeal or petition.

1.10.6.6 If a decision of the Board of Appeals reverses or modifies a refusal, order, or disallowance of the AHJ, or varies the application of any provision of this *Code*, the AHJ shall take action immediately in accordance with such decision.

An order of the Board of Appeals is binding on the AHJ. Therefore, the AHJ needs to take the appropriate action to implement the order from the board with due diligence.

1.11 Records and Reports

1.11.1 A record of examinations, approvals, equivalencies, and alternates shall be maintained by the AHJ and shall be available for public inspection during business hours in accordance with applicable laws.

All examinations, approvals, equivalencies, and alternatives granted are part of a permanent record for the property or event in question and should be maintained as part of the applicable file. Equivalencies granted should also be retained on file as a reference for future inspections. These records should be maintained in accordance with local and state requirements. (See 1.11.2.)

State and local freedom of information laws may require that certain records be made available to the public. These laws also may require or allow some information to remain confidential. Two sets of files might need to be maintained. Files should indicate whether or not the contents are open to the public.

Most freedom of information laws state that the information must be made available to the public. This requirement does not mean it must be immediately available or available without charge. AHJs should consult applicable local ordinances and state statutes for specific guidance on this issue.

The AHJ should make available formal request for information forms to anyone requesting specific files. The form should include the requester's name, address, phone number, and the information requested. If the copies are not free of charge, the amount of the fee should be made clear before the copies are produced. If only a review of the files is requested, such review should be by appointment, and reviewers should not be left unsupervised in order to protect files from theft or destruction. The AHJ should consult applicable local ordinance and state statutes for guidance because some laws prohibit the AHJ from asking for the requestor's contact information and otherwise limit the AHJ's discretion on how public records can be distributed.

1.11.2 The AHJ shall keep a record of all fire prevention inspections, including the date of such inspections and a summary of any violations found to exist, the date of the services of notices, and a record of the final disposition of all violations.

These types of records allow the AHJ and property owner to reconstruct the history of a property. The historical records become important when disputes arise about approval for a condition in the field or if a fire occurs at the property. The AHJ can also use this data as part of a community risk assessment to assist in determining where prevention or other resources should be committed in the community.

1.11.3 Emergency Response Records.

1.11.3.1 The fire department shall keep a record of fire and other emergency responses occurring within its jurisdiction and of facts concerning the same, including statistics as to the extent and damage caused by such fires or emergencies.

Fire department incident records provide statistics needed to determine the community's level of risk and plan for risk reduction. These records, along with the records of fire inspections, provide an important overview of the fire and life safety problems in the community, identify target areas for correction, and assist in determining where to allocate resources.

1.11.3.2 The fire department shall report its incident record data, collected in accordance with 1.11.3, to the recognized state agency responsible for collecting such data.

Fire department incident record data must be reported to the state agency that is responsible for collecting such data. State data collection and analysis allows for state data to be analyzed for trends and resource allocations statewide. This data can also be presented to policymakers at the state level so that the scope of the fire department response demands are understood. This state data can then be submitted to the National Fire Incident Report System (NFIRS) where national fire problems and trends are analyzed and problems are identified. Actions can then be taken on a national level.

1.11.4 All records required to be kept shall be maintained until their usefulness has been served or as required by law.

State or local freedom of information laws and records retention laws may mandate the types of records needed and the length of time those records need to be maintained. The jurisdiction's legal counsel can offer guidance on requirements for records retention.

1.12 Permits and Approvals

1.12.1 The AHJ shall be authorized to establish and issue permits, certificates, and approvals pertaining to conditions, operations, or materials hazardous to life or property pursuant to Section 1.12.

The AHJ must know where and what activities are occurring in its jurisdiction that could affect fire and life safety. By requiring permits and approvals, the AHJ can ensure that the activities or operations are performed safely. Table 1.12.8(a) through Table 1.12.8(d) outline many of the permits and approvals that can be issued by the AHJ. Based on local experience, the AHJ can also require that permits be obtained to conduct other hazardous operations not included in Table 1.12.8(a) through Table 1.12.8(d). The AHJ should review the tables during the adoption of this *Code* to determine which permits are required and to modify them accordingly.

In some jurisdictions, the AHJ may allow the permitting of some of these activities through other departments in the jurisdiction. As an example, the AHJ may allow all permits for new construction to be applied for and issued at the building department, sometimes called a "One Stop Shop." In these circumstances, the AHJ still maintains the permit, plan review, and inspection authority granted in this *Code*.

1.12.2 Applications for permits shall be made to the AHJ on forms provided by the jurisdiction and shall include the applicant's answers in full to inquiries set forth on such forms.

The jurisdiction should have an application form for permits (see Exhibit 1.4), as well as an information sheet to explain how to fill out the form. The information sheet should identify all of the information that must be provided. See 1.12.6.13 for more information.

1.12.2.1 Applications for permits shall be accompanied by such data as required by the AHJ and fees as required by the jurisdiction.

See Section 1.17 for fees.

1.12.2.2 The AHJ shall review all applications submitted and issue permits as required.

1.12.2.3 If an application for a permit is rejected by the AHJ, the applicant shall be advised of the reasons for such rejection.

STATE OF CONNECTICUT
DEPARTMENT OF EMERGENCY SERVICES AND PUBLIC PROTECTION
Fire and Explosion Investigation Unit

Attn: Special Licensing and Firearms Unit
1111 Country Club Road
Middletown, Connecticut 06457-2389

APPLICATION FOR PERMIT TO DISPLAY FIREWORKS OR SPECIAL EFFECTS

1. Application and Proof of Financial Responsibility Form, DPS-884-C, must be completed and submitted to the Special Licensing and Firearms Unit (SLFU), **Attention:** SLFU, Fireworks and Special Effects Licensing, at least fifteen (**15) days** prior to the date of the display.
2. The fee of $100.00 is payable to the ***"Treasurer, State of Connecticut".***
3. A copy of United States Coast Guard Marine Permit (not application) is required for fireworks fired from a barge.
4. Type or print legibly. ***Forms will be returned if they are incomplete or illegible.***

Type of Permit: ☐ **Fireworks** ☐ **Special Effects**

For Fireworks displays, please submit a diagram of the display site indicating the discharge site, location of the spectator viewing area(s), buildings, highways, nearby utilities, trees and any overhead obstructions, compass heading indicating north, the date the diagram was produced and who produced the diagram. **This application will not be reviewed without this required documentation.**

Name of applicant (sponsoring organization):			
Address (number, street, city, state and zip code):			
Name of authorized agent (last, first and middle initial):			
Address of authorized agent (number, street, city, state and zip code):			
Email address of authorized agent:			
Telephone number of authorized agent:		Fax number of authorized agent:	
Exact location of display:			
Date of display:	Time of display:	Rain date:	Time of display:

For **SPECIAL EFFECTS** displays, please submit a diagram of the display site indicating the location and type of devices to be used, location of the audience, a list of all special effects and type of detonation mechanism(s) to be used. Also, include distances and measurements of the display area including audience location as well as between the effects and equipment/fixtures used.
Note: This application will not be reviewed without this required documentation.

Name of show:	
Company name:	
Company address (number, street, city, state and zip code):	
Company telephone number:	Company fax number:

Number and type of fireworks/special effects to be fired: **Please be specific about the type, size and amount to be fired.** (use additional paper if required)

Sample permit application. (Courtesy of State of Connecticut, Department of Public Safety)

The reasons for rejections should be detailed sufficiently so that the applicant can understand what actions are required to resubmit the permit application and potentially receive approval. See Section 1.16 for requirements on serving notice of violations and penalties.

1.12.2.4 Permits for activities requiring evidence of financial responsibility by the jurisdiction shall not be issued unless proof of required financial responsibility is furnished.

1.12.3 Conditions of Approval.

1.12.3.1 Any conditions of the initial approval by the AHJ of a use, occupancy, permit, or construction shall remain with the use, occupancy, permit, or construction unless modified by the AHJ.

1.12.3.2 The AHJ shall be permitted to require conditions of approval be memorialized via recording in the public records, as part of the plat, permit, or other method as approved by the AHJ.

Certain situations will require the AHJ to attach conditions to the approval of a use, occupancy, permit, or construction. Such conditions must remain with the use, occupancy, permit, or construction for the duration of the approval. Examples of such conditions include easements, cross access, occupancy constraints, future limitations on construction, future obligations of the owner, and other site configurations.

1.12.4 Approvals by Other AHJs.

1.12.4.1 The AHJ shall have the authority to require evidence to show that other regulatory agencies having jurisdiction over the design, construction, alteration, repair, equipment, maintenance, process, and relocation of structures have issued appropriate approvals.

Permit activities regulated under this *Code* may also be regulated by other government bodies. One example is the installation of underground petroleum storage tanks. In many jurisdictions, a separate environmental protection agency may be charged with responsibility to review the environmental factors of petroleum storage tank installations. The AHJ for this *Code* may wish to withhold fire code permit approval until confirmation is received that an approval from the environmental permitting body has also been received. See 1.12.6.3 for further requirements to receive approvals from other agencies.

1.12.4.2 The AHJ shall not be held responsible for enforcement of the regulations of such other regulatory agencies unless specifically mandated to enforce those agencies' regulations.

1.12.5 Misrepresentation.

1.12.5.1 Any attempt to misrepresent or otherwise deliberately or knowingly design; install; service; maintain; operate; sell; represent for sale; falsify records, reports, or applications; or other related activity in violation of the requirements prescribed by this *Code* shall be a violation of this *Code*.

1.12.5.2 Such violations shall be cause for immediate suspension or revocation of any related approvals, certificates, or permits issued by this jurisdiction.

1.12.5.3 Such violations shall be subject to any other criminal or civil penalties as available by the laws of this jurisdiction.

In many cases, intentionally providing false or fraudulent information to mislead the AHJ is a criminal offense. In these circumstances, the AHJ should consult with law enforcement to determine if a crime has been committed.

1.12.6 Permits.

1.12.6.1 A permit shall be predicated upon compliance with the requirements of this *Code* and shall constitute written authority issued by the AHJ to maintain, store, use, or handle materials; to conduct processes that could produce conditions hazardous to life or property; or to install equipment used in connection with such activities.

1.12.6.2 Any permit issued under this *Code* shall not take the place of any other approval, certificate, license, or permit required by other regulations or laws of this jurisdiction.

1.12.6.3 Where additional permits, approvals, certificates, or licenses are required by other agencies, approval shall be obtained from those other agencies.

There are times when other regulatory agencies or laws require permits that are similar to those required by this *Code*. In such cases, the applicant must obtain those permits before work can begin. If the AHJ has contact with such agencies, it can help to prevent conflicts on permit approvals. The other permits or approvals might be required before a permit is issued under this *Code*. See 1.12.4 for additional details on approvals by other AHJs.

1.12.6.4 The AHJ shall have the authority to require an inspection prior to the issuance of a permit.

Many required permits are for operations or functions that require an inspection before the permitted activity can take place. Such preliminary inspections ensure compliance with the *Code* and allow the AHJ to review the proposed site or activity before approving the permit application. The preliminary inspection assists the AHJ in making an informed decision on the approval of the application and is useful in determining if additional safeguards are required. Any violations should be corrected before final approval for the permit is issued.

1.12.6.5 A permit issued under this *Code* shall continue until revoked or for the period of time designated on the permit.

The permit expiration date depends largely on the type of work or activity performed. Many permits are issued for periods less than 1 week or for a specific date range, such as those permitting bonfires, traveling amusement shows or carnivals, cutting and welding operations, exhibits, and trade shows. Modifications to, and installation of, fire protection systems might require a 90- or

180-day permit. Still other permits, such as those granted for dust explosion prevention, flammable and combustible liquids, and LP-Gas installations, might require an annual permit. The length of time for which the permit is valid should be based on the time necessary to complete the activity, with adequate time for setup and removal of equipment, as needed.

For construction-related permits, the AHJ should also consider the length of time of building permits issued under the jurisdiction's building code and use a similar time frame. In most cases, model building codes specify that a permit is good for 180 days and may continue beyond that time if active construction is occurring.

1.12.6.6 The permit shall be issued to one person or business only and for the location or purpose described in the permit.

A permit is issued to a particular person or business and is not permitted to be transferred without approval from the AHJ. Transfer of the permit to others, or alteration of the permit, is grounds for revocation of the permit.

1.12.6.7 Any change that affects any of the conditions of the permit shall require a new or amended permit.

If, during the execution of the permit, the conditions of the permit or approval need to be altered, or the field conditions are different than anticipated, the AHJ should be asked to amend the permit or issue a new one.

1.12.6.8 The AHJ shall have the authority to grant an extension of the permit time period upon presentation by the permittee of a satisfactory reason for failure to start or complete the work or activity authorized by the permit.

While work designated on the permit is in progress, certain problems might prevent or hinder completion of the permitted work or activity within the time allotted on the permit. The applicant should provide the AHJ with a written statement outlining the reasons for any failure to complete the permitted work on time, along with a new projected completion date. After review, the AHJ can grant an extension of the permit expiration date.

1.12.6.9 A copy of the permit shall be posted or otherwise readily accessible at each place of operation and shall be subject to inspection as specified by the AHJ.

Depending on the type of activity for which the permit is issued, the permit should be either displayed at the site or carried by the permit holder. Posted permits are generally issued for activities such as the installation of fire alarm and sprinkler systems.

When a permit is issued, the applicant agrees to the inspections required by the granting authority, even if those inspections exceed those required in 1.7.7. Inspections should occur during the time the permitted activities are taking place or after a certain phase of construction has occurred. Inspections before and after occurrence of the permitted activities are also helpful in determining compliance. (See 1.12.6.4.) Subparagraph 1.12.6.9 allows the AHJ to conduct daily or weekly inspections, if necessary, to determine compliance with any conditions attached to the permit.

1.12.6.10 Any activity authorized by any permit issued under this *Code* shall be conducted by the permittee or the permittee's agents or employees in compliance with all requirements of this *Code* applicable thereto and in accordance with the approved plans and specifications.

1.12.6.11 No permit issued under this *Code* shall be interpreted to justify a violation of any provision of this *Code* or any other applicable law or regulation.

Nothing in the permit process allows a person to violate this *Code* or any other regulations in effect within the jurisdiction. Even if the permit is issued mistakenly to authorize an activity or construction that is not compliant with the *Code,* the mistaken issuance of the permit is not justification to violate the *Code*. The person to whom the permit is issued is responsible for ensuring that all the requirements of this *Code* are met. If the permitted activity needs to be altered or expanded, a new or amended permit must be obtained before commencement of the modified activity.

1.12.6.12 Any addition or alteration of approved plans or specifications shall be approved in advance by the AHJ, as evidenced by the issuance of a new or amended permit.

Frequently, field conditions create a situation where plans or specifications need to be modified to address the field conditions. In those situations, revised plans or specifications need to be submitted to the AHJ to amend the existing permit. If the changes are significant, it might be justified to have the applicant acquire a new permit.

1.12.6.13* Permits shall be issued by the AHJ and shall indicate the following:

(1) Operation, activities, or construction for which the permit is issued
(2) Address or location where the operation, activity, or construction is to be conducted
(3) Name, address, and phone number of the permittee
(4) Permit number
(5) Period of validity of the permit
(6) Inspection requirements
(7) Name of the agency authorizing the permit (AHJ)
(8) Date of issuance
(9) Permit conditions as determined by the AHJ

A.1.12.6.13 Figure A.1.12.6.13 shows a sample permit.

After the AHJ reviews the permit application (as described in 1.12.2.2) and determines that the applicant meets its requirements, a permit can be issued. At a minimum, the permit must include all the information listed in 1.12.6.13 and shown in Figure A.1.12.6.13. The AHJ might require additional information, including plans and specifications.

Side 1

PERMIT
FOR CUTTING AND WELDING
WITH PORTABLE GAS OR ARC EQUIPMENT

Date ______________________

Building ______________________

Dept. ____________ Floor ____________

Work to be done ______________________

____

Special precautions ______________________

____

Is fire watch required? ______________________

The location where this work is to done has been examined, necessary precautions taken, and permission is granted for this work. (See other side.)

Permit expires ______________________

Signed ______________________
(Individual responsible for authorizing welding and cutting)

Time Started ____________ Completed ____________

FINAL CHECK

Work area and all adjacent areas to which sparks and heat might have spread [including floors above and below and on opposite side of wall(s)] were inspected 30 minutes after the work was completed and were found firesafe.

Signed ______________________
(Supervisor or Fire Watcher)

Side 2

ATTENTION

Before approving any cutting and welding permit, the fire safety supervisor or appointee shall inspect the work area and confirm that precautions have been taken to prevent fire in accordance with NFPA 51B.

PRECAUTIONS

- ❑ Sprinklers in service
- ❑ Cutting and welding equipment in good repair

WITHIN 35 FT (10.7 M) OF WORK

- ❑ Floors swept clean of combustibles
- ❑ Combustible floors wet down and covered with damp sand, metal, or other shields
- ❑ All wall and floor openings covered
- ❑ Covers suspended beneath work to collect sparks

WORK ON WALLS OR CEILINGS

- ❑ Construction noncombustible and without combustible covering
- ❑ Combustibles moved away from opposite side of wall

WORK ON ENCLOSED EQUIPMENT
(Tanks, containers, ducts, dust collectors, etc.)

- ❑ Equipment cleaned of all combustibles
- ❑ Containers purged of flammable vapors

FIRE WATCH

- ❑ To be provided during and 30 minutes after operation
- ❑ Supplied with extinguisher and small hose
- ❑ Trained in use of equipment and in sounding fire alarm

FINAL CHECK

- ❑ To be made 30 minutes after completion of any operation unless fire watch is provided

Signed ______________________
(Supervisor)

Δ ***FIGURE A.1.12.6.13*** *Sample Permit.*

1.12.6.14 Any application for, or acceptance of, any permit requested or issued pursuant to this *Code* shall constitute agreement and consent by the person making the application or accepting the permit to allow the AHJ to enter the premises at any reasonable time to conduct such inspections as required by this *Code*.

1.12.7 Revocation or Suspension of Permits.

1.12.7.1 The AHJ shall be permitted to revoke or suspend a permit or approval issued if any violation of this *Code* is found upon inspection or in case any false statements or misrepresentations have been submitted in the application or plans on which the permit or approval was based.

All issued permits and approvals can be revoked for just cause in accordance with 1.12.7.1. Changes to the approval require the review and approval of the AHJ. If, during an inspection, variations to the approval conditions granted or instances of noncompliance with the appropriate *Code* are discovered, the permit or approval can be revoked.

Similarly, if during an inspection or an emergency, a permit is determined to be required but has not been obtained, the operation should be terminated until such time as the appropriate permits and approvals are obtained. See 1.7.15 for additional information on stop work orders.

In many cases, intentionally providing false or fraudulent information to mislead the AHJ is a criminal offense. In these circumstances, the AHJ should consult with law enforcement to determine if a crime has been committed.

1.12.7.2 Revocation or suspension shall be constituted when the permittee is duly notified by the AHJ.

A written notification of revocation and the reasons for it are required before the permit is revoked. (See Section 1.16 for details on notice of violations and penalties.) However, in the case of an imminent danger, the operation must be stopped immediately. (See 1.7.15 for details on stop work orders.) When the work is stopped due to an imminent danger, the AHJ should send a written notification immediately, explaining why the work was stopped and why the permit was revoked. If the permittee cannot be notified, posting notification of the revocation or suspension on-site constitutes sufficient notice.

1.12.7.3 Any person who engages in any business, operation, or occupation, or uses any premises, after the permit issued therefore has been suspended or revoked pursuant to the provisions of this *Code*, and before such suspended permit has been reinstated or a new permit issued, shall be in violation of this *Code*.

Δ **1.12.8** Permits shall be required in accordance with Table 1.12.8(a) through Table 1.12.8(d).

Table 1.12.8(a) describes some of the activities for which the AHJ might require a permit. Based on local experience, the AHJ might identify additional hazards, processes, or construction activities for which permits are required.

Δ ***TABLE 1.12.8(a)*** *Permit Requirements*

Operations and Materials	Permit Required	Cross Reference Section Number
Aerosol products	To store or handle an aggregate quantity of Level 2 or Level 3 aerosol products in excess of 500 lb (226.8 kg)	61.1.2
Aircraft fuel servicing	To provide aircraft fuel servicing	42.10.1.2
Aircraft hangars	For servicing or repairing aircraft	21.1.1
Aircraft refueling vehicles	To operate aircraft refueling vehicles	42.10.1.2
Airport terminal buildings	For construction and alteration	21.2.2.1
Ammonium nitrate	For storage	Chapter 74
Amusement parks	For construction, alteration, or operation of amusement park fire protection safety features	10.15.1
Asbestos removal	For the removal of asbestos	16.8.2
Automatic fire suppression systems	For installation, modification, or removal from service of any automatic fire suppression system*	13.1.1.1; 50.4.2
Automobile wrecking yards	To operate automobile wrecking yards	22.2
Automotive fuel servicing	To provide automotive fuel servicing	42.2.2.1; 42.11.2.2.4; 42.11.3.1
Battery systems	To install or operate stationary lead-acid battery systems having an electrolyte capacity of more than 100 gal (378.5 L) in sprinklered buildings or 50 gal (189.3 L) in nonsprinklered buildings	52.2
Candles, open flames, and portable cooking	To use in connection with assembly areas, dining areas of restaurants, or drinking establishments	17.3.2; 20.1.1.1
Carnivals and fairs	To conduct a carnival or fair	10.15.1
Cellulose nitrate film	To store, handle, use, or display	20.15.7.2
Cellulose nitrate plastic	To store or handle more than 25 lb (11.3 kg)	43.1.1.4
Change of occupancy	For the change of occupancy classification of an existing building	1.7.11.5
Cleanrooms	For construction, alteration, or operation	23.3
Combustible fibers	For storage or handling of combustible fibers greater than 100 ft^3 (2.8 m^3)	45.1.3
Combustible material storage	To store more than 2500 ft^3 (70.8 m^3) gross volume	10.19.2; 19.1.1; 31.2
Commercial rubbish-handling operation	To operate	19.1.1

Δ *TABLE 1.12.8(a) Continued*

Operations and Materials	Permit Required	Cross Reference Section Number
Compressed gases	1. To store, use, or handle compressed gases in excess of the amounts listed in Table 1.12.8(b) 2. When the compressed gases in use or storage exceed the amounts listed in Table 1.12.8(b), a permit is required to install, repair damage to, abandon, remove, place temporarily out of service, close, or substantially modify a compressed gas system 3. For additional permit requirements for compressed gases facility closures, see 63.1.2	63.1.2
Construction	For the construction of a building or structure	1.7.11.8
Covered mall buildings	Annual requirement for facilities that utilize mall area for exhibits or displays with 4 conditions	20.1.5.5.1
Crop maze	To operate a crop maze	10.14.11.1
Cryogens	To produce, store, or handle cryogens in excess of amounts listed in Table 1.12.8(c) *Exception: Where federal or state regulations apply or for fuel systems of a vehicle.*	63.1.2
Cutting and welding operation	For operations within a jurisdiction	41.1.5; 41.3.2.2; 41.3.2.2.2
Display fireworks (1.3G)	For possession, transportation, storage, manufacture, sale, handling, and discharge of display fireworks within the jurisdiction	65.2.3; 65.5.2
Drycleaning plants	To engage in business of drycleaning or to change to a more hazardous cleaning solvent	24.2
Dust-producing operations	To operate a grain elevator, flour mill, starch mill, feed mill, or plant pulverizing aluminum, coal, cocoa, magnesium, spices, sugar, or other similar combustible material	40.2
Energy storage systems, including battery stationary storage systems and capacitor energy storage systems	To install and operate energy storage systems exceeding Table 52.2.1 and Table 52.3.1	52.1.2
Exhibit and trade shows	For operation of all exhibits and trade shows held within a jurisdiction	20.1.5.5.1
Explosives	1. Manufacture, sell, dispose, purchase, storage, use, possess, or transport of explosives within the jurisdiction 2. For additional permit requirements for blasting operations, see 65.9.2	65.9.2
Fire alarm and detection systems and related equipment	For installation, modification, or removal from service of any fire alarm and detection systems and related equipment*	13.1.1.1
Fire apparatus access roads	For the construction of a fire apparatus access road	18.1.2
Fire hydrants and water-control valves	To use a fire hydrant or operate a water-control valve intended for fire suppression purposes	13.1.1.1
Fire pumps and related equipment	For installation of, modification to, or removal from service of any fire pumps, jockey pumps, controllers, and generators*	13.1.1.1
Flame effects	Use of flame effects before an audience	65.4.2
Flammable and combustible liquids	1. To use or operate, repair, or modify a pipeline for the on-site transportation of flammable or combustible liquids 2. To store, handle, or use Class I liquids in excess of 5 gal (18.9 L) in a building or in excess of 10 gal (37.9 L) outside of a building *Exception to item (2): A permit is not required for the following:* *(a) The storage or use of Class I liquids in the fuel tank of a motor vehicle, aircraft, motorboat, mobile power plant, or mobile heating plant unless such storage in the opinion of the chief would cause an unsafe condition*	66.1.5

(continues)

△ *TABLE 1.12.8(a) Continued*

Operations and Materials	Permit Required	Cross Reference Section Number
	(b) The storage or use of paints, oils, varnishes, or similar flammable mixtures when such liquids are stored for maintenance, painting, or similar purposes for a period of not more than 30 days 3. To store, handle, or use Class II or Class III-A liquids in excess of 25 gal (94.6 L) in a building or in excess of 60 gal (227.1 L) outside a building *Exception to item (3): Fuel oil used in connection with oil-burning equipment* 4. To remove Class I or Class II liquids from an underground storage tank used for fueling motor vehicles by any means other than the approved, stationary on-site pumps normally used for dispensing purposes 5. To install, construct, alter, or operate tank vehicles, equipment, tanks, plants, terminals, wells, fuel-dispensing stations, refineries, distilleries, and similar facilities where flammable and combustible liquids are produced, processed, transported, stored, dispensed, or used 6. To install, alter, clean, repair, line with a protective coating, remove, abandon, place temporarily out of service, or otherwise dispose of a flammable or combustible liquid tank 7. To change the type of contents stored in a flammable or combustible liquid tank to a material other than those for which the tank was designed and constructed	
Fruit ripening	To operate a fruit-ripening process	63.1.2
General storage	To store materials indoors or outdoors, representing a broad range of combustibles, including plastics, rubber tires, and roll paper	34.1.2
Grandstands, bleachers, and folding and telescopic seating	For construction, location, erection, or placement of grandstands, bleachers, and folding and telescopic seating	25.1.2
Hazardous materials	1. To store, transport on site, dispense, use, or handle hazardous materials in excess of the amounts listed in Table 1.12.8(d) 2. To install, repair, abandon, remove, place temporarily out of service, close, or substantially modify a storage facility or other area regulated by Chapter 60 when the hazardous materials in use or storage exceed the amounts listed in Table 1.12.8(d)	Chapter 60
High-piled combustible storage	To use any building or portion thereof as a high-piled storage area exceeding 500 ft^2 (46.45 m^2)	20.15.8.2
High-powered rocketry	For the manufacture, sale, and use of high-powered rocketry	65.8.2; 65.7.2
Hot work operations	To conduct hot work	17.3.2; 41.1.5; 41.3.4
Industrial ovens and furnaces	For operation of industrial ovens and furnaces covered by Chapter 51	51.1.2
Laboratories	For construction, alteration, or operation	26.3
Liquefied petroleum gases	1. To store, use, handle, or dispense LP-Gas of 125 gal (0.5 m^3) (water capacity) aggregate capacity or greater 2. To install or modify LP-Gas systems	42.11.2.2.4 69.1.2
Liquid- or gas-fueled vehicles	To display, compete, or demonstrate liquid- or gas-fueled vehicles or equipment in assembly buildings	20.1.5.5.1
Lumberyards and woodworking plants	For storage of lumber exceeding 100,000 board ft	31.2
Marijuana growing, processing, or extraction facilities	For the construction, alteration, or operation of a marijuana growing, processing, or extraction facility	38.2
Marine craft fuel servicing	To provide marine craft fuel servicing	42.9.1.4
Means of egress	For the modification of a means of egress system in an existing building	1.7.11.6

Δ *TABLE 1.12.8(a) Continued*

Operations and Materials	Permit Required	Cross Reference Section Number
Membrane structures, tents, and canopies — permanent	For construction, location, erection, or placement	25.1.2
Membrane structures, tents, and canopies — temporary	To erect or operate an air-supported temporary membrane structure or tent having an area in excess of 200 ft^2 (18.6 m^2) or a canopy in excess of 400 ft^2 (37.2 m^2) *Exception: Temporary membrane structures, tents, or canopy structures used exclusively for camping.*	25.1.2
Mobile cooking operations	To conduct mobile cooking operations	50.7
Motion picture and television production studio soundstages and approved production facilities	To design, construct, operate, and maintain soundstages and approved production facilities used in motion picture and television industry productions	32.2
Oil- and gas-fueled heating appliances	To install oil- and gas-fired heating appliances	11.5.1.8
Open burning	1. To conduct open burning 2. For additional permit requirements for open burning, see 10.11.1	10.11.1
Open fires	1. For kindling or maintaining an open fire 2. For additional permit requirements for open fires, see 10.11.4†	10.11.1
Organic coatings	For operation and maintenance of a facility that manufactures organic coatings	43.1.1.4
Organic peroxide formulations	To store, transport on site, use, or handle materials in excess of amounts listed in Tables 1.12.8(c) and (d)	Chapter 75
Outside storage of tires	To store more than 500 tires outside	33.1.2
Oxidizers	To store, transport on site, use, or handle materials in excess of amounts listed in Tables 1.12.8(c) and (d)	Chapter 70
Parade floats	To use a parade float for public performance, presentation, spectacle, entertainment, or parade	10.17.1
Places of assembly	To operate a place of assembly	10.15.1; 20.1.1.1
Pyrotechnic articles	For the manufacture, storage, sale, or use of pyrotechnic articles within the jurisdiction	65.2.3; 65.3.3; 65.5.2
Pyrotechnics before a proximate audience	For the display and use of pyrotechnic materials before a proximate audience	65.3.3
Pyroxylin plastics	For storage, handling, assembly, or manufacture of pyroxylin plastics	43.1.1.4
Private fire hydrants	For installation, modification, or removal from service of any private fire hydrants	13.1.1.1
Refrigeration equipment	To install or operate a mechanical refrigeration unit or system regulated by this *Code*	53.1.3
Repair garages and service stations	For operation of service stations and repair garages	30.1.1.3; 30.2.1.1
Rocketry manufacturing	For the manufacture of model rocket motors	65.7.2
Rooftop heliports	For construction, modification, or operation of a rooftop heliport	21.3.2.1
Solvent extraction	For storage, use, and handling	44.3
Spraying or dipping of flammable finish	For installation or modification of any spray room, spray booth, or preparation work station, or to conduct a spraying or dipping operation utilizing flammable or combustible liquids or powder coating	43.1.1.4
Standpipe systems	For installation, modification, or removal from service of any standpipe system*	13.1.1.1
Special outdoor events	For the location and operation of special outdoor events	10.15.1

(continues)

Δ *TABLE 1.12.8(a) Continued*

Operations and Materials	Permit Required	Cross Reference Section Number
Tar kettles	To place a tar kettle, a permit must be obtained prior to the placement of a tar kettle	16.7.1.2; 17.3.2
Tire storage	To use an open area or portion thereof to store tires in excess of 500 tires	33.1.2; 34.1.2
Torch-applied roofing operation	For the use of a torch for application of roofing materials	16.6.1
Water supply system for fire flow	For the construction of a water supply system for fire flow	18.1.2
Wildland fire–prone areas	For use of hazardous areas within fire-prone areas	17.3.2
Wood products	To store wood chips, hogged material, wood by-products, lumber, or plywood in excess of 200 ft^3 (5.7 m^3)	31.2

*Maintenance performed in accordance with this *Code* is not considered a modification and does not require a permit.

†Cooking and recreational fires are exempt and do not require a permit.

TABLE 1.12.8(b) Permit Amounts for Compressed Gases

Type of Gas	Amount* ft^3	Amount* m^3
Corrosive	200	0.57
Flammable	200	0.57
Highly toxic	Any amount	
Inert and simple asphyxiant	6000	169.9
Oxidizing (including oxygen)	504	14.3
Pyrophoric	Any amount	
Toxic	Any amount	
Unstable (reactive)	Any amount	

Note: See Chapters 41, 42, 60, 63, and 69 for additional requirements and exceptions.

*Cubic feet measured at normal temperature and pressure.

TABLE 1.12.8(c) Permit Amounts for Cryogens

Type of Cryogen	Inside Building (gal)	Outside Building (gal)
Corrosive	Over 1	Over 1
Flammable	Over 1	60
Toxic/highly toxic	Over 1	Over 1
Nonflammable	60	500
Oxidizer (includes oxygen)	10	50

Note: See Chapter 63.

Δ *TABLE 1.12.8(d) Permit Amounts for Hazardous Materials*

Type of Material	Amount U.S. Unit	Amount Metric Unit
Cellulose nitrate	25 lb	11.3 kg
Combustible fiber	100 ft^3	2.8 m^3
Combustible liquids	*See Table 1.12.8(a)*	
Corrosive gases	*See Table 1.12.8(b)*	
Corrosive liquids	55 gal	208 L
Corrosive solids	500 lb	227 kg
Cryogens	*See Table 1.12.8(c)*	
Display fireworks (1.3G)	Any amount	
Explosives	Any amount	
Flammable gases	*See Table 1.12.8(b)*	
Flammable liquids	*See Table 1.12.8(a)*	
Flammable solids	100 lb	45.4 kg
Highly toxic gases	*See Table 1.12.8(b)*	
Highly toxic liquids	Any amount	
Highly toxic solids	Any amount	
LP-Gas	*See Table 1.12.8(b)*	
Nitrate film (cellulose)	Any amount	
Organic peroxides:	*See Table 1.12.8(a)*	
Class I	Any amount	
Class II	Any amount	
Class III	10 lb	4.5 kg
Class IV	20 lb	9 kg
Class V	Not required	
Unclassified detonable	Any amount	
Oxidizing gases	*See Table 1.12.8(b)*	
Oxidizing liquids:	*See Table 1.12.8(a)*	
Class 4	Any amount	
Class 3	1 gal	3.8 L
Class 2	10 gal	38 L
Class 1	55 gal	208 L

Δ ***TABLE 1.12.8(d)*** *Continued*

Type of Material	Amount U.S. Unit	Amount Metric Unit
Oxidizing solids:	*See Table 1.12.8(a)*	
Class 4	Any amount	
Class 3	10 lb	4.5 kg
Class 2	100 lb	45 kg
Class 1	500 lb	227 kg
Pyrophoric gases	*See Table 1.12.8(b)*	
Pyrophoric liquids	Any amount	
Pyrophoric solids	Any amount	
Toxic gases	*See Table 1.12.8(b)*	
Toxic liquids	10 gal	38 L
Toxic solids	100 lb	45 kg
Unstable (reactive) gases	*See Table 1.12.8(b)*	
Unstable (reactive) liquids:		
Class 4	Any amount	
Class 3	Any amount	
Class 2	5 gal	19 L
Class 1	10 gal	38 L
Unstable (reactive) solids:		
Class 4	Any amount	
Class 3	Any amount	
Class 2	50 lb	22.7 kg
Class 1	100 lb	45 kg
Water reactive liquids:		
Class 3	Any amount	
Class 2	5 gal	19 L
Class 1	10 gal	38 L
Water reactive solids:		
Class 3	Any amount	
Class 2	50 lb	22.7 kg
Class 1	100 lb	45 kg

Note: See Chapter 60 for additional requirements and exceptions.

1.13 Certificates of Fitness

1.13.1 Authorization. The AHJ shall have the authority to require certificates of fitness and collect fees for individuals or companies performing any of the following activities:

(1) Inspection, servicing, or recharging of portable fire extinguishers
(2) Installation, servicing, modification, or recharging of fixed fire extinguishing systems
(3) Installation, servicing, or modification of fire alarm or fire communication systems
(4) Installation, modification, or servicing of gas- or oil-burning heating systems
(5) Chimney sweep operations
(6) Installation, inspection, servicing, or modification of range-hood systems
(7) Installation or servicing of private fire service mains and their appurtenances
(8) Crowd management services required by the Code
(9) Utilization of pyrotechnics before a proximate audience
(10) Installation, modification, or maintenance of liquefied petroleum gas or liquefied natural gas tanks or systems
(11) Installation or modification of medical gas systems where a permit is required by Table 1.12.8(a)
(12) Installation, modification, or maintenance of standpipe systems
(13) Installation, modification, or maintenance of automatic sprinkler systems
(14) Installation, modification, or maintenance of fire pumps
(15) Installation, modification, or maintenance of tanks, wells, or drafting points used for fire protection water supplies

Certificates of fitness, which are addressed in Section 1.13, ensure that persons performing certain activities are experienced in the work they are conducting and are capable of performing it safely. The certificate of fitness also gives the consumer greater security, knowing that these individuals have demonstrated a level of competency in the job they perform. In addition, a certificate of fitness gives the AHJ authority over the activities of the certificate holder. The AHJ can discipline a certificate holder for noncode-compliant practices.

In some jurisdictions, a certificate of fitness may also be known as a license. Many jurisdictions issue licenses for contractors. Therefore, for some of these activities, the state or other jurisdictions may preempt the authority of the AHJ to issue certificates of fitness.

The activities for which the AHJ can require a certificate of fitness under this *Code* are listed in the following paragraphs and correlate with 1.13.1(1) through 1.13.1(15). For many of these activities, no national certification programs are available to which the AHJ can turn for guidance in determining that a person is certified. The following sources of information for each activity can assist the AHJ in deciding whether a person is fit to perform it:

1. Inspecting, Servicing, or Recharging Portable Fire Extinguishers. The Fire Equipment Manufacturers' Association (FEMA) is composed of companies that manufacture portable fire extinguishers and interior fire protection devices. The association promotes the proper installation and use of such equipment.

FEMA
1300 Sumner Avenue
Cleveland, OH 44115-2851, (216) 241-7333
www.femalifesafety.org

The National Association of Fire Equipment Distributors (NAFED) promotes better use of equipment, seeks to raise standards of recharge and service, and conducts service-training programs.

NAFED
122 South Michigan Avenue, Suite 1040
Chicago, IL 60603, (312) 461-9600
www.nafed.org

Individual manufacturers provide training and certification to persons on how to inspect and service their portable fire extinguishers. The names and addresses of companies that manufacture portable fire extinguishers can be found in the online *NFPA® Buyers' Guide.*

NFPA® Buyers' Guide
nfpabuyersguide.org

2. Installing, Servicing, Modifying, or Recharging Fixed Fire Extinguishing Systems. The organizations listed in item 1 (above) are also involved in fixed fire extinguishing systems. Certification is generally offered through the individual manufacturers of such fixed systems. Individuals eligible for certification are generally the manufacturers' employees. Names and addresses of companies that install fixed fire protection systems are in the *NFPA Buyers' Guide*.

In addition, two organizations that assist with automatic sprinkler systems are the American Fire Sprinkler Association (AFSA) and the National Fire Sprinkler Association (NFSA).

AFSA
12750 Merit Drive, Suite 350
Dallas, TX 75251, (214) 349-5965
www.sprinklernet.org

NFSA
514 Profess Drive, Suite A
Linthicum Heights, MD 20190, (443) 863-4464
www.nfsa.org

3. Installing, Servicing, or Modifying Fire Alarm or Fire Communication Systems. The National Institute for Certification in Engineering Technologies (NICET) provides certification of individuals at specific levels for servicing fire alarm or fire communication systems.

NICET
1420 King Street
Alexandria, VA 22314-2794, (888) 476-4238
www.nicet.org

The Electronic Security Association (ESA) (formerly the National Burglar and Fire Alarm Association) is composed of dealers and installers of fire alarm equipment. This association has a training and education committee.

ESA
2300 Valley View Lane, Suite 230
Irving, TX 75062, (888) 447-1689
www.alarm.org

The Automatic Fire Alarm Association (AFAA) is composed of manufacturers and installers of fire detection and alarm systems. They have technical information available.

AFAA
81 Mill Street, Suite 300
Gahanna, OH 43230, (614) 416-8076
www.afaa.org

4. Installing, Modifying, or Servicing Gas- or Oil-Burning Heating Systems. The Air Conditioning Contractors of America (ACCA) is composed of contractors involved in the installation and servicing of heating and air-conditioning systems. The organization provides consulting services, technical training, and instructor certification programs.

ACCA
2800 Shirlington Road, Suite 300
Arlington, VA 22206, (703) 575-4477
www.acca.org

The objectives of the National Propane Gas Association (NPGA) are to promote safety in all aspects of storage, handling, and use of propane gas and to develop materials and programs to educate industry personnel, the fire service, and consumers.

NPGA
1899 L Street NW, Suite 350
Washington, DC 20036, (202) 466-7200
www.npga.org

5. Chimney Sweep Operations. The Chimney Safety Institute of America (CSIA) provides information on the proper and safe installation, maintenance, and operation of chimneys, fireplaces, vents, and solid fuel–burning appliances. It sponsors the National Chimney Sweep Training School and training seminars, provides sweep training study materials, and conducts a certification exam.

CSIA
2155 Commercial Drive
Plainfield, IN 46168, (317) 837-5362
www.csia.org

6. Installing, Inspecting, Servicing, or Modifying Range-Hood Systems. See items 1 and 2 (above) for organizations that are associated with the installation, inspection, and service of fixed fire protection systems. Manufacturers of range-hood systems generally certify only their own employees.

7. Installing or Servicing Private Fire Service Mains and Their Appurtenances. See items 1 and 2 (above) for organizations that are associated with the installation, inspection, and service of fixed fire protection systems.

8. Crowd Management Services Required by this *Code*. The International Association of Venue Managers (IAVM) comprises members representing auditoriums, arenas, convention centers, exhibit halls, stadiums, performing arts theaters, and amphitheaters. IAVM offers online crowd management training programs.

IAVM
635 Fritz Drive, Suite 100
Coppell, TX 75019-4442, (972) 906-7441
www.iavm.org

9. Utilization of Pyrotechnics Before a Proximate Audience. The American Pyrotechnics Association (APA) offers a performance checklist for indoor or proximate pyrotechnics events.

APA
7910 Woodmont Avenue, Suite 1220
Bethesda, MD 20814, (301) 907-8181
www.americanpyro.com

10. Installation, Modification, or Maintenance of Liquefied Petroleum Gas or Liquefied Natural Gas Tanks or Systems. See item 4 (above) for the National Propane Gas Association.

11. Installation or Modification of Medical Gas Systems. The American Society of Sanitary Engineering (ASSE) is a nonprofit organization comprising members who represent all disciplines of the plumbing industry. ASSE develops certification standards for medical gas systems personnel. Training and certification is offered by third-party providers. See the ASSE web site for links to such providers.

ASSE International
18927 Hickory Creek Drive, Suite 220
Mokena, IL 60448, (708) 995-3019
www.asse-plumbing.org

12. Installation, Modification, or Maintenance of Standpipe Systems. See item 2 (above) for organizations that are associated with the installation, inspection, and service of fixed fire protection systems.

13. Installation, Modification, or Maintenance of Automatic Sprinkler Systems. See item 2 (above) for organizations that are associated with the installation, inspection, and service of fixed fire protection systems.

14. Installation, Modification, or Maintenance of Fire Pumps. See item 2 (above) for organizations that are associated with the installation, inspection, and service of fixed fire protection systems.

15. Installation, Modification, or Maintenance of Tanks, Wells, or Drafting Points Used for Fire Protection Water Supplies. See item 2 (above) for organizations that are associated with the installation, inspection, and service of fixed fire protection systems.

1.13.2 Mandatory. The AHJ shall require certificates of fitness and collect fees for individuals or companies performing any of the following activities:

(1) Use of explosive materials
(2) Fireworks displays involving display fireworks, 1.3G

While the AHJ has the authority to require certificates of fitness for the activities listed under 1.13.1, the *Code* mandates certificates of fitness for people engaged in the use of explosive materials and fireworks displays involving display fireworks, 1.3G. Conducting these activities comes with significant risk. Therefore, it is mandatory that qualified individuals conduct these activities. The following organizations can help the AHJ make the determination of whether an individual is qualified to perform the noted activity:

1. Use of Explosive Materials. The Institute of Makers of Explosives (IME) and the International Society of Explosives Engineers (ISEE) offer a range of technical information concerning explosive materials and their use.

IME
1120 19th Street NW, Suite 310
Washington, DC 20036-3605, (202) 429-9280
www.ime.org

ISEE
30325 Bainbridge Road
Cleveland, OH 44139-2295, (440) 349-4400
www.isee.org

2. Fireworks Displays Involving Display Fireworks, 1.3G. The American Pyrotechnics Association (APA) promotes safety in the manufacture, transportation, and use of pyrotechnics through information and education programs.

APA
7910 Woodmont Avenue, Suite 1220
Bethesda, MD 20814, (301) 907-8181
www.americanpyro.com

The Pyrotechnics Guild International Inc. (PGI) offers a variety of information related to the display of fireworks and conducts fireworks safety training courses for those who conduct professional fireworks displays.

PGI
3944 Carthage Road
Randallstown, MD 21133, (410) 655-8594
www.pgi.org

1.13.3 The AHJ shall be responsible for the issuance of certificates of fitness required by the AHJ.

The AHJ issues the certificates of fitness it requires and those required by this *Code*. In some cases, another agency issues certificates of fitness for certain activities for the AHJ. In some instances the state issues licenses or certificates of fitness. For example, many states require contractors, electricians, plumbers, and other building professionals to be licensed. State requirements often supersede and preempt the requirements of the local AHJ.

1.13.4 All applications for a certificate of fitness shall be filed with the AHJ on forms provided by the AHJ.

The jurisdiction should have an application form for certificates of fitness, such as that shown in Exhibit 1.5, as well as an information sheet to explain how to fill out the form. This information sheet should list all of the information that is needed or that must be provided.

1.13.5 Certification of Applicant.

1.13.5.1 Every individual or company applying for a certificate of fitness shall furnish to the AHJ evidence of a familiarity with applicable codes, regulations, standards, listings, guidelines, and construction and safety practices for the activity for which the certificate of fitness is issued.

1.13.5.2* The AHJ shall also utilize certification programs provided by national organizations acceptable to the AHJ, where available, to determine evidence of compliance with 1.13.5.1.

A.1.13.5.2 The following is provided for information purposes only and has been provided by outside sources. Information concerning the noted services has not been independently verified, nor have the services been endorsed by the NFPA or any of its technical committees.

Examples of certification programs for fireworks displays include those conducted through the American Pyrotechnics Association (APA) and the Pyrotechnics Guild International (PGI). Both programs are recognized by several state fire marshals' offices throughout the United States. Authorities having jurisdiction should contact the applicable trade organizations or groups that cover each of the activities listed in 1.13.1 for information on recognized certification program(s).

The AHJ should establish policies and procedures to standardize qualification criteria that are used to evaluate individuals and companies for each of the certificates of fitness required by the AHJ. This will ensure that individuals wishing to enter a field to practice in the jurisdiction will know what criteria are accepted by the jurisdictions. Establishing standard qualification criteria will also ensure that all applicants are treated equally when assessed by the AHJ.

SEC. 53a-157. FALSE STATEMENT: CLASS A MISDEMEANOR. (a) A person is guilty of False Statement when he intentionally makes a false written statement under oath or pursuant to a form bearing notice, authorized by law, to the effect that false statements made therein are punishable, which he does not believe to be true and which statement is intended to mislead a public servant in the performance of his official function. (b) False Statement is a Class A Misdemeanor.

The penalty for a Class A Misdemeanor is imprisonment for a term not to exceed one year, or a fine not to exceed $1,000, or both = fine and imprisonment. (Sections 53a-28 (b), 53a-36, and 53a-42.)

The fee for a certificate of Competency is $100.00 and it may be renewed every three years upon payment of a fee of $150.00. Checks should be made payable to the Connecticut Department of Public Safety.

2 of 2

Sample application for a certificate of fitness. (Courtesy of State of Connecticut, Department of Public Safety)

1.13.5.3 The AHJ shall investigate every application for a certificate of fitness.

1.13.5.4* The investigation shall include an examination of the applicant's experience and training in the field of the certificate of fitness for which application has been made.

Δ **A.1.13.5.4** An example of suggested requirements for licensing operators who perform fireworks displays can be found in Annex C, Suggested Requirements for Operator Licensing, of NFPA 1123, 2010 edition.

1.13.5.5 When the AHJ determines that an applicant is not fit to receive the certificate of fitness because of the applicant's inability to comply with the provisions of this *Code*, the AHJ shall refuse to issue the certificate of fitness.

1.13.5.6 If the refusal is based on the applicant's inability to pass an examination given to determine competency, the applicant shall not be permitted to apply again for the certificate of fitness within a 10-day period following the examination.

The AHJ should determine the credentials, courses, experience, and testing necessary for an applicant to qualify for each certificate of fitness. This information should be part of the application package. Applications should not be accepted unless all the appropriate information requested by the AHJ is provided.

If an applicant does not produce the appropriate information as required by the application, the certificate should be refused. Where written or practical tests, or both, are administered and the applicant fails, he or she cannot reapply for a minimum of 10 days. Applicants who fail to provide appropriate credentials or pass an exam should be notified in writing of the reason they are not being issued a certificate of fitness. A failed applicant should also be advised of the procedures required to reapply and any time limits imposed on the reapplication process.

1.13.6 Certificates of fitness shall not be transferable.

1.13.7 Certificates of fitness shall be issued for the period of time as indicated on the certificate of fitness as determined by the AHJ, but such period of time shall not exceed 3 years.

To ensure that applicants keep current with the technology in their fields, certificates of fitness should be issued with an expiration date. This date should not exceed 3 years from the date of issue. Shorter periods might be appropriate for seasonal work or short-term applications, such as for fireworks displays or similar activities.

1.13.8 Applications for renewal of a certificate of fitness shall be filed in the same manner as an application for an original certificate.

Renewal applications should be processed in the same way as first-time applications. After the initial certification period, requirements for maintaining a certificate of fitness could change. This information should be explained in the application, as outlined in 1.13.4. If the applicant does not meet the requirements for renewal, the certificate should not be renewed. A written notice of the reason(s) for nonrenewal should be sent to the applicant. (See Section 1.16.)

1.13.9 Each individual or company holding a certificate of fitness shall notify the AHJ in writing of any address change within 10 days after such change.

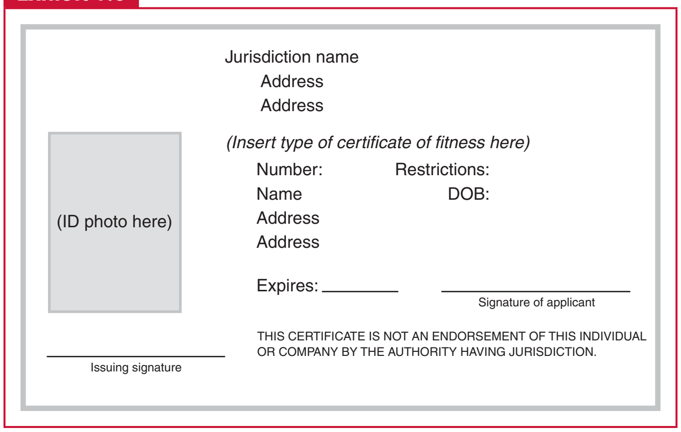
1.13.10 A certificate of fitness shall be in the form of an identification card. The card shall contain the following information:

(1) Purpose for which the certificate of fitness is issued
(2) Date of expiration
(3) Information necessary to easily identify the individual to whom the certificate of fitness is issued
(4) Signature of the individual to whom the certificate of fitness is issued
(5) Name and signature of the AHJ or a designated representative
(6) Statement printed thereon in bold type the following: THIS CERTIFICATE IS NOT AN ENDORSEMENT OF THIS INDIVIDUAL OR COMPANY BY THE AUTHORITY HAVING JURISDICTION.

The certificate of fitness card (see Exhibit 1.6) should contain the information listed in 1.13.10(1) through 1.13.10(6). The best method for identifying the individual certificate holder is a photo, which can be supplied by the applicant. An appropriate photo, similar to a passport photo, can be purchased at numerous retail outlets. A certificate number is also useful for public identification of certificate holders or for specific inquiries.

As stated in the *Code*, the certificate of fitness is not an endorsement by the jurisdiction or AHJ of the certificate holder or any company. The certificate only acknowledges that the holder demonstrated a minimum level of knowledge and skill in a specific activity; this is the reason for the wording on the card. It is important to show clearly on the certificate of fitness card the scope of work that the holder is qualified to perform.

Exhibit 1.6



Sample certificate of fitness card.

Modification of this wording might be necessary, or desirable, to meet local requirements. The legal counsel for the jurisdiction should be consulted on the final wording.

1.13.11 Any individual or company to whom a certificate of fitness has been granted shall, upon request, produce and show proper identification and the certificate of fitness to anyone for whom that individual seeks to render services or to the AHJ.

Any person seeking services, or the AHJ, can request to see the certificate of fitness card at any time. Those who have been issued a certificate should be informed of their duty to carry and produce the card at any time and of the consequences if they fail to do so.

1.13.12 Revocation or Suspension of Certificates of Fitness.

1.13.12.1 The AHJ shall be permitted to revoke or suspend a certificate of fitness issued if any violation of this *Code* is found upon inspection or where any false statements or misrepresentations are submitted in the application on which the approval was based.

Certificates of fitness can be revoked for just cause, which includes a determination that work is performed in an unsafe manner or is in violation of the *Code*.

1.13.12.2 Revocation or suspension shall be constituted when notification is served, posted, or mailed to the address of record for the certificate holder.

If the certificate is revoked, a written notification of the revocation and the reasons for it are required before the revocation is official (see Section 1.16). When a revocation or suspension of a certificate occurs, the AHJ should require that the identification card issued to the certificate holder is returned to the AHJ immediately.

In the case of an imminent danger, the operation in question should be stopped immediately (see 1.7.15). If the work is stopped due to an imminent danger caused by the certificate holder, the certificate of fitness can be revoked immediately, provided that a written notification of the revocation, the reasons for the revocation, and the actions necessary to retain the certificate are provided as soon as possible after the emergency revocation.

1.13.12.3 Failure on the part of an individual to give such notification of a change of address required by 1.13.9 shall constitute grounds for revocation of the certificate of fitness.

1.13.12.4 Revocations or suspensions of a certificate of fitness by the AHJ are appealable to the Board of Appeals as established in Section 1.10.

1.14 Plan Review

1.14.1 Where required by the AHJ for new construction, modification, or rehabilitation, construction documents and shop drawings shall be submitted, reviewed, and approved prior to the start of such work as provided in Section 1.14.

The AHJ has the authority to review plans for *Code* compliance. The AHJ must determine which types of plans to review and ensure that the jurisdiction has the staff and expertise necessary to meet the commitment. The AHJ should also check state and local statutes and ordinances on duties required to be performed to ensure compliance as a minimum with the legal requirements. The AHJ might decide to review plans based on the scope of a project, the occupancies involved, or other criteria. Such criteria should be carefully determined because they will dictate the expected workload.

Once determined, plan review requirements need to be communicated to the developers and architects. Working with the planning/zoning official, local building official, and other local officials, the fire official can ensure that no building permit is issued until all the necessary plan reviews are completed. In many cases, the plan review work of the fire official should start at the civil site plan review stage. This ensures that compliance with Chapter 18 provisions for fire department access and water supply are achieved in the beginning of the site plan design. Work on a project should not begin before a plan review has been conducted and all appropriate approvals and permits have been obtained.

When the AHJ requires a plan review but does not have sufficient time or expertise to perform the review in-house, the AHJ might consider contracting the work to an appropriate expert. In such a case, the property owner or the architect should pay the cost of the contracted review. (See Section 1.15.)

Some communities centralize plan review activity, allowing the applicant to have the plans reviewed by the necessary agencies at a central location. This single-location plan review does not mean the fire official does not review the plans, only that the plans might need to be reviewed at a location other than the fire inspection office, which is usually a town or city hall or building inspector's office. In many cases, a person from the fire official's office is assigned to that location.

Some communities hold a preplan review conference, where the civil engineer, architect, and developer can meet with the AHJ to review the concept for a new project and get initial feedback and review requirements for the project. Conducting this review with all enforcement officials present helps to define the expectations for all parties. The process of getting jurisdictional approvals this way is more beneficial to the applicant.

1.14.2 The applicant shall be responsible to ensure that the following conditions are met:

(1) The construction documents include all of the fire protection requirements.
(2) The shop drawings are correct and in compliance with the applicable codes and standards.
(3) The contractor maintains an approved set of construction documents on site.

The applicant for a plan review must make sure that all required plans are submitted for review and that they meet *Code* requirements, including the civil site design plans, architectural/engineering plans, and shop drawings. An approved set of construction documents must be maintained on-site to ensure that construction is performed in accordance with the approved set of plans. These plans can be referenced by the AHJ when questions arise during site inspections.

1.14.3 It shall be the responsibility of the AHJ to promulgate rules that cover the following:

(1) Criteria to meet the requirements of Section 1.14
(2) Review of documents and construction documents within established time frames for the purpose of acceptance or providing reasons for nonacceptance

The AHJ must specify the criteria and timing for plan review submittals, and the specifications should apply to the types of plans that the AHJ will be concerned with during the review process. These include civil site plans, architectural/engineering plans, and shop drawings.

NFPA 13, *NFPA 72*®, and other installation standards stipulate the information that must be included on or with plans. These codes and standards should be referenced by the AHJ to identify specifications to meet the requirements of 1.14.3.

The turnaround time for the review of plans must be reasonable. If plans must be reviewed by multiple agencies, they should be submitted to each agency at the same time to reduce the overall review time. The submitter should be notified in writing by the AHJ when plans are not approved. The reasons for disapproval should be noted in the letter.

1.14.4 Review and approval by the AHJ shall not relieve the applicant of the responsibility of compliance with this *Code*.

Sometimes items are missed during the design and plan review process, and the plans are approved with *Code* deficiencies. If any *Code* deficiencies are noted during an inspection or after further review of the plans, they must be corrected. Approval of a set of plans by the AHJ does not relieve the permit applicant from complying with this *Code*. Compliance with this *Code* is often part of the licensing requirements for design professionals such as contractors, architects, and engineers. Even after final inspections are passed by the AHJ, the owner is still responsible for correcting items that were missed during the inspection and plan review processes if such violations are brought to the attention of the AHJ and owner at a later date.

1.14.5 When required by the AHJ, revised construction documents or shop drawings shall be prepared and submitted for review and approval to illustrate corrections or modifications necessitated by field conditions or other revisions to approved construction documents.

Conditions often change during construction. Most changes are minor and may not require resubmission of plans before the work continues, or a number of small changes can be captured in one final resubmittal that shows the as-built field conditions. However, some changes might affect system performance, *Code* compliance, or prior approvals. In those circumstances, the AHJ might require that changes be submitted and approved before work proceeds. The resubmission thresholds and criteria are best defined as part of the regulations adopted by the AHJ.

N **1.14.6*** When required by the AHJ, plans and design documents shall be prepared by a registered design professional.

N **A.1.14.6** The AHJ should consider the risk, complexity of the design, qualifications of the AHJ's review staff, and state registration laws/rules to determine if requiring plans/design documents to be prepared by a registered design professional is appropriate.

In some states, scope of work thresholds in statutes or rules state the time within which a design professional is required to complete a set of plans or specifications. In other states, that authority rests solely with the local AHJ. Even in states that have minimum scope of work thresholds that mandate the use of design professionals, there may be circumstances that don't fall within such criteria in which the AHJ thinks a design professional is still necessary. As long as that authority is not preempted to the state, the AHJ has the authority to require a design professional under this section.

1.15 Technical Assistance

1.15.1 The AHJ shall be permitted to require a review by an approved independent third party with expertise in the matter to be reviewed at the submitter's expense.

A third-party review is a common way for an AHJ to get a comprehensive evaluation of a proposed performance-based or other design when the AHJ lacks the expertise in the area covered by the submittal. A third-party review is used in the United States and internationally. Typically, the designer or owner pays for the services of the third-party reviewer, but the reviewer is responsible only to the AHJ.

Choosing a third-party reviewer is partly a function of location. In large metropolitan areas, it is common for the AHJ to maintain a list of local third-party reviewers from which to choose. In other locations, it might be necessary to search beyond the local area for a qualified third-party reviewer. Regardless of how the third-party reviewer is chosen, approval of the use of a particular independent third party rests with the AHJ and not the submitter. The AHJ must ensure that the third party has expertise in the area of review. The expertise of the third party can usually be determined from the resume or CV of the third party and their references.

Guidelines for Peer Review in the Fire Protection Design Process, published by the Society of Fire Protection Engineers (SFPE), can provide additional guidance.

1.15.2 The independent reviewer shall provide an evaluation and recommend necessary changes of the proposed design, operation, process, or new technology to the AHJ.

1.15.3 The AHJ shall be authorized to require design submittals to bear the stamp of a registered design professional.

1.15.4 The AHJ shall make the final determination as to whether the provisions of this *Code* have been met.

Where technical assistance is provided to the AHJ by a third party, the AHJ is ultimately responsible for making the final determination of *Code* compliance and/or granting approval of equivalencies, alternative levels of protection, or modifications. The ethical obligation of the independent third party is to be responsible to the AHJ in achieving the AHJ's objective of *Code* compliance and not to the submitter funding the review or the original designer.

1.16 Notice of Violations and Penalties

1.16.1 Where Required. Whenever the AHJ determines violations of this *Code*, a written notice shall be issued to confirm such findings.

1.16.2 Serving Notice of Violation.

1.16.2.1 Any order or notice of violation issued pursuant to this *Code* shall be served upon the owner, operator, occupant, registered agent, or other person responsible for the condition or violation by one of the following means:

(1) Personal service
(2) Mail to last known address of the owner, operator, or registered agent

A system of issuing orders or notices that is developed in conjunction with the state attorney's office or the jurisdiction's legal counsel can minimize future legal problems. The AHJ's legal counsel should be consulted and assists in prosecuting cases involving violations of this *Code*. In some states, the process for pursuing violations of codes and ordinances may be specified in state law. Therefore, the AHJ should consult the applicable laws before establishing a violation corrections system. Any system that is developed should be used with each notice or order issued, and all procedures must be followed each time to prevent legal problems. In many jurisdictions, a system for pursuing code enforcement action may already exist for pursing other violations such as trash, weeds, junk cars, illegal uses, etc. The AHJ can usually use these existing code enforcement systems for the resolution of *Code* violations if such processes are established before the need to prosecute a *Code* violation.

Where permitted by local or state laws, many of the penalties related to this *Code* can be imposed as a fine via the issuance of a civil citation. In situations where a civil citation process exists, the inspector can write a ticket similar to a traffic ticket. This system reduces prosecution time and generally resolves the issue quickly.

1.16.2.2 For unattended or abandoned locations, a copy of such order or notice of violation shall be posted on the premises in a conspicuous place at or near the entrance to such premises, and the order or notice shall be disseminated in accordance with one of the following:

(1) Mailed to the last known address of the owner, occupant, or registered agent
(2) Published in a newspaper of general circulation wherein the property in violation is located

1.16.2.3 Refusal of an owner, occupant, operator, or other person responsible for the violation to accept the violation notice shall not be cause to invalidate the violation or the notice of violation. When acceptance of a notice of violation is refused, valid notice shall have deemed to have been served under this section provided the methods of service in 1.16.2.1 or 1.16.2.2 have been followed.

1.16.3 Destruction or Removal of Notice. The mutilation, destruction, or removal of a posted order or violation notice without authorization by the AHJ shall be a separate violation of this *Code* and punishable by the penalties established by the AHJ.

1.16.4 Penalties.

1.16.4.1 Any person who fails to comply with the provisions of this *Code*, fails to carry out an order made pursuant to this *Code*, or violates any condition attached to a permit, approval, or certificate shall be subject to the penalties established by the AHJ.

N **1.16.4.2** Violations of the provisions of this *Code* shall be punishable by a fine or imprisonment as determined by a penalty schedule adopted by the AHJ or specified by state law/rules.

1.16.4.3 Where the AHJ has not adopted a separate penalty schedule, or if state laws or rules do not specify a penalty, violations of this *Code* shall be subject to a $100.00 penalty per day for each violation.

AHJs frequently adopt a separate penalty schedule that concerns penalties based on the nature of the violation. As an example, if a building is used without the approval of the AHJ or if an occupancy is overcrowded, a fine of $500 might be appropriate.

1.16.4.4 Failure to comply with the time limits of an order or notice of violation issued by the AHJ shall result in each day that the violation continues being regarded as a separate offense and shall be subject to a separate penalty.

Unless the AHJ adopts a separate penalty schedule to be used with this *Code*, a $100 per day fine would apply to each violation as long as the violations go uncorrected beyond the time specified by the AHJ. As an example, if four violations go uncorrected for 10 days beyond the time limit specified by the AHJ, the penalty would be $4,000.

In determining how long an owner or tenant has to correct a violation before fines begin to accrue, the AHJ should consider the risk created by the existence of the violation. Some violations, such as an out of service fire sprinkler system, overcrowding of an assembly occupancy, or use of a structure without authorization by the AHJ may warrant the need to correct the violation immediately. In other circumstances with relatively minor violations or violations that do not create a significant immediate risk, providing the owner or tenant a limited time frame to correct is appropriate.

It is imperative that the AHJ follow-up on observed *Code* violations. Failure of the AHJ or the AHJ's agents to follow-up on *Code* violations to ensure that they are corrected can put occupants and fire fighters in danger along with exposing property to potential loss. *Code* violations observed but not followed-up on by the AHJ or the AHJ's agents can also create liability for the jurisdiction and the individuals who observed the violation.

1.16.4.5 A separate notice of violation shall not be required to be served each day for a violation to be deemed a separate offense.

The AHJ is not required to issue a separate violation for each day the violation exists. An initial violation notice is sufficient and will continue in force, with penalties accruing each day, as long as the violation continues.

1.16.5 Abatement. Where a violation creates an imminent danger, the AHJ is authorized to abate such hazard in accordance with 1.7.16.

A reasonable time for compliance should be given for all violations other than those that create an imminent danger. Imminent danger violations require immediate action by the AHJ to mitigate the hazard. As an example, this could involve ordering an overcrowded assembly occupancy to reduce the number of occupants immediately, ordering a structure to be vacated since the use is not approved by the AHJ, or ordering a blatantly unsafe hazardous materials process to be shut down. An *imminent danger* is defined in 3.3.159.

N 1.17* Permit Fees

The AHJ shall be authorized to establish a schedule of fees.

N **A.1.17** The schedule of fees should be established to cover the cost of services required to enforce this *Code* by conducting plans review and inspection services. The level of service provided is discussed in detail within NFPA 1730. If fees do not cover the cost of services, then the jurisdiction can choose to subsidize such fees by funding the inspection and plans review services from the general fund or other revenue funding mechanism.

Referenced Publications

2

Chapter 2 is a list of the codes and standards that are referenced in the chapters of NFPA 1. These references are mandatory. Locating the list in a single chapter simplifies the use of the *Code*, making it easier for adopting jurisdictions to update the references in only one location, rather than throughout the *Code*. The editions of the referenced publications listed in Chapter 2 are legally referenced editions, unless the jurisdiction, when adopting the *Code,* modifies or updates the list of codes and standards.

Annex F contains codes, standards, and publications referenced in the annexes. These documents are not enforceable unless they are also listed in Chapter 2 or specifically adopted by the jurisdiction.

2.1 General

The documents referenced in this chapter or portions of such documents are referenced within this *Code* and shall be considered part of the requirements of this document.

(1)* Documents referenced in this chapter or portion of such documents shall only be applicable to the extent called for within other chapters of this *Code.*

A.2.1(1) For example, Chapter 2 references NFPA 10. Such reference does not mean that all buildings must be provided with portable fire extinguishers. Rather, portable fire extinguishers are mandatory only to the extent called for elsewhere in the *Code*.

(2) Where the requirements of a referenced code or standard differ from the requirements of this *Code,* the requirements of this *Code* shall govern.

N **2.1.1* Compliance with Subsequent Editions of the Referenced Publications.** Compliance with subsequent editions of the referenced publications shall be considered evidence of compliance with the editions specified in this *Code*.

N **A.2.1.1** New editions of referenced publications incorporate advances in knowledge, best practices, and technology. Therefore, if an owner or contractor provides compliance with a new edition of a referenced publication that is specified by this *Code*, the AHJ should accept the new edition as evidence of full compliance with the *Code*.

N **2.1.1.1*** Compliance with subsequent editions of reference publications shall be achieved by complying with the entire subsequent edition of the referenced publication.

N **A.2.1.1.1** The intent of 2.1.1 and 2.1.1.1 is that an AHJ should approve the use of subsequent editions of referenced publications only when the entire new edition of the referenced standard is used. This paragraph is not intended to permit the use of "cherry-picking" specific sections of one edition of a referenced standard but to use the entire subsequent edition of the referenced standard.

N **2.1.1.2*** Compliance with individual specific sections contained in subsequent edition referenced publications, and not the entire reference publication, shall only be approved by the AHJ through technical documentation submitted in compliance with 1.4.1 or 1.4.2.

N **A.2.1.1.2** In circumstances where the AHJ is requested to use a specific section in a subsequent edition of a referenced publication and not the entire subsequent edition, the AHJ should require technical documentation submitted in compliance with 1.4.1 or 1.4.2. Before approving the use of specific sections of subsequent editions of referenced documents and not the entire edition of the subsequent edition, the AHJ should ensure that other changes did not occur to the subsequent edition that might affect the overall level of fire and life safety protection.

Definitions

3

This *Code* is unique in that only a handful of definitions are exclusive to this document. Most of the definitions in NFPA 1 are extracted from other NFPA codes and standards, as identified by the citation within brackets [ ] following the definitions.

This chapter has four sections with definitions organized in the following categories:

- Section 3.1 covers the use of terms and general dictionary usage.
- Section 3.2 includes official NFPA definitions, as defined by the NFPA Standards Council.
- Section 3.3 includes general fire protection terms.
- Section 3.4 includes terms specifically related to performance-based designs.

3.1 General

The definitions contained in this chapter shall apply to the terms used in this *Code*. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions

3.2.1* Approved. Acceptable to the AHJ.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the AHJ may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The AHJ may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A common but incorrect assumption is that the term *approved* means *listed* or *labeled*. Although the authority having jurisdiction (AHJ) might use a listing or a label to assist in approving an item, not all approvals are based on listing or labeling, nor will listing or labels automatically allow a component or system to be approved by the AHJ.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the AHJ may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the AHJ. In many circumstances, the property owner or his or her designated agent assumes the role of the AHJ; at government installations, the commanding officer or departmental official may be the AHJ.

The AHJ is the person or agency responsible for enforcing a *code*. In cases where the *code* is to be enforced legally, the AHJ usually is a fire marshal or building official. The AHJ can also be a safety office, an insurance engineering department, an accreditation service, another agency, or specific personnel in these entities, especially where the *code* is to be enforced at a nongovernment level. It is common practice for multiple AHJs to review the same project, enforcing more than one *code* at a time.

3.2.3* Code. A standard that is an extensive compilation of provisions covering broad subject matter or that is suitable for adoption into law independently of other codes and standards.

A.3.2.3 Code. The decision to designate a standard as a "code" is based on such factors as the size and scope of the document, its intended use and form of adoption, and whether it contains substantial enforcement and administrative provisions.

3.2.4 Guide. A document that is advisory or informative in nature and that contains only nonmandatory provisions. A guide may contain mandatory statements such as when a guide can be used, but the document as a whole is not suitable for adoption into law.

3.2.5 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the AHJ and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.6* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the AHJ and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

A.3.2.6 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The AHJ should utilize the system employed by the listing organization to identify a listed product.

As defined in 3.2.5 and 3.2.6, respectively, NFPA neither labels nor lists materials, products, or services.

3.2.7 Recommended Practice. A document that is similar in content and structure to a code or standard but that contains only nonmandatory provisions using the word "should" to indicate recommendations in the body of the text.

3.2.8 Shall. Indicates a mandatory requirement.

3.2.9 Should. Indicates a recommendation or that which is advised but not required.

3.2.10 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions

3.3.1* Absolute Pressure. Pressure based on a zero reference point, the perfect vacuum. [**55,** 2016]

A.3.3.1 Absolute Pressure. Measured from this reference point, the standard atmospheric pressure at sea level is an absolute pressure of 14.7 psi (101.3 kPa). [**55,** 2016]

3.3.2 Access Box. An approved secure box, accessible by the AHJ's master key or control, containing entrance keys or other devices to gain access to a structure or area.

3.3.3 Addition. An increase in building area, aggregate floor area, building height or number of stories of a structure. [**5000,** 2018]

3.3.4* Aerosol Product. A combination of a container, a propellant, and a material that is dispensed. [**30B,** 2015]

A.3.3.4 Aerosol Product. The base product can be dispensed from the container in such form as a mist, spray, foam, gel, or aerated powder. [**30B,** 2015]

3.3.5 Airport (Aerodrome). An area on land or water that is used or intended to be used for the landing and takeoff of aircraft and includes buildings and facilities. [**402,** 2018]

3.3.6 Airport Ramp. Any outdoor area, including aprons and hardstands, where aircraft can be positioned, stored, serviced, or maintained, irrespective of the nature of the surface of the area. [**415,** 2016]

3.3.7* Aisle Width. The horizontal dimension between the face of the loads in racks under consideration. [**13,** 2016]

A.3.3.7 Aisle Width. See Figure A.3.3.7. [**13,** 2016]

3.3.8 Alarm. An indication of the existence of a condition that requires immediate response. [**72,** 2016]

3.3.9 Alarm Signal. See 3.3.240.1.

3.3.10 Alcohol-Based Hand Rub. An alcohol-containing preparation designed for application to the hands for reducing the number of visible microorganisms on the hands and containing ethanol or isopropanol in an amount not exceeding 95 percent by volume.

3.3.11 Alleyway. An accessible clear space between storage piles or groups of piles suitable for housekeeping operations, visual inspection of piling areas, and initial fire-fighting operations.

3.3.12 Alternative. A system, condition, arrangement, material, or equipment submitted to the AHJ as a substitute for a requirement in a standard. [**1144,** 2018]

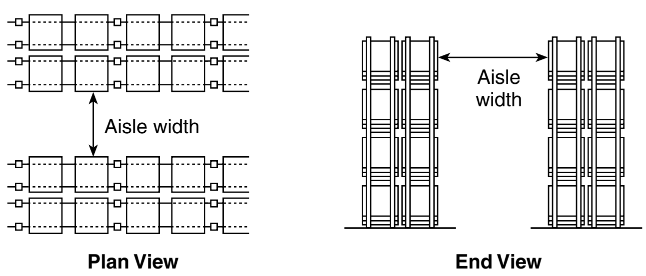

*FIGURE A.3.3.7 Illustration of Aisle Width. [**13,** 2016]*

3.3.13 ANSI/ASME. The designation for American National Standards Institute publication sponsored and published by the American Society of Mechanical Engineers.

3.3.14 Area.

3.3.14.1 Back Stock Area. The area of a mercantile occupancy that is physically separated from the sales area and not intended to be accessible to the public. [**30B,** 2015]

3.3.14.2 Control Area. A building or portion of a building or outdoor area within which hazardous materials are allowed to be stored, dispensed, used, or handled in quantities not exceeding the maximum allowable quantities (MAQ). [**400,** 2016]

3.3.14.3 Fire Area. An area of a building separated from the remainder of the building by construction having a fire resistance of at least 1 hour and having all communicating openings properly protected by an assembly having a fire resistance rating of at least 1 hour. [**30,** 2018]

Fire resistance–rated construction must separate the fire area from all other portions of the building completely, from the floor through the roof or ceiling, in a way that encloses the fire area on the top, bottom, and sides. The fire resistance–rated separation must extend through attic, basement, crawl space, or joist spaces. Thus, in a single-story building, the construction must cut off the crawl space and attic area from the rest of the building, including the joist spaces. Otherwise the ceiling and floor, as well as the walls, must be of rated construction. For further information, see NFPA 220, *Standard on Types of Building Construction*; NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls; and NFPA 5000®, Building Construction and Safety Code®*.

3.3.14.4 Fire Flow Area. The floor area, in square feet, used to determine the required fire flow.

Δ ***3.3.14.5 Indoor Area.*** An area that is within a building or structure having overhead cover, other than a structure qualifying as "weather protection" in accordance with Section 6.6 of NFPA 55. [**55,** 2016]

3.3.14.6 Inside Liquid Storage Area. A room or building used for the storage of liquids in containers or portable tanks, separated from other types of occupancies. [**30,** 2018]

The term *inside liquid storage area* applies to what had been known as "cutoff rooms," "inside rooms," and "attached buildings." The word "inside" now means that the storage room is within a building (i.e., not outdoors); the previous use implied that the storage room was completely enclosed in a building and had no exterior walls. Further, as part of the effort to make the terminology of NFPA 30 consistent with that of NFPA 1, *Fire Code; NFPA 5000*; and the model building and fire codes used throughout the United States, the terms *liquid storage room* and *liquid warehouse* now distinguish between inside liquid storage areas that are less than or equal to 500 ft^2 (46 m^2) and those that are greater than 500 ft^2 (46 m^2), respectively.

3.3.14.7 Organic Peroxide Storage Area. An area used for the storage of organic peroxide formulations. [**400,** 2016]

3.3.14.8 Outdoor Area. An area that is not an indoor area. [**55,** 2016]

3.3.14.9 Permissible Areas.

3.3.14.9.1 Designated Area. A specific location designed and approved for hot work operations that is maintained fire safe such as a maintenance shop or a detached outside location that is of noncombustible or fire-resistive construction, essentially free of combustible and flammable contents, and suitably segregated from adjacent areas. [51B, 2014]

3.3.14.9.2 Permit-Required Area. Any location other than a designated area that is approved for hot work. A permit-required area is an area that is made fire safe by removing or protecting combustibles from ignition sources. [**51B**, 2014]

3.3.14.10 Sales Display Area. The area of a mercantile occupancy that is open to the public for the purpose of viewing and purchasing goods, wares, and merchandise. Individuals are free to circulate among the items, which are typically displayed on shelves, on racks, or on the floor. [**30B,** 2015]

3.3.14.11 Smoking Area. A designated area where smoking is permitted within a premises in which smoking is otherwise generally prohibited.

3.3.14.12* Spray Area. Any fully enclosed, partly enclosed, or unenclosed area in which dangerous quantities of flammable or combustible vapors, mists, residues, dusts, or deposits are present due to the operation of spray processes, including (1) any area in the direct path of a spray application process; (2) the interior of a spray booth, spray room, or limited finishing workstation, as herein defined; (3) the interior of any exhaust plenum, eliminator section, or scrubber section; (4) the interior of any exhaust duct or exhaust stack leading from a spray application process; (5) the interior of any air recirculation path up to and including recirculation particulate filters; (6) any solvent concentrator (pollution abatement) unit or solvent recovery (distillation) unit; and (7) the inside of a membrane enclosure. The following are not part of the spray area: (1) fresh air make-up units; (2) air supply ducts and air supply plenums; (3) recirculation air supply ducts downstream of recirculation particulate filters; and (4) exhaust ducts from solvent concentrator (pollution abatement) units. [**33,** 2016]

A.3.3.14.12 Spray Area. For the purpose of this *Code*, the AHJ can define the limits of the spray area in any specific case. The spray area in the vicinity of spray application operations will necessarily vary with the design and arrangement of the equipment and with the method of operation. Where spray application operations are strictly confined to predetermined spaces that are provided with adequate and reliable ventilation (such as a properly designed and constructed spray booth), the spray area ordinarily will not extend beyond this space. When spray application operations are *not* confined to an adequately ventilated space, then the spray area might extend throughout the room or building area where the spraying is conducted. [**33,** 2016]

- The amount that constitutes "dangerous quantities" in the definition of the term *spray area* is difficult to quantify. If accumulations of residues that have not been cleaned off the walls and floors in a spray area are visible, further inspection is necessary. The AHJ should check behind the overspray collector filters for accumulations of combustible residues.

3.3.15 ASME. American Society of Mechanical Engineers. [**58,** 2017]

3.3.16 ASME Container (or Tank). See 3.3.70.1.

3.3.17 ASTM. American Society for Testing and Materials, now known as "ASTM International." [**55,** 2016]

3.3.18 Automatic Emergency Shutoff Valve. A designated fail-safe automatic closing valve designed to shut off the flow of gases or liquids that is initiated by a control system where the control system is activated by either manual or automatic means. [**55,** 2016]

3.3.19* Baled Cotton. A natural seed fiber wrapped and secured in industry-accepted materials, usually consisting of burlap, woven polypropylene, or sheet polyethylene, and secured with steel, synthetic, or wire bands, or wire; also includes linters (lint removed from the cottonseed) and motes (residual materials from the ginning process).

A.3.3.19 Baled Cotton. See Table A.3.3.19.

The Joint Cotton Industry Bale Packaging Committee (JCIBPC) specifications for baling of cotton now requires that all cotton bales be secured with wire bands, polyester plastic strapping, or cold-rolled high tensile steel strapping, and then covered in fully coated or strip-coated woven polypropylene, polyethylene film, or burlap.

3.3.19.1 Block. A basic yard storage unit for baled cotton comprising multiple-row storage with clear spaces on all sides.

3.3.19.2* Densely Packed Baled Cotton. Cotton, made into banded bales, with a packing density of at least 22 lb/ft^3 (360 kg/m^3), and dimensions complying with the following: a length of 55 in. (ca. 1400 mm ± 20 mm), a width of 21 in. (ca. 530 mm ± 20 mm), and a height of 27.6 in. to 35.4 in. (700 mm to 900 mm).

A.3.3.19.2 Densely Packed Baled Cotton. Experimental work by the U.S. Department of Agriculture, and others (Wakelyn and Hughs, 2002), investigated the flammability of cotton bales with a packing density of at least 22 lb/ft^3 (360 kg/m^2). The research showed that such cotton bales (densely packed cotton bales) did not undergo self-heating or spontaneous combustion, and that the likelihood of sustained smoldering combustion internal to the cotton bale, creating a delayed fire hazard, was extremely low. The same research also showed that, when the cotton bales were exposed to smoldering cigarettes, matches, and open flames (including the gas burner ignition source used for the mattress tests, ASTM E1590, *Standard Test Method for Fire Testing of Mattresses*, and California Technical Bulletin 129), the probability of initiating flaming combustion was at such a low level as not to qualify the densely packed cotton bales as flammable solids. These investigations resulted in harmonization between the U.S. Department of Transportation (49 CFR 172.102, note 137), the United Nations *Recommendations on the Transport of Dangerous Goods,* the International Maritime Organization (the *International Maritime Dangerous Goods Code*), and the International Civil Aviation Organization's *Technical Instructions*, with the removal of the flammable solid designation from densely packed cotton bales, complying with ISO 8115, *Cotton Bales — Dimensions and Density*, and the exemption of such cotton bales from the corresponding transportation hazardous materials regulations.

3.3.19.3 Fire-Packed Baled Cotton. A cotton bale within which a fire has been packed as a result of a process in which ginning is the most frequent cause.

3.3.19.4 Naked Cotton Bale. An unwrapped cotton bale secured with wire or steel straps.

N **3.3.20 Barricade (Explosives or Fireworks).** A natural or artificial barrier that effectively screens a magazine, building, railway, or highway from the effects of an explosion in a magazine or building containing explosives. [**1124,** 2017]

N ***3.3.20.1 Artificial Barricade.*** An artificial mound or revetted wall of earth of a minimum thickness of 3 ft (0.9 m). [**1124,** 2017]

N ***3.3.20.2 Natural Barricade.*** A natural outdoor feature(s), such as hills or trees, with a density sufficient to prevent surrounding

TABLE A.3.3.19 *Typical Cotton Bale Types and Approximate Sizes*

Bale Type	Dimensions in.	Dimensions mm	Average Weight lb	Average Weight kg	Volume ft^3	Volume m^3	Density lb/ft^3	Density kg/m^3
Compressed, standard	57 × 29 × 23	1448 × 736 × 584	500	226.8	22.0	0.62	22.7	366
Gin, standard	55 × 31 × 21	1397 × 787 × 533	500	226.8	20.7	0.58	24.2	391
Compressed, universal	58 × 25 × 21	1475 × 635 × 533	500	226.8	17.6	0.50	28.4	454
Gin, universal	55 × 26 × 21	1397 × 660 × 533	500	226.8	17.4	0.49	28.7	463
Compressed, high density	58 × 22 × 21	1473 × 559 × 533	500	226.8	15.5	0.44	32.2	515
Densely packed baled cotton	55 × 21 × 27.6 to 35.4	1400 × 530 × 700 to 900	500	226.8	21.1	0.60	22.0	360

exposures that require protection from being seen from a magazine or building containing explosives when the trees are bare of leaves. [**1124,** 2017]

3.3.21 Barrel. A unit of volume used in the petroleum industry that is equal to 42 gal (159 L). [**30,** 2018]

The 42 gal (159 L) barrel is a U.S. petroleum industry measurement standard for crude oil and petroleum products. In other countries, petroleum and its products are measured in cubic meters (m^3). The 42 gal (159 L) barrel originated in the early days of the petroleum industry in the United States when crude oil was shipped in 42 gal (159 L) wooden barrels on the basis of 40 gal (150 L) delivered. Supposedly, the 2 gal (7.6 L) difference allowed for evaporation and leakage during transportation. Although no longer used to ship petroleum products, the 42 gal (159 L) barrel has become the petroleum industry's standard unit for measurement, pricing, and application of tax and regulatory codes.

A common mistake is to consider a barrel and a drum as the same item. As used in the *Code,* a barrel is a unit of measure. A drum is a closed container used for shipping and is available in various capacities. The most common drum is one of 55 gal (208 L), although a 30 gal (114 L) size is also used. Larger sizes are available as well [85 gal and 109 gal (322 L and 412 L)]; these are used as environmental recovery drums to hold smaller "leakers."

Although colloquial use treats the terms *barrel* and *drum* as synonyms, this is not the case in the *Code,* and the term *container* is used instead.

3.3.22 Basement. Any story of a building wholly or partly below grade plane that is not considered the first story above grade plane. [**5000,** 2018]

In any particular case, the interpretation of what constitutes a definition of the term *basement* is best left to the AHJ, who should evaluate the extent to which access for fire fighting will be required and the extent to which the configuration of the building might hinder that access. Another factor to consider is whether the configuration of the building would interfere with immediate evacuation by emergency responders.

The definition of the term *basement* might vary. Where the term is used in this *Code* in text extracted from another NFPA code or standard, the source document should be consulted to determine the definition as it applies to the extracted requirement. For example, the definition of *basement* in NFPA 30, *Flammable and Combustible Liquids Code,* differs from the extracted definition of *basement* from *NFPA 5000,* which appears in this *Code*. Exhibit 3.1 illustrates the procedure for determining whether a story is a basement in accordance with NFPA 30 for the purpose of applying requirements.

3.3.23 Battery System. A system that consists of these interconnected subsystems: (1) stationary storage batteries, (2) battery chargers, and (3) a collection of rectifiers, inverters, converters, and associated electrical equipment as required for a particular application.

3.3.24 Battery Types, Stationary.

3.3.24.1 Lithium-Ion Battery. A storage battery that consists of lithium ions imbedded in a carbon graphite or nickel metal-oxide substrate. The electrolyte is a carbonate mixture or a gelled polymer. The lithium ions are the charge carriers of the battery.

3.3.24.2 Lithium Metal Polymer Battery. A storage battery that is comprised of nonaqueous liquid or polymerized electrolytes, which provide ionic conductivity between lithiated positive active material electrically separated from metallic lithium or lithiated negative active material.

3.3.24.3 Nickel Cadmium (NiCad) Battery. An alkaline storage battery in which the positive active material is nickel oxide, the negative contains the cadmium, and the electrolyte is potassium hydroxide.

3.3.24.4* Valve-Regulated (VRLA). A lead-acid battery consisting of sealed cells furnished with a valve that opens to vent the battery whenever the internal pressure of the battery exceeds the ambient pressure by a set amount.

A.3.3.24.4 Valve-Regulated (VRLA). In VRLA batteries, the liquid electrolyte in the cells is immobilized in an absorptive glass mat (AGM cells or batteries) or by the addition of a gelling agent (gel cells or gelled batteries).

3.3.24.5* Vented (Flooded). A lead-acid battery consisting of cells that have electrodes immersed in liquid electrolyte.

A.3.3.24.5 Vented (Flooded). Flooded lead-acid batteries have a provision for the user to add water to the cell and are equipped with a flame-arresting vent that permits the escape of hydrogen and oxygen gas from the cell in a diffused manner such that a spark, or other ignition source, outside the cell will not ignite the gases inside the cell.

3.3.25 Block. See 3.3.19.1.

3.3.26 Board of Appeals. A group of persons appointed by the governing body of the jurisdiction adopting this *Code* for the purpose of hearing and adjudicating differences of opinion between the AHJ and the citizenry in the interpretation, application, and enforcement of this *Code*.

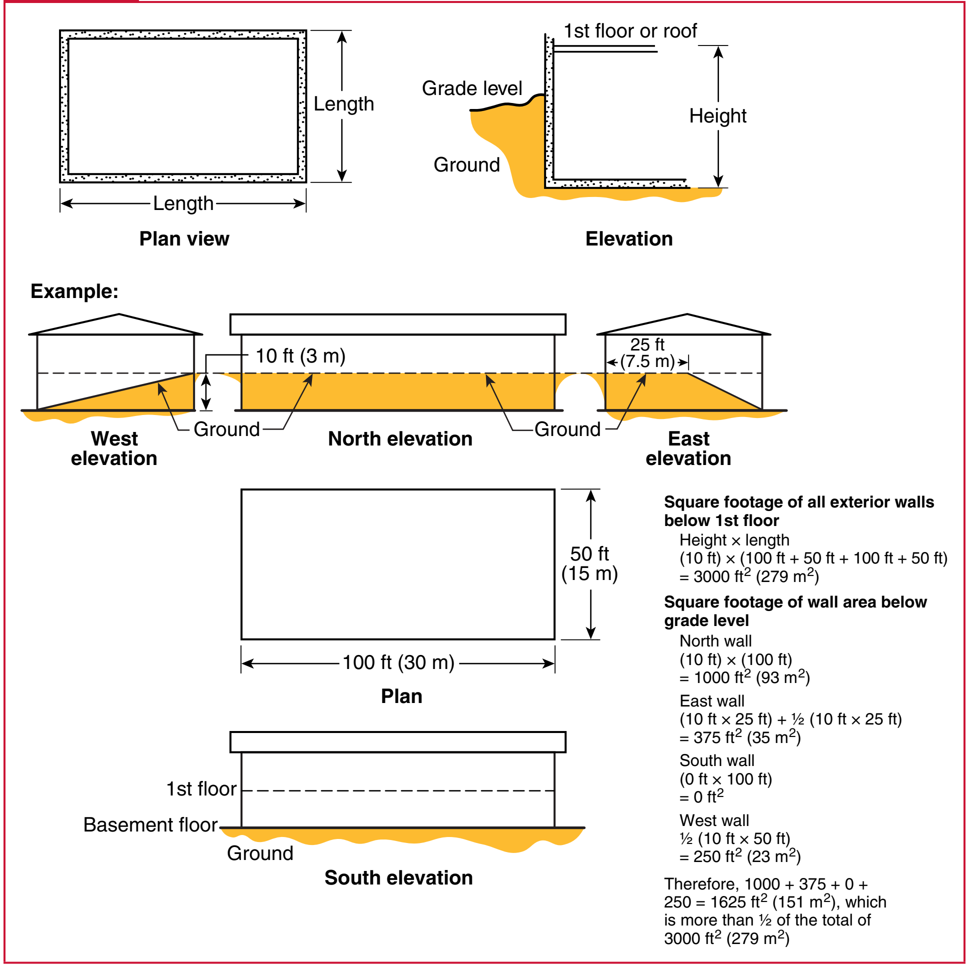
3.3.27* Boiling Point. The temperature at which the vapor pressure of a liquid equals the surrounding atmospheric pressure. [**30,** 2018]

A.3.3.27 Boiling Point. At the boiling point, the surrounding atmospheric pressure can no longer hold the liquid in the liquid state and the liquid boils. A low boiling point is indicative of a high vapor pressure and a high rate of evaporation. [**30,** 2018]

3.3.28* Boil-Over. An event in the burning of certain oils in an open-top tank when, after a long period of quiescent burning, there is a sudden increase in fire intensity associated with expulsion of burning oil from the tank. [**30,** 2018]

Δ **A.3.3.28 Boil-Over.** Boil-over occurs when the residues from surface burning become more dense than the unburned oil and sink below the surface to form a hot layer, which progresses downward much faster than the regression of the liquid surface. When this hot

Exhibit 3.1



Determining whether a lower level of a building is a basement in accordance with NFPA 30.

layer, called a "heat wave," reaches water or water-in-oil emulsion in the bottom of the tank, the water is first superheated and then boils almost explosively, overflowing the tank. Oils subject to boil-over consist of components having a wide range of boiling points, including both light ends and viscous residues. These characteristics are present in most crude oils and can be produced in synthetic mixtures. [**30A,** 2018]

A boil-over is an entirely different phenomenon from a slop-over or froth-over. Slop-over involves a minor frothing that occurs when water is sprayed onto the hot surface of a burning oil. Froth-over is not associated with a fire but results when water is present or enters a tank containing hot viscous oil. Upon mixing, the sudden conversion of water to steam causes a portion of the tank contents to overflow. [**30,** 2018]

Any liquid will boil if heated sufficiently. In open-pool burning, the liquid surface receives radiant energy from the flames, and this energy supports the boiling process. For most liquids, a steady-state condition develops, and burning proceeds until the liquid is consumed. In fact, once a steady state is reached, the burning rate is predictable. In a tank, boiling can result in a rise in the liquid level due to entrained bubbles. Thus, a full tank can overflow if exposed to a surrounding fire. This phenomenon is referred to as a *froth-over*; it is not a boil-over as defined in 3.3.28.

For a boil-over to occur, the liquid must have a range of boiling temperatures and must comprise a substantial proportion of volatile components and a highly viscous residue. It must also have at least a small amount of water-in-oil emulsion. This combination is present in most crude oils but seldom in refined petroleum products or virgin chemical commodities. Sometimes, asphalts are mistakenly presumed to be boil-over liquids. Burning asphalt will certainly froth over when water is applied during firefighting operations, but it is not susceptible to the more violent boil-over phenomenon. Refer to the *Flammable and Combustible Liquids Code Handbook* for more information on boil-over.

3.3.29* Building. Any structure used or intended for supporting or sheltering any use or occupancy. [***101,*** 2018]

Δ **A.3.3.29 Building.** The term *building* is to be understood as if followed by the words *or portions thereof. (See also A.3.3.264, Structure.)* [***101,*** 2018]

3.3.29.1* Airport Terminal Building. A structure used primarily for air passenger enplaning or deplaning, including ticket sales, flight information, baggage handling, and other necessary functions in connection with air transport operations. This term includes any extensions and satellite buildings used for passenger handling or aircraft flight service functions. Aircraft loading walkways and "mobile lounges" are excluded. [**415,** 2016]

A.3.3.29.1 Airport Terminal Building. The term *terminal* is sometimes applied to airport facilities other than those serving passengers, such as cargo- and freight-handling facilities and fuel-handling facilities. These facilities are covered by other NFPA standards, such as NFPA 30. [**415,** 2016]

3.3.29.2 Apartment Building. See 3.3.192.2.

3.3.29.3 Attached Building. A building having only one common wall with another building having other types of occupancies.

3.3.29.4 Bulk Merchandising Retail Building. See 3.3.192.4.

3.3.29.5* Existing Building. A building erected or officially authorized prior to the effective date of the adoption of this edition of the *Code* by the agency or jurisdiction. [***101,*** 2018]

Δ ***A.3.3.29.5 Existing Building.*** With respect to judging whether a building should be considered existing, the deciding factor is not when the building was designed or when construction started but, rather, the date plans were approved for construction by the appropriate AHJ. [***101,*** 2018]

3.3.29.6* High-Rise Building. A building where the floor of an occupiable story is greater than 75 ft (23 m) above the lowest level of fire department vehicle access. [**5000,** 2018]

A.3.3.29.6 High-Rise Building. It is the intent of this definition that, in determining the level from which the highest occupiable floor is to be measured, the enforcing agency should exercise reasonable judgment, including consideration of overall accessibility to the building by fire department personnel and vehicular equipment. Where a building is situated on a sloping terrain and there is building access on more than one level, the enforcing agency might select the level that provides the most logical and adequate fire department access. [**5000,** 2018]

The AHJ must exercise reasonable judgment, including consideration of accessibility to the building by fire department personnel and vehicular equipment, in determining the level from which the highest occupiable floor is to be measured. In the case of a building situated on a sloping terrain with access on more than one level, the AHJ might select the level that provides the most logical and adequate fire department access.

3.3.29.7* Important Building. A building that is considered not expendable in an exposure fire. [**30,** 2018]

A.3.3.29.7 Important Building. Examples of important buildings include occupied buildings where egress within 2 minutes cannot be reasonably expected and control buildings that require presence of personnel for orderly shutdown of important or hazardous processes. Important buildings can also include unprotected storage where products from fire can harm the community or the environment or buildings that contain high-value contents or critical equipment or supplies. [**30,** 2018]

The concept of "important building" is used throughout NFPA 30 to determine the separation between flammable and combustible liquids and the structures, public ways, and property lines to which the liquids represent a fire threat. The intent is that the important building(s) be far enough from a fire involving liquids such that they are not affected by it. What constitutes an important building is determined by the AHJ, but some guidance is provided in this commentary. Certainly, a building that houses high-value contents or critical process control systems would be considered important for the purpose of applying the requirements of NFPA 30. In the latter case, the building might be quite small. Likewise, a building that is normally occupied would be considered important. A large storage building that is used to store spare equipment and that is normally unoccupied might not be considered important within the context of NFPA 30.

3.3.29.8 Mini-Storage Building. See 3.3.192.31.1.

3.3.29.9 Satellite. A structure that can be adjacent to but separated from the airport terminal building, accessible above ground or through subway passages, and used to provide flight service operations, such as passenger check-in, waiting rooms, food service, enplaning or deplaning, etc. [**415,** 2016]

3.3.29.10* Special Amusement Building. A building that is temporary, permanent, or mobile and contains a device or system that conveys passengers or provides a walkway along, around, or over a course in any direction as a form of amusement arranged so that the egress path is not readily apparent due to visual or audio distractions or an intentionally confounded egress path, or is not readily available due to the mode of conveyance through the building or structure. [***101,*** 2018]

A.3.3.29.10 Special Amusement Building. Special amusement buildings include amusements such as a haunted house, a roller coaster–type ride within a building, a multilevel play structure within a building, a submarine ride, and similar amusements where the occupants are not in the open air. [***101,*** 2018]

3.3.29.11 Storage Tank Building. A three-dimensional space that is enclosed by a roof and walls that cover more than one-half of the possible area of the sides of the space, is of sufficient size to allow entry by personnel, will likely limit the dissipation of heat or dispersion of vapors, and restricts access for fire fighting. [**30,** 2018]

A storage tank building was initially conceived as a building housing only storage tanks and their piping plus necessary pumps and other ancillary equipment. The Flammable and Combustible Liquids Code Committee established requirements for storage tank buildings (see Chapter 24 of NFPA 30) to address situations where operators of small tank farms enclosed

Exhibit 3.2

Storage tank installation inside a building.

their tanks with curtain walls and roofs to keep precipitation from accumulating within the tank dike. The reason for doing so was that environmental regulatory agencies had ruled that accumulations of rainwater and snow melt in diked areas had to be collected and treated at great expense. By enclosing the tanks, the accumulation of precipitation was eliminated, as was the need to treat it.

With the exception of inside tanks for fuel oil for oil-burning appliances (NFPA 31, *Standard for the Installation of Oil-Burning Equipment*) and for fuel for stationary engines (NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*), the intent of NFPA 30 is to apply the provisions of Chapter 24 of NFPA 30 to any indoor installation of storage tanks. See Exhibit 3.2 for an example of an indoor storage tank installation.

3.3.30 Bulk Hydrogen Compressed Gas System. See 3.3.267.1.

3.3.31 Bulk Inert Gas System. See 3.3.267.2.

3.3.32 Bulk Liquefied Hydrogen Gas System. See 3.3.267.3.

3.3.33 Bulk Oxygen System. See 3.3.267.4.

3.3.34 Bulk Plant or Terminal. That portion of a property where liquids are received by tank vessel, pipelines, tank car, or tank vehicle and are stored or blended in bulk for the purpose of distributing such liquids by tank vessel, pipeline, tank car, tank vehicle, portable tank, or container.

3.3.35 Burn-It. A fire-fighting strategy that allows for the free-burn of a tire fire.

3.3.36 Bury-It. A fire-fighting strategy in which a tire pile is buried with soil, sand, gravel, cement dust, or other cover material.

3.3.37* Cathodic Protection. A technique to resist the corrosion of a metal surface by making the surface the cathode of an electrochemical cell. [**55,** 2016]

A.3.3.37 Cathodic Protection. This protection renders a metallic container or piping system or component negatively charged with respect to its surrounding environment. [**55,** 2016]

3.3.38 Cathodic Protection Tester. A person who demonstrates an understanding of the principles and measurements of all common types of cathodic protection systems applicable to metal piping and container systems and who has education and experience in soil resistivity, stray current, structure-to-soil potential, and component electrical isolation measurements of metal piping and container systems. [**55,** 2016]

3.3.39 Certificate of Fitness. A written document issued by the AHJ to any person for the purpose of granting permission to such person to conduct or engage in any operation or act for which certification is required.

3.3.40 CFR. The Code of Federal Regulations of the United States Government.

3.3.41 CGA. Compressed Gas Association.

N **3.3.42 Chemical Fume Hood.** A ventilated enclosure designed to contain and exhaust fumes, gases, vapors, mists, and particulate matter generated within the hood interior. [**45,** 2015]

3.3.43 Chemical Heat of Combustion (H_c). The amount of heat released, in Btu/lb (kJ/g), when a substance is oxidized to yield stable end products, including water as a vapor, as measured under actual fire conditions in a normal ambient (air) atmosphere. [**30B,** 2015]

3.3.44 Chemical Name. The scientific designation of a chemical in accordance with the nomenclature system developed by the International Union of Pure and Applied Chemistry or the Chemical Abstracts Service rules of nomenclature, or a name that clearly identifies a chemical for the purpose of conducting an evaluation.

3.3.45 Chemical Plant. A large integrated plant or that portion of such a plant, other than a refinery or distillery, where liquids are produced by chemical reactions or used in chemical reactions. [**30,** 2018]

3.3.46* Chip. A wood chip of various species used in the manufacture of pulp.

A.3.3.46 Chip. Chips are usually ¼ in. to 1¼ in. (6.4 mm to 31.8 mm) in size, with nothing finer than that which is retainable on a ¼ in. (6.4 mm) screen; however, blower and conveyor systems can create some fine dust particles after screening.

3.3.47* Cleaning Media. Materials used to clean piping systems. [**55,** 2016]

Δ **A.3.3.47 Cleaning Media.** Cleaning methods that incorporate chemical washing techniques can include the use of chemical substances, usually liquid, capable of dissolving or dispersing a foreign substance or contaminants and techniques such as rinsing, heating, steaming, or vacuuming applied either individually or in combination with other techniques. Air, inert gas, steam and water are acceptable cleaning media. [**55,** 2016]

3.3.48 Clean Zone. A defined space in which the concentration of airborne particles is controlled to specified limits. [**318,** 2018]

3.3.49 Cleanroom. A room in which the concentration of airborne particles is controlled to specified limits, including areas below the raised floor and above the ceiling grid if these areas are part of the air path and within the rated construction. [**5000,** 2018]

3.3.50 Clear Space. An area free of combustible materials but that can contain noncombustible materials that cannot transmit an exposure fire.

3.3.51 Closed System Use. See 3.3.281.1.

3.3.52 Closed-Top Diking. A dike with a cover intended to minimize the entrance of precipitation into the diked area. [**30,** 2018]

ANSI/UL 142, *Standard for Safety for Steel Aboveground Tanks for Flammable and Combustible Liquids*, defines *closed-top diking* as "a diked aboveground tank with protection on the top of the dike to keep precipitation, debris, or other elements from entering the diked area." Closed-top diking is a construction method used for factory-built horizontal storage tanks in which the tank is mounted in an integral steel dike with a cover at its top (see Exhibit 3.3). The cover is arranged so that precipitation cannot enter the dike, but leakage and overfills from the tank can. ANSI/UL 142 also requires that the closed-top diking be so designed that the diked area cannot be pressurized, even if any fittings should be capped, and that the dike enclosure be provided with emergency relief venting.

3.3.53 Clothes Dryer. A device used to dry wet laundry by means of heat derived from the combustion of fuel or from electric heating elements. [**211,** 2016]

3.3.54 Code.

3.3.54.1 Building Code. The building or construction code adopted by the jurisdiction. [**55,** 2016]

Exhibit 3.3

Aboveground tank with closed-top diking. (Courtesy of Modern Welding Co.)

3.3.54.2 Electrical Code. The electrical code referenced in Section 2.2.

3.3.54.3 Mechanical Code. The mechanical or mechanical construction code adopted by the jurisdiction. [**55,** 2016]

3.3.54.4 Plumbing Code. The plumbing code referenced in Section 2.2.

3.3.55 Cold Deck. A single ranked pile of logs with individual logs of regular or irregular length usually 20 ft to 50 ft (6.1 m to 15.2 m) long, but greater than 8 ft (2.4 m) long.

3.3.56 Column (Paper). A single vertical stack of rolls of paper.

3.3.57 Combustible (Material). A material that, in the form in which it is used and under the conditions anticipated, will ignite and burn; a material that does not meet the definition of noncombustible or limited-combustible. [***101,*** 2018]

3.3.58* Combustible Dust. A finely divided combustible particulate solid that presents a flash fire hazard or explosion hazard when suspended in air or the process-specific oxidizing medium over a range of concentrations. [**654,** 2017]

Δ **A.3.3.58 Combustible Dust.** Dusts traditionally were defined as material 420 μm or smaller (capable of passing through a U.S. No. 40 standard sieve). For consistency with other standards, 500 μm (capable of passing through a U.S. No. 35 standard sieve) is now considered an appropriate size criterion. Particle surface area-to-volume ratio is a key factor in determining the rate of combustion. Combustible particulate solids with a minimum dimension more than 500 μm generally have a surface-to-volume ratio that is too small to pose a deflagration hazard. Flat platelet shaped particles, flakes, or fibers with lengths that are large compared to their diameter usually do not pass through a 500 μm sieve, yet could still pose a deflagration hazard. Many particulates accumulate electrostatic charge in handling, causing them to attract each other, forming agglomerates. Often agglomerates behave as if they were larger particles, yet when they are dispersed they present a significant hazard. Consequently, it can be inferred that any particulate that has a minimum dimension less than or equal to 500 μm could behave as a combustible dust if suspended in air or the process specific oxidizer. If the minimum dimension of the particulate is greater than 500 μm, it is unlikely that the material would be a combustible dust, as determined by test. The determination of whether a sample of combustible material presents a flash fire or explosion hazard could be based on a screening test methodology such as provided in the ASTM E1226, *Standard Test Method for Explosibility of Dust Clouds*. Alternatively, a standardized test method such as ASTM E1515, *Standard Test Method for Minimum Explosible Concentration of Combustible Dusts*, could be used to determine dust explosibility. [**654,** 2017]

There is some possibility that a sample will result in a false positive in the 20 L sphere when tested by the ASTM E1226 screening test or the ASTM E1515 test. This is due to the high energy ignition source overdriving the test. When the lowest ignition energy allowed by either method still results in a positive result, the owner/operator can elect to determine whether the sample is a combustible dust with screening tests performed in a larger scale ($\geq$1 m^3) enclosure, which is less susceptible to overdriving and thus will provide more realistic results. [**654,** 2017]

This possibility for false positives has been known for quite some time and is attributed to "overdriven" conditions that exist in the 20 L chamber due to the use of strong pyrotechnic igniters. For that reason, the reference method for explosibility testing is based on a 1 m^3 chamber, and the 20 L chamber test method is calibrated to produce results comparable to those from the 1 m^3 chamber for most dusts. In fact, the U.S. standard for 20 L testing (ASTM E1226) states, "The objective of this test method is to develop data that can be correlated to those from the 1 m^3 chamber (described in ISO 6184-1 and VDI 3673) . . ." ASTM E1226 further states, "Because a number of factors (concentration, uniformity of dispersion, turbulence of ignition, sample age, etc.) can affect the test results, the test vessel to be used for routine work must be standardized using dust samples whose K_{St} and P_{max} I parameters are known in the 1 m^3 chamber." [**654,** 2017]

NFPA 68 also recognizes this problem and addresses it stating that "the 20 L test apparatus is designed to simulate results of the 1 m^3 chamber; however, the igniter discharge makes it problematic to determine K_{St} values less than 50 bar-m/sec. Where the material is expected to yield K_{St} values less than 50 bar-m/sec, testing in a 1 m^3 chamber might yield lower values." [**654,** 2017]

Any time a combustible dust is processed or handled, a potential for deflagration exists. The degree of deflagration hazard varies, depending on the type of combustible dust and the processing methods used. [**654,** 2017]

A dust deflagration has the following four requirements:

(1) Combustible dust
(2) Dust dispersion in air or other oxidant
(3) Sufficient concentration at or exceeding the minimum explosible concentration (MEC)
(4) Sufficiently powerful ignition source such as an electrostatic discharge, an electric current arc, a glowing ember, a hot surface, welding slag, frictional heat, or a flame

[**654,** 2017]

If the deflagration is confined and produces a pressure sufficient to rupture the confining enclosure, the event is, by definition, an "explosion." [**654,** 2017]

Evaluation of the hazard of a combustible dust should be determined by the means of actual test data. Each situation should be evaluated and applicable tests selected. The following list represents the factors that are sometimes used in determining the deflagration hazard of a dust:

(1) MEC
(2) MIE
(3) Particle size distribution
(4) Moisture content as received and as tested
(5) Maximum explosion pressure at optimum concentration
(6) Maximum rate of pressure rise at optimum concentration
(7) K_{St} (normalized rate of pressure rise) as defined in ASTM E1226, *Standard Test Method for Explosibility of Dust Clouds*
(8) Layer ignition temperature
(9) Dust cloud ignition temperature
(10) Limiting oxidant concentration (LOC) to prevent ignition
(11) Electrical volume resistivity
(12) Charge relaxation time
(13) Chargeability

[**654,** 2017]

It is important to keep in mind that as a particulate is processed, handled, or transported, the particle size generally decreases due to particle attrition. Consequently, it is often necessary to evaluate the explosibility of the particulate at multiple points along the process. Where process conditions dictate the use of oxidizing media other than air (nominally taken as 21 percent oxygen and 79 percent nitrogen), the applicable tests should be conducted in the appropriate process specific medium. [**654,** 2017]

3.3.59* Combustible Fiber. Any material in a fibrous or shredded form that readily ignites when heat sources are present.

A.3.3.59 Combustible Fiber. Combustible fibers can include cotton, sisal, henequen, ixtle, jute, hemp, tow, cocoa fiber, oakum, baled waste, baled wastepaper, kapok, hay, straw, excelsior, Spanish moss, or other like materials.

3.3.60 Combustible Liquid. See 3.3.169.1.

3.3.61 Combustible Particulate Solid. See 3.3.248.1.

3.3.62 Combustible Refuse. All combustible or loose rubbish, litter, or waste materials generated by an occupancy that are refused, rejected, or considered worthless and are disposed of by incineration on the premises where generated or periodically transported from the premises.

3.3.63* Combustible Waste. Combustible or loose waste material that is generated by an establishment or process and, if salvageable, is retained for scrap or reprocessing on the premises where generated or transported to a plant for processing.

A.3.3.63 Combustible Waste. These materials include but are not limited to all combustible fibers, hay, straw, hair, feathers, down, wood shavings, turnings, all types of paper products, soiled cloth trimmings and cuttings, rubber trimmings and buffings, metal fines, and any mixture of the previously listed items, or any other salvageable combustible waste materials.

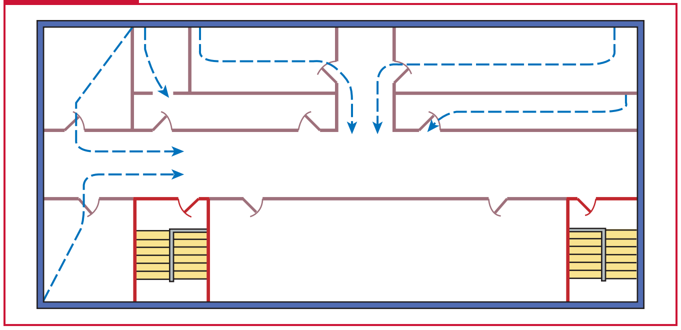
3.3.64 Combustion. A chemical process of oxidation that occurs at a rate fast enough to produce heat and usually light in the form of either a glow or flame.

3.3.65 Commodity. The combination of products, packing material, and container that determines commodity classification. [**13,** 2016]

3.3.66* Common Path of Travel. The portion of exit access that must be traversed before two separate and distinct paths of travel to two exits are available. [***101,*** 2018]

Δ **A.3.3.66 Common Path of Travel.** Common path of travel is measured in the same manner as travel distance but terminates at

Exhibit 3.4



Common paths of travel.

that point where two separate and distinct routes become available. Paths that merge are common paths of travel. [*101,* 2018]

Exhibit 3.4 illustrates the concept of common path of travel. The *Code* limits common path of travel to minimize the probability that occupants will be trapped by a fire by limiting the distance an occupant is forced to travel in one direction before having a choice of traveling in at least two directions to reach separate exits.

3.3.67 Compartment.

3.3.67.1* Fire Compartment. A space within a building that is enclosed by fire barriers on all sides, including the top and bottom. [*101,* 2018]

Δ ***A.3.3.67.1 Fire Compartment.*** Additional fire compartment information is contained in 8.2.2 of NFPA *101*. [*101,* 2018]

In the provisions for fire compartments utilizing the outside walls of a building, it is not intended that the outside wall be specifically fire resistance rated, unless required by other standards. Likewise, it is not intended that outside windows or doors be protected, unless specifically required for exposure protection by another section of this *Code*, NFPA *101*, or by other standards. [*101,* 2018]

3.3.67.2* Smoke Compartment. A space within a building enclosed by smoke barriers on all sides, including the top and bottom. [*101,* 2018]

Δ ***A.3.3.67.2 Smoke Compartment.*** Where smoke compartments using the outside walls or the roof of a building are provided, it is not intended that outside walls or roofs, or any openings therein, be capable of resisting the passage of smoke. Application of smoke compartment criteria where required elsewhere in NFPA *101*, should be in accordance with Section 8.5 of NFPA *101*. [*101,* 2018]

3.3.68 Condition, Existing. See 3.3.104.

3.3.69 Construction Documents. Documents that consist of scaled design drawings and specifications for the purpose of construction of new facilities or modification to existing facilities. *(See also 3.3.239, Shop Drawings.)*

3.3.70 Container. A vessel, including cylinders, tanks, portable tanks, and cargo tanks, used for transporting or storing materials.

3.3.70.1 ASME Container. A container constructed in accordance with the ASME Code. [**58,** 2017]

3.3.70.2 Closed Container. A container as herein defined, so sealed by means of a lid or other device that neither liquid nor vapor will escape from it at ordinary temperatures. [**30,** 2018]

3.3.70.3 Compressed Gas Container. A pressure vessel designed to hold compressed gas at an absolute pressure greater than 1 atmosphere at 68°F (20°C) that includes cylinders, containers, and tanks. [**55,** 2016]

3.3.70.4* Container (Flammable or Combustible Liquid). Any vessel of 119 gal (450 L) or less capacity used for transporting or storing liquids. [**30,** 2018]

A.3.3.70.4 Container (Flammable or Combustible Liquid). The U.S. DOT defines *non-bulk packaging* as having up to 119 gal (450 L) capacity in 49 CFR 171.8. [**30,** 2018]

NFPA 30 defines *container* to be consistent with the U.S. Department of Transportation's (DOT) definition of *non-bulk packaging* in Title 49, Code of Federal Regulations (CFR), Part 171.8, part of which reads "a maximum capacity of 450 L (119 gal) or less as a receptacle for liquids." In this same section, DOT defines *bulk packaging*, as it applies to liquids, as a packaging that has "a maximum capacity greater than 450 L (119 gal)." Bulk packaging includes transport vehicles (in this case, tank vehicles) and large shipping vessels, such as the ISO intermodal tank shown in Exhibit 3.5. Typical ISO tanks are 8 ft (2.4 m), 20 ft (6 m), and 30 ft (9 m) long, with capacities from 10,000 L (2600 gal) to 37,000 L (9800 gal). For the purpose of applying this *Code* and NFPA 30, ISO tanks are treated the same as fixed tanks, as covered in Chapters 21 through 25 of NFPA 30.

Note, however, that Part 178.700 of 49 CFR includes specifications for what it refers to as an "intermediate bulk container" (IBC), a shipping container that has a capacity of not more than 3 m^3 (3000 L, or 793 gal), but not less than 0.45 m^3 (450 L, or

Exhibit 3.5

Typical ISO intermodal tank. (Courtesy of Direct Logistics Pty Ltd.)

Exhibit 3.6

Typical metal intermediate bulk container. (Courtesy of National Packaging Services)

119 gal). Several types of IBCs are available; a metal IBC is shown in Exhibit 3.6. Most IBCs used in the United States tend to be 275 gal to 330 gal (1040 L to 1250 L) capacity and are about 48 in. × 48 in. × 48 in. (1200 mm × 1200 mm × 1200 mm) in size, although the length in any one dimension can range from 40 in. to 50 in. (1015 mm to 1270 mm). The dimensions are compatible with existing rack storage configurations used in warehouses. IBCs of these sizes occupy the same space as four 55 gal (208 L) drums on a pallet, so they represent a 25 to 50 percent increase in warehouse utilization. IBCs are being used more and more in the United States, having been used extensively in Europe for many years.

To minimize confusion, NFPA 30, extracted into this Code, uses a convention whereby containers used to store liquids are separated into three categories:

Container Type	*Capacity, gal (L)*
Non-bulk container	≤119 (450)
Intermediate bulk container	>119 (450) up to 793 (3,000)
Bulk container	>793 (>3,000)

3.3.70.5 Cryogenic Fluids Container. A cryogenic vessel used for transportation, handling, or storage.

3.3.70.6 Intermediate Bulk Container. Any closed vessel having a liquid capacity not exceeding 3000 L (793 gal) and intended for storing and transporting liquids, as defined in Title 49, Code of Federal Regulations, Parts 100 through 199 or in Part 6 of the United Nations *Recommendations on the Transport of Dangerous Goods*. [**30,** 2018]

3.3.70.7 [LP-Gas] Container. Any vessel, including cylinders, tanks, portable tanks, and cargo tanks, used for the transporting or storing of LP-Gases. [**58,** 2017]

As noted in the definition of container, there are several different pressure containers used to store and transport LP-Gas, and each must comply with specific fabrication requirements. The term *container* is a generic description in NFPA 58, *Liquefied Petroleum Gas Code,* and this *Code* for pressure vessels that store LP-Gases and is used by itself whenever it is not necessary to cite a specific type. A container may be either a DOT cylinder or an ASME tank.

3.3.71 Control Area. See 3.3.14.2.

3.3.72* Conventional Pallets. A material-handling aid designed to support a unit load with openings to provide access for material-handling devices. *(See Figure A.3.3.72.)* [**13,** 2016]

A.3.3.72 Conventional Pallets. See Figure A.3.3.72. [**13,** 2016]

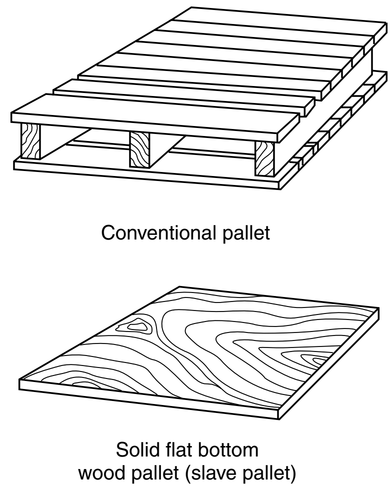


FIGURE A.3.3.72 *Typical Pallets. [**13:**Figure A.3.9.1.10]*

3.3.73 Cooking Fire. The noncommercial, residential burning of materials not exceeding 3 ft (0.9 m) in diameter and 2 ft (0.6 m) in height, other than rubbish in which the fuel burned is contained in an outdoor fireplace, a barbecue grill, or a barbecue pit for the purpose of preparing food.

3.3.74 Cordwood. Logs 8 ft (2.4 m) or less in length customarily intended for pulpwood or fuel uses.

3.3.75 Core. The central tube around which paper is wound to form a roll. [**13,** 2016]

3.3.76* Corrosive Material. See 3.3.180.3.

A.3.3.76 Corrosive Material. A chemical is considered to be corrosive if it destroys or irreversibly changes the structure of the tissue at the site of contact within a specified period of time using one of the *in vivo* or *in vitro* OECD test methods authorized in 49 CFR Part 173.137. For purposes of this code, this term does not refer to action on inanimate surfaces (e.g., steel or aluminum). Available testing data produced prior to September 30, 1995 from the test method in Appendix A to 49 CFR Part 173 in effect on October 1, 1994 can also be used to determine the corrosivity of a material. [**400,** 2016]

3.3.77 Crude Petroleum. Hydrocarbon mixtures that have a flash point below 150°F (65.6°C) and that have not been processed in a refinery. [**30,** 2018]

Technically, a hydrocarbon is a chemical compound that consists only of the elements hydrogen and carbon; for example, heptane [$CH_3(CH2)_5CH_3$]. However, other chemical elements can be present as minor constituents; for example, sulfur (S) or nitrogen (N). For enlightening discussions on the processing of crude petroleum into various petroleum products and into various chemical products, see W. L. Leffler's *Petroleum Refining in Nontechnical Language*, 4th edition, and D. L. Burdick and W. L. Leffler's *Petrochemicals in Nontechnical Language*, 4th edition.

3.3.78 Cryogenic Fluid. A fluid with a boiling point lower than –130°F (–90°C) at an absolute pressure of 14.7 psi (101.3 kPa). [**55,** 2016]

3.3.78.1 Flammable Cryogenic Fluid. A cryogenic fluid that forms flammable mixtures in air when in its vapor state. [**55,** 2016]

3.3.78.2 Inert Cryogenic Fluid. A cryogenic fluid that vaporizes to produce an inert gas when in its vapor state. [**55,** 2016]

3.3.78.3 Oxidizing Cryogenic Fluid. An oxidizing gas in the cryogenic state. [**55,** 2016]

3.3.79* Cultural Resource Properties. Buildings, structures, or sites, or portions thereof, that are culturally significant, or that house culturally significant collections for museums, libraries, and places of worship. [**914,** 2015]

A.3.3.79 Cultural Resource Properties. Such properties include, but are not limited to, museums, libraries, historic structures, and places of worship. [**914,** 2015]

3.3.80 Cylinder. A pressure vessel designed for absolute pressures higher than 40 psi (276 kPa) and having a circular cross-section. It does not include a portable tank, multiunit tank car tank, cargo tank, or tank car. [**55,** 2016]

Exhibit 3.7 illustrates typical U.S. DOT and Transport Canada (U.S. DOT/TC) cylinders. Included are typical industrial truck motor (engine) fuel cylinders and typical stationary and portable cylinders for residential and commercial uses.

Exhibit 3.7

U.S. DOT/TC cylinders. (Courtesy of Manchester Tank)

3.3.81 Cylinder Containment Vessel. A gastight recovery vessel designed so that a leaking compressed gas container can be placed within its confines, thereby encapsulating the leaking container. [**55,** 2016]

3.3.82* Cylinder Pack. An arrangement of cylinders into a cluster where the cylinders are confined into a grouping or arrangement with a strapping or frame system and connections are made to a common manifold. The frame system is allowed to be on skids or wheels to permit movement. [**55,** 2016]

Δ **A.3.3.82 Cylinder Pack.** *Six-packs and twelve-packs* are terms used to further define cylinder packs with a specific number of cylinders. The characteristic internal water volume of individual cylinders in a cylinder pack ranges from 1.52 scf to 1.76 scf (43 L to 50 L) or a water capacity of 95 lb to 110 lb (43 kg to 50 kg). [**55,** 2016]

3.3.83 Damage-Limiting Construction. For the purposes of this code, any set of construction elements, used individually or in combination, which will act to limit damage from an explosion, including open structures, pressure relieving construction, or pressure resistant construction. [**30,** 2018]

With open structures, the force from a combustion explosion — that is, the overpressure — is free to dissipate in all directions. Pressure-relieving construction is used to direct the force in a particular direction by means of pressure-relieving walls or a pressure-relieving roof, with all other structural elements designed to withstand the resulting overpressure. Pressure-resistant construction is designed to contain the force of the explosion.

N **3.3.84 Deficiency.** For the purposes of inspection, testing, and maintenance of water-based fire protection systems, a condition that will or has the potential to adversely impact the performance of a system or portion thereof but does not rise to the level of an impairment. [**25,** 2017]

N ***3.3.84.1 Critical Deficiency.*** A deficiency that, if not corrected, can have a material effect on the ability of the fire protection system or unit to function as intended in a fire event. [**25,** 2017]

N ***3.3.84.2 Noncritical Deficiency.*** A deficiency that does not have a material effect on the ability of the fire protection system or unit to function in a fire event, but correction is needed to meet the requirements of this standard or for the proper inspection, testing, and maintenance of the system or unit. [**25,** 2017]

One of the more difficult tasks associated with the application of this *Code* and NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, is determining how to treat deficiencies that are found while conducting inspections and tests on water-based fire protection systems. While it is clear in the standard that all deficiencies are required to be corrected, NFPA 25 recognizes that all deficiencies do not have the same impact on a system's ability to provide a reasonable degree of protection. Although it might be desirable to treat the correction of all deficiencies the same, it is not practical.

In deference to the concept of reason, the standard recognizes that judgment should be used when determining how to address corrective actions for deficiencies. A system with critical and noncritical deficiencies will still operate, but its performance might be impacted negatively. The term *material effect* is used to separate the deficiencies. There is no way for judgment to be excluded with the classification of deficiencies. Table A.3.3.7 in NFPA 25 provides guidance, but even with this information, it is impossible to classify every situation. Some inspectors classify deficiencies, but the most common industry practice is to have the inspector record all observed deficiencies, followed by a subsequent classification conducted by a qualified individual or team. However, if the inspector identifies any severe impairments, such as a shut water control valve or an inoperable fire pump, those deficiencies must be reported immediately.

3.3.85 Deflagration. Propagation of a combustion zone at a velocity that is less than the speed of sound in the unreacted medium. [**68,** 2013]

N **3.3.86 Desolventizing.** The act of removing a solvent from a material.

3.3.87 Detector. A device suitable for connection to a circuit that has a sensor that responds to a physical stimulus such as gas, heat or smoke. [**72,** 2016]

3.3.87.1 Air Sampling–Type Detector. A detector that consists of a piping or tubing distribution network that runs from the detector to the area(s) to be protected. An aspiration fan in the detector housing draws air from the protected area back to the detector through air-sampling ports, piping, or tubing. At the detector, the air is analyzed for fire products. [**72,** 2016]

Exhibit 3.8

Duct smoke detector (passive). (Source: System Sensor Corp., St. Charles, IL)

Air sampling–type detectors are either passive or active. Duct smoke detectors, as shown in Exhibit 3.8, are typically considered passive detection devices. Active sampling requires the creation of a negative pressure within a sampling tube to draw products of combustion from the protected area or protected space into the sampling network. Vacuum pumps or blower assemblies normally create this negative pressure. An active air-sampling smoke detector is illustrated in Exhibit 3.9.

3.3.87.2 Automatic Fire Detector. A device designed to detect the presence of a fire signature and to initiate action. For the purpose of this *Code*, automatic fire detectors are classified as follows: Automatic Fire Extinguishing or Suppression System Operation Detector, Fire–Gas Detector, Heat Detector, Other Fire Detectors, Radiant Energy–Sensing Fire Detector, and Smoke Detector. [**72,** 2016]

3.3.87.3 Automatic Fire Extinguishing or Suppression System Operation Detector. A device that automatically detects the operation of a fire extinguishing or suppression system by means appropriate to the system employed. [**72,** 2016]

Exhibit 3.9

Air-sampling smoke detectors (active). (Source: Vision Fire & Security Inc., Norwell, MA)

Examples of automatic fire extinguishing or suppression system operation alarm initiating devices are agent discharge flow switches and agent discharge pressure switches.

3.3.87.4* Combination Detector. A device that either responds to more than one of the fire phenomena or employs more than one operating principle to sense one of these phenomena. Typical examples are a combination of a heat detector with a smoke detector or a combination rate-of-rise and fixed-temperature heat detector. This device has listings for each sensing method employed. [**72,** 2016]

A.3.3.87.4 Combination Detector. These detectors do not utilize a mathematical evaluation principle of signal processing more than a simple "or" function. Normally, these detectors provide a single response resulting from either sensing method, each of which operates independent of the other. These detectors can provide a separate and distinct response resulting from either sensing method, each of which is processed independent of the other. [**72,** 2016]

3.3.87.5 Electrical Conductivity Heat Detector. A line-type or spot-type sensing element in which resistance varies as a function of temperature. [**72,** 2016]

3.3.87.6 Fire–Gas Detector. A device that detects gases produced by a fire. [**72,** 2016]

Examples of fire gases include hydrogen chloride (HCl) and carbon monoxide (CO). Fire–gas detectors designed for CO detection should not be confused with CO warning equipment designed to prevent CO poisoning by alerting occupants to the presence of CO gas in the home.

3.3.87.7* Fixed-Temperature Detector. A device that responds when its operating element becomes heated to a predetermined level. [**72,** 2016]

A.3.3.87.7 Fixed-Temperature Detector. The difference between the operating temperature of a fixed-temperature device and the surrounding air temperature is proportional to the rate at which the temperature is rising. The rate is commonly referred to as *thermal lag*. The air temperature is always higher than the operating temperature of the device. [**72,** 2016]

Typical examples of fixed-temperature sensing elements are as follows:

(1) *Bimetallic.* A sensing element comprised of two metals that have different coefficients of thermal expansion arranged so that the effect is deflection in one direction when heated and in the opposite direction when cooled.
(2) *Electrical Conductivity.* A line-type or spot-type sensing element in which resistance varies as a function of temperature.
(3) *Fusible Alloy.* A sensing element of a special composition metal (eutectic) that melts rapidly at the rated temperature.
(4) *Heat-Sensitive Cable.* A line-type device in which the sensing element comprises, in one type, two current-carrying wires separated by heat-sensitive insulation that softens at the rated temperature, thus allowing the wires to make electrical contact. In another type, a single wire is centered in a metallic tube, and the intervening space is filled with a substance that becomes conductive at a critical temperature, thus establishing electrical contact between the tube and the wire.
(5) *Liquid Expansion.* A sensing element comprising a liquid that is capable of marked expansion in volume in response to an increase in temperature.

[**72,** 2016]

Exhibit 3.10 illustrates a typical fixed-temperature heat detector.

3.3.87.8* Flame Detector. A radiant energy–sensing fire detector that detects the radiant energy emitted by a flame. (*Refer to A.17.8.2 of NFPA 72.*) [**72,** 2016]

A.3.3.87.8 Flame Detector. Flame detectors are categorized as ultraviolet, single wavelength infrared, ultraviolet infrared, or multiple wavelength infrared. [**72,** 2016]

Exhibit 3.11 illustrates a typical flame detector.

Exhibit 3.10

Typical fixed-temperature (nonrestorable) heat detector. (Source: Kidde-Fenwal, Ashland, MA)

Exhibit 3.11

Typical flame detector. (Source: Det-Tronics Corp., Minneapolis, MN)

3.3.87.9 Gas Detector. A device that detects the presence of a specified gas concentration. Gas detectors can be either spot-type or line-type detectors. [**72,** 2016]

3.3.87.10 Heat Detector. A fire detector that detects either abnormally high temperature or rate of temperature rise, or both. [**72,** 2016]

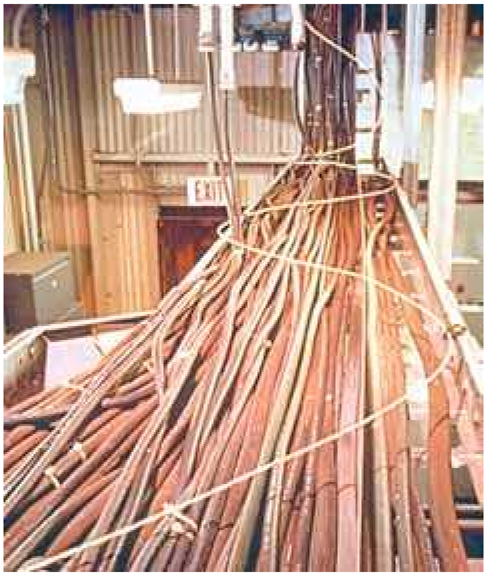
Many types of heat detectors are available. A typical spot-type heat detector is shown in the commentary to 3.3.87.22 (Exhibit 3.13). For descriptions of other types of heat detectors, see the definitions of the terms *electrical conductivity heat detector, fixed-temperature detector* (see Exhibit 3.10), *line-type detector, pneumatic rate-of-rise tubing detector, rate compensation detector,* and *rate-of-rise detector* in 3.3.87.

3.3.87.11 Line-Type Detector. A device in which detection is continuous along a path. Typical examples are rate-of-rise pneumatic tubing detectors, projected beam smoke detectors, and heat-sensitive cable. [**72,** 2016]

Exhibit 3.12 illustrates a typical line-type detector installed in a cable tray application.

3.3.87.12* Multi-Criteria Detector. A device that contains multiple sensors that separately respond to physical stimulus such as heat, smoke, or fire gases, or employs more than one sensor to sense the same stimulus. This sensor is capable of generating only one alarm signal from the sensors employed in the design either independently or in combination. The sensor output signal is mathematically evaluated to determine when an alarm signal is warranted. The evaluation can be performed either at the detector or at the control unit. This detector has a single listing that establishes the primary function of the detector. [**72,** 2016]

Exhibit 3.12



Typical line-type detector. (Courtesy of Protectowire Co. Inc.)

A.3.3.87.12 Multi-Criteria Detector. A multi-criteria detector is a detector that contains multiple sensing methods that respond to fire signature phenomena and utilizes mathematical evaluation principles to determine the collective status of the device and generates a single output. Typical examples of multi-criteria detectors are a combination of a heat detector with a smoke detector, or a combination rate-of-rise and fixed-temperature heat detector that evaluates both signals using an algorithm to generate an output such as pre-alarm or alarm. The evaluation can be performed either at the detector or at the control unit. Other examples are detectors that include sensor combinations that respond in a predictable manner to any combination of heat, smoke, carbon monoxide, or carbon dioxide. [**72,** 2016]

Multi-criteria devices use several sensors to detect multiple conditions and analyze the readings of the sensors. Types of sensors include heat, flame, smoke, and carbon monoxide and predict with improved accuracy, and faster response, the presence of a fire source. The multiple sensing technologies independently collect fire signatures and environmental conditions. The detector uses proprietary software algorithms to evaluate the signals from the array of sensors then provide a single output. Signals are not available as individual outputs. Multi-criteria detectors also have the capability to reject nuisance alarm sources such as dust, smoking, welding, steam, and aerosols.

3.3.87.13* Multi-Sensor Detector. A device that contains multiple sensors that separately respond to physical stimulus such as heat, smoke, or fire gases, or employs more than one sensor to sense the same stimulus. A device capable of generating multiple alarm signals from any one of the sensors employed in the design, independently or in combination. The sensor output signals are mathematically evaluated to determine when an alarm signal is warranted. The evaluation can be performed either at the detector or at the control unit. This device has listings for each sensing method employed. [**72,** 2016]

A.3.3.87.13 Multi-Sensor Detector. Typical examples of multi-sensor detectors are a combination of a heat detector with a smoke detector, or a combination rate-of-rise and fixed-temperature heat detector that evaluates both signals using an algorithm to generate an output such as pre-alarm or alarm. The evaluation can be performed either at the detector or at the control unit. Other examples are detectors that include sensor combinations that respond in a predictable manner to any combination of heat, smoke, carbon monoxide, or carbon dioxide. [**72,** 2016]

3.3.87.14 Other Fire Detectors. Devices that detect a phenomenon other than heat, smoke, flame, or gases produced by a fire. [**72,** 2016]

3.3.87.15 Pneumatic Rate-of-Rise Tubing Heat Detector. A line-type detector comprising small-diameter tubing, usually copper, that is installed on the ceiling or high on the walls throughout the protected area. The tubing is terminated in a detector unit containing diaphragms and associated contacts set to actuate at a predetermined pressure. The system is sealed except for calibrated vents that compensate for normal changes in temperature. [**72,** 2016]

3.3.87.16 Projected Beam–Type Detector. A type of photoelectric light obscuration smoke detector wherein the beam spans the protected area. [**72,** 2016]

Projected beam–type detectors are often used in large open areas such as atria, convention halls, auditoriums, and gymnasiums and where a building or portion of a building has a high ceiling.

3.3.87.17 Radiant Energy–Sensing Fire Detector. A device that detects radiant energy, such as ultraviolet, visible, or infrared, that is emitted as a product of combustion reaction and obeys the laws of optics. [**72,** 2016]

3.3.87.18* Rate Compensation Detector. A device that responds when the temperature of the air surrounding the device reaches a predetermined level, regardless of the rate of temperature rise. [**72,** 2016]

A.3.3.87.18 Rate Compensation Detector. A typical example of a rate compensation detector is a spot-type detector with a tubular casing of a metal that tends to expand lengthwise as it is heated and an associated contact mechanism that closes at a certain point in the elongation. A second metallic element inside the tube exerts an opposing force on the contacts, tending to hold them open. The forces are balanced in such a way that, on a slow rate-of-temperature rise, there is more time for heat to penetrate to the inner element, which inhibits contact closure until the total device has been heated to its rated temperature level. However, on a fast rate-of-temperature rise, there is not as much time for heat to penetrate to the inner element, which exerts less of an inhibiting effect so that contact closure is achieved when the total device has been heated to a lower temperature. This, in effect, compensates for thermal lag. [**72,** 2016]

In addition to the benefit of having limited thermal lag, this type of detector also can be used outdoors in challenging environments. It is a desired substitute initiating device when environmental conditions do not permit the use of a spot-type smoke detector, such as in exterior elevator lobbies where Phase I Emergency Recall Operation is provided.

3.3.87.19* Rate-of-Rise Detector. A device that responds when the temperature rises at a rate exceeding a predetermined value. [**72,** 2016]

A.3.3.87.19 Rate-of-Rise Detector. Typical examples of rate-of-rise detectors are as follows:

(1) *Pneumatic Rate-of-Rise Tubing.* A line-type detector comprising small-diameter tubing, usually copper, that is installed on the ceiling or high on the walls throughout the protected area. The tubing is terminated in a detector unit that contains diaphragms and associated contacts set to actuate at a predetermined pressure. The system is sealed except for calibrated vents that compensate for normal changes in temperature.
(2) *Spot-Type Pneumatic Rate-of-Rise Detector.* A device consisting of an air chamber, a diaphragm, contacts, and a compensating vent in a single enclosure. The principle of operation is the same as that described for pneumatic rate-of-rise tubing.
(3) *Electrical Conductivity–Type Rate-of-Rise Detector.* A line-type or spot-type sensing element in which resistance changes due to a change in temperature. The rate of change of resistance is monitored by associated control equipment, and an alarm is initiated when the rate of temperature increase exceeds a preset value.

[**72,** 2016]

3.3.87.20 Smoke Detector. A device that detects visible or invisible particles of combustion. [**72,** 2016]

The definition of *smoke detector* uses the phrase "particles of combustion" to distinguish the effluent matter consisting of soot particles, gas molecules, vapor molecules, and ash particles from the heat and radiant energy liberated by the combustion reaction that is deemed energy. Matter flowing from the fire in the effluent plume is referenced in the term *smoke*. Types of smoke detectors are distinguished by the technology they use to detect the matter in the smoke plume.

3.3.87.21 Spark/Ember Detector. A radiant energy–sensing fire detector that is designed to detect sparks or embers, or both. These devices are normally intended to operate in dark environments and in the infrared part of the spectrum. [**72,** 2016]

3.3.87.22 Spot-Type Detector. A device in which the detecting element is concentrated at a particular location. Typical examples are bimetallic detectors, fusible alloy detectors, certain pneumatic rate-of-rise detectors, certain smoke detectors, and thermoelectric detectors. [**72,** 2016]

A typical spot-type fixed-temperature heat detector is depicted in Exhibit 3.13.

Exhibit 3.13

A typical spot-type heat detector.

3.3.88 Detonation. Propagation of a combustion zone at a velocity that is greater than the speed of sound in the unreacted medium. [**68,** 2013]

3.3.89 Dispensing. The pouring or transferring of a material from a container tank, or similar vessel whereby vapors, dusts, fumes, mists, or gases could be liberated to the atmosphere. [**5000,** 2018]

3.3.90 Distillery. A plant or that portion of a plant where liquids produced by fermentation are concentrated and where the concentrated products are also mixed, stored, or packaged. [**30,** 2018]

3.3.91 Distributor. A business engaged in the sale or resale, or both, of compressed gases or cryogenic fluids, or both. [**55,** 2016]

3.3.92 Dormitory. See 3.3.192.9

3.3.93 DOT. U.S. Department of Transportation.

3.3.94 Driveway. A clear space suitable for fire-fighting operations by motorized fire apparatus.

3.3.95 Dwelling Unit. One or more rooms arranged for complete, independent housekeeping purposes, with space for eating, living, and sleeping; facilities for cooking; and provisions for sanitation. [**5000,** 2018]

3.3.95.1 One- and Two-Family Dwelling Unit. See 3.3.192.25.1.

3.3.96 Emergency. A fire, explosion, or hazardous condition that poses an immediate threat to the safety of life or damage to property.

3.3.97 Emergency Relief Vent. An opening, construction method, or device that will automatically relieve excessive internal pressure due to an exposure fire. [**30,** 2018]

An emergency relief vent is a device, normally closed, on a storage tank to provide additional pressure relief capacity if the tank is subjected to an external fire. The vent is not there to prevent rupture of the tank due to an explosion within the tank's vapor space. When a storage tank is exposed to an external fire, the contents are heated to the point where vapors evolve faster than can be accommodated by the normal breather vent. The emergency relief vent provides the extra capacity necessary to ensure that the pressure inside the tank does not reach a level that might damage the shell or roof of the tank. This extra capacity is especially important where the exposing fire is intense enough to boil the contents of the tank.

3.3.98 Emergency Shutoff Valve. A designated valve designed to shut off the flow of gases or liquids. [**55,** 2016]

3.3.99 Ethylene Oxide Drum. For the purposes of this code, containers built to UN specification 1A1. [**55,** 2016]

3.3.100 Excess Flow Control. A fail-safe system or approved means designed to shut off flow due to a rupture in pressurized piping systems. [**55,** 2016]

3.3.101 Excess Flow Valve. A valve inserted into a compressed gas cylinder, portable tank, or stationary tank that is designed to positively shut off the flow of gas in the event that its predetermined flow is exceeded.

3.3.102* Exhausted Enclosure. An appliance or piece of equipment that consists of a top, a back, and two sides that provides a means of local exhaust for capturing gases, fumes, vapors, and mists. [**55,** 2016]

A.3.3.102 Exhausted Enclosure. Such enclosures include laboratory hoods, exhaust fume hoods, and similar appliances and equipment used to retain and exhaust locally the gases, fumes, vapors, and mists that could be released. Rooms or areas provided with general ventilation, in and of themselves, are not exhausted enclosures. [**55,** 2016]

3.3.103* Existing. That which is already in existence on the date this edition of the *Code* goes into effect. [***101,*** 2018]

A.3.3.103 Existing. See A.3.3.29.5, Existing Building. [***101,*** 2018]

3.3.104 Existing Condition. Any situation, circumstance, or physical makeup of any structure, premise, or process that was ongoing or in effect prior to the adoption of this *Code*.

3.3.105* Exit. That portion of a means of egress that is separated from all other spaces of the building or structure by construction, location, or equipment as required to provide a protected way of travel to the exit discharge. [***101,*** 2018]

A.3.3.105 Exit. Exits include exterior exit doors, exit passageways, horizontal exits, exit stairs, and exit ramps. In the case of a stairway, the exit includes the stair enclosure, the door to the stair enclosure, stairs and landings inside the enclosure, the door from the stair enclosure to the outside or to the level of exit discharge, and any exit passageway and its associated doors, if such are provided, so as to discharge the stair directly to the outside. In the case of a door leading directly from the street floor to the street or open air, the exit comprises only the door. [***101,*** 2018]

Doors of small individual rooms, as in hotels, while constituting exit access from the room, are not referred to as exits, except where they lead directly to the outside of the building from the street floor. [***101,*** 2018]

The definition of the term *exit* includes the word *location* so as to clarify that the requisite protected way of travel might be accomplished relative to where the exit is located. For example, a door opening to the outside from the main lobby of a building might be considered an exit, although the opening is not separated from other parts of the building. Exhibit 3.14 illustrates an enclosed exit stair that qualifies as being an exit because of its separation from the remainder of the building by fire-rated construction.

3.3.105.1* Horizontal Exit. A way of passage from one building to an area of refuge in another building on approximately the same level, or a way of passage through or around a fire barrier to an area of refuge on approximately the same level in the same building that affords safety from fire and smoke originating from the area of incidence and areas communicating therewith. [***101,*** 2018]

Exhibit 3.14

An enclosed stair that constitutes an exit.

A.3.3.105.1 Horizontal Exit. Horizontal exits should not be confused with egress through doors in smoke barriers. Doors in smoke barriers are designed only for temporary protection against smoke, whereas horizontal exits provide protection against serious fire for a relatively long period of time in addition to providing immediate protection from smoke. *(See 7.2.4 of NFPA 101.)* [***101,*** 2018]

A horizontal exit is a fire barrier with fire doors that provide passage from one fire compartment of a building to another fire compartment in the same building or in an adjoining building on approximately the same level. Substantial fire separations are required because the area to which egress is made serves as a temporary safe haven. The horizontal exit might be a combination of a 2-hour fire resistance–rated barrier separating a building into two areas with 1½-hour fire protection–rated door assemblies that allow travel from one side of the barrier to the other; or the horizontal exit might be a bridge or balcony that allows travel to an adjoining building.

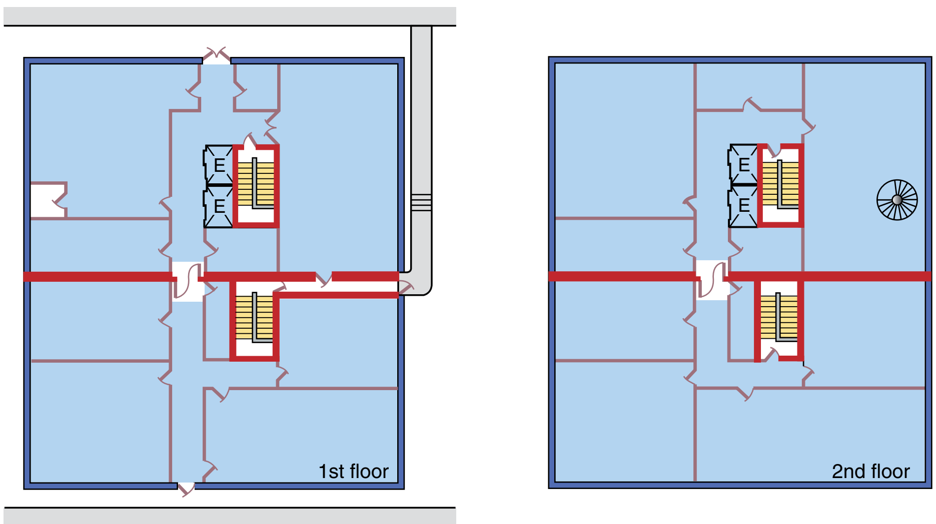
Horizontal exits are useful particularly in health care occupancies and in detention and correctional occupancies where they are important components of an effective defend-in-place occupant protection strategy. Horizontal exits make it possible to move nonambulatory patients to a temporary safe area rather than vertically down stairs. They provide additional safety to residents of detention and correctional occupancies by allowing those residents to be relocated within a building rather than requiring reliance on staff to unlock doors to allow them to evacuate to the outside.

3.3.106 Exit Access. That portion of a means of egress that leads to an exit. [***101,*** 2018]

Exit access includes the rooms and building spaces that people can occupy and the doors, aisles, corridors, unenclosed stairs, and unenclosed ramps that must be traversed to reach an exit. Spaces constituting exit access are shown in Exhibit 3.15.

All spaces occupied and traversed in reaching an exit are considered the exit access portion of the means of egress. From the shading shown in Exhibit 3.15, exit access comprises more

Exhibit 3.15



Spaces constituting exit access.

floor area than either of the other components of means of egress — the exit and exit discharge.

3.3.107 Exit Discharge. That portion of a means of egress between the termination of an exit and a public way. [***101,*** 2018]

Some exits do not discharge directly to a public way, so the exit discharge is defined as a path of travel from the termination of an exit to a public way. This travel might be inside or outside the building. Where an exit opens onto an alley, court, or yard, a safe path of travel must be provided to a public way or equivalent safe area. This portion of the means of egress is the exit discharge. Forms of exit discharge are shown in Exhibit 3.16.

Because occupants leave the building at the first floor only, no exit discharge occurs on the second floor of Exhibit 3.16. On the first floor, the exit discharge includes (a) the exterior path of travel beginning at the exterior doors from the corridor and continuing to the public way (street), (b) the exterior walkway along the side of the building beginning at the door from the exit passageway and continuing to the public way, and (c) the interior path of travel from the second-floor exit stair discharging through a portion of the first-floor corridor. For an occupant from the second floor who must travel across a portion of the first floor, this area is considered exit discharge, yet an occupant of the first floor can travel across the same space and is considered to be within exit access. Requirements for such interior exit discharge arrangements are specified in 14.11.2.

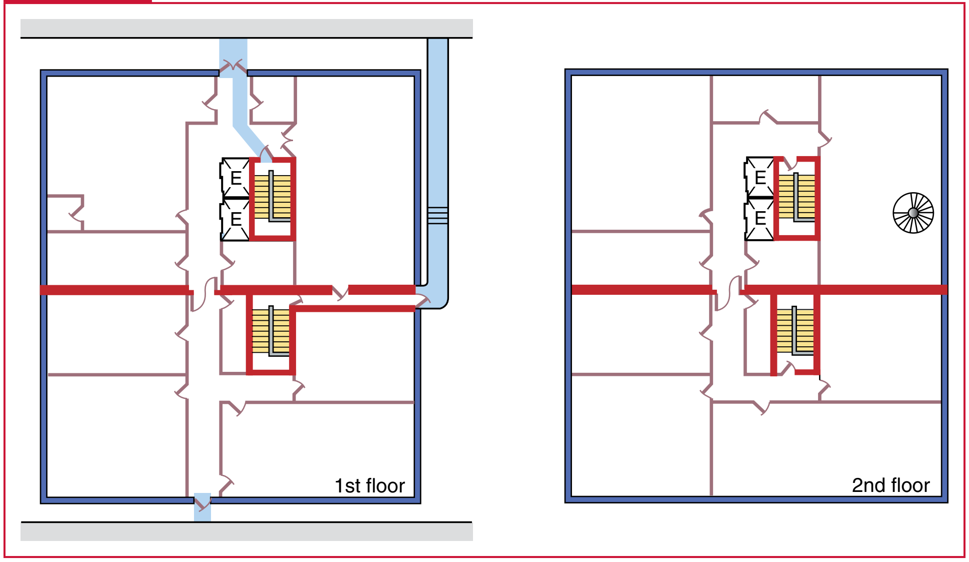
3.3.108 Explosion. The bursting or rupture of an enclosure or a container due to the development of internal pressure from a deflagration. [**69,** 2014]

3.3.109* Explosion Control. A means of either preventing an explosion through the use of explosion suppression, fuel reduction, or oxidant reduction systems or a means to prevent the structural collapse of a building in the event of an explosion through the use of deflagration venting, barricades, or related construction methods. [**55,** 2016]

Δ **A.3.3.109 Explosion Control.** NFPA 68 provides guidance on the use of deflagration venting systems in buildings and other enclosures. The primary purpose of a venting system is to relieve the overpressure produced in an explosion to limit the potential damage to the building where the explosion occurs. Although some structural damage can be anticipated, the use of relief venting is expected to prevent massive building failure and collapse. In cases where detonation is probable, venting is often used in conjunction with barricade construction where the pressure-resistant portions of the building have been constructed to resist the pressures anticipated should an explosive event occur. Design of barricade systems is highly specialized and the subject of military standards applicable to the subject. NFPA 69 provides guidance on the use of suppression, ventilation systems, and the limiting of oxidants as a means to prevent the occurrence of an explosion. When relief vents are to be used as a means to provide explosion relief, the fundamental requirements of the building code for structural elements, including snow, wind, and seismic events, should be considered. In some instances, the requirements for wind resistance can impose more rigorous requirements on the relief vents than required by the engineering analysis used to determine the relief pressure. In such cases, users must demonstrate that the relief vents will not become airborne or release in such a manner as to create secondary hazards within or external to the building in which they are installed. Specific designs might require approval by the AHJ. [**55,** 2016]

3.3.110* Explosive Material. A chemical compound, mixture, or device, the primary or common purpose of which is to function by explosion. [**5000,** 2018]

Exhibit 3.16



Spaces constituting exit discharge.

A.3.3.110 Explosive Material. The term *explosive material* includes, but is not limited to, dynamite, blackpowder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters, and Display Fireworks 1.3G (Class B, Special). The term *explosive* includes any material determined to be within the scope of Title 18, United States Code, Chapter 40, and also includes any material classified as an explosive, other than Consumer Fireworks 1.4G (Class C, Common), by the Hazardous Materials Regulations of the U.S. Department of Transportation (DOT) in 49 CFR. [**5000,** 2018]

The former classification system used by the DOT included the terms *high explosive* and *low explosive*, as further defined in 3.3.406.3.2 of *NFPA 5000*. These terms remain in use by the U.S. Bureau of Alcohol, Tobacco, and Firearms or explosives. Explosive materials classified as hazard Class 1 are further defined under the current system applied by DOT. Compatibility group letters are used in concert with division numbers to specify further limitations on each division noted. For example, the letter G (as in 1.4G) identifies substances or articles that contain a pyrotechnic substance and similar materials. UN/DOT Class 1 Explosives are defined as follows:

(1) Division 1.1 explosives are explosives that are a mass explosion hazard, which is a hazard that instantaneously affects almost the entire load.
(2) Division 1.2 explosives are explosives that are a projection hazard but not a mass explosion hazard.
(3) Division 1.3 explosives are explosives that are a fire hazard and either a minor blast hazard or a minor projection hazard, or both, but not a mass explosion hazard.
(4) Division 1.4 explosives are explosives that pose a minor explosion hazard and meet both of the following criteria:
    (a) The explosive effects are largely confined to the package, and no projection of fragments of appreciable size or range is to be expected.
    (b) An external fire cannot cause virtually instantaneous explosion of almost the entire contents of the package.
(5) Division 1.5 explosives are very insensitive explosives that are comprised of substances that are a mass explosion hazard, but are so insensitive that there is very little probability of initiation or of transition from burning to detonation under normal conditions of transport.
(6) Division 1.6 explosives are extremely insensitive articles that are not a mass explosion hazard, that are comprised of articles that contain only extremely insensitive detonating substances, and that demonstrate a negligible probability of accidental initiation or propagation.

[**5000,** 2018]

N **3.3.111 Extraction Room (Marijuana).** The room or space in which the solvent–based extraction process of marijuana occurs.

3.3.112 Facility. As applied to access and water supply, a structure or use in a fixed location including exterior storage, use, and handling areas that relates to the occupancies and operations covered by this *Code*.

N ***3.3.112.1 Animal Housing Facility.*** Area of a building or structure, including interior and adjacent exterior spaces, where animals are fed, rested, worked, exercised, treated, exhibited, or used for production.

3.3.112.2 Hazardous Material Storage Facility. See 3.3.150.

3.3.112.3 Limited Care Facility. See 3.3.192.16.

3.3.112.4 Motor Fuel Dispensing Facility. See 3.3.192.22.

3.3.112.4.1 Fleet Vehicle Motor Fuel Dispensing Facility. See 3.3.192.22.1.

3.3.112.4.2 Marine Motor Fuel Dispensing Facility. See 3.3.192.22.2.

3.3.112.4.3 Motor Fuel Dispensing Facility Located Inside a Building. See 3.3.192.22.3.

3.3.113 Fail-Safe. A design arrangement incorporating one or more features that automatically counteracts the effect of an anticipated source of failure or which includes a design arrangement that eliminates or mitigates a hazardous condition by compensating automatically for a failure or malfunction.

3.3.114 Festival Seating. A form of audience/spectator accommodation in which no seating, other than a floor or finished ground level, is provided for the audience/spectators gathered to observe a performance. [***101,*** 2018]

3.3.115 Fines (Wood). Small pieces or splinters of wood byproducts that can pass through a 0.25 in. (6.4 mm) screen.

3.3.116 Finish.

3.3.116.1 Interior Ceiling Finish. The interior finish of ceilings. [***101,*** 2018]

3.3.116.2* Interior Finish. The exposed surfaces of walls, ceilings, and floors within buildings. [***101,*** 2018]

A.3.3.116.2 Interior Finish. Interior finish is not intended to apply to surfaces within spaces such as those that are concealed or inaccessible. Furnishings that, in some cases, might be secured in place for functional reasons should not be considered as interior finish. [***101,*** 2018]

3.3.116.3* Interior Floor Finish. The interior finish of floors, ramps, stair treads and risers, and other walking surfaces. [***101,*** 2018]

A.3.3.116.3 Interior Floor Finish. Interior floor finish includes coverings applied over a normal finished floor or stair treads and risers. [***101:***A.3.3.92.3]

3.3.116.4* Interior Wall Finish. The interior finish of columns, fixed or movable walls, and fixed or movable partitions. [***101,*** 2018]

N ***A.3.3.116.4 Interior Wall Finish.*** Such partitions are intended to include washroom water closet partitions. [***101,*** 2018]

3.3.117 Fires, Classification of.

3.3.117.1 Class A Fires. Class A fires are fires in ordinary combustible materials, such as wood, cloth, paper, rubber, and many plastics. [**10,** 2017]

3.3.117.2 Class B Fires. Class B fires are fires in flammable liquids, combustible liquids, petroleum greases, tars, oils, oil-based paints, solvents, lacquers, alcohols, and flammable gases. [**10,** 2017]

3.3.117.3 Class C Fires. Class C fires are fires that involve energized electrical equipment. [**10,** 2017]

3.3.117.4 Class D Fires. Class D fires are fires in combustible metals, such as magnesium, titanium, zirconium, sodium, lithium, and potassium. [**10,** 2017]

3.3.117.5 Class K Fires. Class K fires are fires in cooking appliances that involve combustible cooking media (vegetable or animal oils and fats). [**10,** 2017]

Some hand portable fire extinguishers are acceptable for use only on one class of fire. A water fire extinguisher is very efficient at extinguishing Class A fires but is not safe to use on Class B and Class C fires. Water spreads burning liquids and is a conductor of electricity. Some types of fire extinguishers are effective on several types of fires. An A:B:C-type dry chemical unit can extinguish ordinary combustibles and flammable liquids and is safe to use on energized electrical equipment. Class D fire extinguishers are highly specialized, and each type is designed to extinguish fires in a particular combustible metal or group of metals, as indicated on the fire extinguisher label. Class K fire extinguishers are a newer class of fire extinguishers designed to handle the fire challenges of cooking appliances that use combustible cooking media consisting of vegetable or animal oils and fats.

3.3.118 Fire, Recreational. See 3.3.226.

3.3.119 Fire Alarm System. See 3.3.267.10.

3.3.120 Fire Compartment. See 3.3.67.1.

3.3.121 Fire Department Access Road. The road or other means developed to allow access and operational setup for fire-fighting and rescue apparatus.

3.3.122 Fire Door Assembly. Any combination of a fire door, a frame, hardware, and other accessories that together provide a specific degree of fire protection to the opening. [**80,** 2016]

3.3.123 Fire Flow. The flow rate of a water supply, measured at 20 psi (137.9 kPa) residual pressure, that is available for fire fighting.

3.3.124 Fire Hazard. Any situation, process, material, or condition that, on the basis of applicable data, can cause a fire or explosion or that can provide a ready fuel supply to augment the spread or intensity of a fire or explosion, all of which pose a threat to life or property. [**914,** 2015]

3.3.125* Fire Hydrant. A valved connection on a water supply system having one or more outlets and that is used to supply hose and fire department pumpers with water. [**1141,** 2017]

A.3.3.125 Fire Hydrant. See Figure A.3.3.125(a) and Figure A.3.3.125(b). [**25,** 2017]

3.3.126* Fire Lane. A fire department access road, which is marked with approved signs or other approved notices.

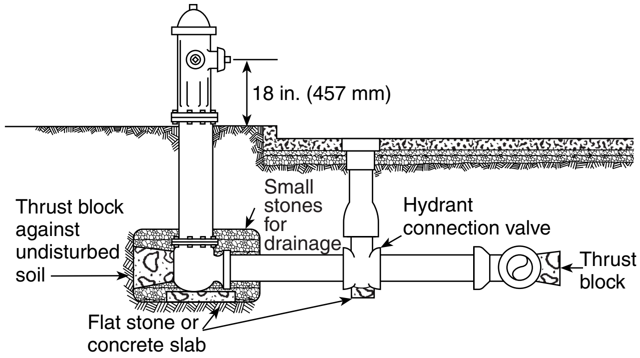


FIGURE A.3.3.125(a) *Typical Fire Hydrant Connection. [**25:**Figure A.3.3.12(a)]*

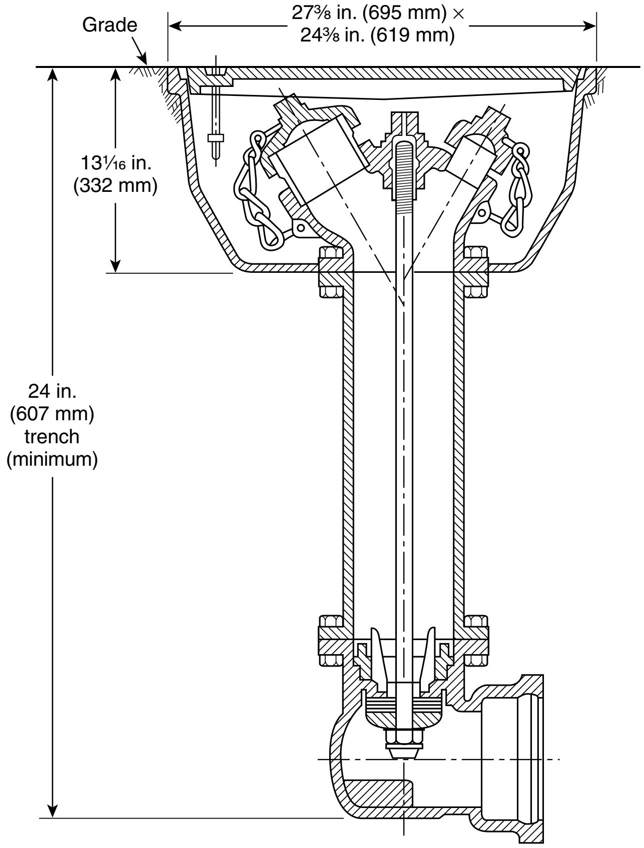

FIGURE A.3.3.125(b) *Flush-Type Hydrant. [**25:**Figure A.3.3.12(b)]*

A.3.3.126 Fire Lane. The traditional term *fire lane* is no longer utilized in this *Code*. However, a fire department access road that is marked and prohibits obstructions in accordance with 18.2.3.6 would meet the traditional intent of a fire lane.

3.3.127 Fire Point. The lowest temperature at which a liquid will ignite and achieve sustained burning when exposed to a test flame in accordance with ASTM D92, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester.* [**30,** 2018]

Fire point (or the lack of one) is used to exempt certain liquids from compliance with the NFPA 30 requirements for container storage, as stated in 9.1.4(5) of NFPA 30. See also the commentary to 4.2.4 and Supplement 2, Basic Properties and Definition of Flammable and Combustible Liquids, of the *Flammable and Combustible Liquids Code Handbook.*

3.3.128 Fire Retardant. A liquid, solid, or gas that tends to inhibit combustion when applied on, mixed in, or combined with combustible materials.

Δ **3.3.129 Fire Watch.** The assignment of a person or persons to an area for the express purpose of notifying the fire department, the building occupants, or both of an emergency; preventing a fire from occurring; extinguishing small fires; protecting the public from fire and life safety dangers.

N **3.3.130* Fireworks.** Any composition or device for the purpose of producing a visible or an audible effect for entertainment purposes by combustion, deflagration, or detonation, that meets the definition of *Consumer Fireworks* or *Display Fireworks* as set forth in NFPA 1124. [**1124,** 2017]

N **A.3.3.130 Fireworks.** Toy caps for use in toy pistols, toy canes, toy guns, and novelties and trick noisemakers are not considered to be fireworks *(see Annex C of NFPA 1124)*. The regulations referred to limit the explosive content of each toy cap to not more than an average of 0.25 gr (16.2 mg). Also, each package containing such caps has to be labeled to indicate the maximum explosive content per cap. For information on the use of model rockets and model rocket motors, see NFPA 1122. For information on the use of high power rockets and high power rocket motors, see NFPA 1127. Model rockets, model rocket motors, high power rockets, and high power rocket motors designed, sold, and used for the purpose of propelling recoverable aero models are not considered to be fireworks. [**1124,** 2017]

Δ ***3.3.130.1* Display Fireworks.*** Large fireworks devices that are explosive materials intended for use in fireworks displays and designed to produce visible or audible effects by combustion, deflagration, or detonation, as set forth in 27 CFR 555, 49 CFR 172, and APA 87-1, *Standard for the Construction and Approval for Transportation of Fireworks, Novelties, and Theatrical Pyrotechnics*. [**1124,** 2017]

N ***A.3.3.130.1 Display Fireworks.*** Display fireworks are described as Fireworks, UN0335 and are classified as Explosives, 1.3G by the U.S. Department of Transportation (U.S. DOT) *(see Annex C of NFPA 1124)*.

Display fireworks include, but are not limited to, the following:

(1) Salutes or firecrackers containing more than 2 gr (130 mg) of explosive composition (salute powder)
(2) Aerial shells containing more than 2.1 oz (60 g) of total pyrotechnic and explosive composition
(3) Other display pieces that exceed the limits for classification as consumer fireworks

Such fireworks are also described as fireworks, 49 CFR 172 by the U.S. DOT. [**1124,** 2017]

3.3.131* Flame Spread. The propagation of flame over a surface. [***101,*** 2018]

Δ ***A.3.3.131 Flame Spread.*** See Section 10.2 of NFPA *101*. [***101,*** 2018]

3.3.132 Flame Spread Index. A comparative measure, expressed as a dimensionless number, derived from visual measurements of the spread of flame versus time for a material tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Burning Materials*. [***101,*** 2018]

3.3.133 Flammable Vapors. Flammable vapors are the concentration of flammable constituents in air that exceed 25 percent of their lower flammability limit (LFL).

Δ **3.3.134* Flash Point.** The minimum temperature of a liquid at which sufficient vapor is given off to form an ignitible mixture with the air, near the surface of the liquid or within the vessel used, as determined by the appropriate test procedure and apparatus specified in Section 4.4 of NFPA 30. [**30,** 2018]

A.3.3.134 Flash Point. Flash point is a direct measure of a liquid's ability to emit flammable vapors. The lower the flash point, the greater the risk of fire. Flash point is determined using one of several different test procedures and apparatus that are specified in Section 4.4 of NFPA 30. [**30,** 2018]

A liquid that has a flash point at or below ambient temperature is easy to ignite and will burn quickly. On ignition, the spread of flame over the surface of such a liquid will be rapid, because it is not necessary for the fire to expend energy heating the liquid to generate more vapor. Gasoline is a familiar example. A liquid with a flash point above ambient temperature presents less risk because it must be heated to generate enough vapor to become ignitible; it is more difficult to ignite and presents less potential for the generation and spread of vapor. A common example is home heating oil (Fuel Oil No. 2). Home heating oil must be atomized to a fine mist in order for it to be easily ignited. [**30,** 2018]

Certain solutions of liquids in water exhibit a flash point using the standard closed-cup test procedures but will not burn and could even extinguish a fire. To assist identifying such solutions, the following standards are helpful:

(1) ASTM D4207, *Standard Test Method for Sustained Burning of Low Viscosity Liquid Mixtures by the Wick Test*
(2) ASTM D4206, *Standard Test Method for Sustained Burning of Liquid Mixtures Using the Small Scale Open-Cup Apparatus* [**30,** 2018]

Liquid mixtures that do not sustain combustion for a specified time at a specified temperature are considered to be noncombustible. The tests described in the references listed in A.3.3.134(1) and

A.3.3.134(2) provide additional data for determining proper storage and handling of such mixtures. In a confined space, such mixtures could still create an ignitible vapor–air mixture, depending on the amount of flammable liquid in the mixture and the quantity of the spill. [**30,** 2018]

Related to the flash point is the fire point. The fire point of a liquid is the temperature at which ignition of vapors will result in continued burning. As the term *flash point* suggests, the vapors generated at that temperature will flash but will not necessarily continue to burn. The difference between flash point and fire point has some significance when conducting flash point tests *[see 9.1.4(5) and 9.1.4(6) ofNFPA 30]*. However, a closed-cup flash point is used to classify the liquid and characterize its hazard. [**30,** 2018]

For more information, see ASTM E502, *Standard Test Method for Selection and Use of ASTM Standards for the Determination of Flash Point of Chemicals by Closed Cup Methods*, and the ASTM *Manual on Flash Point Standards and Their Use*. [**30,** 2018]

3.3.135 Floor Area.

3.3.135.1* Gross Floor Area. The floor area within the inside perimeter of the outside walls of the building under consideration with no deduction for hallways, stairs, closets, thickness of interior walls, columns, elevator and building services shafts, or other features, but excluding floor openings associated with atriums and communicating spaces. [**5000,** 2018]

A.3.3.135.1 Gross Floor Area. Where the term *floor area* is used, it should be understood to be gross floor area, unless otherwise specified. [**5000,** 2018]

3.3.135.2 Net Floor Area. The floor area within the inside perimeter of the outside walls, or the outside walls and fire walls of the building, or outside and/or inside walls that bound an occupancy or incidental use area requiring the occupant load to be calculated using net floor area under consideration with deductions for hallways, stairs, closets, thickness of interior walls, columns, or other features. [**5000,** 2018]

Net area does not always have to be calculated for an entire floor or fire compartment. For example, a conference room within a tenant office space is permitted to have its net floor area calculated for purposes of assigning an occupant load to it as an assembly use.

3.3.136 Forecasting. The ability to predict fire progression in a scrap tire storage location prior to the completion of the inventory fire break using heavy equipment.

3.3.137* Fugitive Emissions. Releases of flammable vapor that continuously or intermittently occur from process equipment during normal operations. [**30,** 2018]

A.3.3.137 Fugitive Emissions. These include leaks from pump seals, valve packing, flange gaskets, compressor seals, process drains, and so forth. [**30,** 2018]

3.3.138 Gallon, U.S. Standard. 1 U.S. gal = 0.833 Imperial gal = 231 in.^{3} = 3.785 L. [**58,** 2017]

3.3.139 Garage. A building or portion of a building in which one or more self-propelled vehicles carrying volatile flammable liquid for fuel or power are kept for use, sale, storage, rental, repair, exhibition, or demonstrating purposes, and all that portion of a building that is on or below the floor or floors in which such vehicles are kept and that is not separated therefrom by suitable cutoffs. [**5000,** 2018]

3.3.140 Gas.

3.3.140.1* Compressed Gas. A material, or mixture of materials, that (1) is a gas at 68°F (20°C) or less at an absolute pressure of 14.7 psi (101.3 kPa) and (2) has a boiling point of 68°F (20°C) or less at an absolute pressure of 14.7 psi (101.3 kPa) and that is liquefied, nonliquefied, or in solution, except those gases that have no other health or physical hazard properties are not considered to be compressed until the pressure in the packaging exceeds an absolute pressure of 40.6 psi (280 kPa) at 68°F (20°C). [**55,** 2016]

Δ ***A.3.3.140.1 Compressed Gas.*** The states of a compressed gas are categorized as follows:

(1) Nonliquefied compressed gases are gases, other than those in solution, that are in a packaging under the charged pressure and are entirely gaseous at a temperature of 68°F (20°C).
(2) Liquefied compressed gases are gases that, in a packaging under the charged pressure, are partially liquid at a temperature of 68°F (20°C). Cryogenic fluids represent a transient state of a gas that is created through the use of refrigeration. Cryogenic fluids cannot exist in the liquid form or partial liquid form at temperatures of 68°F (20°C); hence, they are not “compressed gases” as defined.
(3) Compressed gases in solution are nonliquefied gases that are dissolved in a solvent.
(4) Compressed gas mixtures consist of a mixture of two or more compressed gases contained in a packaging, the hazard properties of which are represented by the properties of the mixture as a whole.

[**55,** 2016]

3.3.140.1.1 Compressed Gas Mixtures. A mixture of two or more compressed gases contained in a packaging, the hazard properties of which are represented by the properties of the mixture as a whole.

3.3.140.1.2 Compressed Gases in Solution. Nonliquefied gases that are dissolved in a solvent.

3.3.140.1.3 Liquefied Compressed Gases. Gases that are contained in a packaging under the charged pressure and are partially liquid at a temperature of 68°F (20°C).

3.3.140.1.4 Nonliquefied Compressed Gases. Gases, other than those in solution, that are contained in a packaging under the charged pressure and are entirely gaseous at a temperature of 68°F (20°C).

3.3.140.2 Corrosive Gas. A gas that causes visible destruction of or irreversible alterations in living tissue by chemical action at the site of contact. [**55,** 2016]

3.3.140.3 Flammable Gas. A material that is a gas at 68°F (20°C) or less at an absolute pressure of 14.7 psi (101.3 kPa), that is ignitable at an absolute pressure of 14.7 psi (101.3 kPa) when in a mixture of 13 percent or less by volume with air, or that has a flammable range at an absolute pressure of 14.7 psi (101.3 kPa) with air of at least 12 percent, regardless of the lower limit. [**55,** 2016]

3.3.140.4 Flammable Liquefied Gas. A liquefied compressed gas that, when under a charged pressure, is partially liquid at a temperature of 68°F (20°C) and is flammable. [**55,** 2016]

3.3.140.5 Highly Toxic Gas. A chemical that has a median lethal concentration (LC_{50}) in air of 200 ppm by volume or less of gas or vapor, or 2 mg/L or less of mist, fume, or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 0.44 lb and 0.66 lb (200 g and 300 g) each. [**55,** 2016]

3.3.140.6* Inert Gas. A nonreactive, nonflammable, noncorrosive gas such as argon, helium, krypton, neon, nitrogen, and xenon. [**55,** 2016]

• ***A.3.3.140.6 Inert Gas.*** Inert gases do not react readily with other materials under normal temperatures and pressures. For example, nitrogen combines with some of the more active metals such as lithium and magnesium to form nitrides, and at high temperatures it will also combine with hydrogen, oxygen, and other elements. The gases neon, krypton, and xenon are considered rare due to their scarcity. Although these gases are commonly referred to as inert gases, the formation of compounds is possible. For example, xenon combines with fluorine to form various fluorides and with oxygen to form oxides; the compounds formed are crystalline solids. Radon is inert under the definition provided, but because it is radioactive, it is not considered inert for the purposes of NFPA 55. [**55,** 2016]

3.3.140.7 Liquefied Gas. A gas, other than in solution, that in a packaging under the charged pressure exists both as a liquid and a gas at a temperature of 68°F (20°C). [**30,** 2018]

3.3.140.8 Liquefied Natural Gas (LNG). A fluid in the cryogenic liquid state that is composed predominantly of methane and that can contain minor quantities of ethane, propane, nitrogen, and other components normally found in natural gas. [**59A,** 2016]

3.3.140.9* Liquefied Petroleum Gas (LP-Gas). Any material having a vapor pressure not exceeding that allowed for commercial propane that is composed predominantly of the following hydrocarbons, either by themselves (except propylene) or as mixtures: propane, propylene, butane (normal butane or isobutane), and butylenes. [**58,** 2017]

A.3.3.140.9 Liquefied Petroleum Gas (LP-Gas). In the pure state propylene (Chemical Abstract Service 105-07-01) has a vapor pressure of 132.8 psig (915.72 kPa) at 70°F (21.1°C). The vapor pressure of commercial propane (Chemical Abstract Service 74-98-6) at 70°F 21.1°C) is 124 psig (855 kPa). Although commercial propane may contain a minor concentration of propylene as in impurity, propylene in the pure state does not meet the definition of LP-Gas. Propylene in the pure state is commonly found in use as an industrial fuel gas. *(See NFPA 51.)* [**58,** 2017]

LP-Gas can comprise any number of different hydrocarbons, but within the scope of NFPA 58 it is limited to a material with a vapor pressure less than or equal to that of commercial propane. Based on this definition, pure butane or a predominantly butane mix would also be considered an LP-Gas. ASTM D1835, *Standard Specification for Liquefied Petroleum Gases*, defines the vapor pressure for commercial propane to be 208 psi at 100°F (1.43 MPa at 38°C). By the same standard, commercial propane must be "predominantly propane," while HD-5 grade propane must be at least 90 percent propane.

3.3.140.10 Nonflammable Gas. A gas that does not meet the definition of a flammable gas. [**55,** 2016]

3.3.140.11* Other Gas. A gas that is not a corrosive gas, flammable gas, highly toxic gas, oxidizing gas, pyrophoric gas, toxic gas, or unstable reactive gas with a hazard rating of Class 2, Class 3, or Class 4 gas. [**55,** 2016]

A.3.3.140.11 Other Gas. A gas classified as an "other gas" might be a nonflammable gas or an inert gas. [**55,** 2016]

3.3.140.12 Oxidizing Gas. A gas that can support and accelerate combustion of other materials more than air does. [**55:** 2016]

3.3.140.13 Pyrophoric Gas. A gas with an autoignition temperature in air at or below 130°F (54.4°C). [**55,** 2016]

3.3.140.14 Scavenged Gas. A residual process gas that is collected for treatment or release at a location remote from the site of use.

3.3.140.15 Simple Asphyxiant Gas. A gas that does not provide sufficient oxygen to support life and that has none of the other physical or health hazards.

3.3.140.16 Toxic Gas. A gas with a median lethal concentration (LC_{50}) in air of more than 200 ppm but not more than 2000 ppm by volume of gas or vapor, or more than 2 mg/L but not more than 20 mg/L of mist, fume, or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 0.44 lb and 0.66 lb (200 g and 300 g) each. [**55,** 2016]

3.3.140.17* Unstable Reactive Gas. A gas that, in the pure state or as commercially produced, will vigorously polymerize, decompose, or condense; become self-reactive; or otherwise undergo a violent chemical change under conditions of shock, pressure, or temperature. [**55,** 2016]

A.3.3.140.17 Unstable Reactive Gas. Unstable reactive materials are subdivided into five classifications. Class 4 materials are materials that in themselves are readily capable of detonation or explosive decomposition or explosive reaction at normal temperatures and pressures. They include the following:

(1) Materials that are sensitive to localized thermal or mechanical shock at normal temperatures and pressures
(2) Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) of 1000 W/mL or greater

[**55,** 2016]

Class 3 materials are materials that in themselves are capable of detonation or explosive decomposition or explosive reaction but require a strong initiating source or heat under confinement before initiation. Class 3 materials include the following:

(1) Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) at or above 100 W/mL and below 1000 W/mL
(2) Materials that are sensitive to thermal or mechanical shock at elevated temperatures and pressures
(3) Materials that react explosively with water without requiring heat or confinement

[**55,** 2016]

Class 2 materials are materials that readily undergo violent chemical change at elevated temperatures and pressures, including the following:

(1) Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) at or above 10 W/mL and below 100 W/mL
(2) Materials that react violently with water or form potentially explosive mixtures with water

[**55,** 2016]

Class 1 materials are materials that in themselves are normally stable but that can become unstable at elevated temperatures and pressures, including the following:

(1) Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) at or above 0.01 W/mL and below 10 W/mL
(2) Materials that react vigorously with water, but not violently
(3) Materials that change or decompose on exposure to air, light, or moisture

[**55,** 2016]

Class 0 materials are materials that in themselves are normally stable, even under fire conditions, including the following:

(1) Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) below 0.01 W/mL
(2) Materials that do not react with water
(3) Materials that do not exhibit an exotherm at temperatures less than or equal to 932°F (500°C) when tested by differential scanning calorimetry

[**55,** 2016]

3.3.141* Gas Cabinet. A fully enclosed, noncombustible enclosure used to provide an isolated environment for compressed gas cylinders in storage or use. [**55,** 2016]

> ***A.3.3.141 Gas Cabinet.*** Doors and access ports for exchanging cylinders and accessing pressure-regulating controls are permitted to be included as part of a gas cabinet. [**55,** 2016]

3.3.142 Gas Manufacturer/Producer. A business that produces compressed gases or cryogenic fluids, or both, or fills portable or stationary gas cylinders, containers, or tanks. [**55:** 2016]

3.3.143 Gas Room. A separately ventilated, fully enclosed room in which only compressed gases, cryogenic fluids, associated equipment, and supplies are stored or used. [**55,** 2016]

3.3.144 Gaseous Hydrogen (GH_2) System. An assembly of equipment that consists of, but is not limited to, storage containers, pressure regulators, pressure relief devices, compressors, manifolds, and piping and that terminates at the source valve. [**55,** 2016]

A.3.3.144 Gaseous Hydrogen (GH_2) System. The system includes stationary or portable containers, pressure regulators, pressure-relief devices, manifolds, interconnecting piping, and controls as required. [**55,** 2016]

3.3.145 Ground Kettle. A container that could be mounted on wheels and is used for heating tar, asphalt, or similar substances.

3.3.146 Handling. The deliberate movement of material by any means to a point of storage or use.

3.3.147* Hazard of Contents.

A.3.3.147 Hazard of Contents. Hazardous materials are materials that present physical or health hazards and are regulated by the *Code*. The categories of materials classified as physical hazards, health hazards, or both have been established in concert with those categories identified by OSHA in 29 CFR that are used by preparers of Material Safety Data Sheets (MSDS). In some cases, the hazard categories are further subdivided into classes that have long been established by NFPA standards. For example, while OSHA recognizes flammable liquids as a broad class, including those that are combustible, such liquids are further categorized by building and fire codes with respect to degree of hazard under the system of classification used by NFPA to include Class I, Class II, and Class III liquids. They are further subdivided within these classes to Class IA, Class IB and so forth. A similar approach is used for materials in other categories where there are subcategories of hazard established by existing NFPA standards, including oxidizers, unstable reactives, organic peroxides, water reactives, and others. [**5000,** 2018]

Under the classification system used by OSHA, a hazardous material can have one or more physical or health hazards in categories not currently regulated by the *Code*; for example, irritants, sensitizers, radioactive materials, etiological agents, and others. This is not to say that these materials are not hazardous materials, but rather that the *Code* does not provide specific regulation for the hazard category represented. [**5000,** 2018]

The *Code* defines contents as either high hazard, low hazard, or ordinary hazard. The category of high hazard, which includes hazardous materials, is subdivided into groups in which the hazards of the groups are comparable, that is, high hazard Level 1-5. *(See also A.34.1.1 of NFPA 5000.)* [**5000,** 2018]

3.3.147.1 High Hazard. High hazard contents shall include materials defined as hazardous materials in 3.3.180.4, whether stored, used, or handled. [**5000:**6.3.2.4.1.1]

3.3.147.1.1 High Hazard Level 1 Contents. High hazard Level 1 contents shall include materials that present a detonation hazard including, but not limited to, the following: (1) Explosives; (2) Unclassified detonable organic peroxides; (3) Class 4 oxidizers; (4) Detonable pyrophoric materials; (5) Class 3 detonable and Class 4 unstable (reactive) materials. [**5000:**6.3.2.4.2]

3.3.147.1.2 High Hazard Level 2 Contents. High hazard Level 2 contents shall include materials that present a deflagration hazard or a hazard from accelerated burning including, but not limited to, the following: (1) Class I, Class II, or Class III-A flammable or combustible liquids that are used or stored in normally open containers or systems, or in closed containers or systems at gauge pressures of more than 15 psi (103 kPa); (2) Combustible dusts stored, used, or generated in a manner creating a severe fire or explosion hazard; (3) Flammable gases and flammable cryogenic liquids; (4) Class I organic peroxides; (5) Class 3 solid or liquid oxidizers that are used or stored in normally open containers or systems, or in closed containers or systems at gauge pressures of more than 15 psi (103 kPa); (6) Nondetonable pyrophoric materials; (7) Class 3 nondetonable unstable (reactive) materials; (8) Class 3 water-reactive materials [**5000:**6.3.2.4.3]

This definition of the term *high hazard Level 2 contents* is extracted from *NFPA 5000*. While the assumption that a Class II or Class IIIA liquid can present a deflagration or flash fire hazard if it escapes from a closed system under pressure is reasonable, it is highly doubtful that the same liquids, when used in an open system and without being heated up to or above the flash point, would present a deflagration hazard or flash fire hazard. Nevertheless, for correlation with *NFPA 5000* and NFPA 1, this definition retains the criteria established by *NFPA 5000*.

3.3.147.1.3 High Hazard Level 3 Contents. High hazard Level 3 contents shall include materials that readily support combustion or present a physical hazard including, but not limited to, the following: (1) Level 2 and Level 3 aerosols; (2) Class I, Class II, or Class III-A flammable or combustible liquids that are used or stored in normally closed containers or systems at gauge pressures of less than 15 psi (103 kPa); (3) Flammable solids, other than dusts classified as high hazard Level 2, stored, used, or generated in a manner creating a high fire hazard; (4) Class II and Class III organic peroxides; (5) Class 2 solid or liquid oxidizers; (6) Class 3 solid or liquid oxidizers that are used or stored in normally closed containers or systems at gauge pressures of less than 15 psi (103 kPa); (7) Oxidizing gases and oxidizing cryogenic liquids; (8) Class 2 unstable (reactive) materials; (9) Class 2 water-reactive materials [**5000:**6.3.2.4.4]

3.3.147.1.4 High Hazard Level 4 Contents. High hazard Level 4 contents shall include materials that are acute health hazards including, but not limited to, the following: (1) Corrosives; (2) Highly toxic materials; (3) Toxic materials [**5000:**6.3.2.4.5]

3.3.147.1.5 High Hazard Level 5 Contents. High hazard Level 5 contents include hazardous production materials (HPM) used in the fabrication of semiconductors or semiconductor research and development. [**5000:**6.3.2.4.6]

3.3.147.2* Low Hazard Contents. Low hazard contents shall be classified as those of such low combustibility that no self-propagating fire therein can occur. [**5000:**6.3.2.2]

Δ ***A.3.3.147.2 Low Hazard Contents.*** Chapter 42 of NFPA *101* recognizes storage of noncombustible materials as low hazard. In other occupancies, it is assumed that, even where the actual contents hazard is normally low, there is sufficient likelihood that some combustible materials or hazardous operations will be introduced in connection with building repair or maintenance, or some psychological factor might create conditions conducive to panic, so that the egress facilities cannot safely be reduced below those specified for ordinary hazard contents. [***101,*** 2018]

Very few occupancies qualify as having low hazard contents. An example of low hazard contents might be metal parts stored in metal containers on metal pallets (not wood pallets) supported by metal shelving. If the same metal parts stored in metal containers were placed on wood pallets, the pallets would be capable of sustaining a self-propagating fire. Therefore, the hazard of contents classification would be ordinary hazard.

3.3.147.3* Ordinary Hazard Contents. Ordinary hazard contents shall be classified as those that are likely to burn with moderate rapidity or to give off a considerable volume of smoke. [**5000:**6.3.2.3]

A.3.3.147.3 Ordinary Hazard Contents. Ordinary hazard classification represents the conditions found in most buildings and is the basis for the general requirements of NFPA *101*. [***101,*** 2018]

The fear of poisonous fumes or explosions is necessarily a relative matter to be determined on a judgment basis. All smoke contains some toxic fire gases but, under conditions of ordinary hazard, there should be no unduly dangerous exposure during the period necessary to escape from the fire area, assuming there are proper exits. [***101,*** 2018]

Occupancies containing low hazard or high hazard contents are relatively rare. In deciding which hazard classification applies, users should ask the following questions: Do the contents qualify as a low hazard classification? Do the contents qualify as a high hazard classification? If the answer to each of these questions is no, then the hazard of contents classification must be ordinary hazard.

3.3.148* Hazard Rating. The numerical rating of the health, flammability, self-reactivity, and other hazards of the material, including its reaction with water. [**55,** 2016]

A.3.3.148 Hazard Rating. The criteria for hazard rating are as defined in NFPA 704. [**55,** 2016]

3.3.149 Hazardous Material. See 3.3.180.4.

3.3.150 Hazardous Material Storage Facility. A building, a portion of a building, or exterior area used for the storage of hazardous materials in excess of exempt amounts.

3.3.151 Hazardous Materials Storage Locker. A movable prefabricated structure, manufactured primarily at a site other than the final location of the structure and transported completely assembled or in a ready-to-assemble package to the final location, and intended to meet local, state, and federal requirements for outside storage of hazardous materials. [**30,** 2018]

Although the structures defined in 3.3.151 are referred to as lockers, most are large enough for a person to enter, and even the smallest locker can accommodate several standard-sized shipping drums. These lockers can be considered highly sophisticated storage sheds, incorporating a spill-retention basin, explosion proof electrical equipment, fire suppression or fire alarm systems, and other features. Despite the presumed all-encompassing term *hazardous materials,* the requirements set forth in Chapter 14 of NFPA 30 apply only to liquids and assume that only liquids are present. Exhibit 3.17 shows two examples of these lockers.

3.3.152* Hazardous Reaction or Hazardous Chemical Reaction. Reactions that result in dangers beyond the fire problems relating to flash point and boiling point of either the reactants or of the products. [**30,** 2018]

Exhibit 3.17

Examples of hazardous materials storage lockers. (Courtesy of DENIOS, Inc.)

A.3.3.152 Hazardous Reaction or Hazardous Chemical Reaction. These dangers might include, but are not limited to, toxic effects, reaction speed (including detonation), exothermic reaction, or production of unstable or reactive materials. [**30,** 2018]

3.3.153 Heat Transfer Fluid (HTF). A liquid that is used as a medium to transfer heat energy from a heater or vaporizer to a remote heat consumer (e.g., injection molding machine, oven, or dryer, or jacketed chemical reactor). [**30,** 2018]

3.3.154* Heliport. An identifiable area located on land, on water, or on a structure, that also includes any existing buildings or facilities thereon, used or intended to be used for landing and takeoff of helicopters. [**418,** 2016]

A.3.3.154 Heliport. The term *heliport* applies to all sites used or intended to be used for the landing and takeoff of helicopters. [**418,** 2016]

3.3.155 Hogged Material. Mill waste consisting mainly of hogged bark but possibly including a mixture of bark, chips, dust, or other by-products from trees; also includes material designated as hogged fuel.

3.3.156 Home.

3.3.156.1 Day-Care Home. See 3.3.192.6.

3.3.156.2 Nursing Home. See 3.3.192.24.

3.3.157 Horizontal Exit. See 3.3.105.1.

3.3.158* Immediately Dangerous to Life and Health (IDLH). A concentration of airborne contaminants, normally expressed in parts per million (ppm) or milligrams per cubic meter, that represents the maximum level from which one could escape within 30 minutes without any escape-impairing symptoms or irreversible health effects. [**55,** 2016]

A.3.3.158 Immediately Dangerous to Life and Health (IDLH). This level is established by the National Institute for Occupational Safety and Health (NIOSH). If adequate data do not exist for precise establishment of IDLH, an independent certified industrial hygienist, industrial toxicologist, or appropriate regulatory agency should make such determination. [**55,** 2016]

3.3.159 Imminent Danger. A condition or practice in an occupancy or structure that poses a danger that could reasonably be expected to cause death, serious physical harm, or serious property loss.

The determination of what does or does not pose an imminent danger can be challenging for the AHJ. Existing buildings typically cannot meet the requirements for new buildings, and the threat to safety can come from the building itself, the contents, or the occupants. Each situation must be evaluated based on its individual characteristics. Certain conditions, such as inadequate means of egress arrangements, could result in deaths or serious injuries if a fire occurs. If the AHJ is not satisfied that a reasonable degree of safety exists for the occupants, the building or portions of the building should not be allowed to be occupied.

3.3.160* Incident Commander (IC). The individual responsible for all incident activities, including the development of strategies and tactics and the ordering and the release of resources. [**472,** 2018]

A.3.3.160 Incident Commander (IC). This position is equivalent to the on-scene incident commander as defined in OSHA 1910.120(8), Hazardous Waste Operations and Emergency Response. The IC has overall authority and responsibility for conducting incident operations and is responsible for the management of all incident operations at the incident site. [**472,** 2018]

3.3.161 Incidental Liquid Use or Storage. Use or storage as a subordinate activity to that which establishes the occupancy or area classification. [**30,** 2018]

The determination of whether a specific use is incidental is usually apparent — for example, the use of flammable cleaning agents to remove grease from metal parts in a machine shop. In other cases, such as a coating operation that uses large quantities of flammable liquid, incidental use might not be so apparent. The final determination is to be made by the AHJ.

3.3.162 Indicating Valve. See 3.3.282.1.

3.3.163 Initiating Device Circuit. A circuit to which automatic or manual initiating devices are connected where the signal received does not identify the individual device operated. [**72,** 2016]

Conventional (nonaddressable/nonanalog) initiating devices are typically detectors that use a switch contact or a solid-state switch to short both sides of the initiating device circuit together. By doing so, the initiating device causes a step-function increase in current flowing through the circuit. The fire alarm control unit (FACU) interprets the increase in current as an "alarm" signal from one of the initiating devices. Since any one of the initiating devices can cause the incremental current flow, and no other initiating devices downstream of the activated device can subsequently activate because both sides of the circuit have been shorted by the first responding device, only one signal can be obtained. Sometimes initiating device circuits are called *zones*, and the activated device puts the entire zone into the alarm state.

3.3.164 Inside Liquid Storage Area. See 3.3.14.6.

3.3.165* ISO Module. An assembly of tanks or tubular cylinders permanently mounted in a frame conforming to International Organization for Standardization (ISO) requirements. [**55,** 2016]

Δ **A.3.3.165 ISO Module.** The characteristic internal water volume of individual tubular cylinders is 43 scf (1218 L) or a water capacity of 2686 lb (1218 kg). The frame of an ISO container module and its corner castings are specially designed and dimensioned to be used in multimodal transportation service on container ships, special highway chassis, and container-on-flatcar railroad equipment. [**55,** 2016]

3.3.166 Jurisdiction. A governmental unit or political division or a subdivision.

3.3.167 Limit.

3.3.167.1* Ceiling Limit. The maximum concentration of an airborne contaminant to which one can be exposed. [**5000,** 2018]

A.3.3.167.1 Ceiling Limit. The ceiling limits utilized are to be those published in 29 CFR 1910.1000. [**5000,** 2018]

3.3.167.2* Permissible Exposure Limit (PEL). The maximum permitted 8-hour, time-weighted average concentration of an airborne contaminant. [**55,** 2016]

A.3.3.167.2 Permissible Exposure Limit (PEL). The maximum permitted time-weighted average exposures to be utilized are those published in 29 CFR 1910.1000. [**55,** 2016]

3.3.167.3* Short-Term Exposure Limit (STEL). The concentration to which it is believed that workers can be exposed continuously for a short period of time without suffering from irritation, chronic or irreversible tissue damage, or narcosis of a degree sufficient to increase the likelihood of accidental injury, impairment of self-rescue, or the material reduction of work efficiency, without exceeding the daily permissible exposure limit (PEL). [**55,** 2016]

A.3.3.167.3 Short-Term Exposure Limit (STEL). STEL limits are published in 29 CFR 1910.1000. [**55,** 2016]

3.3.168 Limited-Combustible (Material). *See 4.5.10*. [**5000,** 2018]

3.3.169 Liquid. A material that has a melting point that is equal to or less than 68°F (20°C) and a boiling point that is greater than 68°F (20°C) and 14.7 psia (101.3 kPa). When not otherwise identified, the term liquid shall mean both flammable and combustible liquids. [**5000,** 2018]

Δ ***3.3.169.1 Combustible Liquid.*** Any liquid that has a closed-cup flash point at or above 100°F (37.8°C), as determined by the test procedures and apparatus set forth in Section 4.4 of NFPA 30. Combustible liquids are classified according to Section 4.3 of NFPA 30. [**30,** 2018]

3.3.169.2* Flammable Liquid. Any liquid that has a closed-cup flash point below 100°F (37.8°C), as determined by the test procedures and apparatus set forth in Section 4.4 of NFPA 30 and a Reid vapor pressure that does not exceed an absolute pressure of 40 psi (276 kPa) at 100°F (37.8°C), as determined by ASTM D323, *Standard Test Method for Vapor Pressure of Petroleum Products (Reid Method).* Flammable liquids are classified according to Section 4.3 of NFPA 30. [**30,** 2018]

Δ ***A.3.3.169.2 Flammable Liquid.*** For the purposes of this *Code*, a material with a Reid vapor pressure greater than an absolute pressure of 40 psi (276 kPa) is considered to be a gas and is, therefore, not within the scope of NFPA 30. See NFPA 58. [**30,** 2018]

A vapor pressure of 40 psi absolute (absolute pressure of 276 kPa) is the accepted dividing line between flammable liquids and flammable gases. For transportation safety regulations, DOT refers to liquefied petroleum gases, liquefied natural gas, and liquefied ammonia as "highly volatile liquids."

The 73°F (22.8°C) dividing line between Classes IA and IB and Class IC is based on an old U.S. Interstate Commerce Commission regulation that required a red label with the word *flammable* on all liquids having flash points below 80°F (26.6°C), using an open-cup flash point procedure, that were shipped in interstate commerce. At the time, an 80°F (26.6°C) open-cup flash point was generally agreed to be about equivalent to a 73°F (22.8°C) closed-cup flash point, and therein lies the basis for using the 73°F (22.8°C) breakpoint. The U.S. Consumer Product Safety Commission uses an 80°F (26.6°C) open-cup criterion in their regulations for flammable consumer commodities.

The boiling point criterion that distinguishes Class IA from Class IB was adopted to identify liquids with unusually low boiling points and consequently very high vapor pressures that can approach the dividing line between liquids and gases (40 psi absolute). Class IA liquids typically require storage in containers other than atmospheric storage tanks. Therefore, NFPA 30 and this *Code* specify stricter requirements for Class IA liquids. Only a relative handful of commercially significant Class IA liquids are available. At normal ambient temperatures, both Class IA and Class IB liquids generate sufficient vapor to create concentrations that are within the flammable range at all times. The differentiation between Class IA and Class IB becomes important in selecting the type of storage tank and in placing limits on quantities stored in buildings.

3.3.169.3 Highly Volatile Liquid. A liquid with a boiling point of less than 68°F (20°C).

3.3.169.4 Stable Liquid. Any liquid not defined as unstable. [**30,** 2018]

3.3.170 Log. Felled tree from which all the branches have been removed.

3.3.171 Loose House. A separate detached building in which unbaled combustible fibers are stored.

3.3.172 Lumber. Wood from felled trees having a section produced by lengthwise sawing or chipping of logs or other solid wood of large dimensions and possible crosscutting and/or further machining to obtain a certain size and includes boards, dimension lumber, timber, and similar wood products.

3.3.173 Manual Emergency Shutoff Valve. A designated valve designed to shut off the flow of gases or liquids that is manually operated. [**55,** 2016]

3.3.174 Manual Fire Alarm Box. A manually operated device used to initiate a fire alarm signal. [**72,** 2016]

Operation of the manual fire alarm box requires one action. One design of a double-action fire alarm box requires the operator to strike a front-mounted hammer to break the glass and expose the recessed pull lever. Another fire alarm box might not use a hammer and glass but might have a push bar. The pull lever then operates as a single action fire alarm box.

Whether one or two actions are involved, it is also permissible to have a listed protective cover, shown in Exhibit 3.18,

Exhibit 3.18

Protective Cover for Double-Action Manual Fire Alarm Box. (Source: Safety Technology International, Inc., Waterford MI)

over the manual fire alarm box. This cover must be lifted to gain access to the double action box, which effectively creates a permitted third action for the user. In some institutional occupancies, the use of key-operated manual fire alarm boxes is permitted by local ordinances, building codes, and NFPA *101*®, *Life Safety Code*®.

3.3.175 Manual Pull Station. See 3.3.174, Manual Fire Alarm Box.

Δ **3.3.176 Marijuana Extraction Equipment.** Equipment or appliances used for the extraction of botanical material, such as essential oils, from marijuana.

Δ **3.3.177 Marijuana Extraction Facility.** A building used for the solvent-based extraction process of marijuana.

3.3.178 Marine Terminal. A facility comprised of one or more berths, piers, wharves, loading and unloading areas, warehouses, and storage yards and used for transfer of people and/or cargo between waterborne and land transportation modes. [**307,** 2016]

3.3.179 Marine Vessel. A water craft or other artificial contrivance used as a means of transportation in or on the water.

3.3.180 Material.

3.3.180.1 Combustible (Material). See 3.3.57.

3.3.180.2 Compatible Material. A material that, when in contact with an oxidizer, will not react with the oxidizer or promote or initiate its decomposition.

3.3.180.3 Corrosive Material. A chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the site of contact. [**400,** 2016]

3.3.180.4 Hazardous Material. A chemical or substance that is classified as a physical hazard material or a health hazard material, whether the chemical or substance is in usable or waste condition. *(See also 3.3.180.6, Health Hazard Material, and 3.3.180.12, Physical Hazard Material.)* [**400,** 2016]

3.3.180.5 Hazardous Production Material (HPM). A solid, liquid, or gas associated with semiconductor manufacturing that has a degree-of-hazard rating of 3 or 4 in health, flammability, instability, or water reactivity in accordance with NFPA 704 and that is used directly in research, laboratory, or production processes that have as their end product materials that are not hazardous. [**5000,** 2018]

3.3.180.6 Health Hazard Material. A chemical or substance classified as a toxic, highly toxic, or corrosive material in accordance with definitions set forth in this *Code*. [**400,** 2016]

3.3.180.7* Highly Toxic Material. A material that produces a lethal dose or lethal concentration that falls within any of following categories: (1) a chemical that has a median lethal dose (LD_{50}) of 50 mg/kg or less of body weight when administered orally to albino rats weighing between 200 g and 300 g each; (2) a chemical that has a median lethal dose (LD_{50}) of 200 mg/kg or less of body weight when administered by continuous contact for 24 hours, or less if death occurs within 24 hours, with the bare skin of albino rabbits weighing between 2 kg and 3 kg each or albino rats weighing 200 g to 300 g each; (3) a chemical that has a median lethal concentration (LC_{50}) in air of 200 parts per million by volume or less of gas or vapor, or 2 mg/L or less of mist, fume, or dust, when administered by continuous inhalation for 1 hour, or less if death occurs within 1 hour, to albino rats weighing between 200 g and 300 g each. [**400,** 2016]

A.3.3.180.7 Highly Toxic Material. While categorization is basically simple in application, the degree of hazard depends on many variables that should be carefully considered individually and in combination. Some examples include the following:

(1) Materials wherein the highly toxic component or mixtures thereof are inextricably bound and cannot be released so there is little or no potential for exposure
(2) Nonfriable solid hazardous materials existing in product forms and in the demonstrated absence of inhalable particles that might not present the same inhalation hazard as the chemical components existing in a friable state
(3) Mixtures of highly toxic materials with ordinary materials, such as water, that might not warrant classification as highly toxic

[**400,** 2016]

Any hazard evaluation that is required for the precise categorization of highly toxic material is required to be performed by experienced, technically competent persons. [**400,** 2016]

3.3.180.8 Hogged Material. See 3.3.155.

3.3.180.9* Incompatible Material. Materials that, when in contact with each other, have the potential to react in a manner that generates heat, fumes, gases or by-products that are hazardous to life or property. [**400,** 2016]

Δ *A.3.3.180.9 Incompatible Material.* Information on incompatible materials can be found in safety data sheets (SDS) or manufacturers' product bulletins. [**400,** 2016]

3.3.180.10 Limited-Combustible Material. See 4.5.10. [**5000,** 2018]

3.3.180.11 Noncombustible Material. See 4.5.9. [**5000,** 2018]

3.3.180.12 Physical Hazard Material. A chemical or substance classified as a combustible liquid, explosive, flammable cryogen, flammable gas, flammable liquid, flammable solid, organic peroxide, oxidizer, oxidizing cryogen, pyrophoric, unstable (reactive), or water-reactive material. [**400,** 2016]

3.3.180.13 Pyrophoric Material. A chemical with an autoignition temperature in air at or below 130°F (54.4°C). [**400,** 2016]

3.3.180.14 Toxic Material.* A material that produces a lethal dose or a lethal concentration within any of the following categories: (1) a chemical or substance that has a median lethal dose (LD_{50}) of more than 50 mg/kg but not more than 500 mg/kg of body weight when administered orally to albino rats weighing between 200 g and 300 g each; (2) a chemical or substance that has a median lethal dose (LD_{50}) of more than 200 mg/kg but not more than 1000 mg/kg of body weight when administered by continuous contact for 24 hours, or less if death occurs within 24 hours, with the bare skin of albino rabbits weighing between 2 kg and 3 kg each; (3) a chemical or substance that has a median lethal concentration (LC_{50}) in air of more than 200 parts per million but not more than 2000 parts per million by volume of gas or vapor, or more than 2 mg/L but not more than 20 mg/L, of mist, fume, or dust when administered by continuous inhalation for 1 hour, or less if death occurs within 1 hour, to albino rats weighing between 200 g and 300 g each. [**400,** 2016]

A.3.3.180.14 Toxic Material. While categorization is basically simple in application, the degree of hazard depends on many variables that should be carefully considered individually and in combination. Some examples include the following:

(1) Materials wherein the toxic component or mixtures thereof are inextricably bound and cannot be released so there is little or no potential for exposure
(2) Nonfriable solid hazardous materials existing in product forms and in the demonstrated absence of inhalable particles that might not present the same inhalation hazard as the chemical components existing in a friable state
(3) Mixtures of toxic materials with ordinary materials, such as water, that might not warrant classification as toxic

Any hazard evaluation that is required for the precise categorization of toxic material is required to be performed by experienced, technically competent persons.
[**400,** 2016]

3.3.180.15 Unstable (Reactive) Material.* A material that, in the pure state or as commercially produced, will vigorously polymerize, decompose or condense, become self-reactive, or otherwise undergo a violent chemical change under conditions of shock, pressure, or temperature. [**400,** 2016]

A.3.3.180.15 Unstable (Reactive) Material. Unstable (reactive) material is classified as follows:

(1) Class 4 unstable (reactive) materials are those that, in themselves, are readily capable of detonation, explosive decomposition, or explosive reaction at normal temperatures and pressures and include, among others, materials that are sensitive to localized thermal or mechanical shock at normal temperatures and pressures.
(2) Class 3 unstable (reactive) materials are those that, in themselves, are capable of detonation, explosive decomposition, or explosive reaction, but that require a strong initiating source or that must be heated under confinement before initiation, and include, among others, materials that are sensitive to thermal or mechanical shock at elevated temperatures and pressures.
(3) Class 2 unstable (reactive) materials are those that readily undergo violent chemical change at elevated temperatures and pressures and include, among others, materials that exhibit an exotherm at temperatures less than or equal to 30°F (−1°C) when tested by differential scanning calorimetry.
(4) Class 1 unstable (reactive) materials are those that, in themselves, are normally stable, but that can become unstable at elevated temperatures and pressures and include among others, materials that change or decompose on exposure to air, light, or moisture and that exhibit an exotherm at temperatures greater than 30°F (−1°C), but less than or equal to 57°F (14°C), when tested by differential scanning calorimetry.

[**400,** 2016]

3.3.180.16 Water-Reactive Material.* A material that explodes, violently reacts, produces flammable, toxic, or other hazardous gases; or evolves enough heat to cause self-ignition or ignition of nearby combustibles upon exposure to water or moisture. [**400,** 2016]

A.3.3.180.16 Water-Reactive Material.

Class 1 Water-Reactive Materials. Materials whose heat of mixing is at or above 30 cal/g and less than 100 cal/g.

Class 2 Water-Reactive Materials. Materials whose heat of mixing is at or above 100 cal/g and less than 600 cal/g.

Class 3 Water-Reactive Materials. Materials whose heat of mixing is greater or equal to 600 cal/g.
[**704:** Table F.2]

• *3.3.181* Maximum Allowable Quantity (MAQ).* The quantity of hazardous material permitted in a control area.

A.3.3.181 Maximum Allowable Quantity (MAQ). Quantities are permitted to exceed the MAQ when they are located in an area complying with Protection Levels 1–5 in accordance with the building code.

3.3.182* Means of Egress. A continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge. [***101,*** 2018]

Δ **A.3.3.182 Means of Egress.** A means of egress comprises the vertical and horizontal travel and includes intervening room spaces, doorways, hallways, corridors, passageways, balconies, ramps, stairs, elevators, enclosures, lobbies, escalators, horizontal exits, courts, and yards. [***101,*** 2018]

A means of egress, by definition, provides a path of egress travel to a public way. In effect, the *Code* emphasizes the need to move building occupants to a safe place. In means of egress arrangements for university campuses, military bases, resorts, and other large complexes are many areas a building occupant could get to before reaching a public way that supplies the intended level of safety from a building fire. The *Code*'s intent is that occupants should be able to move to a safe place from which they can continue to retreat from a burning building, as necessary. At that safe point, *Code* requirements cease to apply. This concept provides the basis for A.14.12.1.1, which applies to illumination of means of egress. This annex text states that the extent to which illumination needs to be provided outside the building — that is, in the exit discharge portions of the means of egress — should lead to either a public way or a distance away from the building that is considered safe, whichever is closer to the building being evacuated.

From every location in a building, a means of egress or path of travel is required over which a person can move to gain access to the outside or to a place of safety. People who enter a building usually have available to them that same route from which they can leave. However, one important consideration makes egressing more than just reversing one's route of entry, especially if emergency conditions exist. This reverse route might consist of features that were not obstacles on entrance but prove to be such at egress. For example, a door leaf hinged to swing in the direction of entry can become an obstacle when multiple occupants attempt to leave the building simultaneously in the opposite direction. The door leaf swings against the flow of traffic — a flow that, during emergency egress, is greatly increased, compared with the leisurely flow of people entering a building. As another example, in assembly occupancies where turnstiles are used to meter ingress, reversing one's route often is not possible if additional openings independent of the turnstiles are not provided.

A basic principle of the *Code* requires that every component of a means of egress be operable by, and under the control of, the occupants attempting egress. Where the *Code* makes exemptions to this concept — for example, in health care occupancies where locked door assemblies are permitted if it is necessary for special protective measures or the clinical needs of the patients — it does so by substituting requirements adequate to achieve the same level of life safety that would exist if the means of egress system were fully under the control of the building occupants. For example, in the case of health care occupancy door assemblies that are locked for the clinical needs of the patients, staff is required to carry the keys needed to unlock those door assemblies at all times.

3.3.183 Means of Escape. A way out of a building or structure that does not conform to the strict definition of means of egress but does provide an alternate way out. [***101,*** 2018]

3.3.184 Mezzanine. An intermediate level between the floor and the ceiling of any room or space. [***101,*** 2018]

N **3.3.185 Miscella.** A mixture, in any proportion, of the extracted oil or fat and the extracting solvent.

3.3.186* Mobile Supply Unit. Any supply source that is equipped with wheels so it is able to be moved around. [**55,** 2016]

A.3.3.186 Mobile Supply Unit. Examples include ISO modules, tube trailers, and cylinder packs. [**55,** 2016]

N **3.3.187* Mobile or Temporary Cooking.** Any cooking apparatus or equipment operated on a one-time basis, interim basis, or for less than 90 days in the same location, other than at a fixed location, building, or structure that has been inspected and permitted under another section of this *Code*, regulation, or statute.

N **A.3.3.187 Mobile or Temporary Cooking.** Mobile or temporary cooking can include self-propelled trucks and vehicles; trailered units; push carts; equipment located under cover of awnings, canopies, or pop-up tents; or other structures for which a building permit has not been issued.

3.3.188 Motor Vehicle Fluid. A fluid that is a flammable, combustible, or hazardous material, such as crankcase fluids, fuel, brake fluids, transmission fluids, radiator fluids, and gear oil.

3.3.189 Nesting. A method of securing cylinders upright in a tight mass using a contiguous three-point contact system whereby all cylinders in a group have a minimum of three contact points with other cylinders or a solid support structure (e.g., a wall or railing). [**55,** 2016]

3.3.190* Normal Temperature and Pressure (NTP). A temperature of 70°F (21°C) at an absolute pressure of 14.7 psi (101.3 kPa). [**55,** 2016]

A.3.3.190 Normal Temperature and Pressure (NTP). There are different definitions of normal conditions. The normal conditions defined here are the ones most commonly used in the compressed gas and cryogenic fluid industry. [**55,** 2016]

N **3.3.191 Observation.** For the purposes of marijuana extraction equipment field verification, a practice or condition not technically noncompliant with other regulations or requirements, but could lead to noncompliance if left unaddressed.

3.3.192 Occupancy. The purpose for which a building or other structure, or part thereof, is used or intended to be used. [**ASCE/SEI 7:**1.2]

3.3.192.1* Ambulatory Health Care Occupancy. An occupancy used to provide services or treatment simultaneously to four or more patients that provides, on an outpatient basis, one or more of the following: (1) treatment for patients that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others; (2) anesthesia that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others; (3) treatment for patients who, due to the nature of their injury or illness, are incapable of taking action for self-preservation under emergency conditions without the assistance of others [***101,*** 2018]

Δ *A.3.3.192.1 **Ambulatory Health Care Occupancy.*** It is not the intent that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches. Rather it is the intent to address treatment centers that receive patients who have been rendered incapable of self-preservation, such as being rendered unconscious as a result of an accident or being unable to move due to sudden illness. [***101,*** 2018]

It is not the intent that the term *anesthesia* be limited to general anesthesia. [***101,*** 2018]

3.3.192.2* Apartment Building. A building or portion thereof containing three or more dwelling units with independent cooking and bathroom facilities. [***101,*** 2018]

*A.3.3.192.2 **Apartment Building.*** The *Code* specifies that, wherever there are three or more living units in a building, the building is considered an apartment building and is required to comply with Chapter 30 or Chapter 31 of NFPA *101*, as appropriate. Townhouse units are considered to be apartment buildings if there are three or more units in the building. The type of wall required between units in order to consider them to be separate buildings is normally established by the AHJ. If the units are separated by a wall of sufficient fire resistance and structural integrity to be considered as separate buildings, then the provisions of Chapter 24 of NFPA *101*, apply to each townhouse. Condominium status is a form of ownership, not occupancy; for example, there are condominium warehouses, condominium apartments, and condominium offices. [***101,*** 2018]

3.3.192.3* Assembly Occupancy. An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load. [***101,*** 2018]

Δ *A.3.3.192.3 **Assembly Occupancy.*** Assembly occupancies might include the following:

(1) Armories
(2) Assembly halls
(3) Auditoriums
(4) Bowling lanes
(5) Club rooms
(6) College and university classrooms, 50 persons and over
(7) Conference rooms
(8) Courtrooms
(9) Dance halls
(10) Drinking establishments
(11) Exhibition halls
(12) Gymnasiums
(13) Libraries
(14) Mortuary chapels
(15) Motion picture theaters
(16) Museums
(17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
(18) Places of religious worship
(19) Pool rooms
(20) Recreation piers
(21) Restaurants
(22) Skating rinks
(23) Special amusement buildings, regardless of occupant load
(24) Theaters

[***101,*** 2018]

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally open or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily occupied by able-bodied persons and are not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation. [***101,*** 2018]

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies. [***101,*** 2018]

For special amusement buildings, see 12.4.8 and 13.4.8 of NFPA *101*. [***101,*** 2018]

Assembly occupancies are characterized by crowds with a potential presence of panic hazard in the event of fire or other emergency. These occupancies are generally or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. The need for alternative egress routes for small commercial assembly occupancies, such as restaurants, lounges, and theaters with capacities of as few as 50 persons, is specially treated in this method of classification.

Paragraph A.3.3.192.3(23) further clarifies that a special amusement building is an assembly occupancy, even if the occupant load is fewer than 50 persons. As an assembly occupancy, a special amusement building is subject to the provisions of 20.1.4 of this *Code* and Chapter 12 or Chapter 13 — especially 12.4.8 or 13.4.8 — of NFPA *101*. If an assembly occupancy were not subject to these provisions, a haunted house amusement building at a carnival, for example, might be treated as a business occupancy because it does not have the minimum 50-person occupant load typically associated with an assembly occupancy. If this building were treated as a business occupancy, the necessary level of life safety would probably not be provided. Because special amusement buildings purposely confound the egress path and further confuse the occupants with sound and lighting effects, they need to meet the special requirements of 20.1.4 of this *Code* and 12.4.8 or 13.4.8 of NFPA *101*. For other than special amusement buildings, the threshold at which an assembly use becomes an assembly occupancy is the 50-person occupant load.

3.3.192.4 Bulk Merchandising Retail Building. A building in which the sales area includes the storage of combustible materials on pallets, in solid piles, or in racks in excess of 12 ft (3660 mm) in storage height. [***101,*** 2018]

3.3.192.5* Business Occupancy. An occupancy used for the transaction of business other than mercantile. [***101,*** 2018]

A.3.3.192.5 Business Occupancy. Business occupancies include the following:

(1) Airport traffic control towers (ATCTs)
(2) City halls
(3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
(4) Courthouses
(5) Dentists' offices
(6) Doctors' offices
(7) General offices
(8) Outpatient Clinics (ambulatory)
(9) Town halls

[***101,*** 2018]

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies. *(See 3.3.192.1.)* [***101,*** 2018]

Birth centers should be classified as business occupancies if they are occupied by fewer than four patients, not including infants, at any one time; do not provide sleeping facilities for four or more occupants; and do not provide treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time. For birth centers occupied by patients not meeting these parameters, see Chapter 18 or Chapter 19 of NFPA *101*, as appropriate. [***101,*** 2018].

Service facilities common to city office buildings such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group. [***101,*** 2018]

City halls, town halls, and courthouses are included in the business occupancy group insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies. [***101,*** 2018]

For birth centers that are occupied by patients but do not meet the criteria in A.3.3.192.5, see the requirements for ambulatory health care facilities (Section 20.6 of this *Code* and Chapters 20 and 21 of NFPA *101*) or health care occupancies (Section 20.4 of this *Code* and Chapters 18 and 19 of NFPA *101*), as appropriate.

3.3.192.6* Day-Care Home. A building or portion of a building in which more than 3 but not more than 12 clients receive care, maintenance, and supervision, by other than their relative(s) or legal guardian(s), for less than 24 hours per day. [***101,*** 2018]

Δ ***A.3.3.192.6 Day-Care Home.*** A day-care home is generally located within a dwelling unit. [***101,*** 2018]

Group day-care homes are often located in buildings that house apartment occupancies, mercantile occupancies, business occupancies, or assembly occupancies. A day-care facility that is housed as a tenant together with another occupancy type cannot control safety issues in hallways and other areas outside of its tenant space. The AHJ can impose additional safeguards, in the form of a larger staff-to-client ratio, to ensure client safety. If safeguards or fire protection features beyond those required by NFPA 1 and NFPA *101* are in place, the AHJ can permit a reduced staff-to-client ratio.

3.3.192.7* Day-Care Occupancy. An occupancy in which four or more clients receive care, maintenance, and supervision, by other than their relatives or legal guardians, for less than 24 hours per day. [***101,*** 2018]

A.3.3.192.7 Day-Care Occupancy. Day-care occupancies include the following:

(1) Adult day-care occupancies, except where part of a health care occupancy
(2) Child day-care occupancies
(3) Day-care homes
(4) Kindergarten classes that are incidental to a child day-care occupancy
(5) Nursery schools

[***101,*** 2018]

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. Because these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed. [***101,*** 2018]

3.3.192.8* Detention and Correctional Occupancy. An occupancy used to house one or more persons under varied degrees of restraint or security where such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control. [***101,*** 2018]

Δ ***A.3.3.192.8 Detention and Correctional Occupancy.*** Detention and correctional occupancies include the following:

(1) Adult and juvenile substance abuse centers
(2) Adult and juvenile work camps
(3) Adult community residential centers
(4) Adult correctional institutions
(5) Adult local detention facilities
(6) Juvenile community residential centers
(7) Juvenile detention facilities
(8) Juvenile training schools

[***101,*** 2018]

It is not the intent to classify as detention and correctional occupancies the areas of health care occupancies where doors are locked against patient egress where needed for the clinical needs of the patients. For example, a dementia treatment center can be adequately protected by the health care occupancies requirements of Chapter 19 of NFPA *101*. *[See 19.1.1.1.7, 19.2.2.2.2, 19.2.2.2.4(1), and 19.2.2.2.6 of NFPA 101.]* [***101,*** 2018]

The one-resident threshold requirement of 23.1.1.1.6 of NFPA *101* is not meant to force a residential occupancy, where security is imposed on one or more occupants, to be reclassified as a detention and correctional occupancy. [***101,*** 2018]

3.3.192.8.1 Detention and Correctional Use Condition. For application of the life safety requirements in Section 20.7, the resident user category is divided into the five use conditions.

Δ ***3.3.192.8.1.1 Use Condition I — Free Egress.*** A condition under which free movement is allowed from sleeping areas and other spaces where access or occupancy is permitted to the exterior via means of egress that meet the requirements of NFPA *101*. [***101,*** 2018]

3.3.192.8.1.2 Use Condition II — Zoned Egress. A condition under which free movement is allowed from sleeping areas and any other occupied smoke compartment to one or more other smoke compartments. [***101,*** 2018]

3.3.192.8.1.3 Use Condition III — Zoned Impeded Egress. A condition under which free movement is allowed within individual smoke compartments, such as within a residential unit comprised of individual sleeping rooms and a group activity space, with egress impeded by remote-controlled release of means of egress from such a smoke compartment to another smoke compartment. [***101,*** 2018]

3.3.192.8.1.4 Use Condition IV — Impeded Egress. A condition under which free movement is restricted from an occupied space, and remote-controlled release is provided to allow movement from all sleeping rooms, activity spaces, and other occupied areas within the smoke compartment to another smoke compartment. [***101,*** 2018]

3.3.192.8.1.5 Use Condition V — Contained. A condition under which free movement is restricted from an occupied space, and staff-controlled manual release at each door is provided to allow movement from all sleeping rooms, activity spaces, and other occupied areas within the smoke compartment to another smoke compartment. [***101,*** 2018]

3.3.192.9* Dormitory. A building or a space in a building in which group sleeping accommodations are provided for more than 16 persons who are not members of the same family in one room, or a series of closely associated rooms under joint occupancy and single management, with or without meals, but without individual cooking facilities. [***101,*** 2018]

Δ ***A.3.3.192.9 Dormitory.*** Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples of dormitories are college dormitories, fraternity and sorority houses, and military barracks. [***101,*** 2018]

The phrase *without individual cooking facilities* refers to the prohibition or required absence of cooking equipment in any room or unit of a dormitory. If this equipment is present throughout a facility, the occupancy should be classified as an apartment building. The phrase with or without meals indicates that a central cafeteria might be available to serve meals for the occupants of the dormitory.

3.3.192.10* Educational Occupancy. An occupancy used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week. [***101,*** 2018]

A.3.3.192.10 Educational Occupancy. Educational occupancies include the following:

(1) Academies
(2) Kindergartens
(3) Schools

[***101,*** 2018]

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present. [***101,*** 2018]

Educational occupancies are limited to facilities used for educational purposes through the twelfth grade. College classroom buildings do not meet this criterion and should be classified as business occupancies. Regardless of the educational level, where the occupant load of a classroom is 50 or more persons, the classroom should be classified as an assembly occupancy.

An educational occupancy is distinguished from an assembly occupancy in that the same occupants use an educational occupancy on a regular basis and are subject to discipline and control.

3.3.192.11* Health Care Occupancy. An occupancy used to provide medical or other treatment or care simultaneously to four or more patients on an inpatient basis, where such patients are mostly incapable of self-preservation due to age, physical or mental disability, or because of security measures not under the occupants' control. [***101,*** 2018]

A.3.3.192.11 Health Care Occupancy. Health care occupancies include the following:

(1) Hospitals
(2) Limited care facilities
(3) Nursing homes

[***101,*** 2018]

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons. [***101,*** 2018]

It is not the intent to consider occupants incapable of self-preservation because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches. [***101,*** 2018]

Health care occupancies, by definition, accommodate four or more persons who are generally incapable of self-preservation.

Since the *Code* allows one- and two-family dwellings to accommodate up to three persons not related to the occupying family, three or fewer persons incapable of self-preservation do not constitute a health care occupancy.

N **3.3.192.12* High-Risk Occupancy.** An occupancy that has a history of high frequency of fires, high potential for loss of life or economic loss, or that has a low or moderate history of fires or loss of life but the occupants have a high dependency on the built-in fire protection features or staff to assist in evacuation during a fire or other emergency. [**1730,** 2016]

N **A.3.3.192.12 High-Risk Occupancy.** Examples of high-risk occupancies are apartment buildings, hotels, dormitories, lodging and rooming, assembly, child care, detention, educational, and health care. [**1730,** 2016]

3.3.192.13 Hospital. A building or portion thereof used on a 24-hour basis for the medical, psychiatric, obstetrical, or surgical care of four or more inpatients. [***101,*** 2018]

A building must house four or more persons incapable of self-preservation on a 24-hour basis to be classified as a hospital. Occupants of hospitals or nursing homes are assumed to be nonambulatory and incapable of self-preservation. In making this judgment, due consideration should be given to the use of physical restraints and tranquilizing drugs, which render occupants immobile. Variable staffing criteria and levels of care further differentiate hospitals from nursing homes.

3.3.192.14* Hotel. A building or groups of buildings under the same management in which there are sleeping accommodations for more than 16 persons and primarily used by transients for lodging with or without meals. [***101,*** 2018]

Δ ***A.3.3.192.14 Hotel.*** So-called apartment hotels should be classified as hotels, because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days. [***101,*** 2018]

A residential occupancy that is called a lodging house or a rooming house by its operators, but that has sleeping accommodations for more than 16 people, must be classified as a hotel. In the definition of the term *hotel,* the reference to a 30-day time period helps to define the term *transient*. A building containing guest rooms with individual cooking facilities should be classified as an apartment building. However, where the AHJ thinks that the potential for hazards associated with both a hotel (which is occupied by guests unfamiliar with surroundings) and an apartment building (which contains a higher fuel load and a greater number of ignition sources and in which egress is subject to travel through multiple rooms) is present, the classification of the building as a mixed occupancy (hotel and apartment building) might be appropriate.

3.3.192.15* Industrial Occupancy. An occupancy in which products are manufactured or in which processing, assembling, mixing, packaging, finishing, decorating, or repair operations are conducted. [***101,*** 2018]

A.3.3.192.15 Industrial Occupancy. Industrial occupancies include the following:

(1) Drycleaning plants
(2) Factories of all kinds
(3) Food processing plants
(4) Gas plants

Industrial occupancies expose occupants to a range of processes and materials of varying hazards. The classification decision should be based on the extent and nature of the associated hazards.

(5) Hangars (for servicing/maintenance)
(6) Laundries
(7) Power plants
(8) Pumping stations
(9) Refineries
(10) Sawmills
(11) Telephone exchanges

[***101,*** 2018]

In evaluating the appropriate classification of laboratories, the AHJ should treat each case individually, based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial; for example, a physical therapy laboratory or a computer laboratory. [***101,*** 2018]

For laboratories within the scope of NFPA 45, the occupancies are defined in NFPA 45, Section 3.3, as follows:

(1) Noninstructional labs are considered industrial.
(2) Labs within the scope of NFPA 99 are considered health care.
(3) Instructional labs for grades 12 and below are considered educational.
(4) Labs for grades above grade 12 and Class D labs are business occupancies.

[**5000,** 2018]

3.3.192.16* Limited Care Facility. A building or portion of a building used on a 24-hour basis for the housing of four or more persons who are incapable of self-preservation because of age; physical limitations due to accident or illness; or limitations such as mental retardation/developmental disability, mental illness, or chemical dependency. [***101,*** 2018]

A.3.3.192.16 Limited Care Facility. Limited care facilities and residential board and care occupancies both provide care to people with physical and mental limitations. However, the goals and programs of the two types of occupancies differ greatly. The requirements in NFPA *101* for limited care facilities are based on the assumption that these are medical facilities, that they provide medical care and treatment, and that the patients are not trained to respond to the fire alarm; that is, the patients do not participate in fire drills but, rather, await rescue. *(See Section 18.7 of NFPA 101.)* [***101,*** 2018]

The requirements for residential board and care occupancies are based on the assumption that the residents are provided with personal care and activities that foster continued independence, that the residents are encouraged and taught to overcome their limitations, and that most residents, including all residents in prompt and slow homes, are trained to respond to fire drills to the extent they are able. Residents are required to participate in fire drills. *(See Section 32.7 of NFPA 101.)* [***101,*** 2018]

Persons with Alzheimer's and related illnesses might be located in a nursing home, limited care facility, or board and care facility. For such persons, it is the level of care provided, not the medical diagnosis, that matters for the purposes of determining whether the facility should meet the requirements for limited care. Where personal care is provided but medical or custodial care is not, the limited care definition does not typically apply. It is the intent of this definition that it not apply to persons not receiving medical or custodial care, provided they are able to assist in their own evacuation, regardless of their medical diagnosis. [***101,*** 2018]

3.3.192.17 Lodging or Rooming House. A building or portion thereof that does not qualify as a one- or two-family dwelling, that provides sleeping accommodations for a total of 16 or fewer people on a transient or permanent basis, without personal care services, with or without meals, but without separate cooking facilities for individual occupants. [***101,*** 2018]

If sleeping accommodations for more than 16 people are provided, the occupancy should be classified as a hotel or dormitory. Chapter 24 of NFPA *101* contains the provision for allowing rooms to be occupied by a maximum of three outsiders in addition to family members in one- and two-family dwellings without changing the occupancy classification.

N ***3.3.192.18* Low-Risk Occupancy.*** An occupancy that has a history of low frequency of fires and minimal potential for loss of life or economic loss. [**1730,** 2016]

N ***A.3.3.192.18 Low-Risk Occupancy.*** Examples of low-risk occupancies are storage, mercantile, and business. [**1730,** 2016]

3.3.192.19* Mercantile Occupancy. An occupancy used for the display and sale of merchandise. [***101,*** 2018]

A.3.3.192.19 Mercantile Occupancy. Mercantile occupancies include the following:

(1) Auction rooms
(2) Department stores
(3) Drugstores
(4) Restaurants with fewer than 50 persons
(5) Shopping centers
(6) Supermarkets

[***101,*** 2018]

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification. [***101,*** 2018]

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building occupied for sales purposes, are a subclass of mercantile occupancies and have a greater potential for hazards than traditional mercantile operations.

3.3.192.19.1 Class A Mercantile Occupancy. All mercantile occupancies having an aggregate gross area of more than 30,000 ft^2 (2800 m^2) or occupying more than three stories for sales purposes. [***101,*** 2018]

3.3.192.19.2 Class B Mercantile Occupancy. All mercantile occupancies of more than 3000 ft^2 (280 m^2), but not more than 30,000 ft^2 (2800 m^2), aggregate gross area and occupying not more than three stories for sales purposes. Class B also includes all mercantile occupancies of not more than 3000 ft^2 (280 m^2) gross area and occupying two or three stories for sales purposes. [***101,*** 2018]

3.3.192.19.3 Class C Mercantile Occupancy. All mercantile occupancies of not more than 3000 ft^2 (280 m^2) gross area and used for sales purposes occupying one story only, excluding mezzanines. [***101,*** 2018]

3.3.192.20 Mixed Occupancy. A multiple occupancy where the occupancies are intermingled. [***101,*** 2018]

N ***3.3.192.21* Moderate-Risk Occupancy.*** An occupancy that has a history of moderate frequency of fires or a moderate potential for loss of life or economic loss. [**1730,** 2016]

N ***A.3.3.192.21 Moderate-Risk Occupancy.*** Examples of moderate-risk occupancies are ambulatory health care, and industrial. [**1730,** 2016]

3.3.192.22 Motor Fuel Dispensing Facility. That portion of a property where motor fuels are stored and dispensed from fixed equipment into the fuel tanks of motor vehicles or marine craft or into approved containers, including all equipment used in connection therewith. [**30A,** 2018]

3.3.192.22.1 Fleet Vehicle Motor Fuel Dispensing Facility. A motor fuel dispensing facility at a commercial, industrial, governmental, or manufacturing property where motor fuels are dispensed into the fuel tanks of motor vehicles that are used in connection with the business or operation of that property by persons within the employ of such business or operation. [**30A,** 2018]

3.3.192.22.2 Marine Motor Fuel Dispensing Facility. A motor fuel dispensing facility at or adjacent to shore, a pier, a wharf, or a floating dock where motor fuels are dispensed into the fuel tanks of marine craft. [**30A,** 2018]

3.3.192.22.3* Motor Fuel Dispensing Facility Located Inside a Building. That portion of a motor fuel dispensing facility located within the perimeter of a building or building structure that also contains other occupancies. [**30A,** 2018]

A.3.3.192.22.3 Motor Fuel Dispensing Facility Located Inside a Building. The motor fuel dispensing facility can be either enclosed or partially enclosed by the building walls, floors, ceilings, or partitions or can be open to the outside. The motor fuel dispensing area is that area required for dispensing of fuels to motor vehicles. Dispensing of fuel at manufacturing, assembly, and testing operations is not included within this definition. [**30A,** 2018]

3.3.192.23 Multiple Occupancy. A building or structure in which two or more classes of occupancy exist. [**101,** 2018]

3.3.192.24 Nursing Home. A building or portion of a building used on a 24-hour basis for the housing and nursing care of four or more persons who, because of mental or physical incapacity, might be unable to provide for their own needs and safety without the assistance of another person. [***101,*** 2018]

A building must house four or more persons who are incapable of self-preservation on a 24-hour basis to be classified as a nursing home. Occupants of nursing homes are assumed to be nonambulatory and incapable of self-preservation. In making this judgment, due consideration should be given to the use of physical restraints and tranquilizing drugs, which can render occupants immobile. Variable staffing criteria and levels of care further differentiate hospitals from nursing homes.

3.3.192.25 One- and Two-Family Dwelling. One- and two-family dwellings include buildings containing not more than two dwelling units in which each dwelling unit is occupied by members of a single family with not more than three outsiders, if any, accommodated in rented rooms.

3.3.192.25.1 One- and Two-Family Dwelling Unit. A building that contains not more than two dwelling units with independent cooking and bathroom facilities. [***101,*** 2018]

3.3.192.26* Parking Structure. A building, structure, or portion thereof used for the parking, storage, or both, of motor vehicles. [**88A,** 2015]

A.3.3.192.26 Parking Structure. A parking structure is permitted to be enclosed or open, use ramps, and use mechanical control push-button-type elevators to transfer vehicles from one floor to another. Motor vehicles are permitted to be parked by the driver or an attendant or are permitted to be parked mechanically by automated facilities. Where automated type parking is provided, the operator of those facilities is permitted either to remain at the entry level or to travel to another level. Motor fuel is permitted to be dispensed, and motor vehicles are permitted to be serviced in a parking structure in accordance with NFPA 30A. [**88A,** 2015] Δ

3.3.192.26.1 Basement and Underground Parking Structures. Parking structures that are located below grade. A basement parking structure has other occupancies above it and an underground parking structure has no occupancy other than parking above it. Basement and underground parking structures are considered as specific cases of enclosed parking structures.

3.3.192.26.2 Enclosed Parking Structure. Any parking structure that is not an open parking structure. [**88A,** 2015]

3.3.192.26.3 Open Parking Structure. A parking structure that meets the requirements of Section 5.5 of *NFPA 88A*. [**88A,** 2015]

3.3.192.27 Repair Garages.

3.3.192.27.1 Major Repair Garage. A building or portions of a building where major repairs, such as engine overhauls, painting, body and fender work, and repairs that require draining of the motor vehicle fuel tank are performed on motor vehicles, including associated floor space used for offices, parking, or showrooms.

3.3.192.27.2 Minor Repair Garage. A building or portions of a building used for lubrication, inspection, and minor automotive maintenance work, such as engine tune-ups, replacement of parts, fluid changes (e.g., oil, antifreeze, transmission fluid, brake fluid, air conditioning refrigerants, etc.), brake system repairs, tire rotation, and similar routine maintenance work, including associated floor space used for offices, parking, or showrooms.

3.3.192.28* Residential Board and Care Occupancy. An occupancy used for lodging and boarding of four or more residents, not related by blood or marriage to the owners or operators, for the purpose of providing personal care services. [***101,*** 2018]

A.3.3.192.28 Residential Board and Care Occupancy. The following are examples of facilities that are classified as residential board and care occupancies:

(1) Group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
(2) Group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities
(3) Group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
(4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
(5) Assisted living facilities
(6) Other group housing arrangements that provide personal care services but not nursing care

[***101,*** 2018]

3.3.192.29* Residential Occupancy. An occupancy that provides sleeping accommodations for purposes other than health care or detention and correctional. [***101,*** 2018]

A.3.3.192.29 Residential Occupancy. Residential occupancies are treated as separate occupancies in this *Code* as follows:

(1) One- and two-family dwellings (Chapter 24 of NFPA *101*)
(2) Lodging or rooming houses (Chapter 26 of NFPA *101*)
(3) Hotels, motels, and dormitories (Chapters 28 and 29 of NFPA *101*)
(4) Apartment buildings (Chapters 30 and 31 of NFPA *101*)

[***101,*** 2018]

3.3.192.30 Separated Occupancy. A multiple occupancy where the occupancies are separated by fire resistance–rated assemblies. [***101,*** 2018]

3.3.192.31* Storage Occupancy. An occupancy used primarily for the storage or sheltering of goods, merchandise, products, or vehicles. [***101,*** 2018]

A.3.3.192.31 Storage Occupancy. Storage occupancies include the following:

(1) Barns
(2) Bulk oil storage

(3) Cold storage
(4) Freight terminals
(5) Grain elevators
(6) Hangars (for storage only)
(7) Parking structures
(8) Truck and marine terminals
(9) Warehouses
[***101,*** 2018]

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area. [***101,*** 2018]

3.3.192.31.1* Mini-Storage Building. A storage occupancy partitioned into individual storage units, with a majority of the individual units not greater than 750 ft^2 in area, that are rented or leased for the purposes of storing personal or business items where all of the following apply: (1) the storage units are separated from each other by less than a 1-hour fire resistance rated barrier, (2) the owner of the facility does not have unrestricted access to the storage units, and (3) the items being stored are concealed from view from outside the storage unit.

A.3.3.192.31.1 Mini-Storage Building. Mini-storage buildings are typically designed to accommodate relatively small transient tenants who are often private individuals or persons who own small businesses and need additional storage space that is generally very small in area to accommodate their short-term storage needs. This definition is not intended to apply to large warehouse buildings designed to be rented or leased to relatively large multiple tenants who are generally storing their wares in conjunction with their businesses. Garage units that are primarily intended for vehicular storage as part of a multifamily development are not intended to be classified as mini-storage buildings. [**5000,** 2018]

3.3.193 Occupant Load. The total number of persons that might occupy a building or portion thereof at any one time. [***101,*** 2018]

3.3.194 Open System Use. See 3.3.281.2.

3.3.195 Operating Pressure. The pressure at which a system operates.

3.3.196* Operating Unit (Vessel) or Process Unit (Vessel). The equipment in which a unit operation or unit process is conducted. *(See also 3.3.277, Unit Operation or Unit Process.)* [**30,** 2018]

A.3.3.196 Operating Unit (Vessel) or Process Unit (Vessel). Unit operations include, but are not limited to, distillation, oxidation, cracking, and polymerization. [**30,** 2018]

The operating unit or process unit can be a simple tank, or it can be a sophisticated piece of equipment such as a distillation column, absorption tower, or catalytic cracking unit in a petroleum refinery.

3.3.197 Operations. A general term that includes, but is not limited to, the use, transfer, storage, and processing of liquids. [**30,** 2018]

3.3.198 Organic Peroxide. Any organic compound having a double oxygen or peroxy (-O-O-) group in its chemical structure. [**400,** 2016]

Δ ***3.3.198.1* Organic Peroxide Formulation.*** A pure or technically pure organic peroxide or a mixture of organic peroxides with an active oxygen (aO) concentration greater than 1 % alone or in combination with one or more materials. [**400,** 2016]

A.3.3.198.1 Organic Peroxide Formulation. Terms such as *accelerator*, *catalyst*, *initiator*, *curing agent*, and so forth, are sometimes used to describe organic peroxide formulations. These terms are misleading because they can also refer to materials that are not or do not contain organic peroxides, some of which might present increased hazard when mixed with organic peroxides. [**400,** 2016]

3.3.198.1.1 Class I. Class I describes those formulations that are more severe than a Class II but do not detonate. [**400,** 2016]

3.3.198.1.2 Class II. Class II describes those formulations that burn very rapidly and that present a severe reactivity hazard. [**400,** 2016]

3.3.198.1.3 Class III. Class III describes those formulations that burn rapidly and that present a moderate reactivity hazard. [**400,** 2016]

3.3.198.1.4 Class IV. Class IV describes those formulations that burn in the same manner as ordinary combustibles and that present a minimal reactivity hazard. [**400,** 2016]

3.3.198.1.5 Class V. Class V describes those formulations that burn with less intensity than ordinary combustibles or do not sustain combustion and that present no reactivity hazard. [**400,** 2016]

3.3.198.2 Organic Peroxide Storage Area. See 3.3.14.7.

3.3.199 OSHA. The Occupational Safety and Health Administration of the U.S. Department of Labor. [**55,** 2016]

3.3.200 Overcrowded. A situation where the occupant load exceeds the exit capacity or the posted occupant load.

3.3.201* Oxidizer. Any solid or liquid material that readily yields oxygen or other oxidizing gas or that readily reacts to promote or initiate combustion of combustible materials and that can, under some circumstances undergo a vigorous self-sustained decomposition due to contamination or heat exposure. [**400,** 2016]

A.3.3.201 Oxidizer. Examples of other oxidizing gases include bromine, chlorine, and fluorine. [**400,** 2016]

The classification of oxidizers is based on the technical committee's evaluation of available scientific and technical data, actual experience, and its considered opinion. Classification refers to the pure oxidizer. Gross contamination can cause oxidizers of all classes to undergo exothermic or explosive reaction, particularly if they also are subjected to confinement and heating. *(See B.5.2.2 through B.5.2.5 for oxidizer classifications.)* [**400,** 2016]

The classification of oxidizers is based on the degree to which an oxidizing chemical increases, if at all, the burning rate of available combustible fuels. Factors that can influence the burning rate of oxidizers are concentration, particle size, product form, product packaging, and packaging configuration. Examples of Class 1, 2, 3, and 4 chemical oxidizers are listed in B.5.2.2. The definition of the current classes and the oxidizers listed as typical of each Class in B.5.2.1 are based on the technical committee's evaluation of available data, experience, and results of tests done by the Bureau of Mines and GE Research in the 1970s. [**400,** 2016]

The definition of Class 1, 2, 3, and 4 oxidizers is subjective. Currently, there is no bench scale test method that adequately measures the burning rate of oxidizers for large scale storage. The UN's *Recommendations on the Transport of Dangerous Goods, Model Regulations,* includes a bench scale test method (Test O.1) to assign packing groups to solid oxidizers. Thirty grams (1.06 oz) of a mixture of the test substance and cellulose powder is ignited with a Nichrome wire. The time from ignition to the end of visible burning of the mixture is compared with the burning time of several different mixtures of potassium bromate (Class 3) and cellulose powder. The test does not characterize chemical reactivity or thermal stability. The test is not representative of packaged oxidizers. The determination of burning time is strongly dependent on test conditions, particle size, and the test operator's perception of the end of active burning. [**400,** 2016]

The Fire Protection Research Foundation (FPRF) published *National Oxidizing Pool Chemicals Storage Fire Test Project* in August 1998. The technical report includes literature abstracts, large-scale calorimetry test data, and intermediate scale rack storage tests. The peak rate of heat release of packaging and packaged oxidizers trichloroisocyanuric acid (Trichlor, Class 1) and calcium hypochlorite (available chlorine >68%, Class 3) are summarized in Table A.3.3.201. [**400,** 2016]

The Class 1 Trichlor did not increase the burning rate of the combustible packaging. Class 3 calcium hypochlorite (available chlorine >68%) caused a severe increase in the burning rate of the combustible packaging. In 2006, the FPRF published a report on the *Development of an Enhanced Hazard Classification System for Oxidizers*. The report includes a review of fire losses, historical test data, and current test methods for oxidizing materials used by transportation and environmental regulatory agencies. Two classification schemes with multiple test methods and performance-based criteria were proposed to distinguish between Class 1, 2, 3, and 4 oxidizers in a storage situation. [**400,** 2016]

Future FPRF effort is proposed to define an appropriate bench scale test, validated by medium scale free burn testing, for oxidizers. The goal of the enhanced classification system would be to prescribe tests and use performance-based criteria to define the different classes of oxidizers based on the degree of burning rate enhancement, chemical reactivity, and thermal stability. [**400,** 2016]

The FPRF completed a project that resulted in the development of a bench-scale test, validated by intermediate scale testing, for solid oxidizers. An enhanced classification system with prescribed tests and performance-based criteria to define the different classes of oxidizers based on the degree of burning rate enhancement was developed. [Buc, Elizabeth C., *Oxidizer Classification Research Project: Tests and Criteria*, Fire Protection Research Foundation, November 2009] [**400,** 2016]

TABLE A.3.3.201 *Results of Large-Scale Calorimetry Tests with Packaging and Packaged Oxidizers on Wood Pallets*

Oxidizer and Packaging	Total Weight with Pallets (lb)	Peak Convective HRR (kW)
40 cartons of empty HDPE 2 lb capacity containers	300	1736
40 cartons of pea gravel filled HDPE 2 lb capacity containers	1631	464
40 cartons of granular Trichlor in HDPE 2 lb capacity containers	1891	649
40 cartons of tablet form Trichlor in HDPE 2 lb capacity containers	1882	877
48 cartons of granular calcium hypochlorite in 1 lb capacity Surlin (plastic) bags	1468	6696
36 cartons of granular calcium hypochlorite in HDPE 1 lb capacity containers	1452	>16184

For SI units, 1 lb = 0.45 kg.

Source: FPRF, *National Oxidizing Pool Chemicals Storage Fire Test Project*, Aug. 1998.

[**400,** 2016]

3.3.201.1 Class 1. An oxidizer that does not moderately increase the burning rate of combustible materials with which it comes into contact or a solid oxidizer classified as Class 1 when tested in accordance with the test protocol set forth in G.1 of NFPA 400. [**400,** 2016]

3.3.201.2 Class 2. An oxidizer that causes a moderate increase in the burning rate of combustible materials with which it comes into contact or a solid oxidizer classified as Class 2 when tested in accordance with the test protocol set forth in G.1 of NFPA 400. [**400,** 2016]

3.3.201.3 Class 3. An oxidizer that causes a severe increase in the burning rate of combustible materials with which it comes into contact or a solid oxidizer classified as Class 3 when tested in accordance with the test protocol set forth in G.1 of NFPA 400. [**400,** 2016]

3.3.201.4 Class 4. An oxidizer that can undergo an explosive reaction due to contamination or exposure to thermal or physical shock and that causes a severe increase in the burning rate of combustible materials with which it comes into contact. [**400,** 2016]

3.3.202 Ozone Generator. Equipment that causes the production of ozone.

3.3.203 Packaging. A commodity wrapping, cushioning, or container. [**13,** 2016]

3.3.204 Paper. Felted sheets made from natural fibrous materials, usually vegetable but sometimes mineral or animal, and formed on a fine wire screen by means of water suspension.

3.3.205 Patch Kettle. Any pot or container with a capacity of less than 6 gal (22.7 L) used for preheating tar, asphalt, pitch, or similar substances for the repair of roofs, streets, floors, pipes, or similar objects.

3.3.206 Permissible Exposure Limit (PEL). See 3.3.167.2.

3.3.207 Permit. A document issued by the AHJ for the purpose of authorizing performance of a specified activity.

3.3.208 Peroxide-Forming Chemical. A chemical that, when exposed to air, forms explosive peroxides that are shock sensitive, pressure sensitive, or heat sensitive.

3.3.209* Personal Care. The care of residents who do not require chronic or convalescent medical or nursing care. [***101,*** 2018]

Δ **A.3.3.209 Personal Care.** Personal care involves responsibility for the safety of the resident while inside the building. Personal care might include daily awareness by management of the resident's functioning and whereabouts, making and reminding a resident of appointments, the ability and readiness for intervention in the event of a resident experiencing a crisis, supervision in the areas of nutrition and medication, and actual provision of transient medical care. [***101,*** 2018]

3.3.210 Pesticide. Any substance or mixture of substances intended for preventing, destroying, repelling, or mitigating any pest or for use as a plant regulator, defoliant, or desiccant.

3.3.211 Physical Hazard. A chemical for which there is scientifically valid evidence that the chemical is an organic peroxide or oxidizer.

3.3.212* Pier. A structure, usually of greater length than width and projecting from the shore into a body of water with direct access from land, that can be either open deck or provided with a superstructure. [**307**, 2016]

A.3.3.212 Pier. The terms *pier* and *wharf* are used interchangeably. [**307,** 2016]

3.3.213* Pressure Vessel. A container, process vessel, or other component designed in accordance with the ASME *Boiler and Pressure Vessel Code*, DOT, or other approved standards. [**400,** 2016]

A.3.3.213 Pressure Vessel. Pressure vessels of any type can be subject to additional regulations imposed by various states or other legal jurisdictions. Users should be aware that compliance with DOT or ASME requirements might not satisfy all of the required regulations for the location in which the vessel is to be installed or used. [**55,** 2016]

3.3.214 Primary Containment. The first level of containment, consisting of the inside portion of that container that comes into immediate contact on its inner surface with the material being contained.

3.3.215* Process or Processing. An integrated sequence of operations. [**30,** 2018]

A.3.3.215 Process or Processing. The sequence can include both physical and chemical operations, unless the term is modified to restrict it to one or the other. The sequence can involve, but is not limited to, preparation, separation, purification, or change in state, energy content, or composition. [**30,** 2018]

3.3.216 Process Unit (Vessel). See 3.3.196, Operating Unit (Vessel) or Process Unit (Vessel).

3.3.217 Proprietary Information. Information regarding compounds or ingredients used in a process or production that do not qualify as trade secrets but that provide an industry or business with a competitive advantage.

3.3.218 Protection for Exposures. Fire protection for structures on property adjacent to liquid storage that is provided by (1) a public fire department or (2) a private fire brigade maintained on the property adjacent to the liquid storage, either of which is capable of providing cooling water streams to protect the property adjacent to the liquid storage. [**30,** 2018]

An important distinction to understand is that the phrase *protection for exposures* refers to fire protection provided for adjacent property, *not* to the property on which the flammable or combustible liquid is located. Protection for exposures depends on some means to provide a barrier to the transmission of the heat generated by a flammable or combustible liquid fire to that adjacent property. The means can be on-site, such as an on-site fire brigade, or it can be the reasonably quick response of a municipal fire department. If protection for the exposed property is present and sufficient, then NFPA 30 and this *Code* allow a reduction in the separation distance between the shell of a storage tank or the wall of a liquid warehouse and the property line between the two facilities. So, for example, a bulk fuel plant can position its storage tanks closer to the property line separating it from a neighboring facility if the latter has protection for exposures, such as a fire brigade. The bulk fuel plant might or might not have a fire brigade of its own.

A public fire department normally has the capability to provide protection to the exposed property. Large plant fire brigades also normally have this capability, but they require an extensive private water supply and hose system or mobile fire apparatus in addition to trained personnel. Ultimately, the AHJ has the responsibility to determine whether protection for exposures exists.

3.3.219 Public Way. A street, alley, or other similar parcel of land essentially open to the outside air deeded, dedicated, or otherwise permanently appropriated to the public for public use and having a clear width and height of not less than 10 ft (3050 mm). [***101,*** 2018]

3.3.220 Purging. A method used to free the internal volume of a piping system of unwanted contents that results in the existing contents being removed or replaced. [**55,** 2016]

3.3.221 Pyrophoric. A chemical that spontaneously ignites in air at or below a temperature of 130°F (54.5°C).

3.3.222 Quality Assurance. The procedures conducted by the registered design professionals (RDPs) responsible for design and the registered design professionals responsible for inspection that provide evidence and documentation to the RDPs, the owner, and the AHJ that the work is being constructed in accordance with the approved construction documents. [**5000,** 2018]

3.3.223 Quality Assurance Program. A predefined set of observations, special inspections, tests, and other procedures that provide an independent record to the owner, AHJ, and RDP responsible for design that the construction is in general conformance with the approved construction documents. [**5000,** 2018]

3.3.224* Rack. Any combination of vertical, horizontal, and diagonal members that supports stored materials.

A.3.3.224 Rack. Some rack structures use solid shelves. Racks are permitted to be fixed, portable, or movable. Loading is permitted to be either manual, using lift trucks, stacker cranes, or hand placement, or automatic, using machine-controlled storage and retrieval systems. *[See Figure A.34.7.3.1(a) through Figure A.34.7.3.1(k).]*

3.3.224.1 Double-Row Racks. Racks less than or equal to 12 ft (3700 mm) in depth or single-row racks placed back to back having an aggregate depth up to 12 ft (3700 mm), with aisles having an aisle width of at least 3.5 ft (1100 mm) between loads on racks. [**13,** 2016]

3.3.224.2* Movable Racks. Racks on fixed rails or guides.

A.3.3.224.2 Movable Racks. Movable racks can be moved back and forth only in a horizontal, two-dimensional plane. A moving aisle is created as abutting racks are either loaded or unloaded, then moved across the aisle to abut other racks.

3.3.224.3 Multiple-Row Racks. Racks greater than 12 ft (3700 mm) in depth or single- or double-row racks separated by aisles less than 3.5 ft (1100 mm) wide having an overall width greater than 12 ft (3700 mm). [**13,** 2016]

3.3.224.4* Portable Racks. Racks that are not fixed in place and can be arranged in any number of configurations. [**13,** 2016]

A.3.3.224.4 Portable Racks. Portable racks can be arranged in any number of configurations.

3.3.224.5 Single-Row Racks. Racks that have no longitudinal flue space and that have a depth up to 6 ft (1.8 m) with aisles having a width of at least 3.5 ft (1.1 m) between loads on racks. [**13,** 2016]

3.3.225* Ramp. A walking surface that has a slope steeper than 1 in 20. [***101,*** 2018]

Δ **A.3.3.225 Ramp.** See 7.2.5 of NFPA *101*. [***101,*** 2018]

3.3.226 Recreational Fire. The noncommercial burning of materials other than rubbish for pleasure, religious, ceremonial, cooking, or similar purposes in which the fuel burned is not contained in an incinerator, a barbecue grill, or a barbecue pit, and the total fuel area is not exceeding 3 ft (0.9 m) in diameter and 2 ft (0.6 m) in height.

3.3.227 Refinery. A plant in which flammable or combustible liquids are produced on a commercial scale from crude petroleum, natural gasoline, or other hydrocarbon sources. [**30,** 2018]

3.3.228 Registered Design Professional (RDP). An individual who is registered or licensed to practice his/her respective design profession as defined by the statutory requirements of the professional registration laws of the state or jurisdiction in which the project is to be constructed. [**5000,** 2018]

3.3.229 Relocatable Power Tap. A device for indoor use consisting of an attachment plug on one end of a flexible cord and two or more receptacles on the opposite end, and has overcurrent protection.

3.3.230 Row. A minimum yard storage unit comprised of adjoining cotton bales.

N **3.3.231 Rubberized Asphalt Melter (Melter).** Portable equipment used for the heating of rubberized asphalt material that is a mix of asphalt, rubber polymer, and filler material.

N **3.3.232 Rural.** Those areas that are not unsettled wilderness or uninhabitable territory but are sparsely populated with densities below 500 persons per square mile. [**1142,** 2017]

3.3.233* Safety Can. A listed container of not more than 5.3 gal (20 L) capacity having a screen or strainer in each fill and pour opening, and having a spring-closing lid and spout cover, designed to safely relieve internal pressure when exposed to fire. [**30,** 2018]

A.3.3.233 Safety Can. Safety cans listed to ANSI/UL 30, *Standard for Metal Safety Cans,* are limited to 5 U.S. gal (19 L). ANSI/UL 1313, *Standard for Nonmetallic Safety Cans for Petroleum Products,* allows for capacities up to 5 Imperial gal (23 L). [**30,** 2018]

Safety cans come in a variety of styles and sizes; however, there are two main types. Type I has a single, short, stubby spout that is used both for filling the can and for pouring from it, such as the one shown in Exhibit 3.19. Type II has separate filling and pouring spouts; the pouring spout is fitted with a flexible or rigid tubular nozzle, as shown in Exhibit 3.20.

There are also special-purpose safety cans. An example is the plunger can shown in Exhibit 3.21, which is used to pump a measured amount of liquid up through the perforated dish to soak a wipe rag. While these special-purpose cans are not considered safety cans, they are covered by their own standard: FM Global's *Approval Standard for Bench, Swab, Plunger, and Dispenser Cans — Class Number 6053, 6054, and 6055.*

Exhibit 3.19

Typical Type I safety can. (Courtesy of Justrite Manufacturing Co.)

Exhibit 3.20

Typical Type II safety can. (Courtesy of Justrite Manufacturing Co.)

Exhibit 3.21

Plunger-type safety can. (Courtesy of Justrite Manufacturing Co.)

The required features of a safety can are as follows:

- A spring-loaded, self-closing spout cover, held open with a handle
- The ability to relieve internal pressure if the can is exposed to a fire
- A capacity of not more than 5.3 gal (20 L)
- A screen or strainer in each spout

Note the maximum capacities stated in A.3.3.233. FM Global's *Approval Standard for Safety Containers and Filling, Supply and Disposal Containers — Class Number 6051 and 6052*, and ANSI/UL 30, *Standard for Metal Safety Cans,* both limit the capacity of a safety can to 5 gal (19 L).

The main purpose of a safety can is to prevent rupture of the container if it is exposed to a fire, while still providing the utility of a closed container. This feature is accomplished by the spring-loaded, self-closing cover on the pouring spout. This cover serves two purposes: It snaps shut as soon as the operating handle is released, so dropping the can would not result in a spill; and, if exposed to a fire, it releases internal pressure before the pressure rises to the point where the can will rupture.

The spring of the self-closing cover is rather strong and will keep the cover closed until some degree of pressure builds up inside the can. When the cover *does* lift, the velocity of the escaping vapors is greater than the intrinsic velocity of a flame through the vapors. Therefore, a flashback into the safety can would be highly unlikely if the vapors were ignited by an external source. For this reason, NFPA 30 does not require a flame arrester. Nevertheless, most safety cans are provided with a screen device, as shown in Exhibit 3.22, to meet listing requirements. Interestingly,

Exhibit 3.22

Internal view of safety can showing flame arrester below spout. (Courtesy of Justrite Manufacturing Co.)

FM Global's standard refers to this device as a *flame arrester* and tests it functionally, while ANSI/UL 30 refers to it as "a screen to trap and permit removal of dirt or other foreign material."

Historically, as explained above, it has been conventional wisdom that a safety can does not require a flash arrester. However, for the 2015 edition of NFPA 30, the definition was revised to acknowledge the fact that each of its spouts has a screen device.

Another feature that is not required but frequently provided is a grounding point. Generally, this is accomplished by taping a convenient spot on the handle before the can is painted. The user removes the tape before using, exposing a bare metal spot that can be used to attach a ground clamp. If this grounding point is not provided, the user must ensure that any ground clamp used "bites" through the paint to establish a good metal-to-metal contact, as shown in Exhibit 3.23.

Safety cans are not intended for use in areas where the periodic release of flammable vapors might create a hazardous atmosphere, such as in the trunk of an automobile or in an outbuilding that will experience wide swings in temperature. A safety can placed in such a location can "burp" vapors as temperatures increase, leading to a buildup of vapors in the enclosed space that could be ignited easily.

Exhibit 3.23

Applying a grounding clamp to a safety can. (Courtesy of Justrite Manufacturing Co.)

N **3.3.234 Safety Data Sheet (SDS).** The document that describes composition of a material, hazardous properties and hazard mitigation, and disposal information. [**400,** 2016]

3.3.235 Sales Display Area. See 3.3.14.10.

3.3.236 Salvage Vehicle. A vehicle that is dismantled for parts or awaiting destruction.

3.3.237 Self-Closing. Equipped with an approved device that ensures closing after opening. [***101,*** 2018]

Exhibit 3.24 illustrates self-closing hardware on a door leaf of a door assembly. The self-closer in this case takes the form of a hydraulic arm. Doors might also be made self-closing via the provision of spring hinges.

Exhibit 3.24

Door leaf with self-closing hardware.

3.3.238 Separation of Hazards. Physically separated by a specified distance, construction, or appliance. [**55,** 2016]

3.3.239 Shop Drawings. Scaled working drawings, equipment cutsheets, and design calculations. *(See 3.3.12, Plan, of NFPA 1031.)* [**1031,** 2014]

3.3.240* Signal. An indication of a condition communicated by electrical, visible, audible, wireless, or other means. [**72,** 2016]

A.3.3.240 Signal.

3.3.240.1* Alarm Signal. A signal that results from the manual or automatic detection of an alarm condition. [**72,** 2016]

A.3.3.240.1 Alarm Signal. Examples of alarm signals include outputs of activated alarm initiating devices, the light and sound from actuated alarm notification appliances, alarm data transmission to a supervising station, and so forth. [**72,** 2016]

An alarm signal is a form of notification to warn of a condition that requires immediate response. It may be related, for example, to a fire or carbon monoxide condition through the automatic activation of an initiating device, or it may be manually activated to warn of a fire, weather, environmental, or hostile situation.

3.3.240.2* Fire Alarm Signal. A signal that results from the manual or automatic detection of a fire alarm condition. [**72,** 2016]

A.3.3.240.2 Fire Alarm Signal. Examples include outputs from activated fire alarm initiating devices (manual fire alarm box, automatic fire detector, waterflow switch, etc.), the light and sound from actuated fire alarm notification appliances, fire alarm data transmission to a supervising station, and so forth. [**72,** 2016]

3.3.240.3* Supervisory Signal. A signal that results from the detection of a supervisory condition. [**72,** 2016]

A.3.3.240.3 Supervisory Signal. Examples include activated supervisory signal-initiating device outputs, supervisory data transmissions to supervising stations, the light and sound from actuated supervisory notification appliances, a delinquency signal indicating a guard's tour supervisory condition, and so forth. [**72,** 2016]

The term *guard's tour supervisory signal*, associated with systems supporting guard's tour supervisory service, is a message indicating that a guard has activated a guard's tour reporting station (not in itself an indication of a supervisory condition). Guard's tour supervisory signals are not a subset of the general category of supervisory signals as used in this *Code*. [**72,** 2016]

3.3.240.4* Trouble Signal. A signal that results from the detection of a trouble condition. [**72,** 2016]

A.3.3.240.4 Trouble Signal. Examples include off-normal outputs from integrity monitoring circuits, the light and sound from actuated trouble notification appliances, trouble data transmission to a supervising station, and so forth. [**72,** 2016]

3.3.241 Simple Asphyxiant Gas. See 3.3.140.15.

3.3.242 Smoke Alarm. A single or multiple-station alarm responsive to smoke. [**72,** 2016]

Exhibit 3.25 illustrates a typical single-station smoke alarm.

Exhibit 3.25

Single-Station Smoke Alarm. (Source: Gentex Corp., Zeeland, MI)

3.3.243* Smoke Barrier. A continuous membrane, or a membrane with discontinuities created by protected openings, where such membrane is designed and constructed to restrict the movement of smoke. [**5000,** 2018]

A.3.3.243 Smoke Barrier. A smoke barrier, such as a wall, floor, or ceiling assembly, might be aligned vertically or horizontally. A smoke barrier might or might not have a fire resistance rating. Application of smoke barrier criteria where required elsewhere in the *Code* should be in accordance with Section 12.9.

3.3.244 Smoke Compartment. See 3.3.67.2.

3.3.245* Smoke Partition. A continuous membrane that is designed to form a barrier to limit the transfer of smoke. [***101,*** 2018]

A.3.3.245 Smoke Partition. A smoke partition is not required to have a fire resistance rating. [***101,*** 2018]

3.3.246 Smoking. The use or carrying of a lighted pipe, cigar, cigarette, tobacco, or any other type of smoking substance.

3.3.247 Smoking Area. See 3.3.14.11.

3.3.248 Solid.

3.3.248.1* Combustible Particulate Solid. An oxidizable, solid-phase material comprising distinct particles or pieces. [**69,** 2014]

A.3.3.248.1 Combustible Particulate Solid. Combustible particulate solids include dusts, fibers, fines, chips, chunks, flakes, and mixtures of these. A definition of this breadth is necessary because it is crucial to address the fact that there is attrition of the material as it is conveyed. Pieces and particles rub against each other and collide with the walls of the duct as they travel through the system. The rubbing and collision break down the material and produce a mixture of pieces and much finer particles, called dusts. Consequently, it is expected that every conveying system produces dusts, regardless of the starting size of the material, as an inherent by-product of the conveying process. [**69,** 2014]

3.3.248.2* Flammable Solid. A solid substance, other than a substance defined as a blasting agent or explosive, that is liable to cause fire resulting from friction or retained heat from manufacture, that has an ignition temperature below 212°F (100°C), or that burns so vigorously or persistently when ignited that it creates a serious hazard. [**400,** 2016]

A.3.3.248.2 Flammable Solid. Flammable solids include finely divided solid materials that, when dispersed in air as a cloud, could be ignited and cause an explosion. [**400,** 2016]

3.3.249 Solid Material. A material that has a melting point, decomposes, or sublimes at a temperature greater than 68°F (20°C). [**5000,** 2018]

3.3.250 Solid Shelving. Shelving that is fixed in place, slatted, wire mesh, or other type of shelves located within racks. The area of a solid shelf is defined by perimeter aisle or flue space on all four sides or by placement of loads that block openings that otherwise serve as the required flue spaces. Solid shelves having an area equal to or less than 20 ft^2 (1.9 m^2) are defined as open racks. Shelves of wire mesh, slats, or other materials more than 50 percent open and where the flue spaces are maintained are defined as open racks. [**13,** 2016]

Exhibit 3.26 illustrates a storage rack with solid shelving, which is defined in 3.3.250.

3.3.251 Special Use. See 3.3.281.3.

3.3.252 Spray Area. See 3.3.14.12.

3.3.253* Spray Booth. A power-ventilated enclosure for a spray application operation or process that confines and limits the escape of the material being sprayed, including vapors, mists, dusts, and residues that are produced by the spraying operation and conducts or directs these materials to an exhaust system. [**33,** 2016]

Exhibit 3.26

Storage Rack with Solid Shelving.

Exhibit 3.27

Example of High-Piled Storage. (Courtesy of Telgian Corporation)

A.3.3.253 Spray Booth. Spray booths are manufactured in a variety of forms, including automotive refinishing, downdraft, open-face, traveling, tunnel, and updraft booths. This definition is not intended to limit the term *spray booth* to any particular design. The entire spray booth is part of the spray area. A spray booth is not a spray room. [**33,** 2016]

3.3.254* Spray Room. A power-ventilated fully enclosed room used exclusively for open spraying of flammable or combustible materials. [**33,** 2016]

A.3.3.254 Spray Room. The entire spray room is considered part of the spray area. A spray booth is not a spray room. [**33,** 2016]

3.3.255 Standard Cubic Foot (scf) of Gas. An amount of gas that occupies one cubic foot at an absolute pressure of 14.7 psi (101 kPa) and a temperature of 70°F (21°C). [**55,** 2016]

3.3.256 Standard Temperature and Pressure (STP). A temperature of 70°F (21°C) and a pressure of 1 atmosphere (14.7 psi or 760 mm Hg).

3.3.257 Standpipe System. See 3.3.267.13.

3.3.258 Storage.

3.3.258.1 Banded Tire Storage. Storage in which a number of tires are strapped together.

3.3.258.2 Cartoned Storage. Storage consisting of corrugated cardboard or paperboard containers that fully enclose the commodity.

3.3.258.3 Detached Storage. Storage in a separate building or in an outside area located away from all structures.

3.3.258.4 High-Piled Storage. Solid-piled, palletized, rack storage, bin box, and shelf storage in excess of 12 ft (3.7 m) in height. [**13,** 2016]

Storage heights exceeding 12 ft (3.7 m) are considered high-piled storage by NFPA 13, *Standard for the Installation of Sprinkler Systems*. See Section 5.6 and Chapter 12 of NFPA 13 for the relevant sprinkler system criteria. Exhibit 3.27 illustrates an example of high-piled storage consisting of on-floor, palletized, and future rack storage.

3.3.258.5 Isolated Storage. Storage in a different storage room or in a separate and detached building located at a safe distance.

3.3.258.6 Laced Tire Storage. Tires stored where the sides of the tires overlap, creating a woven or laced appearance. *[See Figure A.34.8.1(g).]* [**13,** 2016]

3.3.258.7* Miscellaneous Tire Storage. The storage of rubber tires that is incidental to the main use of the building; storage areas do not exceed 2000 ft^2 (186 m^2) and on-tread storage piles, regardless of storage method, do not exceed 25 ft (7.6 m) in the direction of the wheel holes. Acceptable storage arrangements include (a) on-floor, on-side storage up to 12 ft (300 mm) high; (b) on-floor, on-tread storage up to 5 ft (1.5 m) high; (c) double-row or multirow fixed or portable rack storage on-side or on-tread up to 5 ft (1.5 m) high; (d) single-row fixed or portable rack storage on-side or on-tread up to 12 ft (3700 mm) high; and (e) laced tires in racks up to 5 ft (1.5 m) in height. [**13,** 2016]

A.3.3.258.7 Miscellaneous Tire Storage. The limitations on the type and size of storage are intended to identify those situations where tire storage is present in limited quantities and incidental to the main use of the building. Occupancies such as aircraft hangars, automobile dealers, repair garages, retail storage facilities, automotive and truck assembly plants, and mobile home assembly plants are types of facilities where miscellaneous storage could be present. [**13,** 2016]

3.3.258.8 On-Side Tire Storage. Tires stored horizontally or flat. [**13,** 2016]

3.3.258.9 On-Tread Tire Storage. Tires stored vertically or on their treads. [**13,** 2016]

An example of on-side tire storage on portable racks is shown in Exhibit 3.28. Exhibit 3.29 shows an example of on-tread tire storage on racks.

3.3.258.10 Palletized Tire Storage. Storage on portable racks of various types utilizing a conventional pallet as a base. [**13,** 2016]

3.3.258.11 Segregated Storage. Storage located in the same room or inside area that is physically separated by distance from incompatible materials.

3.3.258.12 Yard Storage. Storage of commodities in outdoor areas.

3.3.259 Storage Aids. Commodity storage devices, such as pallets, dunnage, separators, and skids. [**13,** 2016]

Exhibit 3.28

On-Side Tire Storage on Portable Racks. (Courtesy of Ford Motor Company)

Exhibit 3.29

On-Tread Tire Storage on Racks.

3.3.260 Story. The portion of a building located between the upper surface of a floor and the upper surface of the floor or roof next above. [**5000,** 2018]

The definition of *story* includes a usable basement. This detail is important because several of the requirements in this *Code* are based on the number of stories in a building. Therefore, if a requirement applies to a three-story building, and the building in question includes a basement and two stories above grade, the requirement would apply to the building. Where this *Code* uses the phrase *stories in height,* the determination of the number of stories is based on the story that meets the definition of the phrase *level of exit discharge* in accordance with 4.6.3 of NFPA *101.*

3.3.260.1 Occupiable Story. A story occupied by people on a regular basis. [***101,*** 2018]

3.3.261 Street. A public thoroughfare that has been dedicated for vehicular use by the public and can be used for access by fire department vehicles. [***101,*** 2018]

3.3.262* Street Floor. A story or floor level accessible from the street or from outside the building at the finished ground level, with the floor level at the main entrance located not more than three risers above or below the finished ground level, and arranged and utilized to qualify as the main floor. [***101,*** 2018]

A.3.3.262 Street Floor. Where, due to differences in street levels, there are two or more stories accessible from the street, each is a street floor. Where there is no floor level within the specified limits for a street floor above or below ground level, the building has no street floor.

3.3.263 Structural Element. The columns and girders, beams, trusses, joists, braced frames, moment-resistant frames, and vertical and lateral resisting elements, and other framing members that are designed to carry any portion of the dead or live load and lateral forces, that are essential to the stability of the building or structure. [**5000,** 2018]

3.3.264* Structure. That which is built or constructed. [***101,*** 2018]

Δ **A.3.3.264 Structure.** The term *structure* is to be understood as if followed by the words *or portion thereof. (See also 3.3.29, Building.)* [***101,*** 2018]

N **3.3.265* Suburb or Suburban.** Those moderately inhabited areas with population densities of at least 500 persons per square mile but less than 1000 persons per square mile. [**1142,** 2017]

N **A.3.3.265 Suburb or Suburban.** Suburban areas can include populous towns or large villages or be located outside the official limits of a densely settled city of 2500 to 50,000 people per census block, or those areas that interface with the outer rim of an urban cluster (UC). Suburban communities usually exist within commuting distance of urban areas but exhibit their own jurisdictional autonomy. [**1142,** 2017]

3.3.266 Summarily Abate. To immediately judge a condition to be a fire hazard to life or property and to order immediate correction of such condition.

3.3.267 System. Several items of equipment assembled, grouped, or otherwise interconnected for the accomplishment of a purpose or function.

Δ ***3.3.267.1* Bulk Hydrogen Compressed Gas System.*** A gaseous hydrogen (GH_2) system with a storage capacity of more than 5000 scf (141.6 Nm^3) of compressed hydrogen gas. [**55,** 2016]

N ***A.3.3.267.1 Bulk Hydrogen Compressed Gas System.*** The bulk system terminates at the source valve, which is the point where the gas supply, at service pressure, first enters the supply line, or at a piece of equipment that utilizes the hydrogen gas, such as a hydrogen dispenser. The containers are either stationary or movable, and the source gas for the system is stored as a compressed gas.

Bulk hydrogen compressed gas systems can include a bulk storage source, transfer piping and manifold system, compression system, and other components. The gaseous source can include a tube trailer, tube bank, or other high pressure storage vessels used to serve the piping system that transports hydrogen to the end user. Compressors can be installed downstream of the storage supply to boost the pressure of the source gas, and intermediate high pressure storage might be present. This is done where the end use requires hydrogen at a pressure higher than that of the bulk supply. In these instances, there may be intermediate storage vessels used to store the gas at elevated pressures. It is not uncommon for the bulk supply as delivered to be furnished at nominal gauge pressure of 3000 psi (20,684 kPa), and the intermediate high pressure storage to be stored at gauge pressures up to 15,000 psi (103,421 kPa). See Figure A.3.3.267.1(a) through Figure A.3.3.267.1(f).

3.3.267.2 Bulk Inert Gas System. An assembly of equipment that consists of, but is not limited to, storage containers, pressure regulators, pressure relief devices, vaporizers, manifolds, and piping, with a storage capacity of more than 20,000 scf (566 Nm^3) of inert gas, including unconnected reserves on hand at the site, and that terminates at the source valve. [**55,** 2016]

Δ ***3.3.267.3 Bulk Liquefied Hydrogen System.*** A liquefied hydrogen (LH_2) system with a storage capacity of more than 39.7 gal (150 L) of liquefied hydrogen. [**55,** 2016]

3.3.267.4* Bulk Oxygen System. An assembly of equipment, such as oxygen storage containers, pressure regulators, pressure relief devices, vaporizers, manifolds, and interconnecting piping, that has a storage capacity of more than 20,000 scf (566 Nm^3) of oxygen and that terminates at the source valve. [**55,** 2016]

A.3.3.267.4 Bulk Oxygen System. The bulk oxygen system terminates at the source valve, which is commonly the point where oxygen at service pressure first enters the supply line or a piece of equipment that utilizes the oxygen gas or liquid. The oxygen containers are either stationary or movable, and the oxygen is stored as a compressed gas or cryogenic fluid.

Bulk oxygen systems can be used to supply gas in either its compressed gaseous or liquefied form. Systems that may be used to supply both gaseous and liquid forms are referred to as hybrid systems. The following bulk oxygen systems are typical of those in use:

(1) When the primary supply of the gas as stored is from a compressed gaseous source that is used in the compressed and gaseous form, the bulk oxygen system is said to be a bulk compressed oxygen gas system.
(2) When the primary supply of the gas as stored is in a liquid form and the system is designed to transfer only liquid, the system is said to be a bulk liquefied oxygen system.

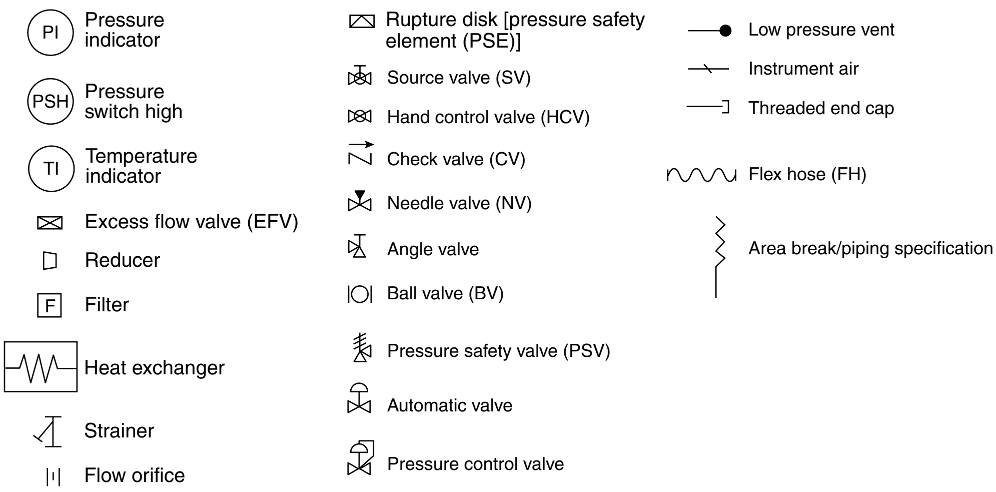

FIGURE A.3.3.267.1(a) *Symbol Legend for Figure A.3.3.258.1(b) through Figure A.3.3.258.1(f). [**55,** 2016]*

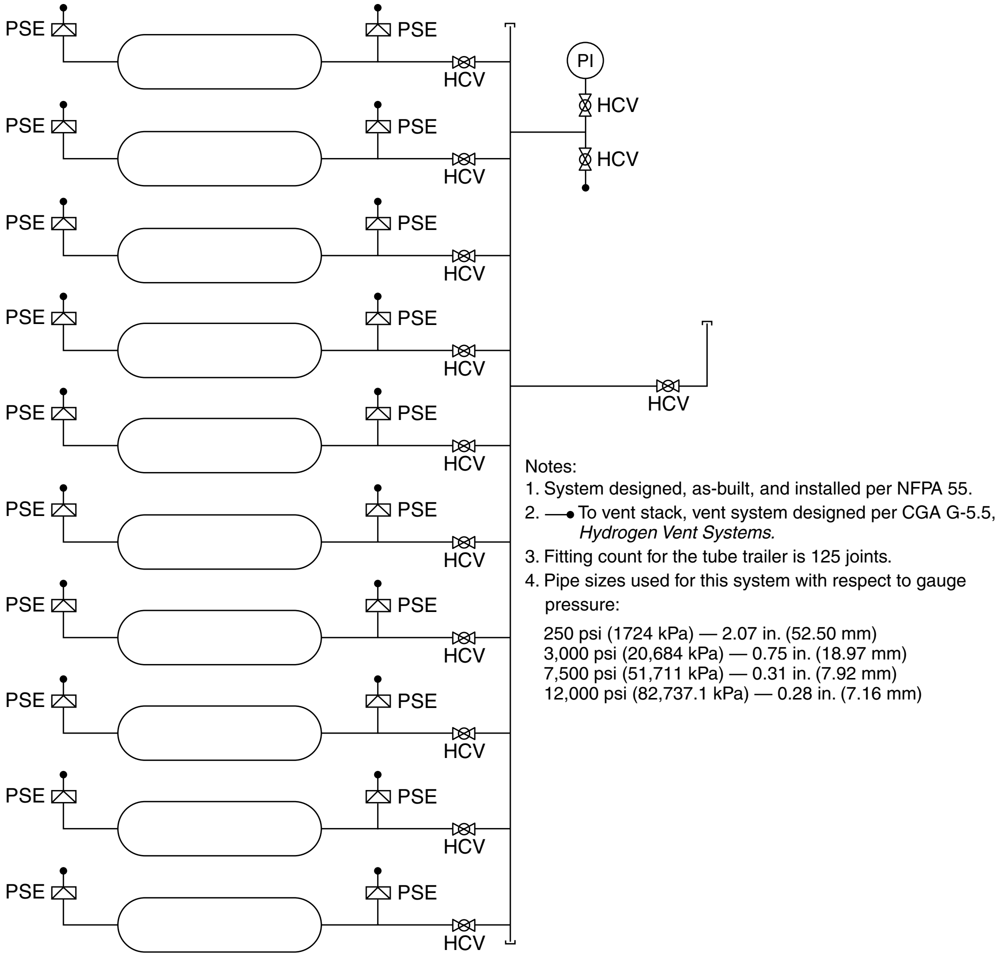

FIGURE A.3.3.267.1(b) *Typical Tube Trailer. [**55,** 2016]*

(3) When the primary supply of the gas as stored is in a liquid form and the system is designed to transfer or store the gas in a compressed gaseous form, with or without a feature that may also allow the subsequent transfer and use of liquid, the bulk oxygen system is said to be a hybrid bulk oxygen system. For the purposes of the application of the code, a hybrid system is viewed as a bulk liquefied oxygen system.

[**55,** 2016]

3.3.267.5 Central Station Service Alarm System. A system or group of systems in which the operations of circuits and devices are transmitted automatically to, recorded in, maintained by, and supervised from a listed central station that has competent and experienced servers and operators who, upon receipt of a signal, take such action as required by *NFPA 72*. Such service is to be controlled and operated by a person, firm, or corporation whose business is the furnishing, maintaining, or monitoring of supervised alarm systems. [**72,** 2016]

An example of a central station fire alarm system monitoring facility is illustrated in Exhibit 3.30.

3.3.267.6 Compressed Gas System. An assembly of equipment designed to contain, distribute, or transport compressed gases. [**318,** 2018]

3.3.267.7 Continuous Gas Detection System. A gas detection system in which the instrument is maintained in continuous operation and the interval between sampling of any point does not exceed 30 minutes. [**55,** 2016]

3.3.267.8 Cylinder Containment System. A gastight recovery system comprising equipment or devices that can be placed over a leak in a compressed gas container, thereby stopping or controlling the escape of gas from the leaking container. [**55,** 2016]

3.3.267.9 Dedicated Smoke-Control System. A system that is intended for the purpose of smoke control only, which are separate systems of air moving and distribution equipment that do not function under normal building operating conditions.

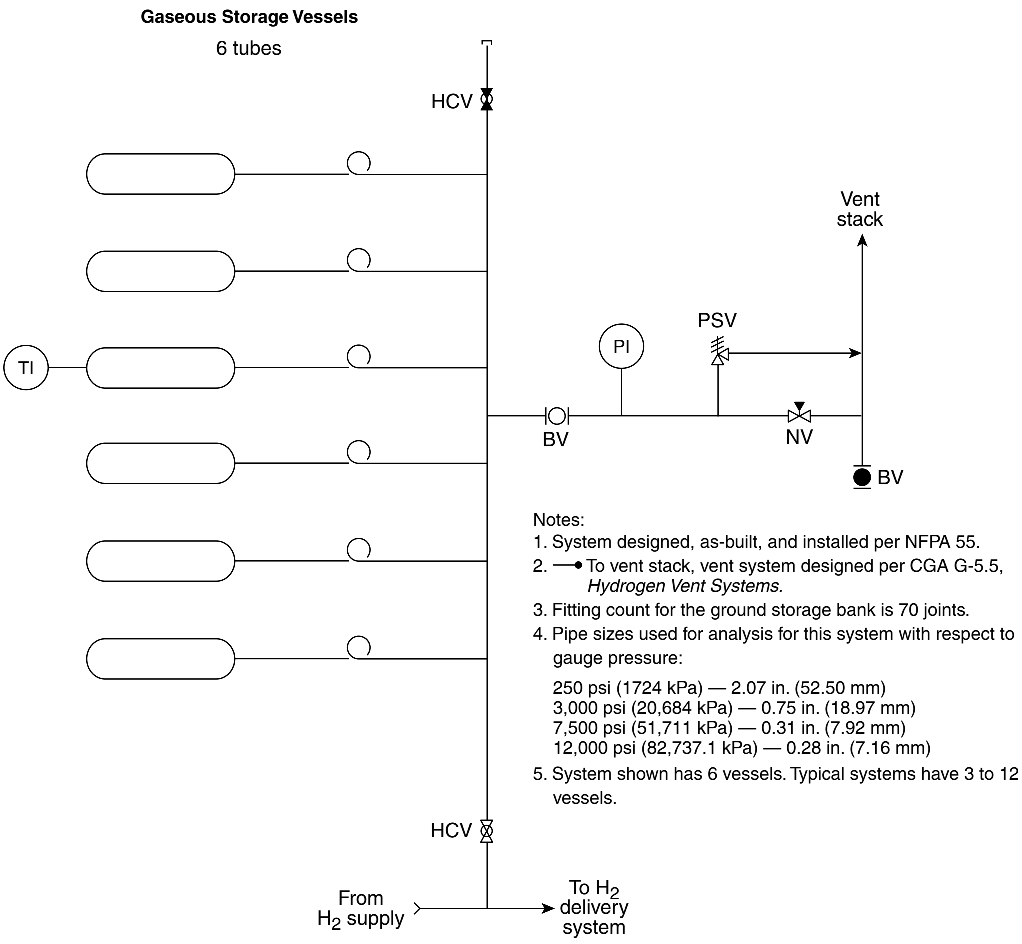

*FIGURE A.3.3.267.1(c) Typical Bulk Compressed Gaseous Storage System. [**55,** 2016]*

Exhibit 3.30

Central Station with Display in Background Indicating Signal Traffic and Availability to Process Incoming Signals. (Source: SimplexGrinnell, Westminster, MA)

3.3.267.10 Fire Alarm System. A system or portion of a combination system that consists of components and circuits arranged to monitor and annunciate the status of fire alarm or supervisory signal-initiating devices and to initiate the appropriate response to those signals. [**72,** 2016]

The definition of *fire alarm system* includes fire alarm systems that provide a specific function or functions, such as sprinkler supervisory service.

3.3.267.11 Fire Protection System. Any fire alarm device or system or fire-extinguishing device or system, or combination thereof, that is designed and installed for detecting, controlling, or extinguishing a fire or otherwise alerting occupants, or the fire department, or both, that a fire has occurred. [**1141,** 2017]

3.3.267.12 Nondedicated Smoke-Control System. A smoke-control system that shares components with some other system(s), such as the building HVAC system, which changes its mode of operation to achieve the smoke-control objective.

3.3.267.13* Standpipe System. An arrangement of piping, valves, hose connections, and associated equipment installed

Notes:
1. System designed, as-built, and installed per NFPA 55.
2. —• To vent stack, vent system designed per CGA G-5.5, *Hydrogen Vent Systems.*
3. Fitting count for the pressure control manifold is 111 joints.
4. Fitting count for the stanchion is 29 joints.
5. Pipe sizes used for analysis for this system with respect to gauge pressure:
   250 psi (1724 kPa) — 2.07 in. (52.50 mm)
   3,000 psi (20,684 kPa) — 0.75 in. (18.97 mm)
   7,500 psi (51,711 kPa) — 0.31 in. (7.92 mm)
   12,000 psi (82,737.1 kPa) — 0.28 in. (7.16 mm)

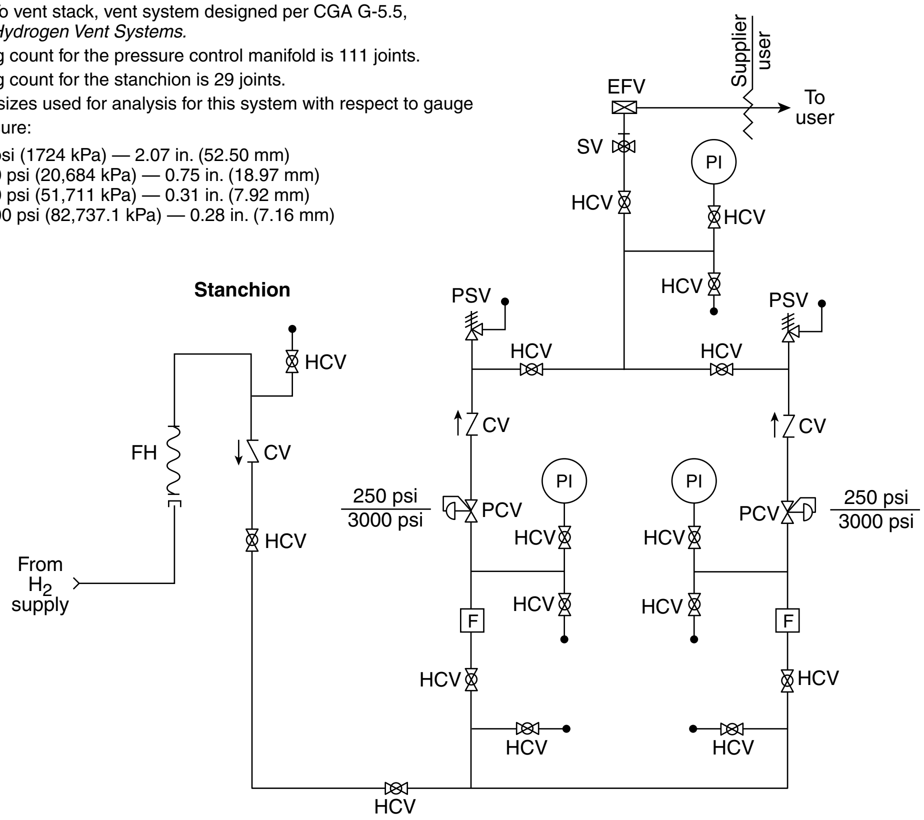

FIGURE A.3.3.267.1(d) Typical Tube Trailer Discharge Stanchion and Pressure Control Manifold. [55, 2016]

in a building or structure, with the hose connections located in such a manner that water can be discharged in streams or spray patterns through attached hose and nozzles, for the purpose of extinguishing a fire, thereby protecting a building or structure and its contents in addition to protecting the occupants. [**14,** 2016]

A.3.3.267.13 Standpipe System. This arrangement is accomplished by means of connections to water supply systems or by means of pumps, tanks, and other equipment necessary to provide an adequate supply of water to the hose connections. [**14,** 2016]

3.3.267.14 Treatment System. An assembly of equipment capable of processing a hazardous gas and reducing the gas concentration to a predetermined level at the point of discharge from the system to the atmosphere. [**55,** 2016]

3.3.267.15* Vapor Processing System. A system designed to capture and process vapors displaced during transfer or filling operations by use of mechanical or chemical means. [**30,** 2018]

A.3.3.267.15 Vapor Processing System. Examples are systems using blower-assist for capturing vapors and refrigeration, absorption, and combustion systems for processing vapors. [**30,** 2018]

3.3.267.16* Vapor Recovery System. A system designed to capture and retain, without processing, vapors displaced during transfer or filling operations. [**30,** 2018]

A.3.3.267.16 Vapor Recovery System. Examples are balanced-pressure vapor displacement systems and vacuum-assist systems without vapor processing. [**30,** 2018]

3.3.268 Tank.

3.3.268.1 Aboveground Storage Tank. A horizontal or vertical tank that is listed and intended for fixed installation, without backfill, above or below grade and is used within the scope of its approval or listing. [**30A,** 2018]

See Exhibit 3.31 for an illustration of horizontal aboveground atmospheric storage tanks.

3.3.268.2 Aboveground Tank. A tank that is installed above grade, at grade, or below grade without backfill. [**30,** 2018]

Exhibit 3.32 illustrates aboveground tanks installed above grade, at grade, and below grade without backfill.

3.3.268.2.1 Protected Aboveground Tank. An atmospheric aboveground storage tank with integral secondary containment

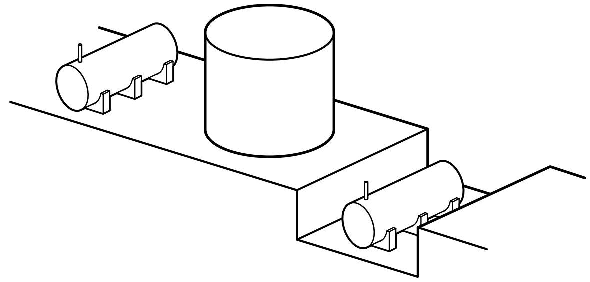
Exhibit 3.31

Horizontal aboveground atmospheric storage tanks.

and thermal insulation that has been evaluated for resistance to physical damage and for limiting the heat transferred to the primary tank when exposed to a hydrocarbon pool fire and is listed in accordance with ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids,* or an equivalent test procedure. [**30:**22.2.3]

3.3.268.3 ASME Tank. See 3.3.70.1, ASME Container.

Exhibit 3.32



Aboveground tanks installed above grade, at grade, and below grade without backfill.

3.3.268.4* Portable Tank. Any vessel having a liquid capacity over 60 gal (230 L) intended for storing liquids and not intended for fixed installation. [**30,** 2018]

The term *portable tank*, in the context of this *Code*, refers strictly to a steel shipping vessel of 60 gal to 660 gal (227 L to 2500 L) capacity used to transport liquid commodities and constructed according to specifications established by the DOT in Title 49, *Code of Federal Regulations,* Part 178.245, "Specification 51 — Steel Portable Tanks." For the purposes of the *Code* and this

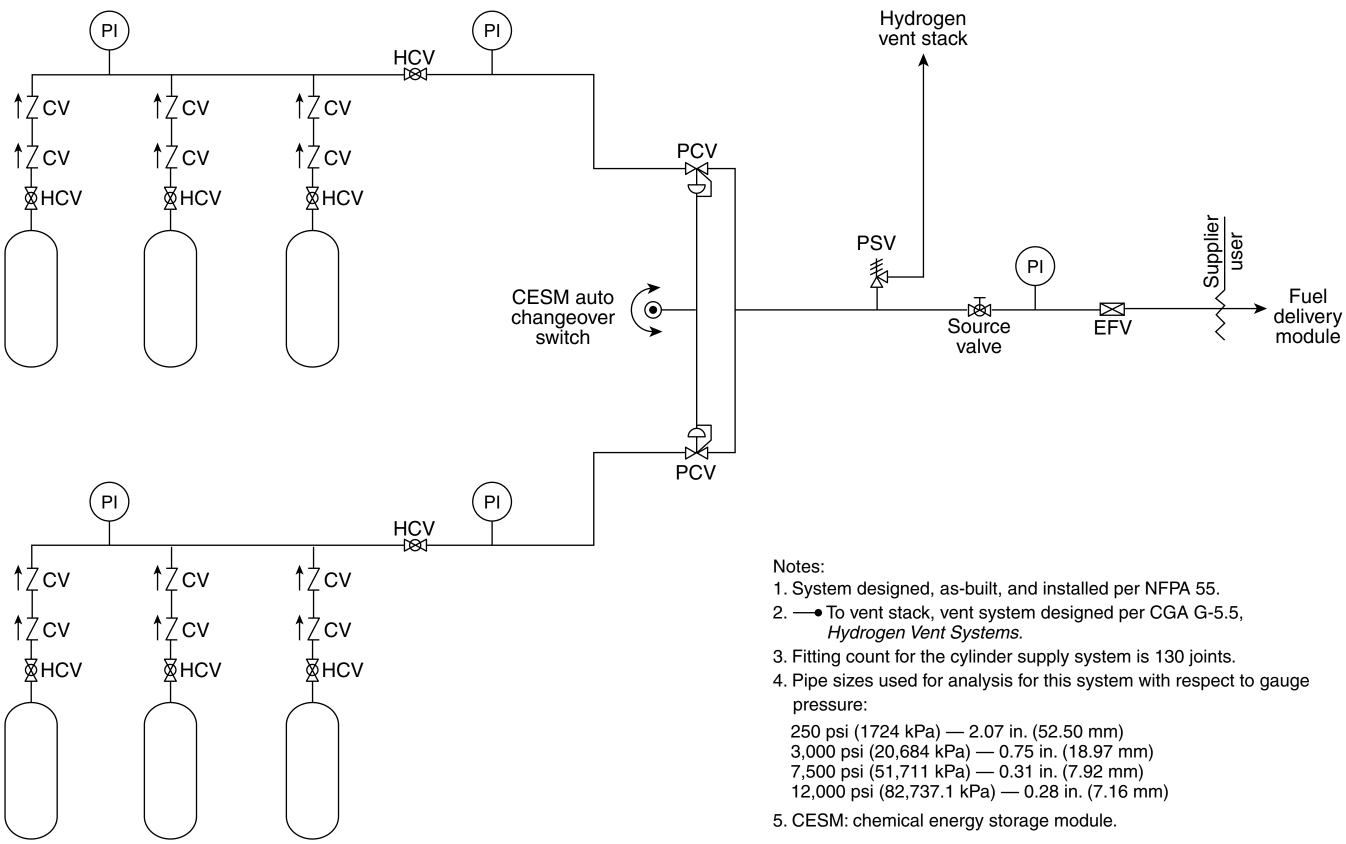


FIGURE A.3.3.267.1(e) *Typical Chemical Energy Storage Module (CESM). [**55,** 2016]*

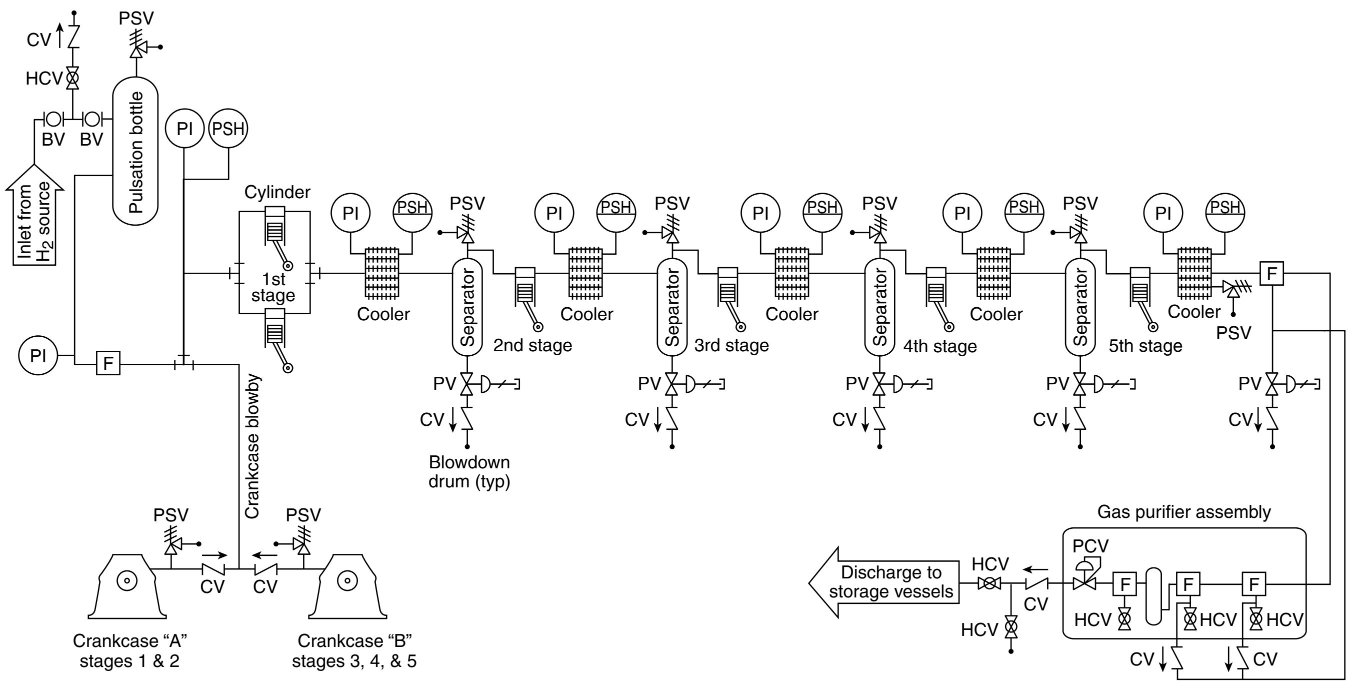

Notes:
1. System designed, as-built, and installed per NFPA 55.
2. —● To vent stack, vent system designed per CGA G-5.5, *Hydrogen Vent Systems.*
3. Fitting count for the compression system is 225 joints.
4. Pipe sizes used for analysis for this system with respect to gauge pressure:

250 psi (1724 kPa) — 2.07 in. (52.50 mm)
3,000 psi (20,684 kPa) — 0.75 in. (18.97 mm)
7,500 psi (51,711 kPa) — 0.31 in. (7.92 mm)
12,000 psi (82,737.1 kPa) — 0.28 in. (7.16 mm)

FIGURE A.3.3.267.1(f) *Typical Compressor Module. [**55,** 2016]*

handbook, the term *portable tank* can be considered a subset of the term *intermediate bulk container.*

Any vessel referred to as a portable tank that exceeds the maximum capacity specified for an intermediate bulk container of 793 gal (3000 L) is to be treated as a storage tank and is governed by Chapters 21 and 22 of NFPA 30. In the transportation arena, many intermodal tanks, such as the one shown in Exhibit 3.5, are referred to colloquially as portable tanks. In this handbook, the term *intermediate bulk container* also refers to Specification 51 portable tanks as already described.

A.3.3.268.4 Portable Tank. A portable tank does not include any cylinder having less than 1000 lb (453.5 kg) water capacity, cargo tank, tank car tank, or trailers carrying cylinders of over 1000 lb (453.5 kg) water capacity. [**55,** 2016]

3.3.268.5 Secondary Containment Tank. A tank that has an inner and outer wall with an interstitial space (annulus) between the walls and that has a means for monitoring the interstitial space for a leak. [**30,** 2018]

A secondary containment tank is an aboveground variant of the double-walled tanks commonly used underground. See Exhibit 3.33. They typically are of double-wall design with means for testing the annular space for a leak. Secondary containment tanks are discussed in more detail in 66.22.11.4. Note that any protected tank that is listed to ANSI/UL 2085, *Standard for*

Exhibit 3.33

Typical secondary containment tank. (Courtesy of Modern Welding Co.)

Protected Aboveground Tanks for Flammable and Combustible Liquids, is also a secondary containment tank. A fire-resistant tank listed to UL 2080, *Standard for Fire Resistant Tanks for Flammable and Combustible Liquids*, might or might not be of secondary containment design.

3.3.268.6* Stationary Tank. A packaging designed primarily for stationary installations not intended for loading, unloading, or attachment to a transport vehicle as part of its normal operation in the process of use. [**55,** 2016]

A.3.3.268.6 Stationary Tank. A stationary tank does not include a cylinder having less than 1000 lb (453.5 kg) water capacity. [**55,** 2016]

3.3.268.7 Storage Tank. Any vessel having a liquid capacity that exceeds 60 gal (230 L), is intended for fixed installation, and is not used for processing. [**30,** 2018]

Any fixed tank, including a portable tank as defined in 3.3.268.4, is considered a storage tank and is thus subject to the requirements of Section 66.21 and either Section 66.22 or Section 66.23, if it is connected to a fixed piping system. The phrase *not used for processing* is intended to minimize conflict between storage tanks, as defined in 3.3.268.7, and tanks that are part of a unit operation or unit process. The lower limit of 60 gal (230 L) was established years ago in NFPA 30 and coincided with the original NFPA 30 definition of the term *container* [up to 60 gal (230 L)] and the lower limit of its definition of the term *portable tank*. Any fixed tank of 60 gal (230 L) or less is not considered to be within the scope of Sections 66.21 through 66.23.

3.3.269 Temporary Wiring. Approved wiring for power and lighting during a period of construction, remodeling, maintenance, repair, or demolition, and decorative lighting, carnival power and lighting, and similar purposes.

3.3.270 Tire.

3.3.270.1 Rubber Tires. Pneumatic tires for passenger automobiles, aircraft, light and heavy trucks, trailers, farm equipment, construction equipment (off-the-road), and buses. [**13,** 2016]

3.3.270.2 Scrap Tire. A tire that can no longer be used for its original purpose due to wear or damage.

3.3.271 TC. Transport Canada. [**55,** 2016]

3.3.272 Toxic Material. See 3.3.180.14.

3.3.273* Traffic Calming Device. A roadway design element utilized to reduce vehicle speeds, decrease motor vehicle volumes, and increase safety for pedestrians and nonmotorized vehicles.

A.3.3.273 Traffic Calming Device. Traffic calming devices typically consist of, but are not limited to, speed bumps, speed humps, and traffic circles.

N **3.3.274* Transfilling.** The process of transferring a gas, either in compressed or liquid form from one cylinder or container to another cylinder or container.

N **A.3.3.274 Transfilling.** Transfilling usually occurs from a bulk container to a smaller container, such as filling a small compressed gas cylinder.

3.3.275* Tube Trailer. A truck or semitrailer on which a number of very long compressed gas tubular cylinders have been mounted and manifolded into a common piping system. [**55,** 2016]

Δ **A.3.3.275 Tube Trailer.** The characteristic internal water volume of individual tubular cylinders ranges from 43 scf to 93 scf (1218 L to 2632 L) or a water capacity of 2686 lb to 5803 lb (1218 kg to 2632 kg). [**55,** 2016]

3.3.276 Unauthorized Discharge. A release or emission of materials in a manner that does not conform to the provisions of this *Code* or applicable public health and safety regulations.

3.3.277 Unit Operation or Unit Process. A segment of a physical or chemical process that might or might not be integrated with other segments to constitute the manufacturing sequence. [**30,** 2018]

3.3.278 Unit Process. See 3.3.277, Unit Operation or Unit Process.

3.3.279 Unit (Vessel), Operating or Process. See 3.3.196.

3.3.280 Unstable (Reactive) Material. See 3.3.180.15.

3.3.281* Use. To place a material, including solids, liquids, and gases into action. [**400,** 2016]

A.3.3.281 Use. Examples of use include, but are not limited to, blending, mixing, reacting, distillation, heating or cooling, pumping, compressing, drying, screening, filling, loading and unloading, repackaging, scrubbing, absorbing, neutralizing, and incineration. [**400,** 2016]

3.3.281.1* Closed System Use. Use of a solid or liquid hazardous material in a closed vessel or system that remains closed during normal operations where vapors emitted by the product are not liberated outside of the vessel or system and the product is not exposed to the atmosphere during normal operations, and all uses of compressed gases. [**400,** 2016]

A.3.3.281.1 Closed System Use. Examples of closed systems for solids and liquids include reaction process operations and product conveyed through a piping system into a closed vessel, system, or piece of equipment. [**400,** 2016]

3.3.281.2* Open System Use. Use of a solid or liquid hazardous material in a vessel or system that is continuously open to the atmosphere during normal operations and where vapors are liberated, or the product is exposed to the atmosphere during normal operations. [**400,** 2016]

A.3.3.281.2 Open System Use. Examples of open systems for solids and liquids include dispensing from or into open beakers or containers, and dip tank and plating tank operations. [**400,** 2016]

3.3.281.3 Special Use. A use that includes, but is not limited to, events or occurrences during which life safety–threatening situations or fire hazards exist or are likely to exist as determined by the AHJ.

3.3.282* Valve.

N **A.3.3.282** See also A.3.3.27.

3.3.282.1 Indicating Valve. A valve that has components that show if the valve is open or closed. Examples are outside screw and yoke (OS&Y) gate valves and underground gate valves with indicator posts.

Exhibit 3.34 and Exhibit 3.35 illustrate types of indicating valves.

Exhibit 3.34

Vertical indicator post.

Exhibit 3.35

Outside screw and yoke (OS&Y) gate valve.

3.3.282.2 Reduced Flow Valve. A valve equipped with a restricted flow orifice that is designed to reduce the maximum flow from the valve under full flow conditions.

3.3.282.3 Valve Outlet Cap or Plug. A removable device that forms a gastight seal on the outlet to the control valve that is provided on a source containing a compressed gas or cryogenic fluid. [**55,** 2016]

3.3.282.4 Valve Protection Cap. A rigid, removable cover provided for container valve protection during handling, transportation, and storage. [**55,** 2016]

3.3.282.5 Valve Protection Device. A device attached to the neck ring or body of a cylinder for the purpose of protecting the cylinder valve from being struck or from being damaged by the impact resulting from a fall or an object striking the cylinder.

3.3.283* Vapor Pressure. The pressure, measured in pounds per square inch, absolute (psia), exerted by a liquid, as determined by ASTM D323, *Standard Test Method for Vapor Pressure of Petroleum Products (Reid Method).* [**30,** 2018]

A.3.3.283 Vapor Pressure. Vapor pressure is a measure of the pressure that the liquid exerts against the atmosphere above it. Just as the atmosphere exerts pressure on the surface of the liquid, the liquid pushes back. Vapor pressure is normally less than atmospheric pressure and is a measure of the liquid's tendency to evaporate (i.e., to move from the liquid to the gaseous state). This tendency is also referred to as volatility, thus the use of the term *volatile* to describe liquids that evaporate very easily. The higher the vapor pressure, the greater the rate of evaporation and the lower the boiling point. Simply put, this means more vapors and increased fire risk. [**30:**A.4.2.6]

3.3.284 Vapor Processing System. See 3.3.267.15.

3.3.285 Vapor Recovery System. See 3.3.267.16.

3.3.286 Warehouse.

Δ ***3.3.286.1 General-Purpose Warehouse.*** A separate, detached building or portion of a building used only for warehousing-type operations and classified as a "storage — low hazard" or "storage — ordinary hazard" occupancy by the building code and by NFPA *101*. [**30,** 2018]

3.3.286.2 Liquid Warehouse. A separate, detached building or an attached building that is used for warehousing-type operations for liquids and whose exterior wall comprises at least 25 percent of the building perimeter. [**30,** 2018]

One key distinction between a general-purpose warehouse and a liquid warehouse is that the former handles a variety of combustible commodities, some of which *might* be flammable or combustible liquids, while the latter handles liquids almost exclusively. Regulations governing each type vary significantly.

3.3.287 Water Capacity. The amount of water at 60°F (16°C) required to fill a container. [**58,** 2017]

The water capacity of a container is the maximum amount of water the container can hold at 60°F (16°C). The water capacity (full of water) is expressed in pounds (kilograms) for cylinders and gallons (cubic meters) for ASME containers.

The water capacity is different from the propane capacity of a container. Water capacity is measured with the container 100 percent full, whereas the maximum permitted filling limit allowed for propane is typically set at 80 percent of the water capacity, although there are exceptions to this practice as described in Chapter 7.

For example, the typical 1000 gal (3.8 m^3) water capacity ASME container is allowed to hold about 800 gal (3 m^3) of propane (80 percent capacity). However, a 30,000 gal (114 m^3) container can be filled to 25,800 gal (98 m^3) of propane [86 percent capacity at 40°F (4°C)]. Larger containers minimize extreme swings in the temperature of the total product due to daytime solar heating and night cooling. This reduces expansion and contraction of the propane, which indirectly reduces large pressure swings.

The maximum propane capacity of a cylinder is determined by its water capacity, but the capacity is given in pounds (kilograms). For cylinders measured by weight, the weight allowance for propane is 42 percent of the weight of the water. This percentage is determined by first taking into account the density difference between propane and water before an additional reduction for expansion/contraction allowances, similar to that for ASME containers, as shown in the following equation:

$$\begin{gathered}84\%\ \text{(expansion and contraction)} \times 50\%\ \text{(density)}\\ \times\ \text{water weight [lb]}\\ = 42\% \times \text{water weight [lb]}\\ = \text{propane weight [lb]}\end{gathered}$$

If the water capacity of a cylinder is marked as being 48 lb (36 kg), the propane capacity is 42 percent of 48 lb (36 kg), or about 20 lb (9 kg).

3.3.288* Wharf. A structure at the shoreline that has a platform built along and parallel to a body of water with either an open deck or a superstructure. [**307,** 2016]

A.3.3.288 Wharf. The terms *wharf* and *pier* are used interchangeably. [**307,** 2016]

3.3.289* Wildland/Urban Interface. An area where wildland fuels abut structures, with a clear line of demarcation between residential, business, and public structures and wildland fuels. [**1144,** 2018]

N **A.3.3.289 Wildland/Urban Interface.** The term *wildland/urban interface* can distort the perception of the primary issue. It can direct attention to "where" structures are located (e.g., at the edge of communities near the wildland) rather than if they are highly ignitable. And if so, the focus on "where" can result in a concern about things that will not make a big difference in reducing structure loss (i.e., how fire fighters and equipment get there, what type of fire equipment is needed, and the location of fire hydrants and water sources). How wide the roads are and where the fire hydrants are located become of little value if there are more structures at risk than equipment to protect them, or if it is too dangerous to safely be there with fire-fighting forces. [**1144,** 2018]

The essence of this issue is not where structures and domestic landscapes adjoin wildland, but the location, density, and availability of ignitable structures. Which structures are at the greatest risk, ignition-resistant homes bordering the wildland or a dense subdivision with wood shingle roofs several miles away from wildland fuels? The wildland/urban interface is not geographic location, but rather a set of conditions that can exist in many communities. [**1144,** 2018]

3.3.290 Wood Panel. Board or sheet made from veneers, particles, or fibers of wood and includes plywood, oriented strandboard, and similar wood products.

3.3.291 Written Notice. A notification in writing delivered in person to the individual or parties intended, or delivered at, or sent by certified or registered mail to, the last residential or business address of legal record.

3.4 Special Performance-Based Definitions

3.4.1 Alternative Calculation Procedure. A calculation procedure that differs from the procedure originally employed by the design team but that provides predictions for the same variables of interest. [***101,*** 2018]

3.4.2 Analysis.

3.4.2.1 Sensitivity Analysis. An analysis performed to determine the degree to which a predicted output will vary given a specified change in an input parameter, usually in relation to models. [**5000,** 2018]

3.4.2.2 Uncertainty Analysis. An analysis intended to (1) identify key sources of uncertainties in the predictions of a model, (2) assess the potential impacts of these uncertainties on the predictions, and (3) assess the likelihood of these potential impacts. Per this definition, sensitivity analysis performs some but not all of the functions of uncertainty analysis. [**805,** 2015]

3.4.3 Data Conversion. The process of developing the input data set for the assessment method of choice. [***101,*** 2018]

3.4.4 Design Fire Scenario. See 3.4.9.1.

3.4.5* Design Specification. A building characteristic and other conditions that are under the control of the design team. [**5000,** 2018]

A.3.4.5 Design Specification. Design specifications include both hardware and human factors, such as the conditions produced by maintenance and training. For purposes of performance-based design, the design specifications of interest are those that affect the ability of the building to meet the stated goals and objectives. [**5000,** 2018]

3.4.6 Design Team. A group of stakeholders including, but not limited to, representatives of the architect, client, and any pertinent engineers and other designers. [***101,*** 2018]

3.4.7* Exposure Fire. A fire that starts at a location that is remote from the area being protected and grows to expose that which is being protected. [***101,*** 2018]

A.3.4.7 Exposure Fire. An exposure fire usually refers to a fire that starts outside a building, such as a wildlands fire or vehicle fire, and that, consequently, exposes the building to a fire. [***101,*** 2018]

3.4.8* Fire Model. Mathematical prediction of fire growth, environmental conditions, and potential effects on structures, systems, or components based on the conservation equations or empirical data. [**805,** 2015]

Δ **A.3.4.8 Fire Model.** Due to the complex nature of the principles involved, models are often packaged as computer software. Any relevant input data, assumptions, and limitations needed to properly implement the model will be attached to the fire models. [***101,*** 2018]

3.4.9* Fire Scenario. A set of conditions that defines the development of fire, the spread of combustion products throughout a building or portion of a building, the reactions of people to fire, and the effects of combustion products. [***101,*** 2018]

A.3.4.9 Fire Scenario. A fire scenario defines the conditions under which a proposed design is expected to meet the fire safety goals. Factors typically include fuel characteristics, ignition sources, ventilation, building characteristics, and occupant locations and characteristics. The term *fire scenario* includes more than the characteristics of the fire itself but excludes design specifications and any characteristics that do not vary from one fire to another; the latter are called assumptions. The term *fire scenario* is used here to mean only those specifications required to calculate the fire's development and effects, but, in other contexts, the term might be used to mean both the initial specifications and the subsequent development and effects (i.e., a complete description of fire from conditions prior to ignition to conditions following extinguishment). [***101,*** 2018]

Δ ***3.4.9.1 Design Fire Scenario.*** A fire scenario selected for evaluation of a proposed design. [***101,*** 2018]

3.4.10* Fuel Load. The total quantity of combustible contents of a building, space, or fire area. [**5000,** 2018]

A.3.4.10 Fuel Load. Fuel load includes interior finish and trim. [**5000,** 2018]

3.4.11 Incapacitation. A condition under which humans do not function adequately and become unable to escape untenable conditions. [***101,*** 2018]

3.4.12 Input Data Specification. Information required by the verification method. [***101,*** 2018]

3.4.13 Occupant Characteristics. The abilities or behaviors of people before and during a fire. [***101,*** 2018]

3.4.14* Performance Criteria. Threshold values on measurement scales that are based on quantified performance objectives. [***101,*** 2018]

A.3.4.14 Performance Criteria. Performance criteria are stated in engineering terms. Engineering terms include temperatures, radiant heat flux, and levels of exposure to fire products. Performance criteria provide threshold values used to evaluate a proposed design. [***101,*** 2018]

3.4.15* Proposed Design. A design developed by a design team and submitted to the AHJ for approval. [***101,*** 2018]

A.3.4.15 Proposed Design. The design team might develop a number of trial designs that will be evaluated to determine whether they meet the performance criteria. One of the trial designs will be selected from those that meet the performance criteria for submission to the AHJ as the proposed design. [***101,*** 2018]

The proposed design is not necessarily limited to fire protection systems and building features. It also includes any component of the proposed design that is installed, established, or maintained for the purpose of life safety, without which the proposed design could fail to achieve specified performance criteria. Therefore, the proposed design often includes emergency procedures and organizational structures that are needed to meet the performance criteria specified for the proposed design. [***101,*** 2018]

3.4.16 Safe Location. A location remote or separated from the effects of a fire so that such effects no longer pose a threat. [***101,*** 2018]

3.4.17 Safety Factor. A factor applied to a predicted value to ensure that a sufficient safety margin is maintained. [***101,*** 2018]

3.4.18 Safety Margin. The difference between a predicted value and the actual value where a fault condition is expected. [***101,*** 2018]

3.4.19 Sensitivity Analysis. See 3.4.2.1.

3.4.20 Stakeholder. An individual, or representative of same, having an interest in the successful completion of a project. [***101,*** 2018]

3.4.21 Uncertainty Analysis. See 3.4.2.2.

3.4.22 Verification Method. A procedure or process used to demonstrate or confirm that the proposed design meets the specified criteria. [***101,*** 2018]

General Requirements

4

Chapter 4 presents general information about goals and objectives, inherent assumptions, and applicable options that concern compliance with the life safety and property protection requirements of NFPA 1, as well as information regarding how the *Code* is applied. (See Sections 4.1 through 4.4.) These goals and objectives establish the broad areas that this *Code* governs. They can be achieved by applying the prescriptive-based compliance option (4.3.1) or the performance-based option (4.3.2). Additionally, the *Code's* goals and objectives can be reviewed when making the determination whether a proposed equivalency meets the *Code's* intent.

General administrative and application requirements that apply to all facilities and buildings are also in this chapter. (See Section 4.5.)

4.1* Goals and Objectives

The goals and objectives of the *Code*, as stated in Section 4.1, identify in broad terms the compliance this *Code* is intended to achieve. Goals are qualitative statements that describe, in general terms, how a building or facility that is designed and constructed in accordance with this *Code,* or how an operation that is regulated by the provisions herein, is expected to perform. Because the requirements in Section 4.1 are written in general terms, they are intended to be easily understood by those without a background in building and facility design and construction or extensive expertise in the operations regulated by this *Code*. However, these general terms do not provide sufficient information for designing or constructing a building or facility or for completely setting up an effective protection system for the operations regulated by this *Code*. Additional details are provided by the *Code*'s objectives. (See 4.1.3 through 4.1.5.)

A.4.1 The overall goals of this *Code* are presented in 4.1.1. These overall goals are treated in greater depth in 4.1.3 through 4.1.5. In each of these subsections, an overall goal for the subsection is defined, specific goals relating to the overall goal are presented next, and the objectives that relate to the specific goal follow. This format is intended to enhance the usability of the *Code*.

The subjects addressed in Chapter 4 are general in nature and supplement the provisions of Chapter 1, Administration. NFPA publication style dictates that Chapter 1 of all codes and standards is to include only title, scope, purpose, application, equivalency, units and formulas, and enforcement sections. All other general provisions are to be contained in Chapter 4, General Requirements, which follows Chapter 2, Referenced Publications, and Chapter 3, Definitions.

Chapter 4 provides general information about the *Code's* goals and objectives, inherent assumptions, options that can be applied for compliance with life safety and property protection requirements, and information regarding how the *Code* is applied *(see Sections 4.1 through 4.5)*. These goals and objectives establish the broad areas that this *Code* governs. They can be achieved via prescriptive-based options or performance-based options. Additionally, the goals and objectives can be reviewed to determine whether satisfactory conditions are being provided when equivalency options are being considered.

General administrative and application requirements that apply to all facilities and buildings are also included in this chapter *(see Section 4.5)*.

4.1.1* Goals. The goals of this *Code* shall be to provide a reasonable level of safety, property protection, and public welfare from the hazards created by fire, explosion, and other hazardous conditions.

A.4.1.1 These highest level goals are intentionally general in nature. Each includes a broad spectrum of topics as shown in 4.1.3. The property protection goal is not just a goal unto itself, as it is also achieved in part as a result of designing to achieve the other stated goals. A reasonable level of safety is further defined by subsequent language in the *Code*. The facility/property owner or an insurance representative might also have other goals, which might necessitate more stringent objectives as well as more demanding criteria.

The primary goals of this *Code* are to provide a reasonable level of the following:

1. Safety to people
2. Protection of property
3. Protection of the public welfare

The protection of property is achieved, in part, as a result of planning to achieve the other stated goals. Another primary goal is safety for people, which is outlined in citing specific requirements and references in NFPA *101*®, *Life Safety Code*®. However, these goals may also be goals or variations of goals of other codes, building codes, or building construction or life safety codes. Any discrepancies in goals between such codes must be resolved to ensure that a building, built in compliance with the applicable building construction code and other codes, is not deemed noncompliant with the fire code that might be enforced. This goal is consistent with the purpose of the *Code*, as indicated in Section 1.2.

4.1.2* Objectives. To achieve the goals stated in 4.1.1, the goals and objectives of 4.1.3 through 4.1.5 shall be used to determine the intent of this *Code*.

A.4.1.2 The objectives apply regardless of which option a user of the *Code* selects for a design — the performance-based option or the prescriptive-based option. The objectives are stated in more specific terms than the goals and tend to be more quantitative. The goals and objectives, taken together, form the broad, general targets at which a performance-based design can take aim. Specific criteria for design follow in Chapter 5.

Although the goals state generally what compliance with NFPA 1 is intended to accomplish, the objectives, stated in 4.1.3 through 4.1.5, provide additional details on how this compliance is achieved.

4.1.3* Safety. This *Code* shall provide for life safety by reducing the probability of injury or death from fire, explosions, or events involving hazardous materials.

A.4.1.3 The concept of providing for safety applies not only to safety during a fire, explosion, or hazardous materials incident, but also during the normal use of a building or facility. A reasonable level of safety should be provided for occupants in and individuals near the facility or building in question. The resultant design in addition to providing for occupant's safety also promotes the public welfare. Public welfare is also provided as a result of the mission continuity provisions of this *Code*.

Safety goals are associated with situations that are immediately or acutely hazardous. Hazards that do not pose an immediate threat but could be harmful to occupants subject to long-term or chronic exposures are not necessarily addressed in this *Code*, but they are typically addressed in building construction codes or other NFPA codes and standards. Examples of these hazards include sanitation, airborne contaminants, and standing water.

4.1.3.1 Safety from Fire.

4.1.3.1.1* Safety-from-Fire Goals. The fire safety goals of this *Code* shall be as follows:

(1) To provide an environment for the occupants in a building or facility and for the public near a building or facility that is reasonably safe from fire and similar emergencies
(2) To protect fire fighters and emergency responders

A.4.1.3.1.1 The phrase *reasonably safe* from fire is defined by subsequent language in this *Code*, primarily in the objectives.

Paragraph 4.1.3.1.1(1) describes providing safety for occupants in a building and for individuals near the building or facility in question. The distance considered to be near a building or facility is determined on a case-by-case basis, depending on the potential damage of a fire or hazardous materials–related event; the proximity of the event to the public, a property line, or an adjacent property; and the number of people nearby who might be injured by the event. For example, hazards associated with the unintentional release of a hazardous material are of a much greater concern if the release is near a busy street and sidewalk, as compared to the same release in a remote, sparsely populated area.

Paragraph 4.1.3.1.1(2) refers to protection of fire fighters and other emergency responders. Such protection, however, is not necessarily intended to be provided for an unlimited period of time. Paragraph 4.1.3.1.2.2 provides guidance for the protection of fire fighters.

4.1.3.1.2 Safety-from-Fire Objectives.

4.1.3.1.2.1 Buildings and facilities shall be designed, constructed, and maintained to protect occupants who are not intimate with the initial fire development for the amount of time needed to evacuate, relocate, or defend in place.

Paragraph 4.1.3.1.2.1 requires protection for occupants who are not intimate with the initial fire development. The corollary of this provision is that the *Code* does not require the protection of people who *are* intimate with initial fire development. The phrase *intimate with the initial fire development* covers situations in which people, through intentional acts, carelessness, or other circumstances, are close to the initial ignition point and thus are unable to flee before being engulfed by fire, succumbing to the by-products of combustion, or becoming exposed to other untenable conditions. Examples of individuals considered to be intimate with the initial fire development include someone who falls asleep in bed smoking a cigarette that ignites the mattress and bedding, or an unprotected worker in an industrial facility that is in the midst of a flash fire caused by the ignition of vapors from a flammable liquid.

The determination of who is and who is not intimate with the initial fire development is subjective and varies greatly depending on the facility itself, its fuel load and ignition sources, and its occupants and their characteristics. From a practical standpoint, determination would most often be made when evaluating individual fire design scenarios as part of a performance-based design option. (See 5.4.2.)

Although not readily achievable or possible in most cases, some features and systems provided in some facilities and buildings, such as ignition-resistant mattresses and flame-resistant garments for protection of industrial personnel against flash fires, can impart a level of protection to occupants who are intimate with ignition. Residential sprinkler systems are another example of a system that imparts some protection to those intimate with initial ignition and might increase their probability of survival.

4.1.3.1.2.2* Buildings shall be designed and constructed to provide reasonable safety for fire fighters and emergency responders during search and rescue operations.

A.4.1.3.1.2.2 In many cases, the provisions of the *Code* to provide safety for occupants satisfies this goal for protection of emergency responders.

As a fire develops, the level of danger to fire fighters carrying out operations inside, on top of, or adjacent to a building increases. Paragraph 4.1.3.1.2.2 requires that fire fighters and emergency responders be protected for the time necessary to perform search and rescue operations. This *Code* does not intend to provide protection for fire fighters conducting an interior attack on a working fire for an indefinite period of time because such an expectation would be unrealistic.

In determining the amount of time needed to conduct search and rescue operations, it is necessary to factor in the times needed for the emergency responders to be alerted, to arrive on the scene and deploy, and to initiate and complete search and rescue operations. In many cases, this time will involve the emergency responders assisting occupants in evacuating the building. Alternatively, it might involve the removal or relocation of nonambulatory patients. The time needed to accomplish search and rescue operations needs to be factored into the final protection scheme for the building or facility.

Structural integrity is anticipated to be maintained for a sufficient time to protect against collapse during search and rescue operations. Another expectation is that the emergency responders will not be exposed to untenable conditions that cannot be mitigated by the equipment they are expected to wear or use during the deployment, such as structural fire-fighting protective clothing (bunker gear) and self-contained breathing apparatus.

4.1.3.1.2.3 Buildings shall be designed, located, and constructed to reasonably protect adjacent persons from injury or death as a result of a fire.

As indicated in A.4.1.3, the concept of providing safety applies not only to safety during a fire, explosion, or hazardous materials incident, but also during the normal use of a building or facility. A reasonable level of safety should be provided for occupants in and individuals near the facility or building in question. The resulting design, in addition to providing for occupant's safety, also promotes the public welfare. Public welfare is also provided as a result of the mission continuity provisions of this *Code*.

4.1.3.1.2.4 Buildings shall be designed, located, and constructed to provide reasonable access to the building for emergency responders.

Emergency responders must arrive quickly to the immediate vicinity of the building or facility to deploy and conduct emergency response operations. Immediate access requires them to transport emergency response equipment and apparatus from the fire station or other staging point to the incident location without delay. To accomplish this, responders must be provided with an acceptable roadway that can be negotiated by their responding vehicles during all reasonably foreseen weather conditions. The roadway must not be too steep or winding to be negotiated by any emergency response vehicle with a potential to be deployed. Provisions must also be made for the passing of vehicles proceeding in the opposite direction and for prohibiting parked vehicles or other obstructions on the roadway or access areas that would hinder responders from initiating search and rescue and suppression operations in a timely fashion. The local fire department or other applicable agency should be consulted as early as possible in the design process to determine the requirements for access, given the emergency vehicles that are likely to be deployed to a fire, hazardous materials, or other emergency event.

Building owners have control over access features and requirements on their own property but might not have control over roadway provisions on public thoroughfares or private property owned by others. However, access limitations experienced anywhere en route to the facility that delay emergency responder deployment to the facility or building must be factored into how the goals and objectives of this *Code* are to be met. Additional safety provisions might need to be incorporated to offset emergency response delays. Examples of anticipated delays include, but are not limited to, the following:

1. Access crossing a heavily traveled rail line
2. Access roads that are subject to frequent flooding or other adverse weather conditions
3. Access roads that experience severe congestion

Access to the building should also take into consideration the location of the building footprint in relation to fire department access roads. Specialized fire apparatus, such as aerial apparatus, often need to be deployed at specific locations relative to the building to effectively perform fire suppression operations. Exhibit 4.1 depicts an access roadway.

Exhibit 4.1

Access roadway.

4.1.3.1.2.5* Operations shall be conducted at facilities in a safe manner that minimizes, reduces, controls, or mitigates the risk of fire injury or death for the operators, while protecting the occupants not intimate with initial fire development for the amount of time needed to evacuate, relocate, or defend in place.

A.4.1.3.1.2.5 This provision addresses the fire safety objectives of operations addressed elsewhere in the *Code*, such as hot work, tar kettle operation, and so forth, that are not directly related to building construction and use.

4.1.3.2 Safety During Building Use.

4.1.3.2.1* Safety-During-Building-Use Goal. The safety-during-building-use goal of this *Code* shall be to provide an environment for the occupants of the building that is reasonably safe during the normal use of the building.

A.4.1.3.2.1 The phrase *reasonably safe during normal use* is defined by subsequent language in this *Code*, primarily in the objectives. Certain requirements, such as heights of guards and stair dimensions, are provided to ensure that the occupants are safe during nonemergency use of the buildings. Failure to address these features could result in falls or other injuries to occupants in their normal day-to-day activities in the building.

The intent of 4.1.3.2.1 is to protect people against injury in the performance of the task they would typically perform in the building during construction, normal use, and demolition.

4.1.3.2.2 Safety-During-Building-Use Objectives.

4.1.3.2.2.1 Buildings shall be designed and constructed to reduce the probability of death or injury of persons from falling during normal use of the building.

The objectives of 4.1.3.2.2.1 are to protect occupants from accidentally falling from an elevation so high that they could be injured and to protect them from tripping hazards associated with stairs and uneven walking surfaces. Providing protective railings, barriers, and nationally recognized stair geometries and walking surfaces are ways these objectives can be met.

4.1.3.2.2.2 Buildings shall be designed and constructed to provide for reasonably safe crowd movement during emergency and non-emergency conditions.

The objective of 4.1.3.2.2.2 is to provide safe crowd movement because overly crowded conditions can be dangerous. In addition to occurring during emergencies, overly crowded conditions occur in routine situations. For example, in 1979, 11 people died in a stampede at a rock concert in Cincinnati, Ohio. In 2003, 21 people died in a crowd crush in a club in Chicago, Illinois.

4.1.3.2.2.3 Buildings shall be designed and constructed to provide reasonable life safety for occupants and workers during construction and demolition.

4.1.3.2.2.4 Buildings shall be designed and constructed to provide reasonable notification to occupants of fire and other emergency situations.

The objective of 4.1.3.2.2.4 is to require reasonable occupant notification in the event of a fire or other emergency. Such notification can be provided in a number of ways, such as the notification of personnel at a constantly attended location, and could require an automatic fire alarm system with audible and visual notification to all occupants.

4.1.3.2.2.5 Buildings shall be designed and constructed to provide reasonable signage and lighting to identify hazards, exits, means of egress, and other building safety features.

The objective of 4.1.3.2.2.5 is to assist occupants during an emergency by providing signage and lighting to identify hazards, exits, means of egress, and other safety features. In some cases, illuminated signs and lighting need to function effectively for a specified time after a loss of primary power, depending on the occupancy characteristics.

4.1.3.3 Safety from Hazardous Materials.

4.1.3.3.1 Safety-from-Hazardous-Materials Goal. The safety-from-hazardous-materials goal of this *Code* shall be to provide an environment for the occupants in a building or facility and to those adjacent to a building or facility that is reasonably safe from exposures to adverse affects from hazardous materials present therein.

4.1.3.3.2 Safety-from-Hazardous-Materials Objectives.

The objectives associated with 4.1.3.3.2 are intended to address hazards associated with the unplanned release of a hazardous material, a fire impinging on the hazardous material, or the unwanted hazardous reaction of the material. The level of safeguards needed to meet this goal depends on a number of factors, including the nature and amounts of the hazardous materials involved.

The owner, occupants, and emergency responders must have a thorough understanding of the hazardous materials on-site, limit the quantities of the materials to agreed on amounts that will not overwhelm the safety systems, and maintain records of the hazardous materials so that emergency response operations are conducted in a more informed manner in the event of a hazardous materials incident. Safe practices should be agreed on and followed in the storage, handling, and use of the hazardous materials.

4.1.3.3.2.1 The storage, use, or handling of hazardous materials in a building or facility shall be accomplished in a manner that provides a reasonable level of safety for occupants and for those adjacent to a building or facility from health hazards, illness, injury, or death during normal storage, use, or handling operations and conditions.

4.1.3.3.2.2* The storage, use, or handling of hazardous materials in a building or facility shall be accomplished in a manner that provides a reasonable level of safety for occupants and for those adjacent to a building or facility from illness, injury, or death due to the following conditions:

(1) An unplanned release of the hazardous material
(2) A fire impinging upon the hazardous material or the involvement of the material in a fire
(3) The application of an external force on the hazardous material that is likely to result in an unsafe condition

A.4.1.3.3.2.2 For item 3, the phrase *external force* refers to the application of factors such as heat, water, shock, or other phenomenon onto hazardous materials that are sensitive to such factors and could react vigorously to produce unsafe conditions.

4.1.4 Property Protection.

4.1.4.1 Property Protection Goal. The property protection goal of this *Code* shall be to limit damage created by a fire, explosion, or event associated with hazardous materials to a reasonable level to the building or facility and adjacent property.

The protection of property is a primary goal of this *Code*, and may be a goal of other codes, building codes, and building construction or life safety codes. Discrepancies between codes in this regard must be resolved to ensure that a building, built in compliance with the applicable building construction code and other codes, is not deemed noncompliant with the fire code that might be enforced. This goal is consistent with the purpose of the *Code*, as stated in Section 1.2.

Determining what constitutes a reasonable level of property loss is a process that should involve the stakeholders in the facility, including the owner, occupant, insurer, authority having jurisdiction (AHJ), and/or other affected parties. Additional information on making such a determination is included in the *SFPE Engineering Guide to Performance-Based Fire Protection* and in A.5.1.4.

4.1.4.2 Property Protection Objectives.

4.1.4.2.1* Prevention of Ignition. The facility shall be designed, constructed, and maintained, and operations associated with the facility shall be conducted, to prevent unintentional explosions and fires that result in failure of or damage to adjacent compartments, emergency life safety systems, adjacent properties, adjacent outside storage, and the facility's structural elements.

A.4.1.4.2.1 Ignition occurs when combustible materials come into contact with a source of heat of sufficient temperature and power for a requisite time in an atmosphere where oxygen is present. Combustible material does not necessarily ignite immediately upon contact with a source of heat.

4.1.4.2.2* Fire Spread and Explosions. In the event that a fire or explosion occurs, the building or facility shall be sited, designed, constructed, or maintained, and operations associated with the facility shall be conducted and protected, to reasonably reduce the impact of unwanted fires and explosions on the adjacent compartments, emergency life safety systems, adjacent properties, adjacent outside storage, and the facility's structural elements.

A.4.1.4.2.2 Examples of specific conditions to avoid include, but are not limited to, flashover, fire spread beyond the item or room of fire origin, overheating of equipment, and overpressure of exterior walls.

4.1.4.2.3 Structural Integrity. The facility shall be designed, constructed, protected, and maintained, and operations associated with the facility shall be conducted, to provide a reasonable level of protection for the facility, its contents, and adjacent properties from building collapse due to a loss of structural integrity resulting from a fire.

4.1.4.2.4 Hazardous Materials. The facility shall be designed, constructed, and maintained, and operations associated with the facility shall be conducted, to provide reasonable property protection from damage resulting from fires, explosions, and other unsafe conditions associated with the storage, use, and handling of hazardous materials therein.

4.1.5 Public Welfare.

Subsection 4.1.5 includes requirements intended to maintain a high probability that certain buildings or facilities operate during and after an emergency event, such as a fire, explosion, or hazardous materials event, to provide an anticipated critical public service. Such facilities might include hospitals and public safety buildings (fire and police stations). (See A.4.1.5.2.)

4.1.5.1* Public Welfare Goal. The public welfare goal of this *Code* shall be to maintain a high probability that buildings and facilities that provide a public welfare role for a community continue to perform the function for their intended purpose following a fire, explosion, or hazardous materials event.

A.4.1.5.1 This goal is applicable to certain buildings and facilities that have been deemed to be necessary to the continued welfare of a community. Depending on the nature of the critical mission provided by the building, various stakeholders, including community leaders, AHJs, and owners will identify the mission critical buildings. Mission critical areas should be identified and appropriately protected. The objectives for property protection and mission continuity are sometimes difficult to differentiate. Achieving the objectives for property protection could, to a certain extent, accomplish the objectives for mission continuity.

4.1.5.2* Public Welfare Objective. Buildings and facilities that provide a public welfare role for a community shall be designed, constructed, maintained, and operated to provide reasonable assurance of continued function following a fire, explosion, or hazardous materials event.

A.4.1.5.2 Examples of buildings and facilities that provide a public welfare role for a community could include hospitals, police and fire stations, evacuation centers, schools, water and sewerage facilities, and electrical generating plants. Also included are buildings and facilities with significant impact on the economic viability of the community. This objective is intended to ensure that such buildings and facilities are capable of providing essential services following a disaster since the community's well-being depends on such service being available.

The objectives of 4.1.5.2 are intended to apply to buildings and facilities that perform essential public service functions, examples of which are included in A.4.1.5.2. Community leadership should identify buildings and facilities required to comply with these goals and objectives and the stakeholder involved with the facility. In some cases, financial institutions might wish to impose such mission continuity goals on their operations to ensure that backed-up data or redundant facilities can make up for the loss of a primary facility due to fire or other disaster. Additional information on a process to determine stakeholder goals and objectives in this regard is included in the *SFPE Engineering Guide to Performance-Based Fire Protection* and in A.5.1.4.

4.2 Assumptions

4.2.1* Single Fire Source.

A.4.2.1 Additional assumptions that need to be identified for a performance-based design are addressed in Chapter 5.

For the user of the traditional, prescriptive, specification-based requirements, the single fire source assumption is a piece of explanatory information, not a requirement. The assumption explains that the *Code* authors developed the requirements with the challenge of a single fire source in mind. Thus, most occupancies require a minimum of two means of egress; if a single fire blocks one, then the other should be available for egress. If the *Code* had been written to protect against fires that begin in two locations, then occupancy requirements for a minimum of three means of egress probably would be common. Historically, the *Code*'s approach to protecting against a single fire source has proved to meet society's expectations and to provide an acceptable level of safety.

4.2.1.1 The fire protection methods of this *Code* shall assume that multiple simultaneous fire incidents will not occur.

4.2.1.2 The single fire source assumption shall not preclude the evaluation of multiple design fire scenarios as required by Section 5.4.

4.2.2* Single Hazardous Material Release.

A.4.2.2 It is not assumed that a design scenario will be considered that simulates the hazards produced when unauthorized releases of hazardous materials occur simultaneously at different locations within a facility, unless it is reasonable to expect that a single incident, such as a fork lift accident or pipe failure, could be expected to create such a condition. However, when hazardous materials are in close proximity to one another, such as on a shelf or in adjacent storage cabinets, it could be reasonable to apply a design scenario where multiple releases of the hazardous materials occur simultaneously from these close proximity areas. In this case, it is not unreasonable to expect the shelf to collapse or a forklift to damage adjacent hazardous materials containers.

A key assumption in this *Code* is that unauthorized releases of hazardous materials from the locations in which they are likely to be stored, used, or handled should be considered, and that protection methods must be provided to mitigate the hazards associated with such releases so that the goals and objectives of the *Code* can be met. It is not considered reasonable to require that the goals and objectives of this *Code* be met, assuming that two completely independent hazardous material releases occur simultaneously in different locations within a facility. Subsection 4.2.2 assumes that unauthorized releases occur because of faulty containment or packaging, not because of external fires or other events impinging on the hazardous materials. See 4.2.3 for assumptions associated with the impingement of unwanted events involving hazardous materials.

4.2.2.1 The protection methods of this *Code* shall assume that multiple simultaneous unauthorized releases of hazardous materials from different locations will not occur.

4.2.2.2 The single hazardous material release assumption shall not preclude the evaluation of multiple design scenarios as required by Section 5.4.

4.2.3* Incidents Impinging on Hazardous Materials. The protection methods of this *Code* shall assume that a fire, explosion, hazardous materials release, or external force that creates a dangerous condition has the potential to impinge on hazardous materials being stored, handled, or used in the building or facility under normal conditions. *(See Section 5.4 for performance-based design scenarios.)*

A.4.2.3 It is not assumed that a design scenario will be considered that simulates the hazards produced when a fire, explosion, or external force that creates a dangerous condition occurs at the same time that hazardous materials have been subject to an unauthorized release. This does not preclude considering a scenario where a fire or explosion occurs and impinges on hazardous materials that are in their normal storage, use, or handling conditions.

The phrase *external force that creates a dangerous condition* refers to the application of factors such as heat, water, shock, or other phenomenon onto hazardous materials that are sensitive to such factors and could react vigorously to produce unsafe conditions.

The assumption stated in 4.2.3 covers a situation in which a fire, explosion, or external force impinges on hazardous materials stored, used, or handled within the facility. See A.4.2.3 for additional details.

4.3 Compliance Options

Compliance with the goals and objectives of Section 4.1 shall be provided in accordance with either of the following:

(1) The prescriptive-based provisions per 4.3.1
(2) The performance-based provisions per 4.3.2

Traditionally, fire and life safety codes have required compliance with prescriptive, specification-based requirements and offered additional design flexibility via an equivalency concept, such as that contained in Section 1.4. This *Code* offers the option of designing buildings and facilities using either the prescriptive-based option described in 4.3.1 or the performance-based option described in 4.3.2.

4.3.1 Prescriptive-Based Option.

4.3.1.1 A prescriptive-based option shall be in accordance with Chapter 1 through Chapter 4, Chapter 6, and Chapter 10 through Chapter 75 of this *Code*.

A prescriptive-based building design is the traditional norm. Each applicable requirement is met individually, and the resultant level of building performance is deemed to meet the goals and objectives of Section 4.1.

4.3.1.2 Where specific requirements contained in Chapter 20 for occupancies differ from general requirements contained in Chapter 1 through Chapter 4 and Chapter 10 through Chapter 75, the requirements of Chapter 20 shall govern.

For buildings designed and constructed in accordance with the prescriptive-based option, compliance with the prescriptive provisions in Chapters 1 through 4 and Chapters 6 through 75 achieves the goals and objectives stated in Section 4.1. For prescriptive-based designs, an analysis of the goals and objectives in Section 4.1 is typically not necessary, except in cases where the equivalency option in 1.4.1 is used. NFPA 1 is formatted such that Chapters 1 through 4 and Chapters 6 through 19 contain administrative provisions and fundamental requirements establishing minimum acceptance criteria for general applications. Chapters 20 through 37 establish detailed criteria for specific occupancies and facilities. Chapters 40 through 44 and Chapters 50 through 54 contain provisions for protecting hazardous processes and hazardous equipment. Finally, Chapters 60 through 75 contain hazardous material–related provisions.

Paragraph 4.3.1.2 clarifies that, where the occupancy-based provisions of Chapter 20 conflict with or differ from similar requirements in the other chapters of this *Code*, the Chapter 20 provisions should be applied.

4.3.2 Performance-Based Option.

By definition, a performance-based design is not expected to comply with the prescriptive provisions in Chapters 10 through 75, but it must meet the administrative and general requirements of Chapters 1 through 4. The performance-based design must also comply with all applicable performance-based option requirements in Chapter 5. Note that Section 5.3 contains a limited number of prescriptive provisions that have been retained from Chapters 10, 14 (via reference to NFPA *101*), and 16 that must be enforced as part of the performance-based option.

4.3.2.1 A performance-based option shall be in accordance with Chapter 1 through Chapter 5 of this *Code*.

4.3.2.2 Prescriptive requirements shall be permitted to be used as part of the performance approach, if they, in conjunction with the performance features, meet the overall goals and objectives of this *Code*.

4.4 Fundamental Requirements

Section 4.4 outlines the fundamental requirements that must be followed to ensure compliance with the *Code*. These apply to both prescriptive-based and performance-based designs. The following fundamental requirements provide an acceptable level of life safety and property protection:

1. Protection must not depend on any single safeguard.
2. Safeguards must be appropriate for the particular application, taking into consideration the unique characteristics of the building, its occupants, and other related factors.
3. Egress paths must be clear and unobstructed.
4. Egress routes must be marked clearly and illuminated sufficiently.
5. Occupants must be provided with an adequate warning of fire.
6. Vertical openings must be provided with suitable protection to avoid unwanted movement of smoke and fire through the building, while allowing for required egress.
7. Fire protection systems must be designed and installed in compliance with applicable installation standards.

4.4.1 Multiple Safeguards.

4.4.1.1 The design of every building or structure intended for human occupancy shall be such that reliance for property protection and safety to life does not depend solely on any single safeguard.

4.4.1.2 Additional safeguard(s) shall be provided for property protection and life safety in the event that any single safeguard is ineffective due to inappropriate human actions, building failure, or system failure.

4.4.2 Appropriateness of Safeguards. Every building or structure shall be provided with means of egress and other safeguards of the kinds, numbers, locations, and capacities appropriate to the individual building or structure, with due regard to the following:

(1) Characteristics of the occupancy
(2) Capabilities of the occupants
(3) Number of persons exposed
(4) Fire protection available
(5) Capabilities of response personnel
(6) Height and type of construction of the building or structure
(7) Other factors necessary to provide occupants with a reasonable degree of safety
(8) Other factors necessary to protect the building and contents from damage

4.4.3 Means of Egress.

4.4.3.1 Unobstructed Egress.

4.4.3.1.1 In every occupied building or structure, means of egress from all parts of the building shall be maintained free and unobstructed.

4.4.3.1.2 No lock or fastening shall be permitted that prevents free escape from the inside of any building other than in health care occupancies and detention and correctional occupancies where staff are continually on duty and effective provisions are made to remove occupants in case of fire or other emergency.

4.4.3.1.3 Means of egress shall be accessible to the extent necessary to ensure reasonable safety for occupants having impaired mobility.

4.4.3.2 Awareness of Egress System.

4.4.3.2.1 Every exit shall be clearly visible, or the route to reach every exit shall be conspicuously indicated.

4.4.3.2.2 Each means of egress, in its entirety, shall be arranged or marked so that the way to a place of safety is indicated in a clear manner.

Δ **4.4.3.2.3 Lighting.** Illumination of means of egress shall be provided. [*See 5.3.4(10)*.]

4.4.4* Occupant Notification. In every building or structure of such size, arrangement, or occupancy that a fire itself could not provide adequate occupant warning, fire alarm systems shall be provided where necessary to warn occupants of the existence of fire.

A.4.4.4 Fire alarms alert occupants to initiate emergency procedures, facilitate orderly conduct of fire drills, and initiate response by emergency services.

4.4.5 Vertical Openings. Every vertical opening between the floors of a building shall be suitably enclosed or protected, as necessary, to provide the following:

(1) Reasonable safety to occupants while using the means of egress by preventing spread of fire, smoke, or fumes through vertical openings from floor to floor to allow occupants to complete their use of the means of egress
(2) Limitation of damage to the buildings and its contents

4.4.6 System Design/Installation. Any fire protection system, building service equipment, feature of protection, or safeguard provided to achieve the goals of this *Code* shall be designed, installed, and approved in accordance with applicable codes and standards referenced in Chapter 2.

4.5 General Requirements

4.5.1 Authority Having Jurisdiction (AHJ).

4.5.1.1 The AHJ shall determine whether the provisions of this *Code* are met.

4.5.1.2 Where it is evident that a reasonable degree of safety is provided, any requirement shall be permitted to be modified if its application would be hazardous under normal occupancy conditions in the judgment of the AHJ.

Paragraph 4.5.1.2 gives the AHJ latitude in permitting a requirement to be modified if strict enforcement of the provision would otherwise create more of a hazard and, thus, lessen the overall safety that is achieved by the modification. For example, the *Code* requires an exit sign at an exit and, via the provisions of 14.14.1.2.1, requires that the sign be visible from any direction of exit access. If the exit door in question were installed in the plane of a corridor wall, the exit sign would need to be positioned perpendicular to the corridor wall. If headroom at the door is limited, perhaps due to a ceiling projection such as a beam running across the corridor at that point, the exit sign might be so low occupants would bump their heads. This provision permits the AHJ to allow the exit sign to be mounted flush against the corridor wall based on the judgment that a reasonable degree of safety is provided.

4.5.2 Historic Structures and Cultural Resource Buildings. The provisions of this *Code* shall be permitted to be modified by the AHJ for buildings or structures identified and classified as historic structures in accordance with Section 20.17.

Rather than providing historic structures and cultural resource buildings undergoing rehabilitation with a blanket exemption from *Code* requirements, 4.5.2 permits the AHJ to modify the provisions of the *Code*, provided that the resulting requirements provide a reasonable level of safety and protection. The AHJ should consult NFPA 909, *Code for the Protection of Cultural Resource Properties — Museums, Libraries, and Places of Worship*, and NFPA 914, *Code for Fire Protection of Historic Structures*, which provide both prescriptive-based and performance-based options that have specific applications to the unique nature of such properties. Also see Section 20.17.

4.5.3 Provisions in Excess of *Code* Requirements. Nothing in this *Code* shall be construed to prohibit a better type of building construction, an additional means of egress, or an otherwise more safe condition than that specified by the minimum requirements of this *Code*.

Although the *Code* specifies minimum requirements, the use of a design that exceeds its provisions is not prohibited. In most cases, economic considerations discourage the use of a design that exceeds minimum requirements. However, in some instances, the building owner or other parties might wish to provide a level of protection that is higher than that required by the *Code*. Exceeding minimum requirements might be considered for a variety of reasons, including mission continuity, where disruption of an operation could result in a significant financial loss to a business.

The AHJ is generally not in a position to require protection unilaterally in excess of *Code* requirements, unless the requirements imposed are essential for the safety of the occupants or the property, and except in cases of imminent danger to address this situation adequately.

4.5.4 Conditions for Occupancy. No new construction or existing building shall be occupied in whole or in part in violation of the provisions of this *Code* unless the following conditions exist:

(1) A plan of correction has been approved.
(2) The occupancy classification remains the same.
(3) No serious life safety hazard exists as judged by the AHJ.

4.5.5 Warrant of Fitness.

4.5.5.1 Where compliance with this *Code* is effected by means of a performance-based design, the owner shall annually certify compliance with the conditions and limitations of the design by submitting a warrant of fitness acceptable to the AHJ.

4.5.5.2 The warrant of fitness shall attest that the building features, systems, and use have been inspected and confirmed to remain consistent with design specifications outlined in the documentation required by 5.1.8 and 5.7.3 and that they continue to satisfy the goals and objectives specified in Section 4.1. *(See 5.1.11.)*

The provisions of 4.5.5.1 and 4.5.5.2 apply only to performance-based designs and require the owner to provide an annual warrant of fitness certifying that the facility continues to comply with the conditions and limitations of the design. This requirement corresponds to the requirements included in 5.1.11. For additional information, see A.5.1.10 and A.5.1.11.

4.5.6 Construction, Repair, and Improvement Operations.

4.5.6.1 Buildings or portions of buildings shall be permitted to be occupied during construction, repair, alterations, or additions only where required means of egress and required fire protection features are in place and continuously maintained for the portion occupied or where alternative life safety measures and building protection measures acceptable to the AHJ are in place.

The provisions of 4.5.6.1 help to control a relatively common practice — the occupancy of completed portions of a partially completed structure. The *Code* permits such occupancy if certain conditions are met. For example, the *Code* requires that egress features for the occupied portion be complete and maintained to be usable. In many cases, the egress facilities, although completed, are not usable because they are blocked with stored building materials and equipment needed for the ongoing construction, or doors are locked to limit access to parts of the building still under construction. In such cases, occupancy is prohibited.

The *Code* also requires that fire protection features be in place and maintained continuously. The incidence of fire is more frequent and, therefore, more likely during construction or rehabilitation. Extra caution and concern need to be exercised to ensure adequate egress capacity and arrangement during periods of construction in an occupied building.

Paragraph 4.5.6.1 recognizes that, in lieu of strict adherence to the egress and fire protection features, alternative life safety measures might make the building safe enough to be occupied. As usual, the AHJ is charged with judging whether the alternative measures provide an acceptable level of safety. Paragraph 4.5.6.1 is conceptually similar to 4.6.10.1 of NFPA *101*.

4.5.6.2 Escape Facilities.

4.5.6.2.1 In buildings under construction, adequate escape facilities shall be maintained at all times for the use of construction workers.

4.5.6.2.2 Escape facilities shall consist of doors, walkways, stairs, ramps, fire escapes, ladders, or other approved means or devices arranged in accordance with the general principles of the *Code* insofar as they can reasonably be applied to buildings under construction.

4.5.6.3 Flammable, hazardous, or explosive substances or equipment for repairs or alterations shall be permitted in a building while the building is occupied if the condition of use and safeguards provided do not create any additional danger or impediment to egress beyond the normally permissible conditions in the building and is such that materials are safeguarded when the building is unoccupied.

4.5.7* Changes of Occupancy.

A.4.5.7 Examples of changes from one occupancy subclassification to another subclassification of the same occupancy could include a change from a Class B to a Class A mercantile occupancy. Hospitals and nursing homes are both health care occupancies and are defined separately, but they are not established as separate suboccupancies; thus, a change from one to the other does not constitute a change of occupancy subclassification.

For example, a building was used as a hospital but has been closed for 4 years. It is again to be used as a hospital. As long as the building was not used as another occupancy during the time it was closed, it would be considered an existing hospital.

Hotels and apartments, although both residential occupancies, are treated separately, and a change from one to the other constitutes a change of occupancy.

4.5.7.1 In any building or structure, whether or not a physical alteration is needed, a change from one occupancy classification to another shall be permitted only where such a structure, building, or portion thereof conforms with the requirements of this *Code* that apply to new construction for the proposed new use, except as follows:

(1) Where, in the opinion of the AHJ, the proposed occupancy or change in use is not more hazardous than the existing use, based on life safety and fire risk, the AHJ shall be permitted to approve such change of occupancy provided compliance with the requirements of this *Code* for buildings of like occupancy or use are specifically incorporated to safeguard the life, health, and welfare of persons.
(2) Change of tenants or ownership shall not be construed to be a change of occupancy classification where the nature of use and assigned occupancy classification remain the same.

4.5.7.2 Where specifically permitted elsewhere in the *Code*, existing construction features shall be permitted to be continued in use in conversions.

4.5.8 Maintenance, Inspection, and Testing.

4.5.8.1 Whenever or wherever any device, equipment, system, condition, arrangement, level of protection, fire-resistive construction, or any other feature is required for compliance with the provisions of this *Code*, such device, equipment, system, condition, arrangement, level of protection, fire-resistive construction, or other feature shall thereafter be continuously maintained. Maintenance shall be provided in accordance with applicable NFPA requirements or requirements developed as part of a performance-based design, or as directed by the AHJ. [***101:***4.6.12.1]

Paragraph 4.5.8.1 emphasizes the importance of maintaining items required by the *Code*. It is useless to have an egress door that will not open, a self-closing device that does not close the door, or a sprinkler system with no water.

4.5.8.2 No existing life safety feature shall be removed or reduced where such feature is a requirement for new construction. [***101:***4.6.12.2]

4.5.8.3* Existing life safety features obvious to the public, if not required by the *Code*, shall be either maintained or removed. [***101:***4.6.12.3]

A.4.5.8.3 Examples of such features include automatic sprinklers, fire alarm systems, standpipes, and portable fire extinguishers. The presence of a life safety feature, such as sprinklers or fire alarm devices, creates a reasonable expectation by the public that these safety features are functional. When systems are inoperable or taken out of service but the devices remain, they present a false sense of safety. Also, before taking any life safety features out of service, extreme care needs to be exercised to ensure that the feature is not required, was not originally provided as an alternative or equivalent, or is no longer required due to other new requirements in the current *Code*. It is not intended that the entire system or protection feature be removed. Instead, components such as sprinklers, initiating devices, notification appliances, standpipe hose, and exit systems should be removed to reduce the likelihood of relying on inoperable systems or features. Conversely, equipment, such as fire or smoke dampers, that is not obvious to the public should be able to be taken out of service if no longer required by this *Code*. Where a door that is not required to be fire protection-rated is equipped with a fire protection listing label, it is not the intent of 4.5.8.3 to require such door to be self- or automatic-closing due merely to the presence of the label. [***101:***A.4.6.12.3]

The *Code* directs that nonrequired life safety features that are obvious to the public be either maintained or removed to prevent false expectations or a false sense of security by building occupants. For example, if the water supply to a nonrequired wet standpipe system were permanently shut off because the system piping leaked, but the hose and nozzle for occupant use were left attached to the standpipe, an occupant could be endangered while attempting to use the system. If the nonrequired standpipe system were turned off and abandoned, it would be necessary, as a minimum, to remove all hose and nozzles and to place prominent signage at each outlet station advising that the system is out of service. The standpipe system piping, however, should not have to be removed.

4.5.8.4* Existing life safety features that exceed the requirements for new buildings shall be permitted to be decreased to those required for new buildings. [***101:***4.6.7.4]

A.4.5.8.4 In some cases, the requirements for new construction are less restrictive, and it might be justifiable to permit an existing building to use the less restrictive requirements. However, extreme care needs to be exercised when granting such permission, because the less restrictive provision might be the result of a new requirement elsewhere in the *Code*. For example, in editions of the *Code* prior to 1991, corridors in new health care occupancies were required to have a 1-hour fire resistance rating. Since 1991, such corridors have been required only to resist the passage of smoke. However, this provision is based on the new requirement that all new health care facilities be protected throughout by automatic sprinklers. *(See A.4.5.8.5.)* [***101:***A.4.6.7.4]

4.5.8.5* Existing life safety features that do not meet the requirements for new buildings, but that exceed the requirements for existing buildings, shall not be further diminished. [***101:***4.6.7.5]

A.4.5.8.5 An example of what is intended by 4.5.8.4 and 4.5.8.5 follows. In a hospital that has 6 ft (1830 mm) wide corridors, such corridors cannot be reduced in width, even though the provisions for existing hospitals do not require 6 ft (1830 mm) wide corridors. However, if a hospital has 10 ft (3050 mm) wide corridors, they are permitted to be reduced to 8 ft (2440 mm) in width, which is the requirement for new construction. If the hospital corridor is 36 in. (915 mm) wide, it would have to be increased to 48 in. (1220 mm), which is the requirement for existing hospitals. [***101:***A.4.6.7.5]

The intent behind 4.5.8.4 and 4.5.8.5 is to prevent life safety features that exceed the requirement for existing buildings from being changed to a level less than that required for new construction. For example, a new hospital is constructed with 8 ft (2440 mm) wide corridors for compliance with 18.2.3.4 of NFPA *101*. In subsequent years, the building becomes an existing hospital subject to the provisions of Chapter 19 of NFPA *101*. The minimum corridor width required by 19.2.3.4 of NFPA *101* for an existing hospital is 48 in. (1220 mm). The minimum 48 in. (1220 mm) criterion is meant to apply to existing situations but is not intended to permit the existing 8 ft (2440 mm) corridor to be decreased in width.

For a similar concept related to the removal of existing life safety features, see 4.6.12.2 of NFPA *101*.

4.5.8.6 Any device, equipment, system, condition, arrangement, level of protection, fire-resistive construction, or any other feature requiring periodic testing, inspection, or operation to ensure its maintenance shall be tested, inspected, or operated as specified elsewhere in this *Code* or as directed by the AHJ. [***101:***4.6.12.4]

4.5.8.7 Maintenance, inspection, and testing shall be performed under the supervision of a responsible person who shall ensure that testing, inspection, and maintenance are made at specified intervals in accordance with applicable NFPA standards or as directed by the AHJ. [***101:***4.6.12.5]

Subsection 4.5.8 stresses that the application of maintenance, inspection, and testing requires a three-component approach. None of the three components — maintenance, inspection, or testing — applied alone, or applied in tandem with only one of the other two, will ensure that the life safety features and systems will continue to work as required.

4.5.9 Noncombustible Material.

Δ **4.5.9.1** A material that complies with any one of the following shall be considered a noncombustible material:

(1)* The material, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat.
(2) The material is reported as passing ASTM E136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750 Degrees C*.
(3) The material is reported as complying with the pass/fail criteria of ASTM E136 when tested in accordance with the test method and procedure in ASTM E2652, *Standard Test Method for Behavior of Materials in a Tube Furnace with a Cone-shaped Airflow Stabilizer, at 750 Degrees C*.

[**5000:**7.1.4.1.1]

Subsection 4.5.9 represents a refinement of what had been the Chapter 3 definition of the term *noncombustible material* before the 2012 edition of the *Code*. The former definition included requirements that should not be part of the defined term. *Code* users who attempt to locate the definition of *noncombustible material* in Chapter 3 are now directed by 3.3.180.11 to see 4.5.9. The provision of 4.5.9.1(1) recognizes that some materials are inherently noncombustible and do not require testing to receive a classification of noncombustible. Examples of such materials are provided in A.4.5.9.1(1).

A.4.5.9.1(1) Examples of such materials include steel, concrete, masonry, and glass. [**5000:**A.7.1.4.1.1(1)]

4.5.9.2 Where the term *limited-combustible* is used in this *Code*, it shall also include the term *noncombustible*. [**5000:**7.1.4.1.2]

4.5.10 Limited-Combustible Material. A material shall be considered a limited-combustible material where both of the following conditions of 4.5.10.1, and 4.5.10.2, and the conditions of either 4.5.10.3 or 4.5.10.4, are met. [**5000:**7.1.4.2]

4.5.10.1 The material does not comply with the requirements for a noncombustible material in accordance with 4.5.9. [**5000:**7.1.4.2(1)]

Δ **4.5.10.2** The material, in the form in which it is used, exhibits a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259. [**5000:**7.1.4.2(2)]

4.5.10.3 The material has a structural base of a noncombustible material with a surfacing not exceeding a thickness of ⅛ in. (3.2 mm) where the surfacing exhibits a flame spread index not greater than 50 when tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. [**5000:**7.1.4.2.1]

4.5.10.4 The material is composed of materials which, in the form and thickness used, neither exhibit a flame spread index greater than 25 nor evidence of continued progressive combustion when tested in accordance with ASTM E84 or ANSI/UL 723, and are of such composition that all surfaces that would be exposed by cutting through the material on any plane would neither exhibit a flame spread index greater than 25 nor evidence of continued progressive combustion when tested in accordance with ASTM E84 or ANSI/UL 723. [**5000:**7.1.4.2.2]

N **4.5.10.5** An alternate approach for a material to be considered a limited combustible material is where the material is tested in accordance with ASTM E2965, *Standard Test for Determination of Low Levels of Heat Release Rate for Materials and Products Using an Oxygen Combustion Calorimeter*, at an incident heat flux of 75 kW/m^2 for a 20-minute exposure, the peak heat release rate does not exceed 150 kW/m^2 for longer than 10 seconds, and the total heat released does not exceed 8 MJ/m^2. [**5000:**7.1.4.2.3]

4.5.10.6 Where the term *limited-combustible* is used in this Code, it shall also include the term *noncombustible*. [**5000:**7.1.4.2.4]

Subsection 4.5.10 represents a refinement of what had been the Chapter 3 definition of the term *limited-combustible material* before the 2012 edition of the *Code*. The former definition included requirements that should not be part of the defined term. *Code* users who attempt to locate the definition of *limited-combustible material* in Chapter 3 are now directed by 3.3.168 to see 4.5.10. The provision of 4.5.10.5 explains that, wherever the *Code* requires a material to be limited-combustible, the use of a noncombustible material is permitted.

SFPE Engineering Guide to Performance-Based Fire Protection, 2007.

Performance-Based Option

5

Chapter 5 provides requirements for performance-based designs applied to building projects. Chapter 5 is used in conjunction with the goals and objectives outlined in Chapter 4.

5.1* General

A.5.1 The performance option of this *Code* establishes acceptable levels of risk for facilities (i.e., buildings and other structures and the operations therewith associated) as addressed in Section 1.3. (Note that "facility" and "building" can be used interchangeably with facility being the more general term.) While the performance option of this *Code* does contain goals, objectives, and performance criteria necessary to provide for an acceptable level of risk, it does not describe how to meet these goals, objectives, and performance criteria. Design and engineering are needed to meet the provisions of Chapter 5. For fire protection designs, the *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* provides a framework for these assessments.

Pre-construction design requirements address those issues, which have to be considered before the certificate of occupancy is issued for a facility.

Historically, fundamental fire code provisions have been prescriptive in nature and have included specific requirements to ensure compliance. Requirements have typically evolved through a number of *Code* revision cycles, often as the result of lessons learned from past failures; new technologies, products, and applications; results obtained from research efforts; changes in construction practices; and many other reasons. Unfortunately, in the course of this evolution, the underlying reasons for particular *Code* provisions often are lost. This loss, in itself, is not necessarily detrimental. However, when a construction method or practice is encountered that is not addressed effectively by the *Code*, and equivalency and alternative provisions of Section 1.4 are needed, the loss of the underlying reason for a requirement can make it difficult to determine whether a proposed alternative provides an equivalent level of safety or protection.

Section 4.1 provides, in general, the goals and objectives of the provisions of the *Code*. Making decisions regarding whether to accept alternative designs and practices on the basis of these goals and objectives should provide for effective *Code* enforcement, since the Section 4.1 provisions apply to both the prescriptive-based and performance-based *Code* provisions.

Where the performance-based design option of 4.3.2 is selected for a particular application, the material included in Chapter 5 becomes a required part of the *Code* requirements to be applied to the design. If the prescriptive-based option in 4.3.1 is selected, Chapter 5 does not apply.

A number of organizations and educational institutions are advancing the science that forms the foundation for an effective performance-based fire protection design. Leading these organizations is the Society of Fire Protection Engineers (SFPE). A number of SFPE resources can be drawn on to support an effective performance-based fire protection design. In particular, the SFPE provides educational seminars and short courses, technical symposia and conferences, books and publications, and other materials designed to advance fire protection engineering and provide technical information to the fire protection community. The SFPE also sponsors task groups that address areas of concern in technical areas related to performance-based fire protection design, including topics such as risk, design performance criteria, design basis fires, human behavior in fire, design team liaison, and other areas. As pointed out in A.5.1.4, the *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* is an excellent resource for determining effective procedures to be followed in the performance-based design process. Another resource is the *SFPE Code Official's Guide to Performance-Based Design Review* (www.sfpe.org).

The U.S. Fire Administration offers a 6-day course to fire personnel, *Evaluating Performance Based Designs,* that can assist authorities having jurisdiction (AHJs) in performance-based designs (see www.usfa.fema.gov for details).

5.1.1 Application. The requirements of this chapter shall apply to facilities designed to the performance-based option permitted by Section 4.3.

5.1.2 Goals and Objectives. The performance-based design shall meet the goals and objectives of this *Code* in accordance with Section 4.1 and Section 4.2.

5.1.3* Approved Qualifications. The performance-based design shall be prepared by a person with qualifications acceptable to the AHJ.

A.5.1.3 Qualifications should include experience, education, and credentials that demonstrate knowledgeable and responsible use of applicable models and methods.

5.1.4* Plan Submittal Documentation. When a performance-based design is submitted to the AHJ for review and approval, the owner shall document, in an approved format, each performance objective and applicable scenario, including any calculation methods or models used in establishing the proposed design's fire and life safety performance.

A.5.1.4 The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* outlines a process for using a performance-based approach in the design and assessment of building fire safety design and identifies parameters that should be considered in the analysis of a performance-based design. As can be seen this process requires the involvement of all stakeholders who have a share or interest in the successful completion of the project. The steps that are recommended by the *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* for this process are shown in Figure A.5.1.4.

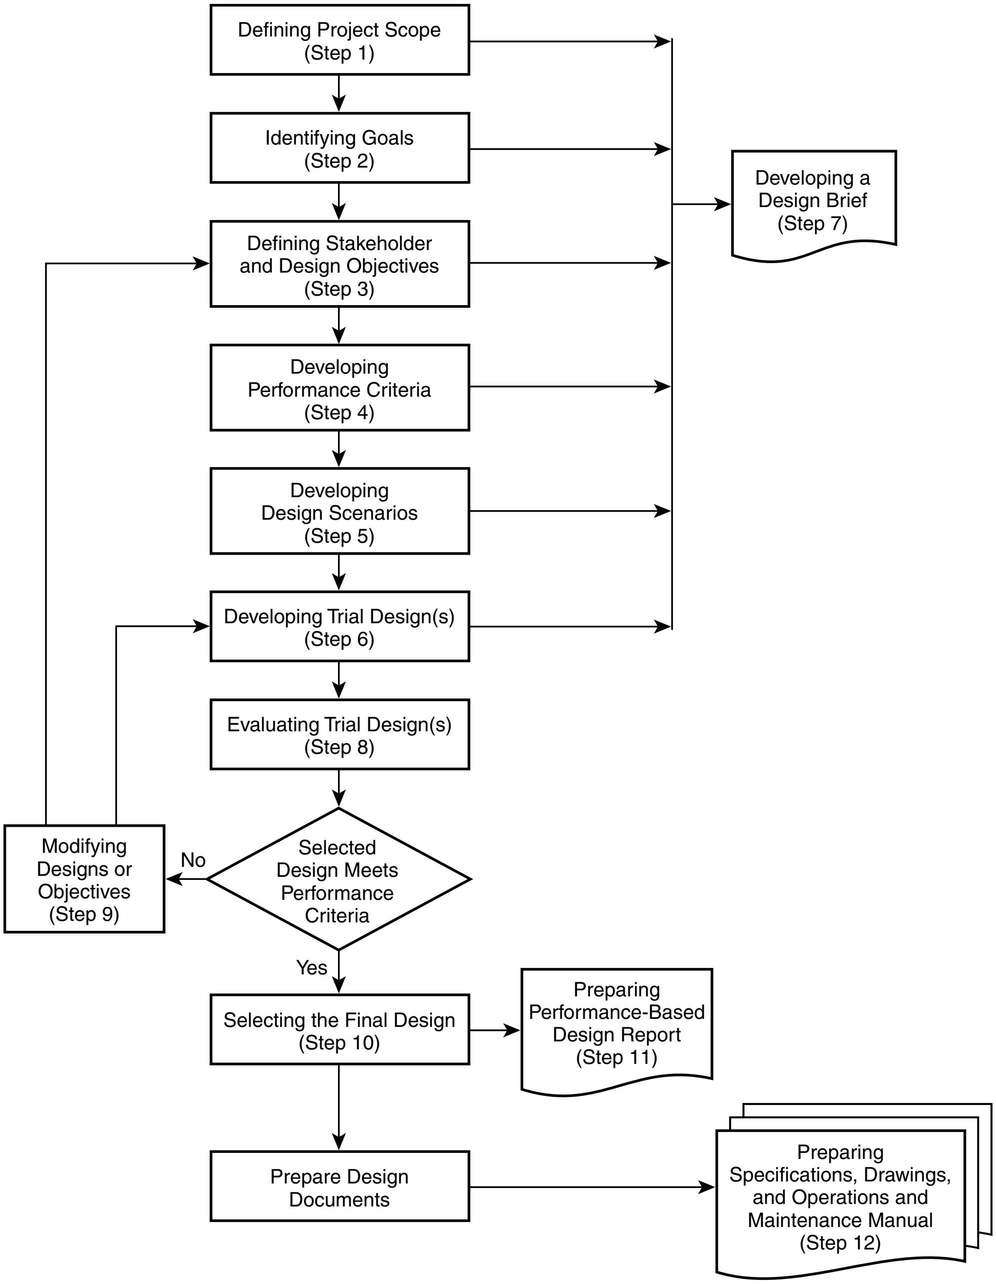

FIGURE A.5.1.4 *Steps in the Performance-Based Analysis and the Conceptual Design Procedure for Fire Protection Design.*

The guide specifically addresses building fire safety performance-based design. It might not be directly applicable to performance-based designs involving other systems and operations covered within this *Code*, such as hot work operations or hazardous materials storage. However, the various steps for defining, developing, evaluating, and documenting the performance-based design should still provide a useful framework for the overall design process.

Paragraph A.5.1.4 provides a summary of the procedure described in the *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* for conducting a performance-based design. This information is useful for understanding the arrangement of Chapter 5 requirements. The concepts, among many others described in A.5.1.4, such as performance criteria, design scenarios, and operations and maintenance manuals, form an integral part of the Chapter 5 requirements. All parties involved in a performance-based design are strongly encouraged to read and understand the recommendations included in the SFPE guide and to conduct the performance-based design, review, approval, and commissioning process in accordance with its recommendations.

The steps in the performance-based design process are as follows:

(1) *Step 1: Defining Project Scope.* The first step in a performance-based design is to define the scope of the project. Defining the scope consists of identifying and documenting the following:
   (a) Constraints on the design and project schedule
   (b) The stakeholders associated with project
   (c) The proposed building construction and features desired by the owner or tenant
   (d) Occupant and building characteristics
   (e) The intended use and occupancy of the building
   (f) Applicable codes and regulations
   An understanding of these items is needed to ensure that a performance-based design meets the stakeholders' needs.
(2) *Step 2: Identifying Goals.* Once the scope of the project is defined, the next step in the performance-based design process is to identify and document the fire safety goals of various stakeholders. Fire safety goals could include levels of protection for people and property, or they could provide for continuity of operations, historical preservation, and environmental protection. Goals could be unique for different projects, based on the stakeholders needs and desires. The stakeholders should discuss which goals are the most important for the project. In order to avoid problems later in the design process, all stakeholders should be aware of and agree to the goals prior to proceeding with the performance-based design process *(see Step 7)*.
(3) *Step 3: Defining Stakeholder and Design Objectives.* The third step in the design process is to develop objectives. The objectives are essentially the design goals that are further refined into tangible values that can be quantified in engineering terms. Objectives could include mitigating the consequences of a fire expressed in terms of dollar values, loss of life, or other impact on property operations, or maximum allowable conditions, such as extent of fire spread, temperature, spread of combustion products, and so forth.
(4) *Step 4: Developing Performance Criteria.* The fourth step in the design process is the development of performance criteria to be met by the design. These criteria are a further refinement of the design objectives and are numerical values to which the expected performance of the trial designs can be compared. Performance criteria could include threshold values for temperatures of materials, gas temperatures, carboxyhemoglobin (COHb) levels, smoke obscuration, and thermal exposure levels.
(5) *Step 5: Developing Design Scenarios.* Once the performance criteria have been established, the engineer will develop and analyze design alternatives to meet performance criteria. The first part of this process is the identification of possible scenarios and design scenarios. Fire scenarios are descriptions of possible fire events, and consist of fire characteristics, building characteristics (including facility operations), and occupant characteristics. The fire scenarios identified will subsequently be filtered (i.e., combined or eliminated) into a subset of design fire scenarios against which trial designs will be evaluated. Hazardous materials scenarios can be treated similarly.
(6) *Step 6: Developing Trial Design(s).* Once the project scope, performance criteria, and design scenarios are established, the engineer develops preliminary designs, referred to as trial designs, intended to meet the project requirements. The trial design(s) include proposed fire protection systems, construction features, and operation that are provided in order for a design to meet the performance criteria when evaluated using the design fire scenarios. The evaluation method should also be determined at this point. The evaluation methods used should be appropriate for the situation and agreeable to the stakeholders.
(7) *Step 7: Developing a Fire Protection Engineering Design Brief.* At this point in the process a fire protection engineering design brief should be prepared and provided to all stakeholders for their review and concurrence. This brief should document the project scope, goals, objectives, trial designs, performance criteria, design fire scenarios, and analysis methods. Documenting and agreeing upon these factors at this point in the design process will help avoid possible misunderstandings later.
(8) *Step 8: Evaluating Trial Designs.* Each trial design is then evaluated using each design scenario. The evaluation results will indicate whether the trial design will meet the performance criteria. Only trial design(s) that meet the performance criteria can be considered as final design proposals. Yet, the performance criteria can be revised with the stakeholders' approval. The criteria cannot be arbitrarily changed to ensure that a trial design meets a criterion, but can be changed based on additional analysis and the consideration of additional data.

(9) *Step 9: Modifying Designs or Objectives.* If none of the trial designs evaluated comply with the previously agreed upon performance criteria, it could be necessary to either develop and evaluate new trial designs, or revisit the objectives and performance criteria previously agreed upon by the stakeholders to determine if stakeholder objectives and performance criteria should be modified.

(10) *Step 10: Selecting the Final Design.* Once an acceptable trial design is identified using the evaluation, it can be considered for the final project design. If multiple trial designs are evaluated, further analysis will be needed to select a final design. The selection of an acceptable trial design for the final design could be based on a variety of factors, such as financial considerations, timeliness of installation, system and material availability, ease of installation, maintenance and use, and other factors.

(11) *Step 11: Preparing Performance-Based Design Report.* Once the final design is identified, design documents need to be prepared. Proper documentation will ensure that all stakeholders understand what is necessary for the design implementation, maintenance, and continuity of the fire protection design. The documentation should include the fire protection engineering design brief, a performance design report, detailed specifications and drawings, and a facility operations and maintenance manual.

(12) *Step 12: Preparing Specifications, Drawings, and Operations and Maintenance Manual.* The specifications and drawings portion of the performance-based design report convey to building and system designers and installing contractors how to implement the performance design. Specifications and drawings could include required sprinkler densities, hydraulic characteristics and spacing requirements, the fire detection and alarm system components and programming, special construction requirements including means of egress and location of fire-resistive walls, compartmentation, and the coordination of interactive systems. The detailed specifications are the implementation document of the performance-based design report. The detailed drawings will graphically represent the results of the performance design. The Operations and Maintenance (O&M) Manual clearly states the requirement of the facility operator to ensure that the components of the performance design are in place and operating properly. The O&M Manual describes the commissioning requirements and the interaction of the different systems' interfaces. All subsystems are identified, and inspection and testing regimes and schedules are created.

The O&M Manual also gives instruction to the facility operator on restrictions placed on facility operations. These limitations are based on the engineering assumptions made during the design and analysis. These limiting factors could include critical fire load, sprinkler design requirements, building use and occupancy, and reliability and maintenance of systems. The O&M Manual can be used to communicate to tenants and occupants these limits and their responsibilities as a tenant. It could also be used as a guide for renovations and changes. It also can be used to document agreements between stakeholders.

5.1.5* Independent Review. The AHJ shall be permitted to require an approved, independent third party to review the proposed design and provide an evaluation of the design to the AHJ at the expense of the owner.

A.5.1.5 A third-party reviewer is a person or group of persons chosen by the AHJ to review proposed performance-based designs. Qualifications of the third-party reviewer should include experience, education, and credentials that demonstrate knowledgeable and responsible use of applicable models and methods.

In some cases, a jurisdiction might have neither the resources nor skills necessary to conduct an effective review of a performance-based design submittal. To evaluate a complex performance-based design submittal effectively, the AHJ should meet the following criteria:

1. Expertise in the scientific foundation on which the design is based
2. Knowledge of the calculations and modeling tools used, as well as their limitations
3. Understanding of how the entire performance-based design process works

Where the staff of a jurisdiction does not possess this expertise, the AHJ is authorized to require a third-party review of the design and a report on the technical basis of the design. The third-party reviewer should possess the necessary qualifications and, as part of the independent review, provide sufficient findings regarding compliance issues so that the AHJ can make an informed decision about the action to be taken on the design (e.g., accept, reject, or require modifications). The third party, or peer reviewer, might be another engineering firm or reviewers from another jurisdiction.

Subsection 5.1.5 specifies that the AHJ has the option of requiring the owner to bear the costs of conducting the peer review. These costs could be recovered as an increased review fee and paid directly to the third party, or the AHJ could require that the owner directly pay the third party. The requirements of Section 1.15 regarding technical assistance can also apply to this independent review.

5.1.6 Sources of Data. Data sources shall be identified and documented for each input data requirement that is required to be met using a source other than a required design scenario, an assumption, or a facility design specification.

5.1.6.1 The degree of conservatism reflected in such data shall be specified, and a justification for the source shall be provided.

5.1.6.2 Copies of all references relied upon by the performance-based design to support assumptions, design features, or any other part of the design shall be made available to the AHJ if requested.

5.1.7 Final Determination. The AHJ shall make the final determination as to whether the performance objectives have been met.

The AHJ has the final decision-making authority regarding whether to accept a design, although the design professionals who prepared the design must also be confident that the design is satisfactory. If questions about the validity of the design arise, the design professional must be in a position to provide convincing evidence to the AHJ that the approach, designs, and methods of the submitted plans provide realistic results and are based on realistic scenarios.

5.1.8* Operations and Maintenance Manual. An approved Operations and Maintenance (O&M) Manual shall be provided by the owner to the AHJ and the fire department and shall be maintained at the facility in an approved location.

A.5.1.8 See Step 12 of A.5.1.4 for a description of these documents.

5.1.9* Information Transfer to the Fire Service. Where a performance-based design is approved and used, the designer shall ensure that information regarding the operating procedures of the performance-based designed fire protection system is transferred to the owner and to the local fire service for inclusion in the pre-fire plan.

A.5.1.9 Information that could be needed by the fire service arriving at the scene of a fire in a performance-based designed facility includes, but is not limited to, the following:

(1) Safe shutdown procedures of equipment and processes
(2) Facility personnel responsible for assisting the fire service
(3) Operating procedures required to maintain the effectiveness of the performance-based designed fire protection system: when it is and is not appropriate to alter, shut down, or turn off a design feature; assumptions that have to be maintained if a fire occurs; suggested fire-fighting tactics that relate to the specific nature of the performance-based design

The design specifications and O&M Manual documentation described in 5.1.8 should provide a guide for the facility owner and tenants to follow in order to maintain the required level of safety anticipated by the original design. It should also provide a guide for the AHJ to use in conducting ongoing inspections of the facility.

5.1.10* Design Feature Maintenance.

A.5.1.10 Continued compliance with the goals and objectives of the *Code* involves many factors. The building construction, including openings, interior finish, and fire- and smoke-resistive construction, and the building and fire protection systems need to retain at least the same level of performance as is provided for by the original design parameters. The use and occupancy should not change to the degree that assumptions made about the occupant characteristics, combustibility of furnishings, and existence of trained personnel are no longer valid. In addition, actions provided by other personnel, such as emergency responders, should not be diminished below the documented assumed levels. Also, actions needed to maintain reliability of systems at the anticipated level need to meet the initial design criteria.

Subsection 5.1.10 deals with issues that arise after the facility has been constructed and a certificate of occupancy has been issued. Therefore, any changes to the facility or the operations conducted therein, up to and including the demolition of the facility, that affect the assumptions of the original design are considered as part of the management of change.

The following is a process for evaluating performance-based facilities:

(1) Review of original design analysis and documentation as follows:
  (a) Assumptions
  (b) Input parameter values
  (c) Predictions and/or results of other calculations
(2) Review of design analysis and documentation for any subsequent renovations, additions, modifications, and so forth, as in Step 1 of A.5.1.4
(3) Review of the facility's operations and maintenance manual, including any and all revisions to it
(4) On-site inspection, involving the following:
  (a) Consideration of "prescriptive" issues (e.g., blocked egress paths, poor maintenance of systems)
  (b) Comparison of assumptions to specific, pertinent on-site conditions
  (c) Comparison of input parameter values to pertinent on-site conditions
  (d) Review of maintenance and testing documentation to ensure adherence to the schedules detailed in the facility's O&M Manual
(5) Reconciliation of discrepancies as follows:
  (a) Develop a list of discrepancies
  (b) Consultation with the facility owner and/or their representative
  (c) Preparation of a schedule that reconciles the discrepancies

The critical features of the initial design must be maintained for the life of the facility to ensure that those initially evaluated in accordance with the performance-based design option continue to comply with *Code* requirements. These features are unique for each design and must be maintained for future reference, since the prescriptive requirements of the *Code* are not applicable to the determination of ongoing compliance.

More important, documentation required as part of the performance-based design option must be maintained and used by both facility personnel and the AHJ to ensure that the facility or building maintains compliance with the *Code*. In particular, the Operations and Maintenance (O&M) Manual required in 5.1.8 is a crucial document.

In conducting periodic inspections of the facility, the AHJ should use the O&M Manual as a crucial part of the inspection because it describes the design features required for compliance. Attempting to use the prescriptive-based *Code* provisions can create problems.

As an example, one particular performance-based design might require the owner to control the quantity of combustible materials in a given area, such as a casino, well below the level of combustibles permitted by the prescriptive-based *Code* provisions. This limitation would be documented in the O&M Manual and would need to be strictly controlled on an ongoing basis by the building owner. If neither the owner nor the AHJ were aware of this critical design feature, and only the less stringent prescriptive requirements for combustibles in this area were applied, the facility would not achieve the *Code*'s basic goals and objectives and would not provide an acceptable level of protection.

Another performance-based design might not require a fire alarm system with automatic detection in a given area, even though such a system would be required by the prescriptive-based *Code* requirements. In this example, the performance-based design requires a constantly attended guard station within the area, along with a means to provide occupant notification initiated by the guards and additional exits from the area in excess of those required by the prescriptive *Code* provisions. An attempt by the AHJ to require a fire alarm system with automatic detection during subsequent inspections would not be warranted because the existing design features achieve the desired goals and objectives and provide an acceptable level of protection.

If changes to the facility's design features are desired, A.5.1.10 describes a process for evaluating compliance for a facility or building that was initially designed in accordance with the performance-based design option.

5.1.10.1 The design features required for the facility to meet the performance goals and objectives shall be maintained by the owner and be readily accessible to the AHJ for the life of the facility.

5.1.10.2 The facility shall be maintained in accordance with all documented assumptions and design specifications.

5.1.10.2.1 Any proposed changes or variations from the approved design shall be approved by the AHJ prior to the actual change.

5.1.10.2.2 Any approved changes to the original design shall be maintained in the same manner as the original design.

5.1.11* Annual Certification. Where a performance-based design is approved and used, the property owner shall annually certify that the design features and systems have been maintained in accordance with the approved original performance-based design and assumptions and any subsequent approved changes or modifications to the original performance-based design.

A.5.1.11 Private fire inspection services can be used to meet this provision provided that they are qualified to assess the impact of changes on the performance-based design and assumptions.

5.1.12 Hazardous Materials.

5.1.12.1 Performance-based designs for facilities containing high hazard contents shall identify the properties of hazardous materials to be stored, used, or handled and shall provide adequate and reliable safeguards to accomplish the following objectives, considering both normal operations and possible abnormal conditions:

(1) Minimize the potential occurrence of unwanted releases, fire, or other emergency incidents resulting from the storage, use, or handling of hazardous materials
(2) Minimize the potential failure of buildings, equipment, or processes involving hazardous materials by ensuring that such buildings, equipment, or processes are reliably designed and are suitable for the hazards present
(3) Minimize the potential exposure of people or property to unsafe conditions or events involving an unintended reaction or release of hazardous materials
(4) Minimize the potential for an unintentional reaction that results in a fire, explosion, or other dangerous condition
(5) Provide a means to contain, treat, neutralize, or otherwise handle plausible releases of hazardous materials to minimize the potential for adverse impacts to persons or property outside of the immediate area of a release
(6) Provide appropriate safeguards to minimize the risk of and limit damage and injury that could result from an explosion involving hazardous materials that present explosion hazards
(7) Detect hazardous levels of gases or vapors that are dangerous to health and alert appropriate persons or mitigate the hazard when the physiological warning properties for such gases or vapors are inadequate to warn of danger prior to personal injury
(8) Maintain power to provide for continued operation of safeguards and important systems that are relied upon to prevent or control an emergency condition involving hazardous materials
(9) Maintain ventilation where ventilation is relied upon to minimize the risk of emergency conditions involving hazardous materials
(10) Minimize the potential for exposing combustible hazardous materials to unintended sources of ignition and for exposing any hazardous material to fire or physical damage that can lead to endangerment of people or property

5.1.12.2 A process hazard analysis and off-site consequence analysis shall be conducted when required by the AHJ to ensure that people and property are satisfactorily protected from potentially dangerous conditions involving hazardous materials. The results of such analyses shall be considered when determining active and passive mitigation measures used in accomplishing the objectives of 4.1.3.3.2 and 4.1.4.2.

5.1.12.3 Written procedures for pre-start-up safety reviews, normal and emergency operations, management of change, emergency response, and accident investigation shall be developed prior to beginning operations at a facility designed in accordance with Section 5.1. Such procedures shall be developed with the participation of employees.

Fire and building codes historically have included prescriptive requirements for regulating the use, handling, and storage of hazardous materials. These requirements often supplemented federal requirements, such as those covered by the U.S. Occupational Safety and Health Administration's Process Safety Management (PSM) program and the U.S. Environmental Protection Agency's Risk Management Planning (RMP) program, which were based on regulations contained in Title 29 and Title 40, Code of Federal Regulations.

Performance-based risk management designs have been used for a number of years for facilities in which hazardous materials are stored, used, or handled. Paragraph 5.1.12.2 includes related requirements for conducting process hazard analyses and off-site consequence analyses when deemed appropriate by the AHJ.

5.1.13 Special Definitions. A list of special terms used in this chapter shall be as follows:

(1) Design Fire Scenario. *(See 3.4.9.1.)*
(2) Design Specification. *(See 3.4.5.)*
(3) Design Team. *(See 3.4.6.)*
(4) Exposure Fire. *(See 3.4.7.)*
(5) Fire Model. *(See 3.4.8.)*
(6) Fire Scenario. *(See 3.4.9.)*
(7) Fuel Load. *(See 3.4.10.)*
(8) Input Data Specification. *(See 3.4.12.)*
(9) Occupant Characteristics. *(See 3.4.13.)*
(10) Performance Criteria. *(See 3.4.14.)*
(11) Proposed Design. *(See 3.4.15.)*
(12) Safety Factor. *(See 3.4.17.)*
(13) Safety Margin. *(See 3.4.18.)*
(14) Sensitivity Analysis. *(See 3.4.2.1.)*
(15) Stakeholder. *(See 3.4.20.)*
(16) Uncertainty Analysis. *(See 3.4.2.2.)*
(17) Verification Method. *(See 3.4.22.)*

5.2 Performance Criteria

Performance criteria are threshold values used to judge the adequacy of a performance-based design and should be stated in engineering terms. For fire protection designs, performance criteria might include maximum temperatures, minimum smoke layer elevations, or maximum heat fluxes. For structural designs, performance criteria might be stated as a minimum load-carrying capability under a range of external loads.

The performance criteria presented in Section 5.2 were written to be general enough for use in any performance-based design project. However, further quantification of the performance criteria is likely to be necessary to provide numerical values that can be used to determine whether a proposed design strategy is acceptable. Annex A is intended to provide information and reference sources that can be used to develop quantitative performance criteria.

Eight types of performance criteria are presented in 5.2.2. These criteria relate to fire conditions (5.2.2.1), explosion conditions (5.2.2.2), hazardous materials exposure (5.2.2.3), property protection (5.2.2.4), public welfare (5.2.2.5), occupant protection from untenable conditions (5.2.2.6), emergency responder protection (5.2.2.7), and occupant protection from structural failure (5.2.2.8). Additional information on determining performance criteria is included in A.5.1.4, Step 4.

5.2.1 General. A design shall meet the objectives specified in Section 4.1 if, for each required design scenario, assumption, and design specification, the performance criteria of 5.2.2 are met.

5.2.2* Specific Performance Criteria.

A.5.2.2 The performance criteria in 5.2.2 define an acceptable level of performance that should be agreed upon by the stakeholders, including the owner and the AHJ. The acceptable level of performance can vary widely between different facilities based on a number of factors, including the existence of potential ignition sources, potential fuel loads present, reactivity and quantity of hazardous materials present, the nature of the operations conducted at the facility, and the characteristics and number of personnel likely to be present at the facility.

5.2.2.1* Fire Conditions.

Δ **A.5.2.2.1** Many of the performance criteria related to safety from fire can also be found in the annex of NFPA *101*.

5.2.2.2* Explosion Conditions. The facility design shall provide an acceptable level of safety for occupants and for individuals immediately adjacent to the property from the effects of unintentional detonation or deflagration.

A.5.2.2.2 It is anticipated that the design provides protection for occupants who are not intimate with the initial unintentional detonation or deflagration of explosive materials, and individuals immediately adjacent to the property. It is recognized that employees should be trained and knowledgeable in the hazards of the materials present in the workplace. It is recognized that some of these individuals could experience psychological and physical injuries, such as hearing problems, on either a short- or long-term basis. However, the intent is that they do not experience thermal burns or loss of life or limb as a direct result of the explosion.

It is not the intent of the *Code* to provide protection against explosions caused by acts of terrorism. This would involve the introduction of an unknown quantity of explosives in an unknown location within or adjacent to a building. Where protection is needed against such acts of terrorism, the appropriate military and law enforcement agencies should be consulted.

5.2.2.3* Hazardous Materials Exposure. The facility design shall provide an acceptable level of safety for occupants and for individuals immediately adjacent to the property from the effects of an unauthorized release of hazardous materials or the unintentional reaction of hazardous materials.

A.5.2.2.3 Given the nature and variety of hazardous materials, more than one performance criterion for a specific facility could need to be developed. Criteria have to be developed for each hazardous material and possibly for different personnel; for example, higher levels of exposure can be tolerated by personnel that are in some way protected than those personnel having no protection. Development of performance criteria for hazardous materials should be developed by the facility owner and the facility's safety personnel in conjunction with the AHJ and the emergency response personnel expected to respond to an incident.

It is anticipated that the design provides protection for occupants inside or immediately adjacent to the facility who are not intimate with the initial unauthorized release of hazardous materials, or the initial unintentional reaction of hazardous materials. However, it is assumed that these individuals depart from the area of the incident in a time frame reasonable for their circumstances, based on their observation of the event, or some other form of notification.

It is also anticipated that employees and emergency response personnel are trained and aware of the hazardous materials present in the facility, and the potential consequences of their involvement in the incident, and take appropriate measures to ensure their own safety during search and rescue operations.

It is not the intent of the *Code* to provide protection against acts of terrorism involving the introduction of hazardous materials into a facility. This involves the introduction of an unknown quantity of materials in an unknown location within or adjacent to a building. Where protection is needed against such acts of terrorism, the appropriate military and law enforcement agencies should be consulted.

5.2.2.4* Property Protection. The facility design shall limit the effects of all required design scenarios from causing an unacceptable level of property damage.

A.5.2.2.4 Each facility designed using a performance-based approach most likely has different levels of acceptable and unacceptable property damage. This reflects the unique aspects of the performance-based designed facility and the reasons for pursuing a performance-based design. Therefore, the definition of an acceptable and an unacceptable level of property damage results from discussions between the facility's owner, manager and engineer, the designer, (possibly) the insurance underwriter and field engineer, and the AHJ. There could be cases where a property damage criterion is not needed.

Note that the structural integrity performance criteria for property damage most likely differs from the structural integrity performance criteria for life safety. This reflects the difference in the associated objectives: a life safety criterion probably is more restrictive than one for property damage.

5.2.2.5* Public Welfare. For facilities that serve a public welfare role as defined in 4.1.5, the facility design shall limit the effects of all required design scenarios from causing an unacceptable interruption of the facility's mission.

A.5.2.2.5 Each facility designed using a performance-based approach most likely has a different level of acceptable and unacceptable interruption of the facility's mission. This reflects the unique aspects of the performance-based designed facility and the reasons for pursuing a performance-based design. Therefore, the definition of an acceptable and an unacceptable interruption of the facility's mission results from discussions between the facility's owner, manager and engineer, the designer, (possibly) the insurance underwriter and field engineer, and the AHJ. There could be cases where a mission continuity criterion is not needed.

5.2.2.6 Occupant Protection from Untenable Conditions. Means shall be provided to evacuate, relocate, or defend in place occupants not intimate with ignition for sufficient time so that they are not exposed to instantaneous or cumulative untenable conditions from smoke, heat, or flames.

5.2.2.7 Emergency Responder Protection. Buildings shall be designed and constructed to reasonably prevent structural failure under fire conditions for sufficient time to enable fire fighters and emergency responders to conduct search and rescue operations.

5.2.2.8 Occupant Protection from Structural Failure. Buildings shall be designed and constructed to reasonably prevent structural failure under fire conditions for sufficient time to protect the occupants.

The requirements of 5.2.2.7 and 5.2.2.8 to protect against structural failure can be met by limiting the size of potential fires. This goal can be accomplished by suppression or control of combustibles, either by creating a structure that would provide sufficient load-carrying capacity at the temperatures the combustibles would be expected to reach in a fire or by providing supplemental protection to the structure. In both cases, the stakeholders must be in agreement on the types of materials likely to be involved in the fire to determine the thermal impact expected to be imposed on key structural members.

Paragraph 5.2.2.7 requires that structural stability be provided long enough for the fire service to conduct search and rescue operations. The requirement does not intend that structural stability be provided indefinitely or for a time sufficient for the fire service to put out a fire.

The total time needed to conduct search and rescue operations needs to be determined and should include the time required for responders to arrive on scene, deploy, conduct search and rescue operations, and vacate the building (or a portion thereof) before its collapse.

The total time anticipated for these operations should be determined and documented in the plan submittal documentation (see 5.1.4). The critical factors associated with these response search and rescue times should be treated as design features and documented in the O&M Manual (see 5.1.8). If factors arise at a later date that affect the emergency responders' ability to complete the search and rescue operations in the allotted time, these factors will need to be evaluated as proposed design changes.

For example, if a particular design assumes a four-person emergency response would be provided from a fire station 5 minutes away and the station was subsequently closed, the increased travel distance from the next closest station would need to be determined and factored into the total response time. Compliance with these performance criteria would then have to be determined.

The inclusion of fire service performance measures as part of the performance-based design has been greatly debated. Questions such as the following arise:

1. Is the fire department part of the design equation?
2. If the design is based on a particular station location, performance measure, or staffing level, can the municipality change these parameters, or are they locked in?

3. What if the first-due personnel are on another run and a second-due company must respond?
4. Can the municipality close or move a fire station?

5.3 Retained Prescriptive Requirements

Section 5.3 includes a number of retained prescriptive requirements from Chapters 10 through 75 that are a required part of the performance-based design option. These prescriptive requirements are an essential part of any facility or building. If compliance with the specific requirements included in this section is not feasible, the equivalency options of Section 1.4 should be considered. However, these equivalencies could be difficult to determine, and it would ultimately be up to the AHJ to rule on the acceptability of any changes to these requirements.

5.3.1 Systems and Features. All fire protection systems and features of the building shall comply with applicable NFPA standards for those systems and features.

5.3.2 Electrical Systems. Electrical systems shall comply with applicable NFPA standards for those systems.

5.3.3 General. The design shall comply with the following requirements in addition to the performance criteria of Section 5.2 and the methods of Section 5.4 through Section 5.7:

(1) Fundamental requirements in Section 10.1
(2) Fire drills in Section 10.5
(3) Smoking in Section 10.9
(4) Open flame, candles, open fires, and incinerators in Section 10.10
(5) Fire protection markings in Section 10.11
(6) Seasonal and vacant buildings and premises in Section 10.12
(7) Combustible vegetation in Section 10.13
(8) Safeguards during building construction, alteration, and demolition operations in Chapter 16

Δ **5.3.4 Means of Egress.** The design shall comply with the following NFPA *101* requirements in addition to the performance criteria of Section 5.2 and the methods of Section 5.4 through Section 5.7:

(1) Changes in level in means of egress: 7.1.7 of NFPA *101*
(2) Guards: 7.1.8 of NFPA *101*
(3) Door openings: 7.2.1 of NFPA *101*
(4) Stairs: 7.2.2 of NFPA *101*

Exception: The provisions of 7.2.2.5.1, 7.2.2.5.2, 7.2.2.6.2, 7.2.2.6.3, and 7.2.2.6.4 of NFPA 101 shall be exempted.

(5) Ramps: 7.2.5 of NFPA *101*

Exception: The provisions of 7.2.5.3.1, 7.2.5.5, and 7.2.5.6.1 of NFPA 101 shall be exempted.

(6) Fire escape ladders: 7.2.9 of NFPA *101*
(7) Alternating tread devices: 7.2.11 of NFPA *101*
(8) Capacity of means of egress: Section 7.3 of NFPA *101*

Exception: The provisions of 7.3.3 and 7.3.4 of NFPA 101 shall be exempted.

(9) Impediments to egress: 7.5.2 of NFPA *101*
(10) Illumination of means of egress: Section 7.8 of NFPA *101*
(11) Emergency lighting: Section 7.9 of NFPA *101*
(12) Marking of means of egress: Section 7.10 of NFPA *101*

5.3.5 Equivalency. Equivalent designs for the features covered in the retained prescriptive requirements mandated by 5.3.1 through 5.3.4 shall be addressed in accordance with the equivalency provisions of Section 1.4.

5.4* Design Scenarios

A.5.4 Many events can occur during the life of a facility; some have a higher probability of occurrence than others. Some events, though not typical, could have a devastating effect on the facility. A reasonable design should be able to achieve the goals, objectives, and performance criteria of this *Code* for any typical or common design scenario and for some of the nontypical, potentially devastating scenarios, up to some level commensurate with society's expectations as reflected in this *Code*.

The challenge in selecting design scenarios is finding a manageable number that are sufficiently diverse and representative so that, if the design is reasonably safe for those scenarios, it should then be reasonably safe for all scenarios, except for those specifically excluded as being unrealistically severe or sufficiently infrequent to be fair tests of the design.

Section 5.4 contains requirements for design scenarios, which characterize the loads or hazards that a building is expected to withstand.

Paragraph 5.4.1.1 requires AHJ approval of the design scenario parameters. The types of parameters involved in a design scenario include quantification of loads, heat release rates, and quantification of the onset of hazardous conditions. The evaluation of design scenarios, as required by 5.4.1.2, is typically accomplished by using models or other tools. See Section 5.5 for additional information. Paragraph 5.4.1.4 addresses translating the design scenario into specifications. For example, the fire scenarios in 5.4.2 can be translated into heat release rates and quantification of hazards.

The commentary that follows suggests how suitable scenarios can be developed.

Introduction

To provide a comprehensive design (i.e., to demonstrate how the fire safety systems or the structural system will respond to a variety of challenges), more than one scenario should be considered. At least the following three types of scenarios should be considered:

1. High frequency, low consequence (typical)
2. Low frequency, high consequence (high challenge)
3. Special problems

For a fire event, the first scenario is used to demonstrate that the fire safety system can manage fires that start as relatively small fires but are frequent, such as a wastebasket fire. The second scenario covers fires such as one in an egress path, which would likely present a greater challenge to the fire safety system. The intent of this scenario is to consider a larger fire than the first scenario but not one so unrealistically large that it ensures the proposed design (or any other) will not perform adequately. The first two scenario types tacitly assume that the fire safety system will function as designed. However, the third scenario is included to account for situations in which some aspect of the fire safety system might be compromised. Examples of the third scenario include an improperly closed valve on a sprinkler system; a detection/alarm system temporarily out of service; multiple ignitions, which are characteristic of an arson fire; or degradation of the egress system after an earthquake or other natural disaster. The third scenario can also be used to consider the reliability of the fire safety system design.

Commentary Table 5.1 provides examples of general scenarios that might be experienced by most, if not all, occupancies. The table presents examples of typical and high-challenge fires, based on slow-, moderate-, and fast-developing fires that expose people in the room of origin who are not intimate with ignition and that occur in a room not normally occupied. Commentary Table 5.1 also presents examples of special problem fires for these same individuals.

The left-hand column of Commentary Table 5.1 indicates a general fire type, characterized by the rate at which a potential fire hazard might develop. Fire development is defined by a heat release rate curve. An additional factor in defining the type of fire is the peak heat release rate, which must be severe enough to challenge the fire safety system but not so severe that no design can reduce the hazards of the hypothetical fires effectively. The peak heat release rate is a function of the amount of fuel of the first item ignited, if the fire doesn't spread beyond it, or the maximum amount of fuel within the room of origin (i.e., room goes to flashover).

Scenario Components

At a minimum, a fire scenario consists of the following:

1. Ignition factors: source, location, and material; other items ignited, if applicable
2. At least one heat release rate curve (HRRC)
3. Occupant locations (see 5.4.5.3 of NFPA *101*®, *Life Safety Code*®)
4. Occupant characteristics (see 5.4.5 of NFPA *101*)
5. Special factors: shielded, systems unreliable, open door

Ignition Factors. Ignition factors include the source of ignition; the material that is first ignited and, if it is a solid, where it is ignited; and whether other items are also ignited. Ignition factors to consider when constructing these aspects of the scenario are shown in Commentary Table 5.2.

Ignition Sources. Ignition sources are of primary interest when considering the frequency of design fires. Sources of ignition include the following:

1. Smoking materials
2. Open flame
3. Electrical source
4. Incendiary
5. Hot surface
6. Spontaneous combustion
7. Radiant source

Various electrical ignition scenarios are possible, and historical data should be consulted to determine which type of ignition is most appropriate for the scenario and occupancy being considered. In addition to smoking-related ignitions and open flames, another example of incendiary ignition might be a runaway chemical reaction. Hot surfaces are most often associated with equipment used with either cooking, such as stoves or hot

COMMENTARY TABLE 5.1 *General Scenarios*

	Scenario	
Fire Type	***Occupant in Room of Fire Origin but Not Intimate***	***Room of Fire Origin Normally Unoccupied***
Slow-developing fire	Cigarette ignition of upholstered furniture Electrical ignition of small appliance or lighting, or overloaded outlet	Overloaded or failed wiring igniting switch gear, electrical devices, or insulation, followed by ignition of wooden structural members
Moderate-developing fire	Kitchen/cooking fire Trash can fire Open flame ignition of upholstered furniture	Wildland or exposure fire (e.g., from a neighboring building or parked car) Lightning-induced ignition of building roof Laundry room fire
Fast-developing fire	Flammable liquids	Flammable liquid storage
Shielded from systems or other problems present	Fire with impaired "first line of defense" Shielded flaming fires; limited fuel and larger	External trash collection or trash chute fire Flammable liquid storage Room of fire origin door open Fire in egress path

plates, or industrial processes, such as engines or furnaces. Spontaneous combustion is essentially an uncontrolled exothermic chemical reaction due to either a buildup of flammable vapors (e.g., due to improper storage or decomposition) or accidental mixing of reactive chemicals (e.g., some cleaning fluids). A common radiant source is a portable heater.

First Item Ignited. The first item ignited is somewhat dependent on the ignition source. For example, an overheated electrical wire is most likely to ignite its own insulation. Cooking fires usually ignite items close to the flames, rather than structural assemblies (e.g., walls or ceiling finish materials). The first item ignited is of interest for two reasons. The first is that it might pose either a thermal or a nonthermal hazard by itself, such as an occupied mattress or the toxic products resulting from its combustion. The second reason is that the first item might ignite a second item that poses an additional or greater hazard. Examples of second items include merchandise, structural assemblies, and carpets capable of releasing toxic combustion products. The column for "second item ignited" in Commentary Table 5.2 might not be necessary if the first item ignited presents enough of a hazard by itself. Certain types of upholstered furniture are in this category because of the toxic combustion products released and a relatively high heat release rate.

Second Item Ignited. Ignition of a second item is important in scenarios involving flashover or where structural stability is an issue. Ignition of a second item should be reflected in the heat release rate curve for the room of origin. Ignition of a second item can have the following two effects on the room heat release rate curve:

1. The peak heat release rate might be increased.
2. The growth phase of the fire might be accelerated.

The possibility of both phenomena occurring might apply to certain scenarios, for example, if the second item involves flammable liquids or gases.

Heat Release Rate Curves. Heat release rate curves can be constructed by referring to the *SFPE Handbook of Fire Protection Engineering* and Drysdale's *An Introduction to Fire Dynamics*, or by using manufacturers' test data.

Special Factors. Several factors, including ignition location, fire spread, relative location, interference with evacuation, and compartmentation barriers, can be critical to the development of scenarios.

Ignition Location. The location of the point of ignition can affect the eventual course and spread of a fire. In some cases, specifying a location also implies additional items in the scenario. For example, a kitchen fire could actually be a cooking fire that involves a burner igniting loose clothing or a grease fire igniting ordinary combustibles nearby.

Fire Spread. With regard to fire spread, the point of ignition is significant because it might, in part, determine the severity of the fire. An aspect of potential severity is the availability of oxygen. If the first item ignited is an upholstered chair, one of the following two scenarios could result, depending on whether the ignition location is other than the chair itself, such as a wastebasket fire, or directly involved with the chair, such as a cigarette located between the seat cushion and an arm of the chair.

Additionally, the point of origin might contribute to localized flashover, which has been observed in experiments involving bunk beds and desks with enclosed leg wells or modesty

COMMENTARY TABLE 5.2 *Ignition Factors*

Ignition Source	*First Item Ignited*	*Second Item Ignited*
Cigarette	Electrical equipment[1]	Structural assembly[2]
Electrical lighting	Wiring	Library book stack
Incendiary	Seating	Merchandise display
Spontaneous combustion	Sets and decorations	Carpets
Stove/hot plate	Exhibit displays	Curtains
Process-inherent[3]	Upholstered furniture	
	Electrical appliance	
	Trash	
	Ordinary combustibles[4]	
	Gas leaks	
	Flammable liquids	
	Mattress	
	Medical equipment	

[1]Includes, but is not limited to, dust collectors, uninterruptible power supplies, generators, HVAC equipment, dryers, and freezers.

[2]Consists of exterior/interior wall or ceiling finish, wall studs, ceiling joists, and insulation.

[3]Applies primarily to industrial settings.

[4]Includes mixtures of paper, common plastics, and other materials.

panels. These geometries tend to concentrate heat energy such that an intense fire is created in a relatively small area.

Relative Location. Relative location can be connected to the localized flashover. These fires are characterized by the fact that the ignition point is shielded from fire protection systems. The initial fire development is not sensed by the fire detection system, and, thus, the detection response is delayed. Delay results in a larger fire at the time of detection and a commensurate decrease in the time to evacuate. A common scenario involving shielded fires is a fire in warehouse rack storage.

Interference with Evacuation. The loss or degradation of any one egress path can place a significant burden on the fire safety system of a facility. One way that such a loss occurs is when a fire originates in part of the egress system. Degrees of severity vary. If more than two exits are available, the loss of one will have less of an impact than if only one or two exits are available. If a fire originates in a location shared by more than one egress path, such as where two egress paths merge into a single corridor or a dead-end corridor, the impact is greater than if the fire originates in one of several parallel egress routes.

Compartmentation Barriers. This situation involves the fire breaching a barrier or originating in a concealed space or on an exterior surface. When the fire breaches a barrier, the potential for a severe fire increases. The problem with fire originating in a concealed space or on an exterior surface is similar to that addressed in the "Relative Location" section of this commentary: the fire is shielded from detection or suppression systems.

General Design Scenarios

The general design scenarios shown in Commentary Table 5.3 are recommended as a starting point because they encompass the issues addressed in earlier commentary. For the instances where Commentary Table 5.3 does not apply, a process is provided for customizing the selection of factors in site-specific scenarios that address the concepts of the general scenarios.

Development of Scenarios. Guidelines that follow are for use in specifying fire scenarios.

1. Scenarios can be described partly through routine statistical analysis of fire experiences in similar buildings. Common or typical scenarios provide a good prediction of a building's performance if fire occurs. Such scenarios also tend to fit easily within the scope of available fire models and calculation methods. The AHJ can review the results for these scenarios to obtain a sense of the building's level of safety and the appropriateness of the calculations.

2. High-challenge scenarios are scenarios that pose unusual fire challenges to the building design. They are developed by refining common scenarios (e.g., changing the area of fire origin) to create a greater challenge. Also, high-challenge scenarios can be developed by reducing the challenge in scenarios previously identified as beyond the design expectations (i.e., too severe to use as the basis for evaluation).

Developing High-Challenge Scenarios from Common Scenarios. The following are illustrative techniques for developing high-challenge scenarios from common scenarios:

1. Change the area of fire origin.

- **a.** Consider an area (e.g., a bedroom) where occupants are likely to be particularly vulnerable.
- **b.** Consider an area (e.g., a concealed space, an external surface) where fire can develop outside the effective range of key fire protection features (such as detectors or sprinklers).
- **c.** Consider an area (e.g., an egress corridor) that is critical to occupant movement to safety.

2. Increase the initial size or speed of the fire's development. This might be done by adjusting the parameters in a fire growth model (e.g., increasing the alpha value in a *t*-squared–modeled fire; creating a scenario that reflects a fast or ultra-fast fire; increasing the peak heat release rate value for the fire) or by

COMMENTARY TABLE 5.3 *General Design Scenarios*

Typical Scenario	***High-Challenge Scenario***	***Special Problem Scenario***
Fast growth in room contents	Flammable liquids in means of egress	Ordinary fire in typical unoccupied room with sprinklers or detectors out of commission
Ordinary fire: • in attic or challenging concealed space • in typical occupied room with people not intimate with ignition	Largest room fire, fastest growth consistent with use Worst-case occupant characteristics	
Slow-developing fire in typical occupied room with worst-case occupant characteristics	Worst-case flame spread fire, if area critical to egress Flammable room linings or decorations	

increasing the assumed room fuel load or decreasing the space between major combustible items.

3. Assume common degradations in design assumptions. For example, assume the doors are blocked open, allowing the passage of fire effects to secondary spaces; or assume an unlimited oxygen supply for fire growth that could result from open doors, broken windows, or other circumstances.

4. Increase the toxicity or yields of products of combustion.

Developing High-Challenge Scenarios from Scenarios Beyond Design Expectations. Developing high-challenge scenarios from scenarios beyond design expectations involves less challenging quantitative assumptions. For example, if the bomb used in the New York City World Trade Center incident of 1993 was deemed too severe for a high-rise office building, how small a bomb would constitute an appropriate high-challenge test? To pose another example, if the *Code* cannot ensure protection of occupants who are intimate with initial fire development, how close can occupants be without being considered intimate?

5.4.1 General.

5.4.1.1 The proposed design shall be considered to meet the goals and objectives if it achieves the performance criteria for each required design scenario. The AHJ shall approve the parameters involved with required design scenarios.

5.4.1.2* Design scenarios shall be evaluated for each required scenario using a method acceptable to the AHJ and appropriate for the conditions. Each scenario shall be as challenging and realistic as any that could realistically occur in the building.

A.5.4.1.2 The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* identifies methods for evaluating fire scenarios.

5.4.1.3* Scenarios selected as design scenarios shall include, but not be limited to, those specified in 5.4.2 through 5.4.5.

A.5.4.1.3 It is desirable to consider a wide variety of different design scenarios to evaluate the complete capabilities of the building or structure. Design scenarios should not be limited to a single or a couple of worst-case events.

5.4.1.3.1 Design fire scenarios demonstrated by the design team to the satisfaction of the AHJ as inappropriate for the building use and conditions shall not be required to be evaluated fully.

5.4.1.3.2 Fire Design Scenario 8 *(see 5.4.2.8)* shall not be required to be applied to fire protection systems or features for which both the level of reliability and the design performance in the absence of the system or feature are acceptable to the AHJ.

5.4.1.4 Each design scenario used in the performance-based design proposal shall be translated into input data specifications, as appropriate for the calculation method or model.

5.4.1.5 Any design scenario specifications that the design analyses do not explicitly address or incorporate and that are, therefore, omitted from input data specifications shall be identified, and a sensitivity analysis of the consequences of that omission shall be performed.

5.4.1.6 Any design scenario specifications modified in input data specifications, because of limitations in test methods or other data generation procedures, shall be identified, and a sensitivity analysis of the consequences of the modification shall be performed.

5.4.2 Required Design Scenarios — Fire.

5.4.2.1* Fire Design Scenario 1. Fire Design Scenario 1 involves an occupancy-specific design scenario representative of a typical fire for the occupancy.

A.5.4.2.1 An example of such a scenario for a health care occupancy involves a patient room with two occupied beds with a fire initially involving one bed and the room door open. This is a cursory example in that much of the explicitly required information indicated in 5.4.2.1 can be determined from the information provided in the example. Note that it is usually necessary to consider more than one scenario to capture the features and conditions typical of an occupancy.

5.4.2.1.1 This design scenario shall explicitly account for the following:

(1) Occupant activities
(2) Number and location of occupants
(3) Room size
(4) Furnishings and contents
(5) Fuel properties and ignition sources
(6) Ventilation conditions

5.4.2.1.2 The first item ignited and its location shall be explicitly defined.

The idea behind Fire Design Scenario 1 in 5.4.2.1 is to ensure that the types of fires most likely to occur in a given occupancy type — that is, the statistically most significant scenarios — are considered in the design analysis. These scenarios can also be considered to be the statistically most significant scenarios — that is, those that happen most often in the type of facility being designed. These scenarios vary greatly, from small fires experienced weekly at aluminum rolling mills to kitchen fires in high-rise apartment buildings (i.e., residences).

5.4.2.2* Fire Design Scenario 2. Fire Design Scenario 2 involves an ultrafast-developing fire in the primary means of egress with interior doors open at the start of the fire. This design scenario shall address the concern regarding a reduction in the number of available means of egress.

A.5.4.2.2 Examples of such scenarios are a fire involving ignition of gasoline as an accelerant in a means of egress, clothing racks in corridors, renovation materials, or other fuel configurations that can cause an ultrafast fire. The means of egress chosen is the doorway with the largest egress capacity among doorways normally used in the ordinary operation of the building. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

Fire Design Scenario 2 is intended to provide information on the maximum potential spread of fire effects, mostly smoke and toxic products. It answers the question, "What is the maximum extent of smoke that might be experienced if an egress path is blocked?"

5.4.2.3* Fire Design Scenario 3. Fire Design Scenario 3 involves a fire that starts in a normally unoccupied room that can potentially endanger a large number of occupants in a large room or other area. This design scenario shall address the concern regarding a fire starting in a normally unoccupied room and migrating into the space that can, potentially, hold the greatest number of occupants in the building.

A.5.4.2.3 An example of such a scenario is a fire in a storage room adjacent to the largest occupiable room in the building. The contents of the room of fire origin are specified to provide the largest fuel load and the most rapid growth in fire severity consistent with the normal use of the room. The adjacent occupiable room is assumed to be filled to capacity with occupants. Occupants are assumed to be somewhat impaired in whatever form is most consistent with the intended use of the building. At ignition, doors from both rooms are assumed to be open. Depending on the design, doorways connect the two rooms or they connect via a common hallway or corridor.

For purposes of this scenario, an occupiable room is a room that could contain people (i.e., a location within a building where people are typically found).

5.4.2.4* Fire Design Scenario 4. Fire Design Scenario 4 involves a fire that originates in a concealed wall or ceiling space adjacent to a large occupied room. This design scenario shall address the concern regarding a fire originating in a concealed space that does not have either a detection system or suppression system and then spreading into the room within the building that can, potentially, hold the greatest number of occupants.

A.5.4.2.4 An example of such a scenario is a fire originating in a concealed wall- or ceiling-space adjacent to a large, occupied function room. Ignition involves concealed combustibles, including wire or cable insulation and thermal or acoustical insulation. The adjacent function room is assumed to be occupied to capacity. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

5.4.2.5* Fire Design Scenario 5. Fire Design Scenario 5 involves a slow-developing fire, shielded from fire protection systems, in close proximity to a high occupancy area. This design scenario shall address the concern regarding a relatively small ignition source causing a significant fire.

A.5.4.2.5 An example of such a scenario is a cigarette fire in a trash can. The trash can is close enough to room contents to ignite more substantial fuel sources but is not close enough to any occupant to create an intimate-with-ignition situation. If the intended use of the property involves the potential for some occupants to be incapable of movement at any time, then the room of origin is chosen as the type of room likely to have such occupants, filled to capacity with occupants in that condition. If the intended use of the property does not involve the potential for some occupants to be incapable of movement, then the room of origin is chosen to be an assembly or function area characteristic of the use of the property, and the trash can is placed so that it is shielded by furniture from suppression systems. At ignition, doors are assumed to be open throughout the building.

5.4.2.6* Fire Design Scenario 6. Fire Design Scenario 6 involves the most severe fire resulting from the largest possible fuel load characteristic of the normal operation of the building. This design scenario shall address the concern regarding a rapidly developing fire with occupants present.

A.5.4.2.6 An example of such a scenario is a fire originating in the largest fuel load of combustibles possible in normal operation in a function or assembly room or in a process/manufacturing area, characteristic of the normal operation of the property. The configuration, type, and geometry of the combustibles are chosen so as to produce the most rapid and severe fire growth or smoke generation consistent with the normal operation of the property. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be closed throughout the building.

This scenario includes everything from a big couch fire in a small dwelling to a rack storage fire in combustible liquids stock in a big box retail store.

The Dupont Plaza Hotel fire of 1986 in San Juan, Puerto Rico, in which 98 persons lost their lives, is an example of Fire Design Scenario 6 described in 5.4.2.6. The storage of chairs was part of the normal operating procedures of the hotel. The location and potential heat release of the chairs were evidently considered a small threat because of the lack of an ignition source. Unfortunately, a source was supplied, with tragic results.

5.4.2.7* Fire Design Scenario 7. Fire Design Scenario 7 involves an outside exposure fire. This design scenario shall address the concern regarding a fire starting at a location remote from the area of concern and either spreading into the area, blocking escape from the area, or developing untenable conditions within the area.

A.5.4.2.7 An example of such a scenario is an exposure fire. The initiating fire is the closest and most severe fire possible consistent with the placement and type of adjacent properties and the placement of plants and combustible adornments on the property. The baseline occupant characteristics of the property are assumed.

This category includes wildland/urban interface fires and exterior wood shingle problems, where applicable.

5.4.2.8* Fire Design Scenario 8. Fire Design Scenario 8 involves a fire originating in ordinary combustibles in a room or area with each passive or active fire protection system or feature independently rendered ineffective. This set of design scenarios shall address concerns regarding each fire protection system or fire protection feature, considered individually, being unreliable or becoming unavailable. This scenario shall not be required to be applied to fire protection systems or features for which both the level of reliability and the design performance in the absence of the system are acceptable to the AHJ.

A.5.4.2.8 This scenario addresses a set of conditions with a typical fire originating in the building with any one passive or active fire protection system or feature being ineffective. Examples include unprotected openings between floors or between fire walls or fire barrier walls, rated fire doors that fail to close automatically or are blocked open, sprinkler system water supply that is shut off, fire alarm system that's nonoperative, smoke management system that is not operational, or automatic smoke dampers that are blocked open. This scenario should represent a reasonable challenge to the other building features provided by the design and presumed to be available.

The exemption from Fire Design Scenario 8 is applied to each active or passive fire protection system individually and requires two different types of information to be developed by analysis and approved by the AHJ. System reliability is to be analyzed and accepted. Design performance in the absence of the system is also to be analyzed and accepted, but acceptable performance does not require fully meeting the stated goals and objectives. It might not be possible to meet fully the goals and objectives if a key system is unavailable, and yet no system is totally reliable. The AHJ determines which level of performance, possibly short of the stated goals and objectives, is acceptable, given the very low probability (that is, the system's unreliability probability) that the system will not be available.

Fire Design Scenario 8 provides information to the AHJ by answering a series of "What if . . . " questions. For example, what if the hotel sprinkler system is out of service when a fire occurs? What might be the extent of the fire and smoke and their subsequent effects on the egress system? Similar questions can be posed for other fire protection system components and subsystems.

5.4.3 Required Design Scenarios — Explosion.

5.4.3.1* Explosion Design Scenario 1.

A.5.4.3.1 This scenario is intended to address facilities where explosives, and products containing explosives, are manufactured, stored, sold, or handled. From an overall safety standpoint, the operations being performed at these facilities should include stringent safety procedures that significantly reduce the likelihood of an explosion from occurring. However, if an explosion does occur, protection methods such as storage magazines, property set backs, deflagration, and explosion venting and containment need to be in place, as appropriate, to minimize potential injury and loss of life and property.

Where products containing explosives, such as pyrotechnic displays or fireworks, are stored, handled, or used in buildings, such as arenas, an explosion scenario should not result in significant injuries to occupants not intimate with the materials.

5.4.3.1.1 Explosion Design Scenario 1 is the detonation or deflagration of explosive materials being manufactured, stored, handled, or used in a facility.

5.4.3.1.2 Explosion Design Scenario 1 shall address the concern regarding safety of individuals not intimate with the explosion and property protection of adjacent properties and buildings.

5.4.4* Required Design Scenarios — Hazardous Materials.

A.5.4.4 Design hazardous materials scenarios should explicitly account for the following:

(1) Occupant activities, training, and knowledge
(2) Number and location of occupants
(3) Discharge location and surroundings
(4) Hazardous materials' properties
(5) Ventilation, inerting, and dilution systems and conditions
(6) Normal and emergency operating procedures
(7) Safe shutdown and other hazard mitigating systems and procedures
(8) Weather conditions affecting the hazard
(9) Potential exposure to off-site personnel

Design hazardous materials scenarios should be evaluated as many times as necessary by varying the factors previously indicated. Design hazardous materials scenarios could need to be established for each different type of hazardous material stored or used at the facility.

5.4.4.1 Hazardous Materials Design Scenario 1. Hazardous Materials Design Scenario 1 involves an unauthorized release of hazardous materials from a single control area. This design scenario shall address the concern regarding the spread of hazardous conditions from the point of release.

5.4.4.2 Hazardous Materials Design Scenario 2. Hazardous Materials Design Scenario 2 involves an exposure fire on a location where hazardous materials are stored, used, handled, or dispensed. This design scenario shall address the concern regarding how a fire in a facility affects the safe storage, handling, or use of hazardous materials.

5.4.4.3 Hazardous Materials Design Scenario 3. Hazardous Materials Design Scenario 3 involves the application of an external factor to the hazardous material that is likely to result in a fire, explosion, toxic release, or other unsafe condition. This design scenario shall address the concern regarding the initiation of a hazardous materials event by the application of heat, shock, impact, or water onto a hazardous material being stored, used, handled, or dispensed in the facility.

5.4.4.4 Hazardous Materials Design Scenario 4.

5.4.4.4.1 Hazardous Materials Design Scenario 4 involves an unauthorized discharge with each protection system independently rendered ineffective. This set of design hazardous materials scenarios shall address concern regarding each protection system or protection feature, considered individually, being unreliable or becoming unavailable.

5.4.4.4.2* Hazardous Materials Design Scenario 4 shall not be required to be applied to protection systems or features for which both the level of reliability and the design performance in the absence of the system are acceptable to the AHJ.

A.5.4.4.4.2 This provision should be applied to each protection system individually and requires two different types of information to be developed by analysis and approved by the AHJ. System reliability is to be analyzed and accepted. Design performance in the absence of the system is also to be analyzed and accepted, but acceptable performance does not require fully meeting the stated goals and objectives. It might not be possible to meet fully the goals and objectives if a key system is unavailable, and yet no system is totally reliable. The AHJ determines which level of performance, possibly short of stated goals and objectives, is acceptable, given the very low probability (that is, the systems' unreliability probability) that the system will be unavailable.

The four hazardous materials design scenarios of 5.4.4 are intended to cover a variety of fault scenarios related to the storage, use, and handling of hazardous materials. Scenarios 1 through 3 require compliance with the goals and objectives to be achieved under a single fault condition related to the normal facility operations. These scenarios do not anticipate that simultaneous faults will occur concurrently, such as the simultaneous release of reactive materials for different control areas, the unauthorized release of a hazardous material, and simultaneous application of a force that causes that material to react violently. This scenario would include, as an example, the unauthorized release of a water-reactive material and the simultaneous application of water from an automatic sprinkler system in a location where the material is not normally stored, used, or handled.

Note that Scenario 4 *does* require a design to comply with the performance criteria in the event that an unauthorized release occurs and a detection or protection system is rendered ineffective (two simultaneous fault conditions). However, as noted in 5.4.4.4.2, this scenario is not required if the protection system has a high degree of reliability and the performance without a protection system is acceptable to the AHJ.

Part of the basis for requiring only a single fault condition to be considered for most of these scenarios is the assumption that protection systems are present in facilities containing hazardous materials, and quality control and safety-related practices are in place and used effectively by both facility management personnel and the workers involved with the materials and safety systems. Such systems and practices, if critical to achieve the goals and objectives of this *Code,* should be carefully documented in the facility's O&M Manual and verified during periodic inspections and other quality control audits.

5.4.5 Required Design Scenarios — Safety During Building Use.

5.4.5.1* Building Use Design Scenario 1. Building Use Design Scenario 1 involves an event in which the maximum occupant load is in the assembly building and an emergency event occurs blocking the principal exit/entrance to the building. This design scenario shall address the concern of occupants having to take alternative exit routes under crowded conditions.

A.5.4.5.1 An example of such a scenario would involve a fire or earthquake effectively blocking the principal entrance/exit but not immediately endangering the occupants. The full occupant load of the assembly space has to exit using secondary means.

5.4.5.2 Building Use Design Scenario 2. Building Use Design Scenario 2 involves a fire in an area of a building undergoing construction or demolition while the remainder of the building is occupied. The normal fire suppression system in the area undergoing construction or demolition has been taken out of service. This design scenario shall address the concern regarding the inoperability of certain building fire safety features during construction and demolition in a partially occupied building.

The two building use design scenarios described in 5.4.5 ensure some redundancy in the event primary exits are obstructed, blocked, or otherwise unavailable (Scenario 1), and they identify which effects might be imposed on egress time if select fire protection systems are unavailable.

Building Use Design Scenario 1 is directed at assembly occupancies where the principal exit, which is usually the means used by most occupants to enter the venue, is not available. This scenario, in many ways, is an adjunct to Fire Design Scenario 2 and Fire Design Scenario 7. (See 5.4.2.2 and 5.4.2.7.) Paragraph 5.4.5.1 does not, however, limit itself to fire events that might trigger the emergency. Fights, civil disturbances outside the building, and even weather-related events could cause crowd movement incidents that should be considered.

Building Use Design Scenario 2 is directed at any occupancy where the normal complement of safety features and systems is not present because of construction or demolition operations. Scenario 2 is an adjunct to Fire Design Scenario 8. (See 5.4.2.8.) Any proposed design should include alternate safety measures that would either remain in place or be provided temporarily until the work is complete and the permanent systems and features are back in place.

5.5 Evaluation of Proposed Designs

Evaluating proposed designs in accordance with Section 5.5 is typically accomplished by using models or other tools to compare the conditions that result through the use of a proposed design strategy to the performance criteria in Section 5.2. The types of models that might be used to evaluate proposed designs include physical models, such as full-scale or reduced-scale models, computer models, or hand calculations using simple equations.

5.5.1 General.

5.5.1.1 A proposed design's performance shall be assessed relative to each performance objective in Section 4.1 and each applicable scenario in Section 5.4, with the assessment conducted through the use of appropriate calculation methods.

5.5.1.2 The choice of assessment methods shall require the approval of the AHJ.

5.5.2 Use. The design professional shall use the assessment methods to demonstrate that the proposed design achieves the goals and objectives, as measured by the performance criteria in light of the safety margins and uncertainty analysis, for each scenario, given the assumptions.

5.5.3 Input Data.

5.5.3.1 Data.

5.5.3.1.1 Input data for computer fire models shall be obtained in accordance with ASTM E1591, *Standard Guide for Data for Fire Models*.

5.5.3.1.2 Data for use in analytical models that are not computer-based fire models shall be obtained using appropriate measurement, recording, and storage techniques to ensure the applicability of the data to the analytical method being used.

5.5.3.2 Data Requirements. A complete listing of input data requirements for all models, engineering methods, and other calculation or verification methods required or proposed as part of the performance-based design shall be provided.

5.5.3.3 Uncertainty and Conservatism of Data. Uncertainty in input data shall be analyzed and, as determined appropriate by the AHJ, addressed through the use of conservative values.

Just as evaluation methods have limitations, input data, as addressed in 5.5.3, might have limitations that must be identified and addressed. For example, heat release rate data obtained from burning a piece of furniture might be limited to that specific make and model of furniture. Use of data applicable to other types of furniture might introduce uncertainty, which would need to be addressed.

5.5.4 Output Data. The assessment methods used shall accurately and appropriately produce the required output data from input data based on the design specifications, assumptions, and scenarios.

5.5.5 Validity. Evidence shall be provided confirming that the assessment methods are valid and appropriate for the proposed facility, use, and conditions.

5.6* Safety Factors

Approved safety factors shall be included in the design methods and calculations to reflect uncertainty in the assumptions, data, and other factors associated with the performance-based design.

A.5.6 The assessment of precision required in 5.7.2 requires a sensitivity and uncertainty analysis, which can be translated into safety factors.

Sensitivity Analysis. The first run a model user makes should be labeled as the base case, using the nominal values of the various input parameters. However, the model user should not rely on a single run as the basis for any performance-based fire safety system design. Ideally, each variable or parameter that the model user made to develop the nominal input data should have multiple runs associated with it, as should combinations of key variables and parameters. Thus, a sensitivity analysis should be conducted that provides the model user with data that indicates how the effects of a real fire could vary and how the response of the proposed fire safety design could also vary.

The interpretation of a model's predictions can be a difficult exercise if the model user does not have knowledge of fire dynamics or human behavior.

Reasonableness Check. The model user should first try to determine whether the predictions actually make sense, that is, they don't upset intuition or preconceived expectations. Most likely, if the results don't pass this test, an input error has been committed.

Sometimes the predictions appear to be reasonable but are, in fact, incorrect. For example, a model can predict higher temperatures farther from the fire than close to it. The values themselves could be reasonable, for example, they are not hotter than the fire, but they don't "flow" down the energy as expected.

A margin of safety can be developed using the results of the sensitivity analysis in conjunction with the performance criteria to provide the possible range of time during which a condition is estimated to occur.

Safety factors and margin of safety are two concepts used to quantify the amount of uncertainty in engineering analyses. Safety factors are used to provide a margin of safety and represent, or address, the gap in knowledge between the theoretically perfect model, that is, reality and the engineering models that can only partially represent reality.

Safety factors can be applied to either the predicted level of a physical condition or to the time at which the condition is predicted to occur. Thus, a physical or a temporal safety factor, or both, can be applied to any predicted condition. A predicted condition (that is, a parameter's value) and the time at which it occurs are best represented as distributions. Ideally, a computer fire model predicts the expected or nominal value of the distribution. Safety factors are intended to represent the spread of these distributions.

Given the uncertainty associated with data acquisition and reduction, and the limitations of computer modeling, any condition predicted by a computer model can be thought of as an expected or nominal value within a broader range. For example, an upper layer temperature of 1110°F (600°C) is predicted at a given time. If the modeled scenario is then tested (that is, full-scale experiment based on the computer model's input data), the actual temperature at that given time could be 1185°F or 1085°F (640°C or 585°C). Therefore, the temperature should be reported as 1110°F + 75°F, –25°F (600°C + 40°C, –15°C) or as a range of 1085°F to 1184°F (585°C to 640°C).

Ideally, predictions are reported as a nominal value, a percentage, or an absolute value. As an example, an upper layer temperature prediction could be reported as 1112°F (600°C), 86°F (30°C) or 1112°F (600°C), 5 percent. In this case, the physical safety factor is 0.05 (that is, the amount by which the nominal value should be degraded and enhanced). Given the state-of-the-art of computer fire modeling, this is a very low safety factor. Physical safety factors tend to be on the order of tens of percent. A safety factor of 50 percent is not unheard of.

Part of the problem in establishing safety factors is that it is difficult to state the percentage or range that is appropriate. These values can be obtained when the computer model predictions are compared to test data. However, using computer fire models in a design mode does not facilitate this since (1) the room being analyzed has not been built yet and (2) test scenarios do not necessarily depict the intended design.

A sensitivity analysis should be performed based on the assumptions that affect the condition of interest. A base case that uses all nominal values for input parameters should be developed. The input parameters should be varied over reasonable ranges, and the variation in predicted output should be noted. This output variation can then become the basis for physical safety factors.

The temporal safety factor addresses the issue of when a condition is predicted and is a function of the rate at which processes are expected to occur. If a condition is predicted to occur 2 minutes after the start of the fire, then this can be used as a nominal value. A process similar to that described for physical safety factors can also be employed to develop temporal safety factors. In this case, however, the rates (for example, of heat release and toxic product generation) will be varied instead of absolute values (for example, material properties).

The margin of safety can be thought of as a reflection of societal values and can be imposed by the AHJ for that purpose. Since the time for which a condition is predicted is most likely the focus of the AHJ (for example, the model predicts occupants have 5 minutes to safely evacuate), the margin of safety is characterized by temporal aspects and tacitly applied to the physical margin of safety.

Escaping the harmful effects of fire (or mitigating them) is, effectively, a race against time. When assessing fire safety system designs based on computer model predictions, the choice of an acceptable time is important. When an AHJ is faced with the predicted time of untenability, a decision needs to be made regarding whether sufficient time is available to ensure the safety of facility occupants. The AHJ is assessing the margin of safety. Is there sufficient time to get everyone out safely? If the AHJ feels that the predicted egress time is too close to the time of untenability, then the AHJ can impose an additional time that the designer has to incorporate into the system design. In other words, the AHJ can impose a greater margin of safety than that originally proposed by the designer.

5.7 Documentation Requirements

5.7.1* General.

A.5.7.1 The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* describes the documentation that should be provided for a performance-based design.

Proper documentation of a performance design is critical to the design acceptance and construction. Proper documentation also ensures that all parties involved understand what is necessary for the design implementation, maintenance, and continuity of the fire protection design. If attention to details is maintained in the documentation, then there should be little dispute during approval, construction, start-up, and use.

Poor documentation could result in rejection of an otherwise good design, poor implementation of the design, inadequate system maintenance and reliability, and an incomplete record for future changes or for testing the design forensically.

5.7.1.1 All aspects of the design, including those described in 5.7.2 through 5.7.14, shall be documented.

5.7.1.2 The format and content of the documentation shall be acceptable to the AHJ.

5.7.2* Technical References and Resources.

A.5.7.2 The sources, methodologies, and data used in performance-based designs should be based on technical references that are widely accepted and used by the appropriate professions and professional groups. This acceptance is often based on documents that are developed, reviewed, and validated under one of the following processes:

(1) Standards developed under an open consensus process conducted by recognized professional societies, codes or standards organizations, or governmental bodies
(2) Technical references that are subject to a peer review process and published in widely recognized peer-reviewed journals, conference reports, or other publications
(3) Resource publications such as the *SFPE Handbook of Fire Protection Engineering*, which are widely recognized technical sources of information

The following factors are helpful in determining the acceptability of the individual method or source:

(1) Extent of general acceptance in the relevant professional community. Indications of this acceptance include peer-reviewed publication, widespread citation in the technical literature, and adoption by or within a consensus document.
(2) Extent of documentation of the method, including the analytical method itself, assumptions, scope, limitations, data sources, and data reduction methods.
(3) Extent of validation and analysis of uncertainties. This includes comparison of the overall method with experimental data to estimate error rates as well as analysis of the uncertainties of input data, uncertainties and limitations in the analytical method, and uncertainties in the associated performance criteria.
(4) Extent to which the method is based on sound scientific principles.
(5) Extent to which the proposed application is within the stated scope and limitations of the supporting information, including the range of applicability for which there is documented validation. Factors such as spatial dimensions, occupant characteristics, and ambient conditions can limit valid applications.

In many cases, a method is built from and includes numerous component analyses. These component analyses should be evaluated using the same factors that are applied to the overall method as outlined in items (1) through (5).

A method to address a specific fire safety issue, within documented limitations or validation regimes, might not exist. In such a case, sources and calculation methods can be used outside of their limitations, provided that the design team recognizes the limitations and addresses the resulting implications.

The technical references and methodologies to be used in a performance-based design should be closely evaluated by the design team and the AHJ, and possibly by a third-party reviewer. The strength of the technical justification should be judged using criteria in items (1) through (5). This justification can be strengthened by the presence of data obtained from fire testing.

5.7.2.1 The AHJ shall be provided with sufficient documentation to support the validity, accuracy, relevance, and precision of the proposed methods.

5.7.2.2 The engineering standards, calculation methods, and other forms of scientific information provided shall be appropriate for the particular application and methodologies used.

5.7.3 Facility Design Specifications. All details of the proposed facility design that affect the ability of the facility to meet the stated goals and objectives shall be documented.

5.7.4 Performance Criteria. Performance criteria, with sources, shall be documented.

5.7.5 Occupant Characteristics. Assumptions about occupant characteristics shall be documented.

5.7.6 Design Scenarios. Descriptions of design hazard scenarios shall be documented.

5.7.7 Input Data. Input data to models and assessment methods, including sensitivity analysis, shall be documented.

5.7.8 Output Data. Output data from models and assessment methods, including sensitivity analysis, shall be documented.

5.7.9 Safety Factors. Safety factors utilized shall be documented.

5.7.10 Prescriptive Requirements. Retained prescriptive requirements shall be documented.

5.7.11* Modeling Features.

A.5.7.11 Documentation for modeling should conform to ASTM E1472, *Standard Guide for Documenting Computer Software for Fire Models*, although most, if not all, models were originally developed before this standard was promulgated.

5.7.11.1 Assumptions made by the model user, and descriptions of models and methods used, including known limitations, shall be documented.

5.7.11.2 Documentation shall be provided that the assessment methods have been used validly and appropriately to address the design specifications, assumptions, and scenarios.

5.7.12 Evidence of Modeler Capability. The design team's relevant experience with the models, test methods, databases, and other assessment methods used in the performance-based design proposal shall be documented.

5.7.13 Performance Evaluation. The performance evaluation summary shall be documented.

5.7.14 Use of Performance-Based Design Option. Design proposals shall include documentation that provides anyone involved in ownership or management of the facility with all of the following notification:

(1) The facility was approved as a performance-based design with certain specified design criteria and assumptions.
(2) Any remodeling, modification, renovation, change in use, or change in the established assumptions requires a re-evaluation and re-approval.

Classification of Occupancy

6

Chapter 6 addresses the following considerations needed for accurately determining which *Code* provisions apply to a specific building:

1. Classification of occupancy
2. Choice of treating multiple occupancies as either mixed occupancies or separated occupancies
3. Categorization of the relative hazard presented by the contents or use of the building

Proper classification of the occupancy is crucial. Since the *Code* is not a one-size-fits-all document, the selection of the proper occupancy is of paramount importance to ensure that the correct chapters and sections of the *Code* are used. The occupancy classification scheme uses general descriptions of each occupancy (e.g., assembly, educational, day-care, or health care). The annex text that accompanies each of the occupancy classifications provides lists of the most common building uses for each classification.

Occupancy classification of a building often encompasses more than one category. Multiple occupancy types commonly coexist within a single building. For example, a hotel often consists of a multiple occupancy that includes hotel, assembly, mercantile, and business occupancies. Paragraph 6.1.14.1.1 permits multiple occupancies to be treated as either mixed occupancies or separated occupancies. An office building with a newsstand and sundries shop located off the main lobby might be classified wholly as a business occupancy by considering the mercantile use as incidental to the predominant business use as permitted by 6.1.14.1.3(1), thus avoiding the provisions applicable to a multiple occupancy.

6.1 Classification of Occupancy

Each of the occupancy groupings addressed by Chapter 6 was initially developed for use in NFPA *101*®, *Life Safety Code*®, to reflect the design features, usage patterns, and unique life safety needs of occupants who are characteristic of a given occupancy. This approach was used to assess the degree to which the features contained in the core chapters of NFPA *101* need to be combined to achieve the minimum level of life safety necessary for an occupancy. Correct classification of the occupancy is extremely important, because the *Code* requirements differ for each type of occupancy. Improper classification might result in an inadequate level of life safety or overspending on nonrequired items. The occupancy groupings are as follows:

1. *Assembly*. Assembly occupancies generally contain large numbers of people who are unfamiliar with the space and are, therefore, subject to indecision regarding the best means of egress in an emergency.

2. *Educational*. Educational occupancies primarily include large numbers of young people found in school buildings.

3. *Day-care.* Day-care occupancies contain both young and adult clients who are under the supervision of adults other than their relatives or legal guardians. In cases where day-care occupancies cater to preschool-age children, the occupants might need to be carried out of the facility during evacuation.

4. *Health care.* Health care occupancies are characterized by occupants who are incapable of self-preservation and occupy the occupancy on an inpatient basis. (For occupancies that provide health care services on an outpatient basis, see the description that follows on ambulatory health care occupancies.) In a health care occupancy, the occupants may not be able to use exits, regardless of the number of exits provided. Occupants might be immobile, connected to monitoring equipment, debilitated, recovering from surgery, or disabled in some other way. The *Code,* in this instance, calls for a defend-in-place design strategy that uses horizontal movement and compartmentation. It recognizes that the occupants are to be provided enough protection to enable them to survive the fire by remaining in the structure, at least temporarily.

5. *Ambulatory health care.* Ambulatory health care occupancies are similar to health care occupancies in that the occupants are generally incapable of self-preservation, but, unlike health care occupancies, the patients receive medical care on an outpatient basis. In many cases, the treatment causes the patient to be incapable of self-preservation. In other cases, a procedure, such as administering general anesthesia that is needed in conjunction with a treatment, renders the patient incapable of self-preservation. In yet other cases, the patient arrives at the ambulatory health care facility incapable of self-preservation due to an injury or illness, as is common in an emergency or urgent care outpatient facility. The ambulatory health care occupancy operates on an outpatient basis, so no individual patient occupies the building for a period of 24 hours or more.

6. *Detention and correctional.* Detention and correctional occupancies, as in the case of health care occupancies, house occupants who are incapable of self-preservation. In a detention and correctional occupancy, however, the incapability for self-preservation is due to the security imposed on the occupants. Because doors are not unlocked to allow free egress to the public way, the defend-in-place design strategy is used.

7. *Residential.* Residential occupancies are characterized by occupants who are asleep for a portion of the time they occupy the building. The sleeping that takes place is for normal restorative rest, as opposed to the sleeping that takes place in a hospital or residential board and care facility where caretakers are present. Sleeping occupants might be unaware of an incipient fire and might be trapped before egress can occur, thus creating a need for early warning smoke alarms. This occupancy group is further divided into one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and apartment buildings. Each occupancy in the group has characteristic needs that differ from the others. For this reason, separate occupancy-specific provisions address each of these subgroups.

8. *Residential board and care.* Residential board and care occupancies, as in the case of residential occupancies, provide sleeping accommodations. However, the residents also receive personal care services by caretakers who live with the residents. Personal care includes assistance with many of the activities of daily living, such as bathing and dressing. Personal care does not include medical care.

9. *Mercantile.* Mercantile occupancies, as in the case of assembly occupancies, are characterized by large numbers of people who gather in a space that is relatively unfamiliar to them. In addition, mercantile occupancies often contain sizable quantities of combustible contents and use circuitous egress paths that are deliberately arranged to force occupants to travel around displays of materials that are available for sale.

10. *Business.* Business occupancies generally have a lower occupant density than mercantile occupancies, and the occupants are usually more familiar with their surroundings. However, confusing and indirect egress paths are often developed due to office layouts and the arrangement of tenant spaces. The *Code* requirements for such occupancies address the needs of visitors unfamiliar with the building.

11. *Industrial.* Industrial occupancies expose occupants to a wide range of processes and materials of varying hazard. Special-purpose industrial occupancies, which are characterized by large installations of equipment that dominate the space, are addressed separately from general-purpose industrial facilities, which have higher densities of human occupancy.

12. *Storage.* Storage occupancies are characterized by relatively low human occupancy in comparison with building size and by varied hazards associated with the materials stored.

6.1.1 General.

6.1.1.1 Occupancy Classification. The occupancy of a building or structure, or portion of a building or structure, shall be classified in accordance with 6.1.2 through 6.1.13. Occupancy classification shall be subject to the ruling of the AHJ where there is a question of proper classification in any individual case. [***101:***6.1.1.1]

Because the appropriate occupancy classification is not always easily determined, the *Code* assigns the authority having jurisdiction (AHJ) the responsibility of determining whether the designer, the owner's representative, or other applicable person has correctly classified the occupancy.

6.1.1.2 Special Structures. Occupancies in special structures shall conform to the requirements of Section 20.16. [***101:***6.1.1.2]

The provision of 6.1.1.2 clarifies that placing an occupancy in a special structure — such as a limited access, underground, water-surrounded, or high-rise building — does not create a unique occupancy. Rather, the occupancy is classified as one of those addressed by Chapters 12 through 42 of NFPA *101*. Chapter 11 is then consulted to identify any permitted leniencies or additional requirements that apply to the special structure.

6.1.2 Assembly.
For requirements, see Section 20.1. [***101:***6.1.2]

6.1.2.1* Definition — Assembly Occupancy. An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load. [***101:***6.1.2.1]

Δ **A.6.1.2.1 Assembly Occupancy.** Assembly occupancies might include the following:

(1) Armories
(2) Assembly halls
(3) Auditoriums
(4) Bowling lanes
(5) Club rooms
(6) College and university classrooms, 50 persons and over
(7) Conference rooms
(8) Courtrooms
(9) Dance halls
(10) Drinking establishments
(11) Exhibition halls
(12) Gymnasiums

(13) Libraries
(14) Mortuary chapels
(15) Motion picture theaters
(16) Museums
(17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
(18) Places of religious worship
(19) Pool rooms
(20) Recreation piers
(21) Restaurants
(22) Skating rinks
(23) Special amusement buildings, regardless of occupant load
(24) Theaters

[***101:***A.6.1.2.1]

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation. [***101:***A.6.1.2.1]

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies. [***101:***A.6.1.2.1]

Occupancy of any room or space for assembly purposes by fewer than 50 persons in another occupancy, and incidental to such other occupancy, should be classified as part of the other occupancy and should be subject to the provisions applicable thereto. [***101:***A.6.1.2.1]

For special amusement buildings, see 12.4.7 and 13.4.7 of NFPA *101*. [***101:***A.6.1.2.1]

No *Code*-sanctioned occupancy is termed a *small assembly occupancy*. An occupancy used for the purposes of item (1) in 6.1.2.1 either is or is not an assembly occupancy, based on the 50-person criterion, with an exception for special amusement buildings, as addressed in item (2) of 6.1.2.1. As the fourth paragraph of A.6.1.2.1 advises, small assembly uses, which have an occupant load of fewer than 50 people, are considered part of the predominant occupancy [see 6.1.14.1.3(2)]. Except for special amusement buildings, as addressed in item (2) of 6.1.2.1, occupancies with occupant loads of fewer than 50 persons are not considered assembly occupancies. Exhibit 6.1 depicts an assembly occupancy.

6.1.2.2 Other. (Reserved)

6.1.3 Educational. For requirements, see Section 20.2. [***101:***6.1.3]

6.1.3.1* Definition — Educational Occupancy. An occupancy used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week. [***101:***6.1.3.1]

Exhibit 6.1

An assembly occupancy. (© Álvaro Germán Vilela, Dreamstime.com)

A.6.1.3.1 Educational Occupancy. Educational occupancies include the following:

(1) Academies
(2) Kindergartens
(3) Schools

[***101:***A.6.1.3.1]

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present. [***101:***A.6.1.3.1]

6.1.3.2 Other Occupancies. Other occupancies associated with educational institutions shall be in accordance with the appropriate parts of this *Code* and NFPA *101*. [***101:***6.1.3.2]

6.1.3.3 Incidental Instruction. In cases where instruction is incidental to some other occupancy, the section of this *Code* and NFPA *101* governing such other occupancy shall apply. [***101:***6.1.3.3]

Exhibit 6.2 depicts an educational occupancy.

An elementary school classroom used for the requisite hours detailed in 6.1.3.1, with an occupant load of 50 or more,

Exhibit 6.2

An educational occupancy. (© Cynthia Farmer, Dreamstime.com) is classified as an educational occupancy, not an assembly occupancy. The assembly occupancy criteria of 6.1.2.1 involve not just the minimum 50-person criterion but also the use criterion of gathering for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar use. See 14.2.5.4 and 15.2.5.4 of NFPA *101*, which require a second exit access door from any educational occupancy room with an occupant load of more than 50 persons.

Educational occupancies are limited to facilities used for educational purposes through the twelfth grade. A college classroom does not meet this criterion and is classified as a business occupancy or, where the college classroom has an occupant load of 50 or more, as an assembly occupancy.

Incidental instruction, as addressed in 6.1.3.3, conducted in some other occupancy is permitted to be considered part of that other occupancy and is subject to the provisions applicable to such other occupancy. For example, a developer of learning software might have a test lab where students, under the direction of teaching specialists, test the effectiveness of such software. The laboratory experience does not substitute for the students' normal schooling. The instruction is incidental to the building functioning as a business occupancy. The occupancy is classified as a business occupancy and is subject to the provisions of Section 20.13 of this *Code* and Chapter 38 or Chapter 39 of NFPA *101*.

6.1.4 Day Care. For requirements, see Section 20.3. [***101***:6.1.4]

6.1.4.1* Definition — Day-Care Occupancy. An occupancy in which four or more clients receive care, maintenance, and supervision, by other than their relatives or legal guardians, for less than 24 hours per day. [***101***:6.1.4.1]

A.6.1.4.1 Day-Care Occupancy. Day-care occupancies include the following:

(1) Adult day-care occupancies, except where part of a health care occupancy
(2) Child day-care occupancies
(3) Day-care homes
(4) Kindergarten classes that are incidental to a child day-care occupancy
(5) Nursery schools

[***101***:A.6.1.4.1]

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. Because these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed. [***101***:A.6.1.4.1]

Exhibit 6.3 depicts a day-care occupancy.

Day-care occupancies have some similarities with educational occupancies. However, in lieu of educational activity involving classroom occupants and teachers, the activities involve clients and staff, with staff serving as caretakers. The clients of a day-care occupancy might be adults. It has become fairly common practice for elderly adults to attend a day-care facility.

Exhibit 6.3

A day-care occupancy. (© Designpicssub, Dreamstime.com)

The provision of 6.1.14.1.3(2) permits a nonresidential use with an occupant load lower than the threshold established by Section 6.1 for a given occupancy to be considered part of the predominant occupancy where such nonresidential use is incidental to the predominant occupancy. Consider a day-care center for 10 clients where such center occupies less than 1000 ft² (93 m²) in a 100,000 ft² (9300 m²) office building. The day-care center is a nonresidential use. The occupancy threshold for day-care occupancy classification is four or more clients per 6.1.4.1. The day-care center occupies less than 1 percent of the building area, but it cannot be considered incidental to the business use. Per 6.1.4.1 and 6.1.14.1.3(2), it must be classified as a day-care occupancy. Thus, the building is classified as a multiple occupancy comprising both a business occupancy and a day-care occupancy. The building must meet the provisions of 6.1.14, including protection as either separated occupancies or mixed occupancies. In other words, the provisions for day-care occupancies must be applied, even though the day-care center is small in comparison to the remainder of the building. Otherwise, the day-care clients would not be adequately protected.

6.1.4.2 Other. (Reserved)

6.1.5 Health Care. For requirements, see Section 20.4. [***101***:6.1.5]

6.1.5.1* Definition — Health Care Occupancy. An occupancy used to provide medical or other treatment or care simultaneously to four or more patients on an inpatient basis, where such patients are mostly incapable of self-preservation due to age, physical or mental disability, or because of security measures not under the occupants' control. [***101***:6.1.5.1]

A.6.1.5.1 Health Care Occupancy. Health care occupancies include the following:

(1) Hospitals
(2) Limited care facilities
(3) Nursing homes
[*101:*A.6.1.5.1]

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons. [*101:*A.6.1.5.1]

Exhibit 6.4 depicts a health care occupancy.

Section 20.4 of this *Code* and Chapters 18 and 19 of NFPA *101* address hospitals, nursing homes, and limited care facilities as health care occupancies. These subclassifications of health care occupancies are defined in 3.3.192.13, 3.3.192.24, and 3.3.192.11, respectively. The definitions specify that each type of facility accommodate four or more persons. Because 24.1.1.2 of NFPA *101* permits a living unit housing a family and up to three outsiders to be classified as a one-family dwelling, a home with three or fewer persons incapable of self-preservation does not constitute a health care occupancy.

The definition of the term *health care occupancy* in 6.1.5.1 clarifies that it applies to patient care on an inpatient basis. In editions prior to 2009, the *Code* user learned this clarification by inference after reading the definition of the term *ambulatory health care occupancy,* which clearly stipulates the outpatient criterion. See 18.1.1.1.5, 18.1.1.1.9, 19.1.1.1.5, and 19.1.1.1.9 of NFPA *101* for criteria related to providing sleeping accommodations for more than 24 hours (i.e., the inpatient criterion). Health care occupancies, if they are to be protected by the provisions of Chapter 18 or Chapter 19 of NFPA *101*, must have at least four inpatients. A health care facility used only for outpatients is addressed by 6.1.6.1 as an ambulatory health care occupancy and is subject to the provisions of Section 20.6 of this *Code* and to those of Chapter 20 or Chapter 21 of NFPA *101*.

A definition of the term *birth center* appears in 3.3.34 of NFPA *101*. Also, guidance for whether a birth center is to be classified as a business occupancy or as a health care occupancy is provided in the third paragraph of A.6.1.11.1.

6.1.5.2 Other. (Reserved)

6.1.6 Ambulatory Health Care. For requirements, see Section 20.6. [*101:*6.1.6]

Δ **6.1.6.1* Definition — Ambulatory Health Care Occupancy.** An occupancy used to provide services or treatment simultaneously to four or more patients that provides, on an outpatient basis, one or more of the following:

(1) Treatment for patients that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others
(2) Anesthesia that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others
(3) Emergency or urgent care for patients who, due to the nature of their injury or illness, are incapable of taking action for self-preservation under emergency conditions without the assistance of others

[*101:*6.1.6.1]

A.6.1.6.1 Ambulatory Health Care Occupancy. It is not the intent that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches. Rather, it is the intent to address emergency care centers that receive patients who have been rendered incapable of self-preservation due to the emergency, such as being rendered unconscious as a result of an accident or being unable to move due to sudden illness. [*101:*A.6.1.6.1]

Exhibit 6.5 depicts an ambulatory health care occupancy.

Note that the definition of the term *ambulatory health care occupancy* in 6.1.6.1 stipulates an outpatient criterion and that

Exhibit 6.4

A health care occupancy. (© Paul Brennan, Dreamstime.com)

Exhibit 6.5

An ambulatory health care occupancy. (© Mark Winfrey, Dreamstime .com) the definition of the term *health care occupancy* in 6.1.5.1 stipulates an inpatient criterion. A health care facility used only for outpatients is addressed by 6.1.6.1 as an ambulatory health care occupancy and is subject to the provisions of Section 20.6 of this *Code* and to those of Chapter 20 or Chapter 21 of NFPA *101*. Health care occupancies, if they are to be protected by the provisions of Section 20.4 of this *Code* and by Chapter 18 or Chapter 19 of NFPA *101*, must have at least four inpatients. See 18.1.1.1.5, 18.1.1.1.9, 19.1.1.1.5, and 19.1.1.1.9 of NFPA *101* for criteria related to providing sleeping accommodations for more than 24 hours (i.e., the inpatient criterion).

Section 20.6 of this *Code* and Chapters 20 and 21 of NFPA *101* address the outpatient form of a health care occupancy. The requirements draw heavily from those applicable to business occupancies but supplement them with special provisions that address the fact that some patients in such occupancies are incapable of self-preservation. As is the case with other health care occupancies, the facility must accommodate at least four persons. The provisions of 6.1.6.1(1) through (3) further define the treatment, care, and initial condition of the patient that can render the patient incapable of self-preservation.

Dialysis treatment centers that accommodate four or more patients at one time generally fall under the classification of ambulatory health care occupancy based on 6.1.6.1(1). The blood-filtering treatment often wreaks havoc with the patients' blood pressure. Even if the patients are provided with instructions on how to clamp and cut their blood-filtering tubing, there is no guarantee that they have the capability of immediately evacuating the facility without the assistance of others.

Day surgery centers that accommodate four or more patients at one time generally fall under the classification of ambulatory health care occupancy based on 6.1.6.1(2). The anesthesia used prevents the patients from taking action for self-preservation under emergency conditions without the assistance of others.

Urgent-care centers that accommodate four or more patients at one time generally fall under the classification of ambulatory health care occupancy based on 6.1.6.1(3). The nature of the injury, illness, or condition present when the patients arrive for treatment prevents the patients from taking action for self-preservation under emergency conditions without the assistance of others.

The four-person criterion of 6.1.6.1 is meant to be applied independently on an area-by-area basis within a building. For example, a common practice is for individual health care practitioners to rent their own tenant space within a multi-tenant office building. Assume three dentists, each specializing in tooth extraction where the patients are under general anesthesia, have their own tenant spaces. Each of the three dentists does not have more than two patients under anesthesia or recovering from the effects of anesthesia at any time. Although, collectively, the three dentists might have six patients simultaneously rendered incapable of self-preservation due to anesthesia, the four-person criterion is not satisfied within any tenant space considered independently. Each dentist's office would be considered a business occupancy and not an ambulatory health care occupancy.

6.1.6.2 Other. (Reserved)

6.1.7 Detention and Correctional. For requirements, see Section 20.7. [***101:***6.1.7]

6.1.7.1* Definition — Detention and Correctional Occupancy. An occupancy used to house one or more persons under varied degrees of restraint or security where such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control. [***101:***6.1.7.1]

A.6.1.7.1 Detention and Correctional Occupancy. Detention and correctional occupancies include the following:

(1) Adult and juvenile substance abuse centers
(2) Adult and juvenile work camps
(3) Adult community residential centers
(4) Adult correctional institutions
(5) Adult local detention facilities
(6) Juvenile community residential centers
(7) Juvenile detention facilities
(8) Juvenile training schools

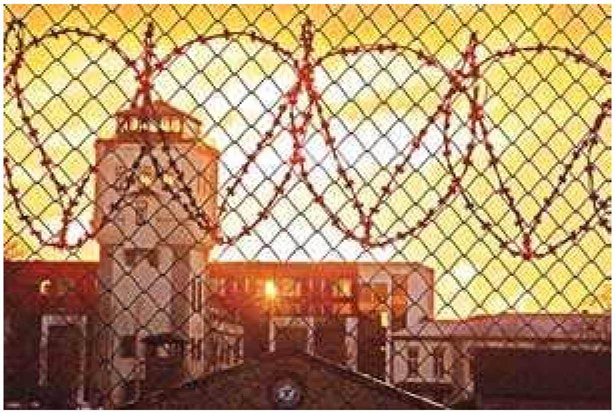
[***101:***A.6.1.7.1]

See A.22.1.1.1.6 and A.23.1.1.1.6 of NFPA *101*. [***101:***A.6.1.7.1]

Exhibit 6.6 depicts a detention and correctional occupancy.

The definition of the term *detention and correctional occupancy* (see 6.1.7.1) applies at the threshold of one or more persons. In editions prior to 2006, the threshold was four or more persons. This criterion for one person correlates with the provisions for lockups in other than detention and correctional occupancies, as addressed in 22.4.5 and 23.4.5 of NFPA *101*, which were added to that *Code* in 2006. The provisions for lockups are needed for application, even when only one

Exhibit 6.6



A detention and correctional occupancy. (© Maigi, Dreamstime.com) person is detained, because the locked doors characteristic of such detention deny the occupant free egress as required by 7.2.1.5 of NFPA *101*. A lockup in an occupancy other than detention and correctional that detains any individual for more than 24 hours is required to be classified as a detention and correctional occupancy (see 22.4.5.1.2 and 23.4.5.1.2 of NFPA *101*) and is subject to the provisions of Section 20.7 of this *Code* and to Chapter 22 or Chapter 23 of NFPA *101*. Thus, the provisions of Section 20.7 of this *Code* and of Chapters 22 and 23 of NFPA *101* needed to be made applicable to one or more residents.

Section 20.7 of this *Code* and Chapters 22 and 23 of NFPA *101* are intended to apply only to those areas of detention and correctional facilities used for occupant housing, such as sleeping and day activity areas. Other occupied spaces within the facility are to receive an occupancy classification representative of their use and are to be regulated by the applicable provisions of Chapter 20 of this *Code* and Chapters 12 through 21 and Chapters 24 through 42 of NFPA *101*. For example, cafeterias are regulated using the assembly occupancy chapters, and metal shops follow the requirements of the industrial occupancy chapter. The AHJ usually modifies the occupancy requirements of those chapters due to special security needs.

6.1.7.2* Nonresidential Uses. Within detention and correctional facilities, uses other than residential housing shall be in accordance with the appropriate chapter of this *Code* and NFPA *101*. *(See 22.1.2.3 and 23.1.2.3 of* NFPA *101.)* [***101:***6.1.7.2]

A.6.1.7.2 Chapters 22 and 23 of NFPA *101* address the residential housing areas of the detention and correctional occupancy as defined in 3.3.178.5 of NFPA *101*. Examples of uses, other than residential housing, include gymnasiums or industries. [***101:***A.6.1.7.2]

6.1.8 Residential. For requirements, see Sections 20.5 and 20.8 through 20.11. [***101:***6.1.8]

6.1.8.1 Definition — Residential Occupancy. An occupancy that provides sleeping accommodations for purposes other than health care or detention and correctional. [***101:***6.1.8.1]

6.1.8.1.1* Definition — One- and Two-Family Dwelling Unit. A building that contains not more than two dwelling units, each dwelling unit occupied by members of a single family with not more than three outsiders, if any, accommodated in rented rooms. [***101:***6.1.8.1.1]

A.6.1.8.1.1 One- and Two-Family Dwelling Unit. The application statement of 24.1.1.1 of NFPA *101* limits each dwelling unit to being "occupied by members of a single family with not more than three outsiders." This *Code* and NFPA *101* do not define the term *family*. The definition of family is subject to federal, state, and local regulations and might not be restricted to a person or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

(1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with Chapter 24 of NFPA *101*.
(2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to four or more individuals, but not more than 16, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26 of NFPA *101*.
(3) A residential building that is occupied by four or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26 of NFPA *101*.

[***101:***A.6.1.8.1.1]

Exhibit 6.7 depicts a one-family dwelling unit. The definition of the term *one- and two-family dwelling unit* was revised in 6.1.8.1.1 for the 2018 edition of the *Code* to correlate with application of Chapter 24 (see 24.1.1.2) of NFPA *101*.

Exhibit 6.7

A one-family dwelling unit. (© Ligonography, Dreamstime.com)

6.1.8.1.2 Definition — Lodging or Rooming House. A building or portion thereof that does not qualify as a one- or two-family dwelling, that provides sleeping accommodations for a total of 16 or fewer people on a transient or permanent basis, without personal care services, with or without meals, but without separate cooking facilities for individual occupants. [***101:***6.1.8.1.2]

Exhibit 6.8 depicts a lodging or rooming house.

6.1.8.1.3* Definition — Hotel. A building or groups of buildings under the same management in which there are sleeping accommodations for more than 16 persons and primarily used by transients for lodging with or without meals. [***101:***6.1.8.1.3]

Exhibit 6.8

A lodging or rooming house. (© Margiew, Dreamstime.com)

A.6.1.8.1.3 Hotel. So-called apartment hotels should be classified as hotels, because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days. [***101:***A.6.1.8.1.3]

Exhibit 6.9 depicts a hotel.

6.1.8.1.4* Definition — Dormitory. A building or a space in a building in which group sleeping accommodations are provided for more than 16 persons who are not members of the same family in one room, or a series of closely associated rooms, under joint occupancy and single management, with or without meals, but without individual cooking facilities. [***101:***6.1.8.1.4]

Exhibit 6.9

A hotel. (© Arbaes, Dreamstime.com)

A.6.1.8.1.4 Dormitory. Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples of dormitories include college dormitories, fraternity and sorority houses, and military barracks. [***101:***A.6.1.8.1.4]

Exhibit 6.10 depicts a dormitory.

Exhibit 6.10

A dormitory. (© Arim44, Dreamstime.com)

6.1.8.1.5 Definition — Apartment Building. A building or portion thereof containing three or more dwelling units with independent cooking and bathroom facilities. [***101:***6.1.8.1.5]

Exhibit 6.11 depicts an apartment building.

Residential occupancies are characterized by occupants who are asleep for a portion of the time they occupy the building. The sleeping that takes place is for normal restorative rest, as opposed to the sleeping that takes place in a hospital or residential board and care facility, where caretakers are present. Sleeping occupants might be unaware of an incipient fire and might be trapped before egress can occur. This occupancy group is further divided into one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and apartment buildings. Each occupancy in the group has characteristic needs that differ from the others. For this reason, separate chapters of the *Code* address each of these subgroups or subclassifications.

The residential occupancy subclassifications of one- and two-family dwellings, lodging or rooming houses, hotels, dormitories, and apartment buildings are defined in 6.1.8.1.1 through 6.1.8.1.5.

The definition of *apartment building* in 6.1.8.1.5 is copied from that in 3.3.192.2, which has advisory text in A.3.3.192.2. The text of A.3.3.192.2 clarifies that town house–type apartments — particularly those under condominium ownership — are to be

Exhibit 6.11

An apartment building. (© Tupungato, Dreamstime.com)

classified as apartment buildings. It is sometimes mistakenly believed that condominiums are a form of occupancy rather than a form of ownership.

Although people sleep in health care occupancies and detention and correctional occupancies, they occupy such facilities for other than normal residential purposes. Because the occupants of those facilities are incapable of self-preservation — in one case due to illness or infirmity and in the other as a result of security measures — the provisions that apply to normal residential occupancies might not provide the necessary level of life safety. The user is referred to Section 20.4 of this *Code* and Chapters 18 and 19 of NFPA *101* for inpatient health care occupancies and Section 20.7 of this *Code* and Chapters 22 and 23 of NFPA *101* for detention and correctional occupancies. See also 6.1.5 and 6.1.7.

6.1.8.2 Other. (Reserved)

6.1.9 Residential Board and Care. For requirements, see Section 20.5. [***101:***6.1.9]

6.1.9.1* Definition — Residential Board and Care Occupancy. An occupancy used for lodging and boarding of four or more residents, not related by blood or marriage to the owners or operators, for the purpose of providing personal care services. [***101:***6.1.9.1]

A.6.1.9.1 Residential Board and Care Occupancy. The following are examples of facilities classified as residential board and care occupancies:

(1) Group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
(2) Group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities
(3) Group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
(4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
(5) Assisted living facilities
(6) Other group housing arrangements that provide personal care services but not nursing care

[***101:***A.6.1.9.1]

Exhibit 6.12 depicts a residential board and care occupancy.

Residential board and care occupancies, as in the case of residential occupancies, provide sleeping accommodations. However, the residents also receive personal care services by caretakers who live with the residents. Personal care includes assistance with many of the activities of daily living, such as bathing and dressing. Personal care does not include medical care.

The provision of personal care services to residents of residential board and care facilities is an indicator that the residents might have special needs. The requirements of Chapters 32 and 33 of NFPA *101* credit the combined abilities of staff and residents to evacuate the building or relocate to a point of safety.

6.1.9.2 Other. (Reserved)

6.1.10 Mercantile. For requirements, see Section 20.12. [***101:***6.1.10]

Exhibit 6.12

A residential board and care occupancy. (© Jennifer Walz, Dreamstime .com)

6.1.10.1* Definition — Mercantile Occupancy. An occupancy used for the display and sale of merchandise. [***101:***6.1.10.1]

A.6.1.10.1 Mercantile Occupancy. Mercantile occupancies include the following:

(1) Auction rooms
(2) Department stores
(3) Drugstores
(4) Restaurants with fewer than 50 persons
(5) Shopping centers
(6) Supermarkets
[***101:***A.6.1.10.1]

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification. [***101:***A.6.1.10.1]

Exhibit 6.13 depicts a mercantile occupancy.

Mercantile occupancies, as in the case of assembly occupancies, are characterized by large numbers of people who gather in a space that is relatively unfamiliar to them. In addition, mercantile occupancies often contain sizable quantities of combustible contents and use circuitous egress paths that are deliberately arranged to force occupants to travel around displays of materials that are available for sale.

Mall buildings, while predominantly occupied by mercantile occupancies, typically have assembly occupancies within them (e.g., food courts or cinemas), classifying the mall building as a multiple occupancy building. In 12.1.3.3 and 13.1.3.3 of NFPA *101*, applicable to new and existing assembly occupancies, respectively, the provisions are made applicable to the assembly occupancy tenant space, but the specialized mall criteria of 36.4.4 and 37.4.4 of NFPA *101* are made applicable to the space outside the assembly occupancy tenant space, because that space might be used for egress by the occupants of the assembly occupancy.

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building occupied for sales purposes, are a subclass of mercantile occupancy with a greater potential for hazards than more traditional mercantile operations. See also Section 20.12 of this *Code* and 36.4.5 and 37.4.5 of NFPA *101*.

Exhibit 6.13

A mercantile occupancy. (© Michael Ludwig, Dreamstime.com)

6.1.10.2 Other. (Reserved)

6.1.11 Business. For requirements, see Section 20.13. [***101:***6.1.11]

6.1.11.1* Definition — Business Occupancy. An occupancy used for the transaction of business other than mercantile. [***101:***6.1.11.1]

A.6.1.11.1 Business Occupancy. Business occupancies include the following:

(1) Airport traffic control towers (ATCTs)
(2) City halls
(3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
(4) Courthouses
(5) Dentists' offices
(6) Doctors' offices
(7) General offices
(8) Outpatient clinics (ambulatory)
(9) Town halls [***101:***A.6.1.11.1]

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies. *(See 3.3.188.1 of NFPA 101.)* [***101:***A.6.1.11.1]

Birth centers should be classified as business occupancies if they are occupied by fewer than four patients, not including infants, at any one time; do not provide sleeping facilities for four or more occupants; and do not provide treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time. For birth centers occupied by patients not meeting these parameters, see Chapter 18 or Chapter 19 of NFPA *101*, as appropriate. [***101:***A.6.1.11.1]

Service facilities common to city office buildings, such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group. [***101:***A.6.1.11.1]

City halls, town halls, and courthouses are included in this occupancy group, insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies. [***101:***A.6.1.11.1]

Exhibit 6.14 depicts a business occupancy.

Business occupancies generally have a lower occupant density than mercantile occupancies, and the occupants are usually more familiar with their surroundings. However, confusing and indirect egress paths often exist due to office layouts and the arrangement of tenant spaces. The *Code* requirements for such occupancies address the needs of visitors unfamiliar with the building.

Depending on the characteristics of a laboratory, it may be classified as a business occupancy, industrial occupancy, or other occupancy.

Paragraph A.6.1.11.1 provides guidance in classifying a birth center as a business occupancy or a health care occupancy. The definition of the term *birth center* appears in 3.3.34 of NFPA *101*, along with explanatory material in A.3.3.34 of NFPA *101*.

A medical office that provides treatment or performs procedures that render patients incapable of self-preservation might be classified as an ambulatory health care occupancy or as a business occupancy. Guidance on the subject appears in the commentary that follows A.6.1.6.1.

6.1.11.2 Other. (Reserved)

6.1.12 Industrial. For requirements, see Section 20.14. [***101:***6.1.12]

6.1.12.1* Definition — Industrial Occupancy. An occupancy in which products are manufactured or in which processing, assembling, mixing, packaging, finishing, decorating, or repair operations are conducted. [***101:***6.1.12.1]

A.6.1.12.1 Industrial Occupancy. Industrial occupancies include the following:

(1) Drycleaning plants
(2) Factories of all kinds
(3) Food processing plants
(4) Gas plants
(5) Hangars (for servicing/maintenance)
(6) Laundries
(7) Power plants
(8) Pumping stations
(9) Refineries
(10) Sawmills
(11) Telephone exchanges

[***101:***A.6.1.12.1]

In evaluating the appropriate classification of laboratories, the AHJ should treat each case individually, based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial; for example, a physical therapy laboratory or a computer laboratory. [***101:***A.6.1.12.1]

Exhibit 6.15 depicts an industrial occupancy.

Industrial occupancies expose occupants to a wide range of processes and materials of varying hazards. Special-purpose industrial occupancies, which are characterized by large installations of equipment that dominate the space, are addressed separately from general-purpose industrial facilities, which have higher densities of human occupancy.

Industrial occupancy buildings, along with storage occupancy buildings, are more likely than any other occupancy to have contents with a wide range of hazards. Where industrial operations in a special-purpose industrial occupancy or general-purpose industrial occupancy include high hazard materials, processes, or contents (see 6.2.2.4 of NFPA *101*), the occupancy is to be classified as a high hazard industrial occupancy and not as a special-purpose or general-purpose industrial occupancy.

Depending on the characteristics of a laboratory, it may be classified as a business occupancy, industrial occupancy, or other occupancy.

6.1.12.2 Other. (Reserved)

6.1.13 Storage. For requirements, see Section 20.15. [***101:***6.1.13]

6.1.13.1* Definition — Storage Occupancy. An occupancy used primarily for the storage or sheltering of goods, merchandise, products, or vehicles. [***101:***6.1.13.1]

Exhibit 6.14

A business occupancy. (© Brianguest, Dreamstime.com)

Exhibit 6.15

An industrial occupancy. (© Typhoonski, Dreamstime.com)

A.6.1.13.1 Storage Occupancy. Storage occupancies include the following:

(1) Barns
(2) Bulk oil storage
(3) Cold storage
(4) Freight terminals
(5) Grain elevators
(6) Hangars (for storage only)
(7) Parking structures
(8) Truck and marine terminals
(9) Warehouses
[***101:***A.6.1.13.1]

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area. [***101:***A.6.1.13.1]

Exhibit 6.16 depicts a storage occupancy.

Storage occupancies are characterized by relatively low human occupancy in comparison to building size and by varied hazards associated with the materials stored.

Storage occupancy buildings, along with industrial occupancy buildings, are more likely than any other type of occupancy to have contents with a wide range of hazards.

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building occupied for sales purposes, are a subclass of mercantile occupancy rather than a storage occupancy. See 36.4.5 and 37.4.5 of NFPA *101*.

In *Code* editions prior to 2009, the sheltering of animals was one of the examples of a storage occupancy. The phrase *sheltering of animals* was deleted, because not all facilities housing animals are storage occupancies. See NFPA 150, *Standard on Fire and Life Safety in Animal Housing Facilities.*

Exhibit 6.16

A storage occupancy. (© Pemmett, Dreamstime.com)

6.1.13.2 Other. (Reserved)

6.1.14 Multiple Occupancies.

6.1.14.1 General.

Δ **6.1.14.1.1** Multiple occupancies shall comply with the requirements of 6.1.14.1 and one of the following:

(1) Mixed occupancies — 6.1.14.3
(2) Separated occupancies — 6.1.14.4
[***101:***6.1.14.1.1]

Classifying a building simply as a multiple occupancy is an incomplete classification, since the options for occupancy classification are limited to assembly, educational, day-care, health care, ambulatory health care, detention and correctional, residential (one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, or apartment buildings), residential board and care, mercantile, business, industrial, and storage. Rather, a classification of multiple occupancy needs to include mention of the occupancy types involved. For example, a multiple occupancy building with spaces used for sales and spaces used for storage should be classified as a multiple occupancy that is part mercantile occupancy and part storage occupancy.

Once a building is classified as a multiple occupancy and the occupancy types present are identified, the provisions of 6.1.14.1.1 are applied. Paragraph 6.1.14.1.1 offers the option of protecting multiple occupancies via the mixed occupancies requirements of 6.1.14.3 or via the separated occupancies requirements of 6.1.14.4.

If the mixed occupancies option of 6.1.14.3 is chosen for the protection of the multiple occupancy, the *Code* provisions for all occupancy types present must be compared. For each subject area addressed, the most stringent requirement from the applicable occupancy chapters must be identified and followed. Consider, for example, a new multiple occupancy building that is part ordinary hazard mercantile occupancy and part ordinary hazard storage occupancy for which the mixed occupancies form of protection is to be provided. In comparing the requirements of Chapter 36 for new mercantile occupancies and Chapter 42 for ordinary hazard storage occupancies in NFPA *101*, it becomes evident that neither occupancy is consistently stricter than the other on all features and systems addressed by the occupancy chapter. For example, both occupancies are permitted to use sensor-release of electrical locking systems in accordance with 14.5.3.2, but mercantile occupancies are permitted to do so only if the entire building is protected throughout by either a fire detection system or a sprinkler system (see 36.2.2.2.6 and 42.2.2.2.3 of NFPA *101*). Mercantile occupancies are permitted to use horizontal or vertical security grilles or doors in accordance with 7.2.1.4.1(3) of NFPA *101* as part of the means of egress from a tenant space (see 36.2.2.2.7 of NFPA *101*), but no such permission is given for storage occupancies in 42.2.2.2 of NFPA *101*. In each case, the more stringent provision must be followed in the multiple occupancy being protected as a mixed occupancy.

If the separated occupancies option of 6.1.14.4 is chosen for the protection of the multiple occupancy, the *Code* user must identify the appropriate cell or cells of Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b) to determine the minimum hourly fire resistance rating needed for the barriers separating the occupancies from each other.

6.1.14.1.2 Where exit access from an occupancy traverses another occupancy, the multiple occupancy shall be treated as a mixed occupancy. [***101:***6.1.14.1.2]

Paragraph 6.1.14.1.2 was new to the 2006 edition of the *Code*. It was added to clarify the original intent, which was not fully explained when the provisions for multiple occupancies were added to the 2003 edition. Users incorrectly believed they could satisfy the provisions for multiple occupancies protected as separated occupancies by complying with the following two-step approach:

1. Separate the multiple occupancies from each other by the fire resistance–rated construction required by Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b).
2. Provide egress paths from one of the occupancies to involve travel through doors in the separating construction into the other occupancy (meaning that the two occupancies would share exit access, e.g., in a common corridor). See Exhibit 6.17.

The shared exit access corridor system does not permit the multiple occupancy to be protected as separated occupancies. Instead, the multiple occupancy must be protected as mixed occupancies.

In Exhibit 6.18, the two required means of egress for the business occupancy are provided by two remotely located doors opening directly to the outside. The door openings to the corridor, located in the fire resistance–rated occupancy separation barrier, are convenient extras not required by the *Code*. With this arrangement, the multiple occupancy is permitted to be protected as separated occupancies.

Δ **6.1.14.1.3*** Where incidental to another occupancy, areas used as follows shall be permitted to be considered part of the predominant occupancy and shall be subject to the provisions of this *Code* and NFPA *101* that apply to the predominant occupancy:

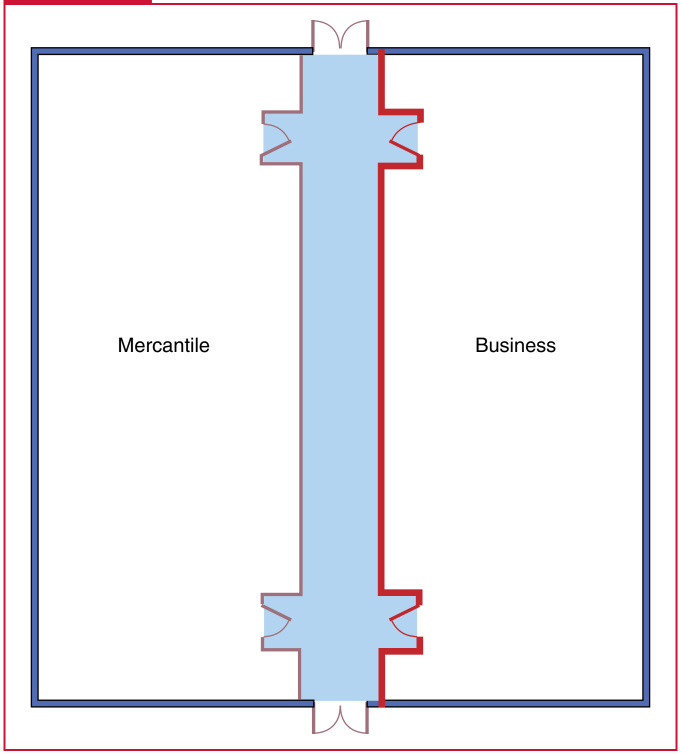
(1) Mercantile, business, industrial, or storage use
(2)* Nonresidential use with an occupant load fewer than that established by Section 6.1 for the occupancy threshold

[***101:***6.1.14.1.3]

A.6.1.14.1.3 Examples of uses that might be incidental to another occupancy include the following:

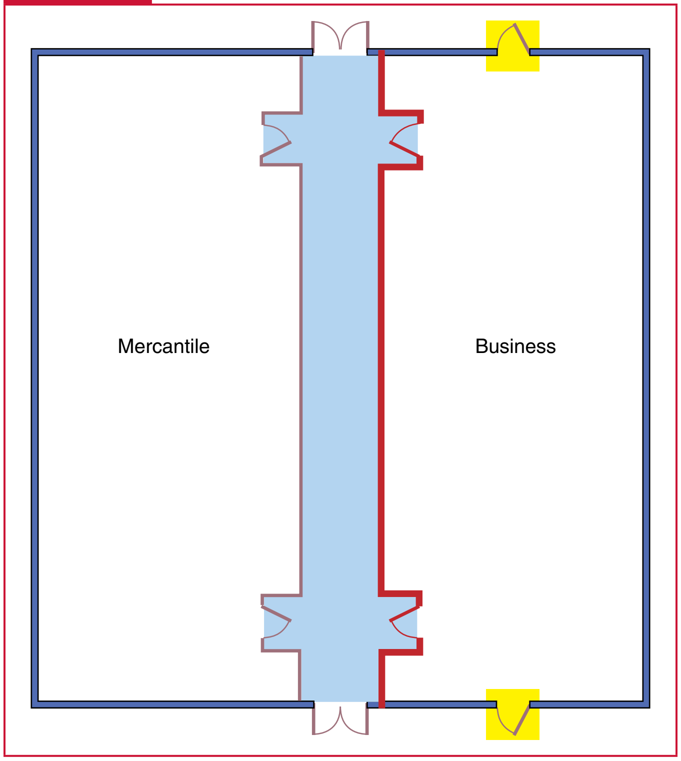
(1) Newsstand (mercantile) in an office building
(2) Giftshop (mercantile) in a hotel

Exhibit 6.17



Multiple occupancy building with shared egress corridor, which prohibits it from protection via the separated occupancy provisions.

Exhibit 6.18



Multiple occupancy building permitted to be protected via the separated occupancy provisions.

(3) Small storage area (storage) in any occupancy
(4) Minor office space (business) in any occupancy
(5) Maintenance area (industrial) in any occupancy
[***101:***A.6.1.14.1.3]

A.6.1.14.1.3(2) Examples of uses that have occupant loads below the occupancy classification threshold levels include the following:

(1) Assembly use with fewer than 50 persons within a business occupancy
(2) Educational use with fewer than 6 persons within an apartment building.
[***101:***A.6.1.14.1.3(2)]

Paragraph 6.1.14.1.3 clarifies that some, but not all, incidental uses can be considered part of the predominant occupancy. Incidental residential uses, regardless of the number of persons for whom sleeping accommodations are provided, are classified as residential occupancies and are subject to the appropriate residential occupancy chapter requirements. For example, if there are sleeping facilities for five fire fighters in a fire station, the *Code* does not permit the building to be classified simply as a storage occupancy where motor vehicles are sheltered. Rather, the proper classification is a multiple occupancy that is part storage occupancy and part residential occupancy (i.e., lodging or rooming house in this case). The requirements that apply to both occupancies need to be compared, with the more stringent provisions applied in accordance with 6.1.14.3, or the occupancies need to be separated from each other by fire resistance–rated construction in accordance with 6.1.14.4, in which case each occupancy is prohibited from sharing the other occupancy's exit access per 6.1.14.1.2.

In addition, a day-care use with more than 3 clients is not exempted by either of the criteria of 6.1.14.1.3. For example, a small day-care center with 14 clients located in a high-rise office building is not part of the predominant business occupancy. The more stringent of the requirements that apply to day-care occupancies and business occupancies need to be implemented in accordance with 6.1.14.3, or the occupancies need to be separated from each other by fire resistance–rated construction in accordance with 6.1.14.4, in which case each occupancy is prohibited from sharing the other occupancy's exit access per 6.1.14.1.2.

If the day-care use in the high-rise office building addressed in the preceding paragraph had only 3 clients, that number of clients would be less than the threshold number of 4 clients at which a day-care use becomes a day-care occupancy (see 6.1.4.1). The day-care use could, therefore, be classified as incidental to the business occupancy as permitted by 6.1.14.1.3(2).

6.1.14.2 Definitions.

6.1.14.2.1 Multiple Occupancy. A building or structure in which two or more classes of occupancy exist. [***101:***6.1.14.2.1]

6.1.14.2.2 Mixed Occupancy. A multiple occupancy where the occupancies are intermingled. [***101:***6.1.14.2.2]

6.1.14.2.3 Separated Occupancy. A multiple occupancy where the occupancies are separated by fire barriers. [***101:***6.1.14.2.3]

6.1.14.3 Mixed Occupancies.

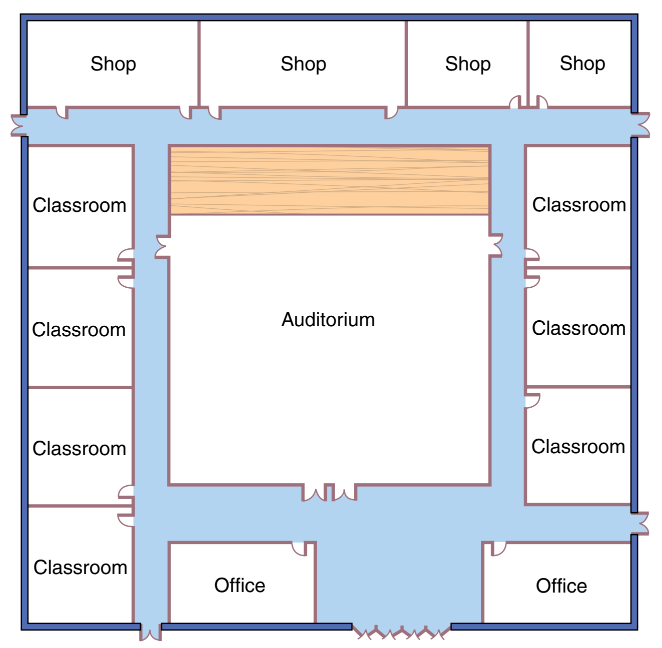
6.1.14.3.1 Each portion of the building shall be classified as to its use in accordance with Section 6.1. [***101:***6.1.14.3.1]

6.1.14.3.2 The building shall comply with the most restrictive requirements of the occupancies involved unless separate safeguards are approved. [***101:***6.1.14.3.2]

An example of a multiple occupancy building that is protected as a mixed occupancy is illustrated in Exhibit 6.19. Because the assembly occupancy (i.e., the auditorium) shares the internal corridor egress system with the educational occupancy classrooms and shops, separating the individual occupancies from each other so that they do not share any common exit access is impractical. Therefore, the provision of 6.1.14.1.2 requires that the multiple occupancy be protected as a mixed occupancy.

In the building depicted in Exhibit 6.19, assume that the office space (business occupancy) is considered incidental and that the predominant occupancies are educational (i.e., the classrooms and shops) and assembly (i.e., the auditorium) as permitted by 6.1.14.1.3(1). Assuming also that the building is new, the occupancy requirements of Section 20.1 of this *Code* and Chapter 12 of NFPA *101* for new assembly occupancies are

Exhibit 6.19



Multiple occupancy building protected via the mixed occupancy provisions.

compared with those of Section 20.2 of this *Code* and Chapter 14 of NFPA *101* for new educational occupancies for each of the subjects addressed by the *Code*. In each comparison of requirements between the applicable occupancy chapters, the more stringent requirement is chosen as having applicability to the multiple occupancy.

For example, the 6 ft (1830 mm) minimum corridor width requirement of 14.2.3.2 of NFPA *101* for educational occupancies is stricter than the 44 in. (1120 mm) minimum requirement of 12.2.3.8 of NFPA *101* for assembly occupancies and, thus, applies throughout the floor. The panic hardware requirement of 12.2.2.2.3 of NFPA *101* for assembly occupancies is identical to that in 14.2.2.2.2 of NFPA *101* for educational occupancies; therefore, this common requirement applies to all doors provided with latches or locks throughout the multiple occupancy. With regard to travel distance, in assembly occupancies, travel distance to the nearest exit is limited by 12.2.6.2 of NFPA *101* to a maximum of 200 ft (61 m) in a nonsprinklered building or 250 ft (76 m) in a sprinklered building; educational occupancies are limited by 14.2.6.2 and 14.2.6.3 of NFPA *101* to a 150 ft (46 m) travel distance in a nonsprinklered building and 200 ft (61 m) in a sprinklered building. So, the stricter travel distance requirement from the educational occupancy chapter applies to the multiple occupancy.

Paragraph 6.1.14.3.2 was revised for the 2012 edition of the *Code*. The revision reinstitutes a concept that was lost when the provisions for multiple occupancy buildings were rewritten for the 2003 edition of NFPA *101*. Where separate safeguards are approved (see 3.2.1), one or more of the applicable *Code* requirements are permitted to be relaxed to that applicable to the occupancy in question, rather than the most restrictive requirement of the occupancies involved. For example, a common path of travel that occurs wholly in a business tenant space in a multiple occupancy building containing assembly and business occupancies should not have to meet the assembly occupancy common path of travel limitation.

6.1.14.4 Separated Occupancies. (See also 6.1.14.4.2.) [***101:*** 6.1.14.4]

6.1.14.4.1 Where separated occupancies are provided, each part of the building comprising a distinct occupancy, as described in this chapter, shall be completely separated from other occupancies by fire-barriers as specified in 6.1.14.4.2, 6.1.14.4.3, and Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b), unless separation is provided by approved existing separations or as otherwise permitted by 6.1.14.4.6. [***101:***6.1.14.4.1]

6.1.14.4.2 Occupancy separation fire barriers shall be classified as 3-hour fire resistance–rated, 2-hour fire resistance–rated, or 1-hour fire resistance–rated and shall meet the requirements of Chapter 8 of NFPA *101*. [***101:***6.1.14.4.2]

6.1.14.4.3 The fire barrier minimum fire resistance rating specified in Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) shall be permitted to be reduced by 1 hour, but in no case shall it be reduced to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with NFPA 13 and supervised in accordance with 13.3.1.8, unless prohibited by the double-dagger footnote entries in the tables. [***101:***6.1.14.4.3]

6.1.14.4.4 Occupancy separation fire barriers shall be vertical, horizontal, or both or, when necessary, of such other form as required to provide complete separation between occupancy divisions in the building. [***101:***6.1.14.4.4]

6.1.14.4.5* Each separated portion of the building shall comply with the requirements for the occupancy therein. [***101:***6.1.14.4.5]

A.6.1.14.4.5 Where the Code text states that the provision has applicability to the building, rather than just to the occupancy, the provision applies to the entire building, regardless of whether the separated occupancies form of protection is used. For example, the provision of 18.3.5.1 of NFPA *101* requires that the entire building housing a health care occupancy be sprinklered. Contrast that with the requirement of 20.3.4.1 of NFPA *101* which requires an ambulatory health care facility, and not the entire building, to be provided with a fire alarm system. [***101:***A.6.1.14.4.5]

Δ **6.1.14.4.6** Where permitted in Chapters 11 through 43 of NFPA *101*, atrium walls shall be permitted to serve as part of the separation required by 6.1.14.4.1 for creating separated occupancies on a story-by-story basis, provided all of the following are met:

(1) The atrium is separated from adjacent areas by walls that are smoke partitions in accordance with Section 8.4 of NFPA *101*.
(2) Doors in the smoke partitions required by 6.1.14.4.6(1) are equipped with positive latching hardware.
(3) The atrium meets the provisions of 8.6.7 of NFPA *101* that are applicable to new atriums.

[***101:***6.1.14.4.6]

Note that 6.1.14.4.1 requires the fire barriers separating occupancies protected as separated occupancies to have the minimum fire resistance rating specified in Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b), unless separation is provided by approved existing separations. The phrase "unless separation is provided by approved existing separations" does not mean that existing separations are exempt from the requirements of Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b). An approved existing separation is a separation approved by the current authority having jurisdiction and is different from a previously approved separation. See 3.3.84.1 in NFPA *101* for the definition of the term *approved existing* and 3.3.221 in NFPA *101* for the definition of the term *previously approved*. If the current AHJ refuses to approve an existing separation, the provisions of Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) can be invoked, as applicable. For example, where an existing separation stops at the underside of a suspended ceiling, the AHJ can withhold approval of the existing separation and require compliance with Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b). In another example, the existing separation in a sprinklered building is judged to have approximately 45 minutes of fire resistance rating, but Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b) require a

NP: Not permitted.

[†]*Minimum Fire Resistance Rating.* The fire resistance rating is permitted to be reduced by 1 hour, but in no case to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with NFPA 13 and supervised in accordance with 13.3.1.8.

[‡]The 1-hour reduction due to the presence of sprinklers in accordance with the single-dagger footnote is not permitted. [***101:***Table 6.1.14.4.1(a)]

minimum 1-hour rating in such a building. The AHJ judges the existing separation acceptable and approves it. The existing separation becomes an approved existing separation not subject to the requirements of Table 6.1.14.4.1(a) and Table 6.1.14.4.1(b).

Exhibit 6.20 illustrates a simple example of a multiple occupancy building where the individual occupancies can easily be protected as separated occupancies. Because each individual-use space is arranged to meet its egress requirements independently of its neighbors, meeting only the requirements that apply to the occupancy of that individual-use space (see 6.1.14.4.5) is adequate to protect each space if the fire resistance–rated

Exhibit 6.20

NP: Not permitted.

[†]*Minimum Fire Resistance Rating.* The fire resistance rating is permitted to be reduced by 1 hour, but in no case to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with NFPA 13 and supervised in accordance with 13.3.1.8.

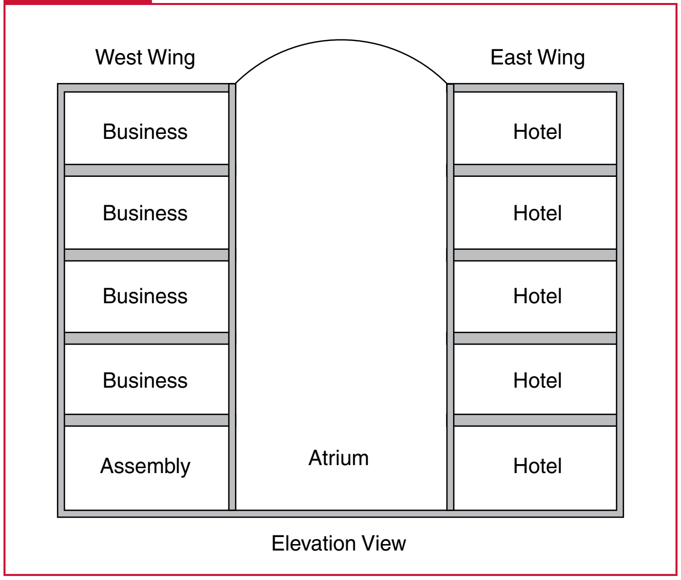
[‡]The 1-hour reduction due to the presence of sprinklers in accordance with the single-dagger footnote is not permitted. [***101:***Table 6.1.14.4.1(b)]

separations required by Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b) are provided.

In the case of a multiple occupancy that is part mercantile occupancy and part business occupancy, the corresponding cell in Table 6.1.14.4.1(b) specifies that a 2-hour fire barrier is required to achieve protection of the multiple occupancy as separated occupancies if the building is not sprinklered. If the multiple occupancy building is sprinklered and the sprinkler system is electrically supervised, the 2-hour fire barrier is permitted to be reduced to 1 hour per the dagger symbol footnote to Table 6.1.14.4.1(b) and its reference to the sprinkler system supervision requirements of 9.7.2.

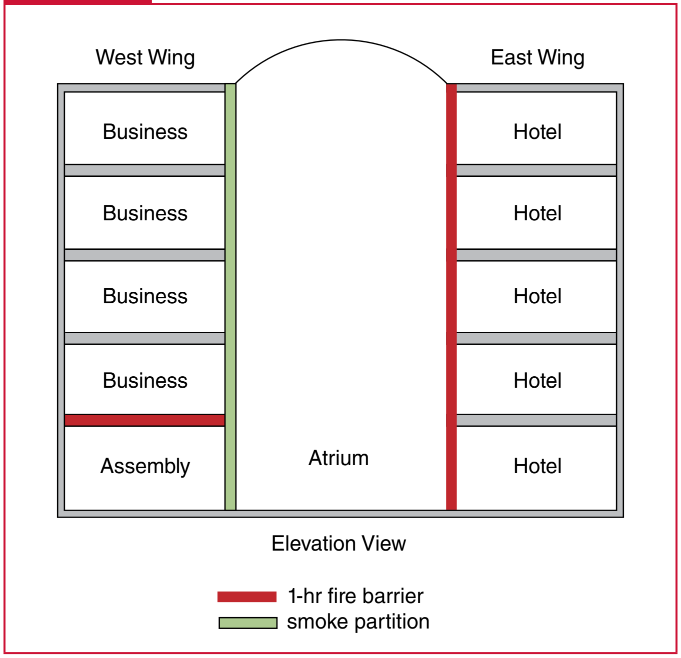
The provision of 6.1.14.4.6 recognizes an atrium as part of the separation required for protecting multiple occupancies as separated occupancies, but only where an occupancy chapter specifically permits its use. For example, health care occupancies permit the use of 6.1.14.4.6 in 18.1.3.2 and 19.1.3.2 of NFPA *101*. Further, 6.1.14.4.6 permits the atrium to serve as part of the separation of occupancies only on a story-by-story basis. This concept is explained in the following paragraphs.

Exhibit 6.21



Multiple occupancy building with atrium.

Exhibit 6.22



Multiple occupancy building utilizing atrium walls in occupancy separations.

Exhibit 6.21 illustrates a multiple occupancy building, with an atrium, under design. The west wing will include assembly occupancy on floor 1 and business occupancy on floors 2 through 4. The east wing will be hotel occupancy on floors 1 through 4. The building (i.e., the combination of the west wing, atrium, and east wing) will be protected throughout by approved sprinkler systems in accordance with 9.7.1.1(1) NFPA *101* that are supervised in accordance with 9.7.2 of NFPA *101*. For purposes of simplifying this example, the atrium will be an indoor garden with occupants relegated only to the paths connecting the west and east wings. The atrium will fully comply with the requirements of 8.6.7 that are applicable to new atriums, meaning that the atrium will have a smoke control system for compliance with the performance criteria of 8.6.7(5) of NFPA *101*.

The multiple occupancy building illustrated in Exhibit 6.21 could be protected as mixed occupancies in accordance with 6.1.14.1.1(1) or as separated occupancies in accordance with 6.1.14.1.1(2). The building designer, on behalf of the owner, has chosen to protect the multiple occupancy building as separated occupancies. Further, the designer has chosen to utilize the provision of 6.1.14.4.6 as permitted by 12.1.3.2 of NFPA *101* for assembly occupancies and by 38.1.3.3 of NFPA *101* for business occupancies. As a point of interesting, but unneeded, information — as addressed below — the hotel occupancy provisions of 28.1.3.3 of NFPA *101* also permit the use of 6.1.14.4.6. Occupants of each occupancy will have access to their required exits without using the exit access paths of any other occupancy (see 6.1.14.1.2). The required separation between occupancies is a 1-hour fire barrier based on the presence of sprinkler protection as detailed in the daggered footnote to Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b).

Exhibit 6.22 illustrates that the required separation between the assembly occupancy on floor 1 and the business occupancy on floors 2 through 4 of the west wing will be provided by the combination of the 1-hour fire resistance–rated floor-ceiling assembly and the smoke partition composed of the west wall of the atrium, as shown in the exhibit. Given that 6.1.14.4.6 permits the atrium wall to serve as part of an occupancy separation only on a floor-by-floor basis, the hotel occupancy in the east wing can meet its required separation from the west wing only via the traditional side-by-side arrangement. It achieves the separation from the west wing by making the east wall of the atrium a 1-hour fire barrier. Note that the smoke partition at the atrium west wall serves only as part of an occupancy separation in conjunction with a floor-ceiling assembly, whereas the fire-rated atrium east wall serves, by itself, as an occupancy separation.

Combining the Mixed Occupancies and Separated Occupancies Forms of Protection

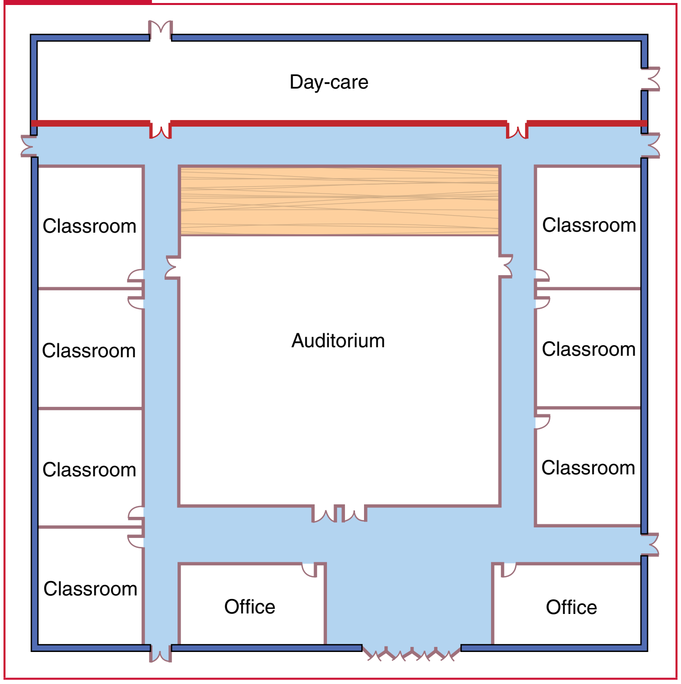
Exhibit 6.19 and the commentary that follows 6.1.14.3.2 address the mixed occupancies form of protection. Exhibits 6.20 through 6.22 and the commentary that follows 6.1.14.4.6 address the separated occupancies form of protection. In multiple occupancy buildings with three or more occupancies, it is not the intent of 6.1.14.1.1 to require all the occupancies to be protected by one common scheme, whether the scheme be that for mixed occupancies or that for separated occupancies. In other words, it is possible for a portion of a multiple occupancy building to be protected as a mixed occupancy and for another portion of the same multiple occupancy building to be separated from the mixed occupancies by fire-rated barriers as required by Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b) so as to be considered a separated occupancy.

Exhibit 6.23 assumes that (1) the building is new; (2) the building is protected throughout by an approved automatic sprinkler system in accordance with NFPA 13 and supervised in accordance with 13.3.1.8; and (3) the office space (business occupancy) is considered incidental to the predominant occupancies of educational (i.e., the classrooms), assembly (i.e., the auditorium, which, in this case, has an occupant load exceeding 300), and day-care, as permitted by 6.1.14.1.3(1). The day-care occupancy space satisfies all required egress features via the two sets of doors that discharge directly outside; the doors from the day-care space to the corridor are convenience doors provided in excess of *Code* requirements. The day-care occupancy space is separated from the combined assembly occupancy and educational occupancy spaces by 1-hour fire resistance–rated construction in compliance with Table 6.1.14.4.1(a) so as to meet the separated occupancies form of protection. Table 6.1.14.4.1(a) was used to establish the minimum 1-hour fire-rated separation as follows:

1. In the first column, in the row for Assembly >300 to ≤1000, the user moves across the table to the column for Day-care >12 clients, noting the required fire rating of 2 hours.
2. In the first column, in the row for Educational, the user moves across the table to the column for Day-care >12 clients, noting the required fire rating of 2 hours.
3. In the title of Table 6.1.14.4.1(a), the user notes the superscript dagger symbol and references the corresponding footnote. The building is protected throughout by an approved automatic sprinkler system in accordance with NFPA 13 and supervised in accordance with 13.3.1.8, so the required fire-rated separation values of 2 hours from the applicable table cells are reduced to 1 hour.

Returning to Exhibit 6.23, the assembly occupancy space, which is landlocked at the center of the building, shares its exit access with that of the educational occupancy spaces. The provision of 6.1.14.1.2 requires that the portion of the multiple occupancy building that houses the assembly occupancy and the educational occupancy be protected as mixed occupancies. The occupancy requirements for new assembly occupancies (Section 20.1 of this *Code* and Chapter 12 of NFPA *101*) are compared with those for new educational occupancies (Section 20.2 of this *Code* and Chapter 14 of NFPA *101*) for each of the subjects addressed by the *Code*. In each comparison of requirements between the applicable occupancy chapters, the more stringent requirement is chosen as having applicability to the portion of the multiple occupancy building housing the assembly occupancy and educational occupancy spaces being protected as mixed occupancies, unless separate safeguards are approved (see 6.1.14.3.2).

Exhibit 6.23



Multiple occupancy building protected via combination of the mixed occupancy and separated occupancy provisions.

General Safety Requirements

10

Chapter 10 includes requirements for new and existing buildings, structures, and premises in the following key areas:

- Fundamental requirements (Section 10.1)
- Owner/occupant responsibilities (Section 10.2)
- Occupancy (Section 10.3)
- Building evacuation (Section 10.4)
- Fire drills (Section 10.5)
- Reporting of fires and other emergencies (Section 10.6)
- Tampering with fire safety equipment (Section 10.7)
- Emergency action plans (Section 10.8)
- Smoking (Section 10.9)
- Open flames, candles, open fires, and incinerators (Section 10.10)
- Fire protection markings (Section 10.11)
- Seasonal and vacant buildings and premises (Section 10.12)
- Combustible vegetation (Section 10.13)
- Special outdoor events, carnivals, and fairs (Section 10.14)
- Outside storage (Section 10.15)
- Parade floats (Section 10.16)
- Powered industrial trucks (Section 10.17)
- Storage of combustible materials (Section 10.18)
- Indoor children's playground structures (Section 10.19)

10.1 Fundamental Requirements

10.1.1 Every new and existing building or structure shall be constructed, arranged, equipped, maintained, and operated in accordance with this *Code* so as to provide a reasonable level of life safety, property protection, and public welfare from the actual and potential hazards created by fire, explosion, and other hazardous conditions.

The premise of this *Code* is that a minimum level of safety to life and property is required for all buildings, structures, and premises, whether they are new or existing. This protection takes many forms, from active protection, such as fire alarm systems and sprinkler systems, to passive protection, such as fire doors and fire barriers, or a combination of these features. The goal is to prevent injuries and death from fire, explosions, and other hazardous conditions and to limit property damage.

Δ **10.1.2*** ***Life Safety Code.*** Every new and existing building shall comply with this *Code* and NFPA *101*.

Δ **A.10.1.2** It is the intent of this *Code* that all existing buildings comply with the referenced edition of NFPA *101*.

NFPA *101*®, *Life Safety Code*®, is the key document for defining the requirements to protect building occupants from fire and similar emergencies in new and existing buildings. This *Code* and NFPA *101* work together to provide a protection package for life safety and property protection. NFPA *101* is the primary document from which the life safety requirements of NFPA 1, *Fire Code,* are drawn.

10.1.3 Building Code. Where a building code has been adopted, all new construction shall comply with this *Code* and the building code.

In jurisdictions where no building code has been adopted, this *Code* does not require that the fire official adopt a building code. Where a building code has been adopted, it must be applied to all new construction in addition to the requirements of this *Code.*

10.1.4 Structural Hazards.

10.1.4.1 Where structural elements have visible damage, the AHJ shall be permitted to require a technical analysis prepared in accordance with Section 1.15 to determine if repairs are necessary to restore structural integrity.

Fire inspectors frequently find damage to structural elements during inspections. The authority having jurisdiction (AHJ) can require an analysis of the damage to ensure structural stability and should notify the building department. This analysis in most cases will take place by or under the auspices of the building department. The fire department should be notified when structural deficiencies are found, because such deficiencies can impact fire fighter safety.

10.1.4.2 Where the technical analysis recommends repairs to the structure, such repairs shall be made.

10.1.5 Any person who deliberately, or through negligence, sets fire to or causes the burning of any combustible material in such a manner as to endanger the safety of any person or property shall be deemed to be in violation of this *Code*.

The intent of 10.1.5 is not to prohibit nonhostile fires, such as those used for cooking, heating, or industrial processes, provided that they do not otherwise violate the applicable requirements of this *Code*.

10.1.6 The AHJ shall have the authority to prohibit any or all open flames or other sources of ignition where circumstances make such conditions hazardous.

This *Code* does not specifically address all types of open flame or other sources of ignition. Therefore, 10.1.6 permits the AHJ to prohibit open flame or other ignition sources when it is judged such flame or other ignition source presents a hazard. Examples might include fire jugglers and the use of candles.

10.1.7 Listed and Labeled. Listed and labeled equipment, devices, and materials shall be installed and used in accordance with the listing limitations and the manufacturers' instructions.

10.2 Owner/Occupant Responsibilities

10.2.1 The owner, operator, or occupant shall be responsible for compliance with this *Code*.

As stated in 10.2.1, the person responsible for the property is responsible for complying with this *Code*. The AHJ should work with property owners, operators, and occupants to educate them on the requirements of this *Code*. Such cooperation can help correct violations and prevent the need to issue citations when inspections are conducted. If a violation notice is issued as a result of an inspection, the responsible party should ensure that the violations are corrected as soon as possible after the notice is received. If management takes a proactive approach to fire safety, others in the organization will likely do the same, thus increasing the fire safety of the property and reducing violations.

10.2.2 The owner, operator, or occupant of a building shall notify the AHJ prior to a change of occupancy as specified in 4.5.7 and 10.3.4.

A building might undergo a change in occupancy classification without requiring physical modification, thus alleviating the usual requirement for a building permit. The requirement of 10.2.2 ensures that the AHJ will be notified of such change of occupancy classification so compliance with the *Code* requirements applicable to the new occupancy can be verified. An example might be a former military barracks (dormitory) converted to a nursing home (health care) or a restaurant with fewer than 50 occupants (mercantile) to a restaurant with an occupant load of 50 or more occupants (assembly) with no associated construction. Such a change in occupancy classification will most likely significantly alter the protection requirements specified by the *Code*. Chapter 43 of NFPA *101* provides detailed requirements addressing change of occupancy classification.

10.2.3 The AHJ shall be permitted to require the owner, operator, or occupant to provide tests or test reports, without expense to the AHJ, as proof of compliance with the intent of this *Code*.

If the AHJ is not confident of *Code* compliance (e.g., where a fire protection system is in questionable working order, or a particular interior finish lacks documentation of *Code* compliance), 10.2.3 permits the AHJ to require the property owner to conduct the necessary testing or to produce test reports showing that the system or materials in question comply with the *Code*. The AHJ can require receipt of the documentation on testing and maintenance of fire protection systems after such work has been performed. The cost of such tests or reports is the responsibility of the property owner or agent.

10.2.4 The owner, operator, or occupant of a building that is deemed unsafe by the AHJ shall abate, through corrective action approved by the AHJ, the condition causing the building to be unsafe either by repair, rehabilitation, demolition, or other corrective action approved by the AHJ.

Any proposed corrective action requires approval of the AHJ. To avoid any misunderstanding, the AHJ should require a written corrective plan of action, including key completion dates, from the property owner. The AHJ should then issue its approval of the plan in writing. Once the work has begun, the AHJ should monitor the progress of the work to ensure that the corrections are being made in a timely manner and according to approvals. Plans and permits might be required before some corrective actions take place. (See Sections 1.12 and 1.14.)

10.2.5 The owner, operator, or occupant, or any person in control of a building or premises shall keep records of all maintenance, inspections, and testing of fire protection systems, fire alarm systems, smoke control systems, emergency evacuation and relocation drills, emergency action plans, emergency power, elevators, and other equipment as required by the AHJ.

10.2.6 All records required to be kept shall be maintained until their useful life has been served, as required by law, or as required by the AHJ.

Maintenance, testing, and inspection reports are necessary to ensure that fire protection and other systems are maintained in accordance with the *Code* and are in operating condition. Records of evacuation and fire drills and other records required by this *Code* need to be available to the AHJ upon request. The inspector should ask to see these records at each inspection to ensure that the appropriate maintenance and testing are being performed and that all required records are being retained.

Most states have laws requiring records retention. Some NFPA codes and standards also have requirements for how long records are to be kept. Records should be maintained long enough for the fire inspector to review at least the last two reports. If the inspection cycle is every 3 years, at least 3 years, if not 6 years, of records should be retained. The jurisdiction's legal counsel should be consulted to determine how long each type of record must be maintained.

N **10.2.7 Minimum Fire Prevention Inspection Frequencies for Existing Occupancies.**

N **10.2.7.1** Fire prevention inspections shall occur on existing premises in accordance with the minimum inspection frequency schedule specified in Table 10.2.7.1.

N **10.2.7.2** Where required or permitted by the AHJ, the required fire prevention inspection shall be conducted by an approved party that is qualified in accordance with NFPA 1031.

N **10.2.7.3** The AHJ shall be permitted to approve alternative qualifications for the approved party specified in 10.2.7.2.

N **10.2.7.4** The provisions of 10.2.7 shall not apply to detached one- and two-family dwellings or townhomes.

NFPA 1730, *Standard on Organization and Deployment of Fire Prevention Inspection and Code Enforcement, Plan Review, Investigation, and Public Education Operations,* from which Table 10.2.7.1 is extracted, is the first edition of that standard. It addresses the organization and deployment of a fire prevention organization, which includes code enforcement, plans examinations, investigation, and public education and also contains minimum inspection frequencies for existing occupancies. To ensure that existing occupancies comply with the fire prevention code, a fire prevention inspection is required as part of the standard of care as specified in NFPA 1730. Section 10.2.7 is new for 2018 and incorporates that standard of care into NFPA 1. The default is that the local fire AHJ should conduct the inspection in accordance with Table 10.2.7.1. However, if staffing does not permit or if the local jurisdiction does not have a qualified individual, the owner, occupant, or operator can retain an AHJ-approved NFPA 1031–qualified individual to conduct the inspection, thereby achieving fire code compliance in accordance with NFPA 1730.

TABLE 10.2.7.1 *Minimum Inspection Frequency*

Occupancy Risk Classification	Frequency
High	Annually
Moderate	Biennially
Low	Triennially
Critical infrastructure	Per AHJ

[**1730:**Table 6.7]

10.3 Occupancy

10.3.1 No new construction or existing building shall be occupied in whole or in part in violation of the provisions of this *Code*.

From an enforcement standpoint, 10.3.1 is probably one of the most important paragraphs in this *Code,* because it states that a building, whether new or existing, is prohibited from being occupied if it is in violation of the provisions of the *Code*. In no case should a new building be occupied unless it complies with the *Code*.

10.3.2 Existing buildings that are occupied at the time of adoption of this *Code* shall remain in use provided that the following conditions are met:

(1) The occupancy classification remains the same.
(2) No condition deemed hazardous to life or property exists that would constitute an imminent danger.

Because this *Code* applies retroactively, 10.3.1 prohibits the use of existing nonconforming facilities. However, 10.3.2 permits the building to continue to be used, provided that the occupancy classification remains the same and no serious life safety hazard is present, as judged by the AHJ, which would constitute an imminent danger. This provision does not exempt the building from compliance with the *Code* but permits it to continue in use until it is brought into compliance.

10.3.3* Buildings or portions of buildings, except for routine maintenance or repair, shall not be occupied during construction, repair, or alteration without the approval of the AHJ if required means of egress are impaired or required fire protection systems are out of service.

A.10.3.3 The AHJ should take into account the maintenance of required means of egress and fire protection systems during the construction, repair, alteration, or addition to the building. If necessary, alternative protection features can be required to ensure that no imminent hazards exist as the result of modifications.

Care should be taken when reviewing plans for construction in an existing building. Often during construction, egress routes are blocked or removed and fire protection systems are taken out of service. *Code* requirements should be reviewed to ensure that the building is still in compliance before construction work is approved. See 10.3.2 and Chapter 16 for additional guidance.

10.3.4 Change of Use or Occupancy Classification.

10.3.4.1 In any building or structure, whether or not a physical alteration is needed, a change from one use or occupancy classification to another shall comply with 4.6.7 of NFPA *101*. [***101:***4.6.11]

Change of use or change of occupancy classification is treated as a category of rehabilitation. Such changes are required by 4.6.7 of NFPA *101* to comply with the provisions of Chapter 43 of NFPA *101*.

10.3.4.2 Occupancy classifications and subclassifications, as defined, shall be in accordance with Chapter 6.

See Chapter 3 for definitions of specific occupancies and their subclassifications and Chapter 6 for further information on occupancy classification.

The reference to NFPA *101* in 10.3.4.1 requires buildings undergoing a change of use or change of occupancy classification to comply with the requirements of Chapter 43 of NFPA *101* on building rehabilitation, regardless of associated construction or the lack thereof. NFPA *101* defines a change of use as a change in the purpose or level of activity within a structure that involves a change in application of the requirements of the *Code*. An example of a change of use might be the conversion of a restaurant (assembly occupancy with an occupant load of 150) to a nightclub (assembly occupancy with an occupant load of 300). While such conversion does not constitute a change of occupancy (assembly to assembly), the increased occupancy load leads to a change in the character of use and affects the application of the *Code*.

The term *change of occupancy classification* is defined in NFPA *101* as "the change in the occupancy classification of a structure or portion of a structure." In evaluating changes of occupancy classification, NFPA *101* assigns each occupancy a hazard category that relates to the relative occupant risk. If the change of occupancy classification involves a change to an occupancy having the same or a lesser hazard category, the new occupancy is permitted to comply with requirements applicable to existing occupancies. Automatic sprinklers, fire alarm systems, and hazardous areas, however, must comply with the requirements applicable to new occupancies. For example, where a former office building (business occupancy) is converted into a hotel (hotel and dormitory), the two classifications are within the same hazard category; therefore, the *Code* requirements applicable to *existing* hotels and dormitories are applied to the *new* hotel. The new hotel and dormitory requirements must be consulted, however, to determine requirements for sprinkler and fire alarm systems and any hazardous areas.

In all cases where a change of occupancy classification involves a change to a higher hazard category, the new occupancy must comply with the requirements applicable to new occupancies. An example is the conversion of a bed and breakfast (lodging or rooming house) to a group home for developmentally disabled residents (residential board and care). The new residential board and care facility is required to comply with all *Code* requirements applicable to new residential board and care occupancies. Chapter 43 of NFPA *101* should be consulted for details on its application to changes of use and changes of occupancy classification.

10.4 Building Evacuation

10.4.1 Persons shall not fail to leave a building when notified to do so or when directed by the AHJ as a result of a known or perceived emergency.

10.4.2* Persons shall not fail to leave any overcrowded premises when ordered to do so by the AHJ.

A.10.4.2 Premises are deemed to be overcrowded when the occupant load exceeds the exit capacity or the posted occupant load.

Subsection 10.4.2 applies to all occupancies, but overcrowding is commonly a problem in assembly occupancies such as nightclubs and bars. All assembly occupancies are required to have the occupancy load posted in a conspicuous place near the main entrance. See Exhibit 10.1 for an example of an occupant load sign for a multipurpose assembly room used for dining and receptions. See Section 20.1 of this *Code* and 12.7.9.3 and 13.7.9.3 of NFPA *101* for more information on occupant load posting in assembly occupancies.

The AHJ should verify the occupant load during inspections. See 14.8.1 for guidance on determining occupant loads. Note that the occupant load calculated in accordance with 14.8.1 is the minimum number of occupants for which sufficient means of egress and other protection features must be provided; it is not necessarily the maximum number of occupants permitted in a building or portion thereof.

10.4.3* Persons shall not fail to leave a building when a fire alarm system is activated, unless otherwise provided for in an approved building fire evacuation plan or during routine testing or maintenance.

A.10.4.3 This requirement is not necessarily intended to apply to facilities utilizing a "defend in place" strategy or other occupancies where total evacuation is not intended or desired (detention, health care, high rise). A written emergency response plan can clarify how a facility can conform to this requirement.

Many times, responding fire personnel arrive at a building where a fire alarm system has activated to find the occupants still in the building. Fire fighters must then tell people to leave while also trying to locate the cause of the alarm, wasting valuable time and possibly placing occupants in harm's way. The provision of 10.4.3 requires all occupants to leave the building on notification of a fire alarm activation. Occupancies that have an approved fire evacuation plan, such as a defend-in-place or relocation strategy, must follow that plan, which may not call for building evacuation. Building occupants can remain in the building during

Exhibit 10.1

Typical occupant load signage for an assembly occupancy.

testing and maintenance as long as they have been advised that testing is taking place and that they are to disregard the alarms unless otherwise informed.

10.5* Fire Drills

A.10.5 The purpose of emergency egress and relocation drills is to educate the participants in the fire safety features of the building, the egress facilities available, and the procedures to be followed. Speed in emptying buildings or relocating occupants, while desirable, is not the only objective. Prior to an evaluation of the performance of an emergency egress and relocation drill, an opportunity for instruction and practice should be provided. This educational opportunity should be presented in a nonthreatening manner, with consideration given to the prior knowledge, age, and ability of audience. [***101:***A.4.7]

The usefulness of an emergency egress and relocation drill, and the extent to which it can be performed, depends on the character of the occupancy. [***101:***A.4.7]

In buildings where the occupant load is of a changing character, such as hotels or department stores, no regularly organized emergency egress and relocation drill is possible. In such cases, the emergency egress and relocation drills are to be limited to the regular employees, who can be thoroughly schooled in the proper procedure and can be trained to properly direct other occupants of the building in case of emergency evacuation or relocation. In occupancies such as hospitals, regular employees can be rehearsed in the proper procedure in case of fire; such training is always advisable in all occupancies, regardless of whether regular emergency egress and relocation drills can be held. [***101:***A.4.7]

10.5.1 Where Required. Emergency egress and relocation drills conforming to the provisions of this *Code* shall be conducted as specified by the provisions of Chapter 20 of this *Code* or Chapters 11 through 42 of NFPA *101*, or by appropriate action of the AHJ. Drills shall be designed in cooperation with the local authorities. [***101:***4.7.1]

10.5.2* Drill Frequency. Emergency egress and relocation drills, where required by Chapter 20 of this *Code* or Chapters 11 through 42 of NFPA *101*, or the AHJ, shall be held with sufficient frequency to familiarize occupants with the drill procedure and to establish conduct of the drill as a matter of routine. Drills shall include suitable procedures to ensure that all persons subject to the drill participate. [***101:***4.7.2]

A.10.5.2 If an emergency egress and relocation drill is considered merely as a routine exercise from which some persons are allowed to be excused, there is a grave danger that, in an actual emergency, the evacuation and relocation will not be successful. However, there might be circumstances under which all occupants do not participate in an emergency egress and relocation drill, for example, infirm or bedridden patients in a health care occupancy. [***101:***A.4.7.2]

10.5.3 Orderly Evacuation. When conducting drills, emphasis shall be placed on orderly evacuation rather than on speed. [***101:***4.7.3]

10.5.4* Simulated Conditions. Drills shall be held at expected and unexpected times and under varying conditions to simulate the unusual conditions that can occur in an actual emergency. [***101:***4.7.4]

A.10.5.4 Fire is always unexpected. If the drill is always held in the same way at the same time, it loses much of its value. When, for some reason during an actual fire, it is not possible to follow the usual routine of the emergency egress and relocation drill to which occupants have become accustomed, confusion and panic might ensue. Drills should be carefully planned to simulate actual fire conditions. Not only should drills be held at varying times, but different means of exit or relocation areas should be used, based on an assumption that fire or smoke might prevent the use of normal egress and relocation avenues. [***101:***A.4.7.4]

10.5.5 Relocation Area. Drill participants shall relocate to a predetermined location and remain at such location until a recall or dismissal signal is given. [***101:***4.7.5]

10.5.6* A written record of each drill shall be completed by the person responsible for conducting the drill and maintained in an approved manner. [***101:***4.7.6]

A.10.5.6 The written record required by this paragraph should include such details as the date, time, participants, location, and results of that drill. [***101:***A.4.7.6]

10.6 Reporting of Fires and Other Emergencies

10.6.1 Fire Reporting.

10.6.1.1 The person discovering any unwanted fire, regardless of magnitude, shall immediately notify the fire department.

10.6.1.2 Facilities that have established on-premises fire-fighting organizations and have coordinated and arranged procedures approved by the AHJ shall not need to notify the fire department.

Where an established on-premises fire-fighting organization exists, the AHJ must review and approve procedures that can replace or provide specific guidance on notification of the jurisdiction's fire department. Individuals occupying an on-premises fire-fighting site must still notify the on-site fire-fighting organization when a fire occurs.

10.6.1.3* The owner, manager, occupant, or any person in control of such building or premises, upon discovery of an unwanted fire or evidence of a previous unwanted fire that had apparently been extinguished, shall immediately notify the fire department.

A.10.6.1.3 This requirement should not be construed to forbid the owner, manager, or other person in control of the aforementioned building or premises from using all diligence necessary to extinguish such fire prior to the arrival of the fire department.

The fire department, building owner, and building occupants must be aware of any fire, regardless of how small. Many cases have been documented in which building occupants were not notified of a fire in the building, with disastrous and often fatal results. For example, when a rubbish fire is discovered and quickly extinguished by a building occupant, the fire department is often not notified. Such action is in violation of the *Code* requirements. All fires should be reported to the fire department so full extinguishment can be determined and the fire cause can be investigated.

10.6.1.4 Persons shall not make, issue, post, or maintain any regulation or order, written or verbal, that would require any person to take any unnecessary delaying action prior to reporting a fire to the fire department.

Paragraph 10.6.1.4 prohibits any person from restricting or delaying another person from notifying the fire department or building occupants when a fire is discovered. This provision is violated where building management requires security or building employees to check on the source of an alarm or a reported fire before notifying the fire department. This provision is also violated if a building occupant is prevented from notifying the fire department or other occupants of a fire in the building by persons representing building management.

10.6.2 Persons shall not deliberately or maliciously turn in an alarm of fire when in fact that person knows that no fire exists.

10.6.3 Notification of unauthorized discharge of hazardous materials shall be in accordance with Chapter 60.

See 60.5.1.3.4 for the requirements for reporting discharges of hazardous materials.

10.6.4 Any person who willfully makes any false, fraudulent, misleading, or unfounded report or statement or willfully misrepresents any fact with the intention of misleading any fire department personnel or who interferes with the operation of the fire department shall be in violation of this *Code*.

Subsection 10.6.4 can be used to cite persons found to be dishonest with an inspector when questioned about the amounts of flammable liquids or gases on the property or found to have misrepresented other facts regarding the property.

Paragraph 10.6.4 also gives fire investigators the authority to cite persons involved in a fire investigation who are uncooperative with fire investigators. The *Code* recognizes that persons do have rights against self-incrimination, and 10.6.4 is not intended to diminish those rights. Also see 1.8.3 for information on obstruction of operations.

10.7 Tampering with Fire Safety Equipment

10.7.1 Persons shall not render any portable or fixed fire-extinguishing system or device or any fire-warning system or device inoperative or inaccessible.

Fire safety devices and fire-extinguishing systems or devices protect buildings, equipment, and building occupants. Anyone who willfully disables a fire protection system or device is in violation of this *Code*. Tampering with fire safety equipment can have dire consequences. Part of ensuring that occupants do not tamper with or render fire safety equipment inoperative involves educating occupants on the type of equipment present in buildings as well as its purpose. Increasing awareness of equipment such as fire extinguishers, smoke alarms and detectors, automatic sprinklers, and notification appliances can help to prevent tampering with the systems. Common examples of violations to this Code section include covering or removing smoke detection equipment, blocking access to fire extinguishers, and tampering with sprinkler heads.

10.7.1.1 As necessary during emergencies, maintenance, drills, prescribed testing, alterations, or renovations, portable or fixed fire-extinguishing systems or devices or any fire-warning system or device shall be permitted to be made inoperative or inaccessible.

Extra diligence should be exercised to ensure proper notification when fire protection systems are out of service for the purpose of alterations, renovations, or maintenance and testing. Such impairments should be handled by following the requirements in the applicable codes and standards, with proper precautions taken to reduce exposure and the size and duration of the impairment. For example, NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, contains detailed requirements for both planned and unplanned impairments of such systems. Also see 13.3.3.6 for sprinkler system impairments and 13.7.1.4.3 for fire alarm system impairments. All systems should be restored to a ready state as soon as possible after alterations, renovations, testing, maintenance, or an emergency.

10.7.2 Persons shall not render a fire protection system or device inoperative during an emergency unless by direction of the incident commander.

Subsection 10.7.2 prohibits those in the employ of the building management or anyone else from shutting off an alarm system, a sprinkler system, or any other system that could affect the outcome of a fire, without the permission of the incident commander. See also 1.8.3 and 10.6.4.

10.7.3 Persons, except a person authorized by the AHJ, shall not remove, unlock, destroy, or tamper with in any manner any locked gate, door, or barricade; chain; enclosure; sign; tag; or seal that has been required by the AHJ pursuant to this *Code*.

The AHJ might require locks, barricades, signs, or other items to be placed at or attached to fire protection equipment or buildings. The removal of these items is prohibited, except under the orders of, or by a representative of, the AHJ. The AHJ should have a formal procedure for a lockout/tagout system in accordance with Occupational Safety and Health Administration (OSHA) regulations.

10.8 Emergency Action Plans

10.8.1 Where Required. Emergency action plans shall be provided for high-rise, health care, ambulatory health care, residential board and care, assembly, day-care centers, special amusement buildings, hotels and dormitories, detention and correctional occupancies, educational, underground and windowless structures, facilities storing or handling materials covered by Chapter 60, or where required by the AHJ.

Subsection 10.8.1 requires emergency action plans for all high-rise buildings, regardless of occupancy and also for the other listed occupancies and structures, regardless of whether they are high rise or not. The emergency action plans required by 10.8.1 are in addition to any plans that might be required by the occupancy provisions in Chapter 20 or elsewhere in this *Code*. The emergency action plan requirements of 10.8.2 are extracted from NFPA *101*.

10.8.2 Plan Requirements.

10.8.2.1* Emergency action plans shall include the following:

(1) Procedures for reporting of emergencies
(2) Occupant and staff response to emergencies
(3)* Evacuation, relocation and shelter-in-place procedures appropriate to the building, its occupancy, emergencies, and hazards
(4) Appropriateness of the use of elevators
(5) Design and conduct of fire drills
(6) Type and coverage of building fire protection systems
(7) Other items required by the AHJ

[***101:***4.8.2.1]

Δ **A.10.8.2.1** Items to be considered in preparing an emergency plan should include the following:

(1) Purpose of plan
(2) Building description, including certificate of occupancy
(3) Appointment, organization, and contact details of designated building staff to carry out the emergency duties
(4) Identification of events (man-made and natural) considered life safety hazards impacting the building
(5) Responsibilities matrix (role-driven assignments)
(6) Policies and procedures for those left behind to operate critical equipment
(7) Specific procedures to be used for each type of emergency
(8) Requirements and responsibilities for assisting people with disabilities
(9) Procedures for accounting for employees
(10) Training of building staff, building emergency response teams, and other occupants in their responsibilities
(11) Documents, including diagrams, showing the type, location, and operation of the building emergency features, components, and systems
(12) Practices for controlling life safety hazards in the building
(13) Inspection and maintenance of building facilities that provide for the safety of occupants
(14) Conducting fire and evacuation drills
(15) Interface between key building management and emergency responders
(16) Names or job titles of persons who can be contacted for further information or explanation of duties
(17) Post-event (including drill) critique/evaluation, as addressed in Chapter 9 of *NFPA 1600*
(18) Means to update the plan, as necessary

[***101:***A.4.8.2.1]

A lesson learned from the September 11, 2001, terrorist attacks on the World Trade Center towers in New York City and the Pentagon building in Arlington, Virginia, is the importance of having a detailed emergency action plan that is tailored to the building and its occupants. The 18 topics listed in A.10.8.2.1 for the development of an emergency action plan broadly cover the needed facets of such a plan.

Δ **A.10.8.2.1(3)** It is assumed that a majority of buildings will use a total evacuation strategy during a fire. It should be noted that evacuation from a building could occur for reasons other than a fire, but such other reasons are not the primary focus of the *Code*. As used herein, total evacuation is defined as the process in which all, or substantially all, occupants leave a building or facility in either an unmanaged or managed sequence or order. An alternative to total evacuation, is partial evacuation, which can be defined as the process in which a select portion of a building or facility is cleared or emptied of its occupants while occupants in other portions mostly carry on normal activity. In either case, the evacuation process can be ordered or managed in accordance with an established priority in which some or all occupants of a building or facility clear their area and utilize means of egress routes. This is typically done so that the more endangered occupants are removed before occupants in less endangered areas. Alternative terms describing this sequencing or ordering of evacuation are *staged evacuation* and *phased evacuation*. [***101:***A.4.8.2.1(3)]

Table A.10.8.2.1(3) illustrates options for extent of management and extent of evacuation. Some of the options shown might not be appropriate. As noted in Table A.10.8.2.1(3), either total or partial evacuation can include staged (zoned) evacuation or phased evacuation, which is referred to as managed or controlled evacuation. It should also be noted that the evacuation process might not include relocation to the outside of the building but might instead include relocation to an area of refuge or might defend the occupants in place to minimize the need for evacuation. [***101:***A.4.8.2.1(3)]

The different methods of evacuation are also used in several contexts throughout NFPA *101*. Though most of the methods of evacuation are not specifically defined or do not have established criteria, various sections of NFPA *101* promulgate them as alternatives to total evacuation. The following sections of NFPA *101* discuss these alternatives in more detail:

(1) Section 4.7 — Provides requirements for fire and relocation drills
(2) 7.2.12 — Provides requirements for area of refuge
(3) 7.2.4 — Provides requirements for horizontal exits
(4) 9.6.3.6 — Provides the alarm signal requirements for different methods of evacuation
(5) 9.6.3.9 — Permits automatically transmitted or live voice evacuation or relocation instructions to occupants and requires them in accordance with *NFPA 72*

TABLE A.10.8.2.1(3) Occupant Evacuation Strategies

	Extent of Management	
Extent of Evacuation	**Managed Sequence**	**Unmanaged Sequence**
Shelter in place	No movement — shelter in place upon direction	No movement — shelter in place per prior instruction
Relocation or partial evacuation	Managed or controlled partial evacuation In-building relocation on same floor In-building relocation to different floors Occupants of some floors leave building	Unmanaged movement
Total evacuation	Managed or controlled total evacuation	Unmanaged or uncontrolled total evacuation

[***101:*** Table A.4.8.2.1(3)]

(6) 14.3.4.2.3 (also Chapter 15) — Describes alternative protection systems in educational occupancies
(7) 18.1.1.2/18.1.1.3/Section 18.7 (also Chapter 19) — Provide methods of evacuation for health care occupancies
(8) Chapters 22 and 23 — Provide methods of evacuation for detention and correctional occupancies, including the five groups of resident user categories
(9) Chapters 32 and 33 — Provide methods of evacuation for residential board and care occupancies
(10) 32.1.5/33.1.5 — For residential board and care occupancies, state that "no means of escape or means of egress shall be considered as complying with the minimum criteria for acceptance, unless emergency evacuation drills are regularly conducted"
(11) 40.2.5.2.2 — For industrial occupancies, states that "ancillary facilities in special-purpose industrial occupancies where delayed evacuation is anticipated shall have not less than a 2-hour fire resistance–rated separation from the predominant industrial occupancy and shall have one means of egress that is separated from the predominant industrial occupancy by 2-hour fire resistance–rated construction"[***101:***A.4.8.2.1(3)]

The method of evacuation should be accomplished in the context of the physical facilities, the type of activities undertaken, and the provisions for the capabilities of occupants (and staff, if available). Therefore, in addition to meeting the requirements of the *Code*, or when establishing an equivalency or a performance-based design, the following recommendations and general guidance information should be taken into account when designing, selecting, executing, and maintaining a method of evacuation:

(1) When choosing a method of evacuation, the available safe egress time (ASET) must always be greater than the required safe egress time (RSET).
(2) The occupants' characteristics will drive the method of evacuation. For example, occupants might be incapable of evacuating themselves because of age, physical or mental disabilities, physical restraint, or a combination thereof. However, some buildings might be staffed with people who could assist in evacuating. Therefore, the method of evacuation is dependent on the ability of occupants to move as a group, with or without assistance. For more information, see the definitions under the term *Evacuation Capability* in Chapter 3 of NFPA *101*.
(3) An alternative method of evacuation might or might not have a faster evacuation time than a total evacuation. However, the priority of evacuation should be such that the occupants in the most danger are given a higher priority. This prioritization will ensure that occupants more intimate with the fire will have a faster evacuation time.
(4) Design, construction, and compartmentation are also variables in choosing a method of evacuation. The design, construction, and compartmentation should limit the development and spread of a fire and smoke and reduce the need for occupant evacuation. The fire should be limited to the room or compartment of fire origin. Therefore, the following factors need to be considered:
   (a) Overall fire resistance rating of the building
   (b) Fire-rated compartmentation provided with the building
   (c) Number and arrangement of the means of egress
(5) Fire safety systems should be installed that complement the method of evacuation and should include consideration of the following:
   (a) Detection of fire
   (b) Control of fire development
   (c) Confinement of the effects of fire
   (d) Extinguishment of fire
   (e) Provision of refuge or evacuation facilities, or both
(6) One of the most important fire safety systems is the fire alarm and communication system, particularly the notification

system. The fire alarm system should be in accordance with *NFPA 72* and should take into account the following:

(a) Initial notification of only the occupants in the affected zone(s) (e.g., zone of fire origin and adjacent zones)
(b) Provisions to notify occupants in other unaffected zones to allow orderly evacuation of the entire building
(c) Need for live voice communication
(d) Reliability of the fire alarm and communication system

(7) The capabilities of the staff assisting in the evacuation process should be considered in determining the method of evacuation.
(8) The ability of the fire department to interact with the evacuation should be analyzed. It is important to determine if the fire department can assist in the evacuation or if fire department operations hinder the evacuation efforts.
(9) Evacuation scenarios for hazards that are normally outside of the scope of the *Code* should be considered to the extent practicable. (*See 4.3.1 of NFPA 101.*)
(10) Consideration should be given to the desire of the occupants to self-evacuate, especially if the nature of the building or the fire warrants evacuation in the minds of the occupants. Self-evacuation might also be initiated by communication between the occupants themselves through face-to-face contact, mobile phones, and so forth.
(11) An investigation period, a delay in the notification of occupants after the first activation of the fire alarm, could help to reduce the number of false alarms and unnecessary evacuations. However, a limit to such a delay should be established before a general alarm is sounded, such as positive alarm sequence as defined in *NFPA 72*.
(12) Consideration should be given to the need for an evacuation that might be necessary for a scenario other than a fire (e.g., bomb threat, earthquake).
(13) Contingency plans should be established in the event the fire alarm and communication system fail, which might facilitate the need for total evacuation.
(14) The means of egress systems should be properly maintained to ensure the dependability of the method of evacuation.
(15) Fire prevention policies or procedures, or both, should be implemented that reduce the chance of a fire (e.g., limiting smoking or providing fire-safe trash cans).
(16) The method of evacuation should be properly documented, and written forms of communication should be provided to all of the occupants, which might include sign postings throughout the building. Consideration should be given to the development of documentation for an operation and maintenance manual or a fire emergency plan, or both.
(17) Emergency egress drills should be performed on a regular basis. For more information, see Section 4.7 of NFPA *101*.
(18) The AHJ should also be consulted when developing the method of evacuation.

[***101:***A.4.8.2.1(3)]

Measures should be in place and be employed to sequence or control the order of a total evacuation, so that such evacuations proceed in a reasonably safe, efficient manner. Such measures include special attention to the evacuation capabilities and needs of occupants with disabilities, either permanent or temporary. For comprehensive guidance on facilitating life safety for such populations, go to www.nfpa.org. For specific guidance on stair travel devices, see ANSI/RESNA ED-1, *Emergency Stair Travel Devices Used by Individuals with Disabilities.* [***101:***A.4.8.2.1(3)]

In larger buildings, especially high-rise buildings, it is recommended that all evacuations — whether partial or total — be managed to sequence or control the order in which certain occupants are evacuated from their origin areas and to make use of available means of egress. In high-rise buildings, the exit stairs, at any level, are designed to accommodate the egress flow of only a very small portion of the occupants — from only one or a few stories, and within a relatively short time period — on the order of a few minutes. In case of a fire, only the immediately affected floor(s) should be given priority use of the means of egress serving that floor(s). Other floors should then be given priority use of the means of egress, depending on the anticipated spread of the fire and its combustion products, and for the purpose of clearing certain floors to facilitate eventual fire service operations. Typically, this means that the one or two floors above and below a fire floor will have secondary priority immediately after the fire floor. Depending on where combustion products move, for example, upward through a building with cool-weather stack effect, the next priority floors will be the uppermost occupied floors in the building. [***101:***A.4.8.2.1(3)]

Generally, in order to minimize evacuation time for most or all of a relatively tall building to be evacuated, occupants from upper floors should have priority use of exit stairs. For people descending many stories of stairs, this priority will maximize their opportunity to take rest stops without unduly extending their overall time to evacuate a building. Thus, the precedence behavior of evacuees should be that people already in an exit stair should normally not defer to people attempting to enter the exit stair from lower floors, except for those lower floors most directly impacted by a fire or other imminent danger. Notably, this is contrary to the often observed behavior of evacuees in high-rise building evacuations where lower floor precedence behavior occurs. (Similarly, in the most commonly observed behavior of people normally disembarking a passenger airliner, people within the aisle defer to people entering the aisle, so that the areas closest to the exit typically clear first.) Changing, and generally managing, the sequence or order within which egress occurs will require effectively informing building occupants and evaluating resulting performance in a program of education, training, and drills. [***101:***A.4.8.2.1(3)]

When designing the method of evacuation for a complex building, all forms of egress should be considered. For example, consideration could be given to an elevator evacuation system. An elevator evacuation system involves an elevator design that provides protection from fire effects so that elevators can be used safely for egress. See 7.2.13 and A.7.2.12.2.4 of NFPA *101* for more information. [***101:***A.4.8.2.1(3)]

For further guidance, see the following publications:

(1) *SFPE Engineering Guide to Human Behavior in Fire*, which provides information on occupant characteristics, response to fire cues, decision making in fire situations, and methods for predicting evacuation time

(2) *NFPA Fire Protection Handbook*, 20th edition, Section 1, Chapter 9, which provides good methodology for managing exposures and determining the method of evacuation
(3) *NFPA Fire Protection Handbook*, 20th edition, Section 20, which provides further commentary on methods of evacuation for different occupancies
(4) *SFPE Handbook of Fire Protection Engineering*, Volume II, Chapters 58-61, which provide an overview of some of the research on methods of evacuation and methods for predicting evacuation times

[***101:***A.4.8.2.1(3)]

The text of A.10.8.2.1(3) serves as a primer on the subject of evacuation strategies. A wide range of strategies is offered, from total evacuation to partial evacuation to sheltering in place without evacuation. For any given building and its occupants, no one evacuation strategy fits all possible emergencies. An effective action plan calls for more than one evacuation strategy and for a way to communicate to occupants at the time of an emergency the strategy that is to be employed.

10.8.2.2 Emergency action plans shall be submitted to the AHJ for review when required by the AHJ.

10.8.2.3* Emergency action plans shall be reviewed and updated as required by the AHJ. [***101:***4.8.2.3]

No one generic emergency plan can adequately address the needs of all buildings. The AHJ has great latitude in establishing requirements that will result in the creation and upkeep of an emergency action plan tailored to the needs of a particular facility. See A.10.8.2.3 for additional details on updating emergency action plans based on lessons learned from emergency relocation or evacuation drills and lessons learned from actual fire incidents that necessitated emergency relocation or evacuation. Such lessons should become inputs to an improved, more customized emergency action plan.

A.10.8.2.3 Emergency action plans are a critical component of assuring life safety in buildings. Life safety is the result of an interaction of technical and social systems within the building and in the community. Gathering information to evaluate the performance and effectiveness of emergency action plans is important for verifying system performance and as a basis for improvement. Such reports should be retained by building management and used to inform the process for revision of the building emergency action plan. [***101:***A.4.8.2.3]

Following any drill or actual emergency or reported emergency occurring in the building, an after action report should be prepared by the building owner or designated representative to document the function of the building's life safety hardware, procedures, and occupant emergency organization. [***101:***A.4.8.2.3]

For ordinary drills and reported emergencies, areas of success and areas for improvement should be identified. [***101:***A.4.8.2.3]

For actual emergencies in the building, where there is major occupant movement, damage, or casualties, additional information should be collected. This includes questions concerning the event, as well as performance of life safety systems. It also identifies improvements in areas such as training, maintenance, interaction with local emergency response organizations, or occupant management. The reports from these significant events should be shared with the local emergency response organization. [***101:***A.4.8.2.3]

10.9 Smoking

For the purposes of this *Code*, smoking is defined as carrying lighted pipes, cigars, cigarettes, tobacco, or any other lighted type of smoking substance through an area. People might mistakenly believe that they actually have to be smoking a tobacco product in order to violate the nonsmoking designation. Certain areas are often designated as nonsmoking areas because of the presence of combustible materials or the possible presence of flammable vapors or gas. Carrying lighted tobacco products through, or depositing them in, nonsmoking areas can be as dangerous as actually using the products in proximity to such materials, vapors, or gases.

10.9.1 Where smoking is considered a fire hazard, the AHJ shall be authorized to order the owner in writing to post "No Smoking" signs in conspicuous, designated locations where smoking is prohibited.

The "No Smoking" sign should be large enough to be readily seen, and either the sign or the lettering on the sign should be of a color that contrasts with the background of the location where it is posted. The sign text also needs to be in languages appropriate for the building occupants. Exhibit 10.2 shows an example of a "No Smoking" sign complying with 10.9.1.

10.9.2 In areas where smoking is permitted, noncombustible ashtrays shall be provided.

10.9.3 Removal or destruction of any required "No Smoking" sign shall be prohibited.

10.9.4 Smoking or depositing any lighted or smoldering substance in a place where required "No Smoking" signs are posted shall be prohibited.

Exhibit 10.2

"No Smoking" sign.

10.10 Open Flames, Candles, Open Fires, and Incinerators

10.10.1 Permits. Permits, where required, shall comply with Section 1.12.

Section 1.12 gives the AHJ the power to issue a permit for the kindling or maintenance of any open fire or a fire in any public street, alley, road, or other public or private ground.

10.10.1.1 Permits shall not be required for cooking and recreational fires.

10.10.1.2 Where burning is conducted on public property or the property of someone other than the permit applicant, the permit applicant shall demonstrate that permission has been obtained by the appropriate government agency, the owner, or the owner's authorized agent.

10.10.1.3 When limits for atmospheric conditions or hours restrict burning, such limits shall be designated in the permit restrictions.

Some atmospheric conditions that could cause open fires to be hazardous are high winds, heavy fog, and smog alerts. An example of a local condition that could lead the AHJ to prohibit an open fire would be when the fire department is extremely busy, such as during an outdoor event, a major emergency, or another large event that would limit fire-fighting resources.

10.10.1.4 Instructions or stipulations of permit shall be followed.

10.10.2 The AHJ shall have the authority to prohibit any or all open flames, candles, and open, recreational, and cooking fires or other sources of ignition, or establish special regulations on the use of any form of fire or smoking material where circumstances make such conditions hazardous.

In many parts of the country, the danger of fire is extremely high during certain times of the year. During such periods, as stated in 10.10.2, the AHJ should prohibit any open burning. The public should be notified that burning is prohibited, and special care should be taken to prevent fires from occurring.

The reference to candles in 10.10.2 gives the AHJ the authority to prohibit their use wherever such use is deemed to be hazardous. While this provision gives the AHJ broad authority to prohibit candles, reasonable judgment should be exercised. For example, in a restaurant, protected candles with noncombustible, substantial bases on the dining tables should not be deemed to be overly hazardous.

10.10.3 Outdoor Fires.

10.10.3.1* Outdoor fires shall not be built, ignited, or maintained in or upon hazardous fire areas, except by permit from the AHJ.

A.10.10.3.1 Areas for such use can include inhabited premises or designated campsites where such fires are built in a permanent barbecue, portable barbecue, outdoor fireplace, incinerator, or grill.

10.10.3.2 Permanent barbecues, portable barbecues, outdoor fireplaces, or grills shall not be used for the disposal of rubbish, trash, or combustible waste material.

10.10.4 Open Fires.

10.10.4.1 Permitted open fires shall be located not less than 50 ft (15 m) from any structure.

In the event that brands and embers are given off or that the fire is out of control, the 50 ft (15 m) requirement provides some distance between the fire and the structures. Depending on conditions, the AHJ can increase this distance to provide adequate protection.

10.10.4.2 Burning hours shall be prescribed by the AHJ.

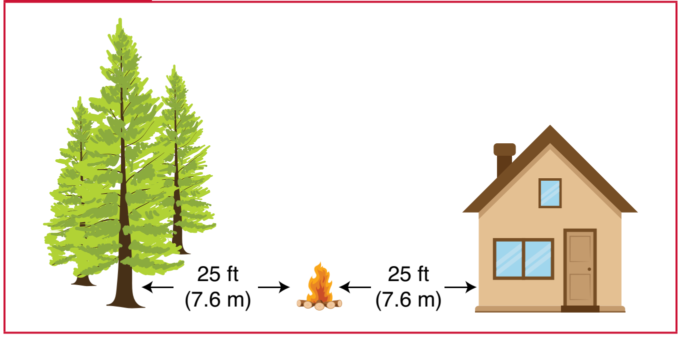
The AHJ can determine the hours that burning is to take place. Many jurisdictions permit burning during daylight hours and others only at night. The fire department and the dispatch center should be kept informed of where burning is taking place, because they will undoubtedly receive calls reporting smoke or flames in the area.

10.10.4.3 Recreational fires shall not be located within 25 ft (7.6 m) of a structure or combustible material unless contained in an approved manner.

10.10.4.4 Conditions that could cause a fire to spread to within 25 ft (7.6 m) of a structure shall be eliminated prior to ignition.

Recreational fires may include campfires or other similar-type fires. The 25 ft (7.6 m) separation requirement provides a safe distance between the fire and other structures or combustible materials. Caution should be used when differentiating between a recreational fire and a permitted open fire as addressed in 10.10.4.1. A permitted open fire is usually larger and more regulated. It should not be considered a recreational fire. Exhibit 10.3 shows the minimum separation distance between a recreational fire and a structure or combustible material. This is not occupancy specific and should be enforced as best as possible within the capacity of the local AHJ.

Exhibit 10.3



Minimum separation distance between recreational fire and structure or combustible material.

Where it is not possible for a recreational fire to be located at least 25 ft (7.6 m) from a structure or combustible material, the AHJ can approve a method to contain the fire. Anyone wanting to start a recreational fire must consult local requirements. Some areas of the United States have strict provisions, even prohibitions, on recreational fires, based upon geography, weather conditions, conservation and preservation efforts, and local wildfire risks. Recreational fires can go wrong quickly and every effort must be made to keep the fire under control at all times.

10.10.5 Fire Attendant.

10.10.5.1 Open, recreational, and cooking fires shall be constantly attended by a competent person until such fire is extinguished.

The presence of a competent person who has access to readily available fire-extinguishing equipment and knowledge of how to use that equipment is important to maintaining a safe outdoor fire. Outdoor fires frequently burn out of control because no one is in attendance to notify the fire department and to take action to prevent fire spread. The AHJ should establish guidelines for safe burning and can require fire apparatus to be present where the situation warrants.

10.10.5.2 This person shall have a garden hose connected to the water supply or other fire-extinguishing equipment readily available for use.

10.10.6 Cooking Equipment.

10.10.6.1 For other than one- and two-family dwellings, no hibachi, grill, or other similar devices used for cooking, heating, or any other purpose shall be used or kindled on any balcony, under any overhanging portion, or within 10 ft (3 m) of any structure.

10.10.6.2 For other than one-and two-family dwellings, no hibachi, grill, or other similar devices used for cooking shall be stored on a balcony.

10.10.6.3* Listed equipment permanently installed in accordance with its listing, applicable codes, and manufacturer's instructions shall be permitted.

A.10.10.6.3 It is not the intent of this paragraph to allow the permanent installation of portable equipment unless it is permitted by its listing.

For all occupancies other than one- and two-family dwellings, the use of gas grills, charcoal grills, fireplaces, and other heat-producing devices is prohibited on balconies and patios, under any overhang, and within 10 ft (3 m) of any structure, unless such cooking equipment is permanently installed in accordance with its listing. In addition, 10.10.6.2 prohibits the storage of such cooking equipment on balconies of other than one- and two-family dwellings; where grills are stored on balconies, the probability is high they will be used there as well.

With regard to 10.10.6, a frequently asked question is whether electric grills are included in this provision. The answer is yes. Some research into past *Code* changes shows that in the 2006 edition, 10.11.7 (now 10.10.6.1) read as follows:

> **10.11.7** For other than one- and two-family dwellings, no hibachi, gas-fired grill, charcoal grill, or other similar devices used for cooking, heating, or any other purpose, shall be used or kindled on any balcony or under any overhanging portion or within 10 ft (3 m) of any structure. Listed electric ranges, grills, or similar electrical apparatus shall be permitted.

However, for the 2009 edition of the *Code*, that paragraph was revised to read as follows:

> **10.11.6** For other than one- and two-family dwellings, no hibachi, grill, or other similar devices used for cooking, heating, or any other purpose shall be used or kindled on any balcony, under any overhanging portion, or within 10 ft (3 m) of any structure.

In the 2009 text, the last sentence was removed, thus including electric ranges, grills, and similar electrical apparatus in its application. While the answer to this frequently asked question requires the user to look back to the 2006 edition, it is still relevant in the application of the 2018 edition of the *Code*.

The inspection of every balcony of every multifamily dwelling is an impractical enforcement task. Compliance through public education is more readily achievable. The AHJ can provide written notification of these requirements to condominium associations, property management agencies, and others who are affected. When the potential danger posed by grills is understood, voluntary compliance is easier to obtain. Landlords can also include this prohibition in leases to ensure that tenants are aware of the restrictions.

10.10.7 Installation of Patio Heaters. The installation of patio heaters shall comply with 69.3.13.

The requirements addressing patio heaters in 69.3.13, as referenced by 10.10.7, recognize the growing use of these portable outdoor appliances used to heat outdoor areas when the climate is too cool to comfortably sit or stand outdoors. They are used extensively in restaurants with outdoor seating areas to enable the areas to be used for a greater number of weeks each year. They are also used where attendants, such as those working for a valet parking service, wait outdoors. Exhibit 10.4 depicts typical patio heaters.

A minimum 5 ft (1.5 m) separation between patio heaters and exits in assembly occupancies is specified by 69.3.13.1.3 and recognizes that patio heaters are commonly used in restaurants. The term *assembly occupancy* is defined in Chapters 3 and 6. While restaurants are the most likely assembly occupancies to use patio heaters in outdoor areas, other assembly occupancies might use them as well.

Exhibit 10.4

Patio heaters. (Courtesy of Richard Fredenberg, North Carolina Department of Agriculture and Consumer Services)

Exhibit 10.5

Sky lanterns. (Solarseven/shutterstock)

10.10.8 Incinerators and Fireplaces.

10.10.8.1 Incinerators, outdoor fireplaces, permanent barbecues, and grills shall not be built, installed, or maintained without prior approval of the AHJ.

10.10.8.2 Incinerators, outdoor fireplaces, permanent barbecues, and grills shall be maintained in good repair and in a safe condition at all times.

10.10.8.3 Openings in incinerators, outdoor fireplaces, permanent barbecues, and grills shall be provided with an approved spark arrester, screen, or door.

10.10.9 Open-Flame Devices.

10.10.9.1* Welding torches, tar pots, decorative torches, and other devices, machines, or processes liable to start or cause fire shall not be operated or used in or upon any areas, except by permit from the AHJ.

Δ **A.10.10.9.1** Areas for such use can include inhabited premises or designated campsites that maintain a defensible space in accordance with NFPA 1144.

10.10.9.2 Flame-employing devices, such as lanterns or kerosene road flares, and fuses shall not be operated or used as a signal or marker in or upon any areas unless at the scene of emergencies or railroad operations. *(See Chapter 16 and Chapter 65 for additional guidance.)*

10.10.9.3 The use of unmanned, free-floating sky lanterns and similar devices utilizing an open flame shall be prohibited.

The provision of 10.10.9.3 was new to the 2015 edition of the *Code* and gives the AHJ specific language that can be cited to prohibit the use of unmanned, free-floating sky lanterns and similar devices, such as those depicted in Exhibit 10.5. The potential hazard posed by sky lanterns should be obvious — once ignited and released, the device becomes an uncontrolled, flying ignition source, whose direction of travel is dependent on the wind direction, which can change unpredictably. Although the combustible fuel load of the device itself might be small, the potential exists for the device to ignite vegetation or other combustibles in the area and cause a significant fire if it is not quickly extinguished.

10.10.10* Discontinuance. The AHJ shall be authorized to require any fire or smoke to be immediately discontinued if the fire is determined to constitute a hazardous condition.

N **A.10.10.10** A hazardous condition is intended to include any fire that generates smoke or products of combustion that could obstruct visibility in traffic, create health issues, damage property, or contribute to conditions that create property, safety, or health hazards. As numerous variables can go into this determination, the authority having jurisdiction will need to evaluate each situation on a case-by-case basis.

10.11 Fire Protection Markings

10.11.1* Premises Identification.

N **A.10.11.1** An additional means to identify the locations of new and existing buildings is to co-geolocate each building with U.S. National Grid 108 ft^2 (10 m^2) coordinates to the primary entrance.

10.11.1.1* New and existing buildings shall have approved address numbers placed in a position to be plainly legible and visible from the street or road fronting the property.

A.10.11.1.1 Where a building is not routinely identified by a street address, other means of building identification such as building name or number should be permitted.

Exhibit 10.6

Address number.

To assist emergency responders in locating properties, building address numbers must be visible from the street. Address numbers can be mounted either on the building itself or, if the building is not visible from the street, on a post located on the street. The numbers should contrast with the background of the building or post and be large enough to be easily seen from the street. Exhibit 10.6 depicts an example of effective address numbers.

N **10.11.1.2** Address numbers shall be a minimum of 4 in. (100 mm) high with a minimum stroke width of ½ in. (13 mm).

N **10.11.1.3*** Telecommunications equipment utilized to communicate address data to E911 communication centers shall be programmed and maintained to accurately convey such address information to the E911 communication center.

N **A.10.11.1.3** E911, or Enhanced 911, attempts to automatically associate a location with a call's origin. The location could be a physical address or a geographic reference point. When E911 is in place, the address or geographic reference point is transmitted to the public safety answering point (PSAP). Paragraph 10.11.1.xx ensures that telecommunications equipment that is part of the transmission path is programmed to communicate correct address information to the E911 PSAP. It is not the intent of this provision to require E911 capability of the telecommunications equipment where the PSAP is not capable of receiving such data.

N **10.11.1.4** The assignment of addresses to buildings shall be in accordance with a method approved by the AHJ.

N **10.11.1.5** Addresses shall not be changed unless approved by that AHJ.

N **10.11.1.6** Address numbers for suites within a multiple tenant building or complex shall be individually identified in a manner approved by the AHJ.

10.11.1.7 Address numbers shall contrast with their background.

10.11.1.8 Address numbers shall be arabic numerals or alphabet letters.

Paragraphs 10.11.1.2 through 10.11.1.8 are new to the 2018 edition of the *Code* and expand and further clarify the existing requirements for premises identification. Details such as minimum height and width for address numbers help to ensure a reasonable level of visibility to emergency responders. Paragraph 10.11.1.1 requires only that addresses be plainly legible and visible from the street, which could result in conflict and differences of opinion.

Proper programing of telecommunications equipment to convey correct address information in the event of an E911 call is imperative. Incorrect information can result in a delayed response to a fire, medical, or other emergency. The code should require owners/occupants to do their part in ensuring that their chain in the E911 communication is correct and maintained.

Assignment of addresses to buildings and changes of addresses to existing buildings can create significant difficulties for emergency responders if a consistent approach is not utilized. Maintaining a current addressing methodology is becoming increasingly important as addressing databases are being used in new technology application during a response, such as a geographic information system (GIS). The AHJ should have a formal initial addressing mechanism and method to review and approve changes to existing addresses in order to ensure that databases are maintained and response times are not adversely affected.

In previous editions of the *Code*, 10.11.1 has not provided any provision for the addressing of individual suites in a multiple-tenant environment. A shopping center could have one single address, displayed at the street in accordance with 10.11.1.1, but specific suites that are unidentified could still have been in compliance with 10.11.1.1. That created the potential for significant delays in response times by emergency responders trying to locate a particular suite within a multiple-suite complex. New 10.11.1.6 clarifies that address numbers for suites within a multiple-tenant building or complex are to be individually identified in a manner approved by the AHJ.

10.11.2 Shaftways to Be Marked for Fire Fighter Safety.

10.11.2.1 Every outside opening accessible to the fire department that opens directly on any hoistway or shaftway communicating between two or more floors in a building shall be plainly marked with a sign in accordance with 10.11.2.2 and 10.11.2.3.

Markings are required to protect fire fighters from falling into a shaftway. Paragraph 10.11.2.1 requires exterior shaft openings to be marked where the shaft connects two or more stories. For added safety, all openings to shaftways, whether interior or exterior, should be marked to alert persons to the potential hazard.

10.11.2.2 Shaftway signs shall be in red letters at least 6 in. (152 mm) high on a white background stating "SHAFTWAY."

10.11.2.3 Such warning signs shall be placed so as to be readily discernible from the outside of the building.

FIGURE A.10.11.3 *Example of a Stairway Marking Sign. [**101:**Figure A.7.2.2.5.4]*

10.11.3* Stairway Identification.

A.10.11.3 Figure A.10.11.3 shows an example of a stairway marking sign. [***101:***A.7.2.2.5.4]

10.11.3.1 New enclosed stairs serving three or more stories and existing enclosed stairs other than those addressed in 10.11.3.1.16, serving five or more stories shall comply with 10.11.3.1.1 through 10.11.3.1.15. [***101:***7.2.2.5.4.1]

10.11.3.1.1 The stairs shall be provided with special signage within the enclosure at each floor landing. [***101:***7.2.2.5.4.1(A)]

10.11.3.1.2 The signage shall indicate the floor level. [***101:***7.2.2.5.4.1(B)]

10.11.3.1.3 The signage shall indicate the terminus of the top and bottom of the stair enclosure. [***101:***7.2.2.5.4.1(C)]

10.11.3.1.4 The signage shall indicate the identification of the stair enclosure. [***101:***7.2.2.5.4.1(D)]

10.11.3.1.5 The signage shall indicate the floor level of, and the direction to, exit discharge. [***101:***7.2.2.5.4.1(E)]

10.11.3.1.6 The signage shall be located inside the stair enclosure. [***101:***7.2.2.5.4.1(F)]

10.11.3.1.7 The bottom of the signage shall be located a minimum of 48 in. (1220 mm) above the floor landing and the top of the signage shall be located a maximum of 84 in. (2135 mm) above the floor landing. [***101:***7.2.2.5.4.1(G)]

10.11.3.1.8 The signage shall be in a position that is visible from within the stair enclosure when the door is in the open or closed position. [***101:***7.2.2.5.4.1(H)]

10.11.3.1.9 The signage shall comply with 14.14.8.1 and 14.14.8.2. [***101:***7.2.2.5.4.1(I)]

Δ **10.11.3.1.10** The floor level designation shall also be tactile in accordance with ICC/ANSI A117.1, *Accessible and Usable Buildings and Facilities*. [***101:***7.2.2.5.4.1(J)]

10.11.3.1.11 The signage shall be painted or stenciled on the wall or on a separate sign securely attached to the wall. [***101:***7.2.2.5.4.1(K)]

10.11.3.1.12 The stairway identification shall be located at the top of the sign in minimum 1 in. (25 mm) high lettering and shall be in accordance with 14.14.8.2. [***101:***7.2.2.5.4.1(L)]

10.11.3.1.13* Signage that reads NO ROOF ACCESS shall designate stairways that do not provide roof access. Lettering shall be a minimum of 1 in. (25 mm) high and shall be in accordance with 14.14.8.2. [***101:***7.2.2.5.4.1(M)]

A.10.11.3.1.13 It is not the intent to require a sign that reads ROOF ACCESS, as such message might be misinterpreted by building occupants as an alternative egress route. However, signs that read ROOF ACCESS are not prohibited, as many such signs have been installed in existing buildings so as to make a requirement for removal impractical. Historically, the ROOF ACCESS sign has provided information for the fire department. Where there is no roof access, such information will be posted via a NO ROOF ACCESS sign. The absence of the NO ROOF ACCESS sign should be understood by the fire department to mean that roof access is possible. [***101:***A.7.2.2.5.4.1(M)]

10.11.3.1.14 The floor level number shall be located below the stairway identifier in minimum 5 in. (125 mm) high numbers and shall be in accordance with 14.14.8.2. Mezzanine levels shall have the letter "M" or other appropriate identification letter preceding the floor number, while basement levels shall have the letter "B" or other appropriate identification letter preceding the floor level number. [***101:***7.2.2.5.4.1(N)]

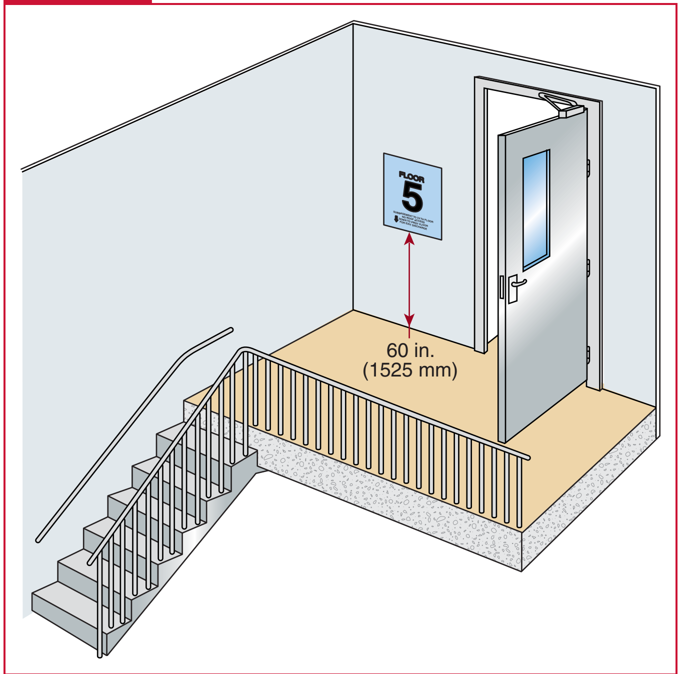
10.11.3.1.15 Identification of the lower and upper terminus of the stairway shall be on the sign in minimum 1 in. (25 mm) high letters or numbers and shall be in accordance with 14.14.8.2. [***101:***7.2.2.5.4.1(O)]

10.11.3.1.16 Previously approved, existing signage shall not be required to comply with 10.11.3.1.12 through 10.11.3.1.15. [***101:***7.2.2.5.4.1(P)]

The provisions of 10.11.3.1 require the posting of important information at each floor landing in each stairwell if a new stair serves three or more stories or an existing stair serves five or more stories. The information is for fire-fighting personnel and building occupants in an emergency. The term *signage* is used to signify that the required information might appear on multiple signs mounted adjacent to each other. The information most helpful to fire fighters can be put on one sign, and the information most useful to occupants on another. See Figure A.10.11.3.

The signage must identify the stair, indicate the floor level of the landing [this element additionally must be tactile per 10.11.3.1.10] and where the stairwell terminates at the top and bottom, and identify and show the direction to the exit discharge.

Exhibit 10.7



Stair sign placement.

Exhibit 10.8

Stairway identification sign with tactile floor level designator.

Exhibit 10.7 illustrates the placement required to ensure that the sign is readily visible, whether the door leaf is open or closed.

The indication of the direction to the level of exit discharge can be extremely useful to occupants of a building, especially if the occupants are below the level of exit discharge. The natural tendency of occupants is to attempt egress by traveling downward in a stair; this is counterproductive where the exit discharge is located on an upper level. Also, many buildings have multiple levels of entrance, which create confusion with respect to travel direction in a given stair.

The requirements of 10.11.3 are not exempted for existing buildings, because it is feasible and cost effective to install signs providing the required information. Because stair enclosures are usually not as aesthetically well finished as occupied portions of a building, the requirement for the signage (other than for the tactile floor level designator) is often met by stenciling the information directly onto the walls.

The provision of 10.11.3.1.13 was revised for the 2009 edition of the *Code*. In prior editions, roof access or lack of roof access was required to be designated by a sign. In many cases, roof access was provided for emergency responders only, and a sign reading "Roof Access" was misleading to building occupants. The current provision requires that only the lack of roof access be designated by a sign.

The provision of 10.11.3.1.7 was new to the 2015 edition of the *Code*. It replaced a provision that required the signage to be located approximately 60 in. (1525 mm) above the floor landing. The *Code* user now has a definitive height range for placement of the sign above the floor landing. Other criteria were moved or combined for clarification.

The provision of 10.11.3.1.16 is needed so that signs installed prior to 2009, when subitems (L) through (O) were added, are not unfairly reclassified as noncompliant.

The provision of 10.11.3.1.8 was revised for the 2018 edition of the *Code* to add the words "from within the stair enclosure," because misinterpretations were being made that occupants must be able to see the sign before entering the exit stair enclosure.

Exhibit 10.8 shows a stairway identification sign with the information required by 10.11.3.1. The element reading *Level 2* was provided for compliance with 10.11.3.1.2, which requires that the signage indicate the floor level, and for compliance with 10.11.3.1.10, which requires that the floor level designation also be tactile in accordance with ICC/ANSI A117.1, *Accessible and Usable Buildings and Facilities*. The minimum 5 in. (125 mm) high floor level number — the large *2* in this case — that was provided for compliance with 10.11.3.1.14 cannot serve as the tactile floor level designation because ICC/ANSI A117.1 limits raised characters to being not more than 2 in. (51 mm) in height. Further, the floor level designation is provided in braille below the tactile element, because ICC/ANSI A117.1 requires that raised letters be duplicated in braille.

Δ **10.11.3.2** Wherever an enclosed stair requires travel in an upward direction to reach the level of exit discharge, special signs with directional indicators showing the direction to the level of exit discharge shall be provided at each floor level landing from which upward direction of travel is required, unless otherwise provided in 10.11.3.2.1 and 10.11.3.2.2, and both of the following also shall apply:

(1) Such signage shall comply with 14.14.8.1 and 14.14.8.2.
(2) Such signage shall be visible when the door leaf is in the open or closed position.

[***101:***7.2.2.5.4.2]

10.11.3.2.1 The requirement of 10.11.3.2 shall not apply where signs required by 10.11.3.1.1 are provided. [***101:***7.2.2.5.4.2(A)]

10.11.3.2.2 The requirement of 10.11.3.2 shall not apply to stairs extending not more than one story below the level of exit discharge where the exit discharge is clearly obvious. [***101:***7.2.2.5.4.2(B)]

10.11.3.3* Stairway Tread Marking. Where new contrasting marking is applied to stairs, such marking shall comply with all of the following:

(1) The marking shall include a continuous strip as a coating on, or as a material integral with, the full width of the leading edge of each tread.
(2) The marking shall include a continuous strip as a coating on, or as a material integral with, the full width of the leading edge of each landing nosing.
(3) The marking strip width, measured horizontally from the leading vertical edge of the nosing, shall be consistent at all nosings.
(4) The marking strip width shall be 1 in. to 2 in. (25 mm to 51 mm).

[***101:***7.2.2.5.4.3]

A.10.11.3.3 Where environmental conditions (such as illumination levels and directionality or a complex visual field that draws a person's attention away from stair treads) lead to a hazardous reduction in one's ability to perceive stair treads, they should be made of a material that allows ready discrimination of the number and position of treads. In all cases, the leading edges of all treads should be readily visible during both ascent and descent. A major factor in injury-producing stair accidents, and in the ability to use stairs efficiently in conditions such as egress, is the clarity of the stair treads as separate stepping surfaces. [***101:***A.7.2.2.5.4.3]

For stair nosing marking, surface-applied material, such as adhesive-backed tape and magnetic strips, should not be used, as it is not durable under the scuffing from users' feet and, in coming loose, it creates a tripping hazard. While a carefully applied and consistently maintained coating is acceptable, contrasting color or photoluminescent material integral with the nosings is preferable because of its permanence. See also 7.1.6.4 and 7.2.2.3.6 of NFPA *101* for slip resistance uniformity requirements, as well as prohibition of projections on the treads. [***101:***A.7.2.2.5.4.3]

Guidance on the use of photoluminescent marking is provided by ASTM E2030, *Guide for Recommended Uses of Photoluminescent (Phosphorescent) Safety Markings*. Additional marking, for example, at the side boundaries of the stair, should be applied in accordance with the guidance provided therein. [***101:***A.7.2.2.5.4.3]

10.11.3.4* Where new contrast marking is provided for stairway handrails, it shall be applied to, or be part of, at least the upper surface of the handrail; have a minimum width of ½ in. (13 mm); and extend the full length of each handrail. After marking, the handrail shall comply with 7.2.2.4.4 of NFPA *101*. Where handrails or handrail extensions bend or turn corners, the stripe shall be permitted to have a gap of not more than 4 in. (100 mm). [***101:***7.2.2.5.4.4]

A.10.11.3.4 Coatings and other applied markings, if used, should be durable for the expected usage, especially at end terminations of the marking and at changes in stair direction where usage is more extensive and hand forces are larger. [***101:***A.7.2.2.5.4.4]

The criteria of 10.11.3.3(1) through (4) are needed to prevent the marking strips from providing misleading cues to stair users that might make use of the stair less safe or more confusing than if the marking strips were not installed. For example, 10.11.3.3 (4) limits the marking strip to a maximum width of 2 in. (51 mm) to ensure that all but the leading edge of the tread is left unmarked, so a person using the stair in the downward direction sees individual tread edges and not one continuously marked sloping plane. The undesired continuously marked sloping plane would create a ramp effect, with no indication of the location of the leading edge of each tread. Exhibit 10.9 shows an outside stair where tread marking provided by paint application has worn away to the point that the tread locations are imperceptible.

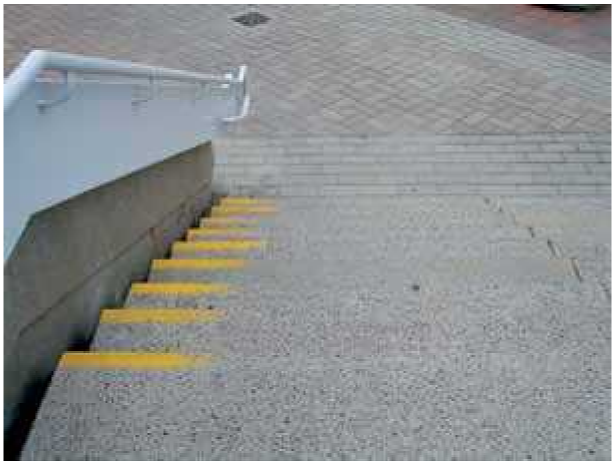
The provisions of 10.11.3.4 do not mandate that contrasting marking be applied to stair handrails. Where such contrast marking is provided for handrails, it regulates such installation so that the markings are useful and not misleading. For example, it requires that the marking stripe extend the full length of each handrail so the stair user can assess the extent of the stair flight before beginning any vertical movement on the stair.

Contrast marking, where applied, will usually be in the form of a photoluminescent or glow-in-the-dark material. See 7.2.2.5.5.10 of NFPA *101*. The third sentence of 10.11.3.4 permits short gaps in the contrast marking striping at handrail bends and turns in recognition of the fact that some photoluminescent materials are too rigid to be applied effectively at bends and turns.

10.11.3.5 These signs shall be maintained in an approved manner.

10.11.3.6 Existing approved signs shall be permitted.

Exhibit 10.9



Stair tread marking worn away so as to make tread location imperceptible. (Photo courtesy of Jake Pauls)

10.12 Seasonal and Vacant Buildings and Premises

Vacant buildings, such as the one shown in Exhibit 10.10, especially those of combustible construction, pose a hazard to adjacent exposures, fire fighters, and the community. For example, 6 fire fighters in Worcester, Massachusetts, died in late 1999 fighting a fire in an abandoned cold storage warehouse. More recently, 2 Chicago, Illinois, fire fighters died while fighting a fire in an abandoned warehouse on December 22, 2010, which, coincidentally, was the 100th anniversary of the 1910 Union Stockyard fire that killed 21 Chicago fire fighters.

Reducing the fuel load in a vacant building is critical because, in the event of a fire, little or no combustible contents should contribute to the spread of the fire. Seasonal buildings are exempt from the requirement for removal of combustibles by 10.12.1.1.

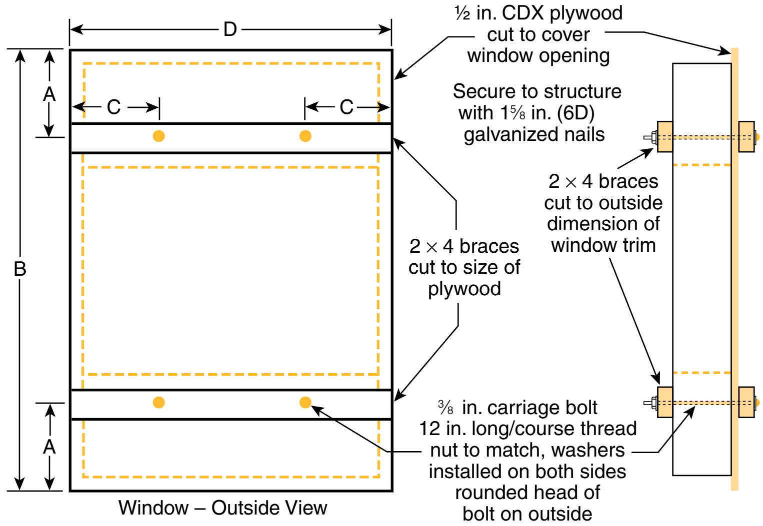
Vacant buildings are subject to vandalism and arson and, therefore, must be kept secure by placing substantial barricades on all doors, windows, and other openings at all levels where access can be gained. (See Exhibit 10.11.)

Barricades should be of plywood or other material acceptable to the AHJ. They should be screwed (not nailed) every 6 in. (152 mm), on center, around the entire perimeter of the barricade or should have substantial backer boards of at least 2 in. × 4 in. (51 mm × 102 mm) nominal dimension that span the opening, with ⅜ in. (10 mm) carriage bolts that are through-bolted to secure the plywood barricade in the opening. Sources of ignition or fuel such as energized electrical circuits, fuel gas lines, and heating appliances should be limited to those necessary to

Exhibit 10.10

Vacant building. (Source: © Acesarek, Dreamstime.com)

Exhibit 10.11



Notes:
1. For double hung windows, slide sash to center of unit and pass bolts through openings at top and bottom.
2. Storm windows ahould be removed and stored inside structure.
3. Outside trim may have to be removed to accommodate a flush and tight fit.
4. Tighten nuts from inside enough to slightly compress 2 × 4 brace.
5. Brace locations: A = ⅓B (SEE DIMENSION LOCATIONS ON DRAWING)
6. Location of bolt holes: C = ⅓D (SEE DIMENSION LOCATIONS ON DRAWING)

Suggested methods of barricading exterior windows or doors in a vacant building. (Courtesy of USFA) maintain fire protection systems in the building. During times when no tenants are in the building or when the building is being remodeled, security should be maintained at a level equal to that which would be provided to an occupied building or area.

For additional guidance in dealing with vacant/abandoned buildings, the United States Fire Administration and International Association of Arson Investigators have developed a free Abandoned Building Project Tool Box, available at www.interfire.org. It contains a background paper on the hazards posed, lesson plans and a PowerPoint presentation, a building evaluation form, a flowchart for identifying building owners, a template for developing floor plans, a reference list, specifications and drawings for securing buildings, and case studies.

10.12.1 Every person owning or having charge or control of any vacant building, premises, or portion thereof shall remove all combustible storage, waste, refuse, and vegetation and shall lock, barricade, or otherwise secure the building or premises to prohibit entry by unauthorized persons.

10.12.1.1 The requirement of 10.12.1 shall not apply to buildings used on a seasonal basis, or the temporary vacancy of a building for tenant change or remodeling purposes.

10.12.2 All fire protection systems shall be maintained in service in seasonal and vacant buildings, unless otherwise approved by the AHJ.

10.12.2.1* With the approval of the AHJ, fire protection and fire alarm systems in seasonal and vacant buildings shall be permitted to be removed from service.

A.10.12.2.1 Issues to be considered by the AHJ should include, but not be limited to, the availability of utilities to the building.

10.12.2.2 When required by the AHJ, other systems or components pertaining to fire protection shall be maintained.

All fire protection systems, including fire alarm, sprinkler, and standpipe systems, and all associated waterflow and supervisory alarm systems must be maintained in a manner acceptable to the AHJ. The maintenance of the associated alarm systems and supervisory systems is important to ensure that they are monitored properly and have the ability to transmit alarms when needed. In climates where freezing is of concern, the conversion from a wet sprinkler or standpipe system to a dry system might be necessary if heat is not maintained in the building.

Vacant buildings of totally fire-resistant construction that are void of any combustible contents and that pose no hazard to exposures might be exempt from maintaining fire alarm, sprinkler, and standpipe systems where approved by the AHJ.

Fire protection components referenced in 10.12.2.2 might include fire doors, fire barriers, and other passive and active systems.

10.12.3 The AHJ shall have the authority to require an inspection and test of any fire protection system or fire alarm system that has been out of service for 30 days or more before restored back into service.

Whenever a fire protection system is shut off for an extended period of time, an inspection and test of the system for system integrity are necessary before the system is put back in service. Wet pipe systems can develop leaks in gaskets, seals, and joints that have dried out from nonuse. Standpipe valves can be open, caps missing, or hose or threads damaged. Fire alarm system detection devices can accumulate dirt or develop battery problems if a proper charge is not maintained. When any system is out of service, the potential exists for damage or vandalism that might not be detected until the system is tested.

10.13 Combustible Vegetation

Combustible vegetation can include a variety of items, such as hay bales, limbs, leaves, and Christmas trees. These items, by their nature, are initially fire retardant. The problem arises when they have been cut and packaged without access to water for extended periods of time. The fire danger of Christmas trees and similar vegetation increases when the butt or bottom end of the tree is not freshly cut and immediately placed in water when purchased.

Other concerns include the length of time Christmas trees are on display (retail stores often set up outdoor displays of trees before Thanksgiving) and the misconception that fire retardants for Christmas trees are effective. The effectiveness of fire retardants on Christmas trees is a controversial issue, particularly when a fire marshal's approval is shown on a label. Research at the University of Washington indicates that most retardants are salt-based and actually accelerate the drying process. Trees that are displayed in water will fare better than those that are treated.

The species of tree and the rate of moisture loss are important factors in determining the extent of moisture loss. Of the various types of evergreen trees available, the Noble fir retains its moisture longer than other species.

The best preventive measures include using a freshly harvested tree, cutting the butt or bottom end immediately before placing it in water, and checking the water level frequently to ensure that the tree water container is filled. To check the tree itself for dryness, the person responsible for the display should periodically grasp a branch near the trunk and allow it to slide between the thumb and forefinger. When needles shed easily, the tree should be removed or replaced, since trees dry from the inside out. See "Pining for Water" in the November/December 1999 issue of *NFPA Journal*®.

10.13.1 Combustible vegetation, including natural cut Christmas trees, shall be in accordance with Section 10.13.

Christmas trees are prohibited or limited in their placement in occupancies that pose special problems due to the capabilities of occupants, occupant or management control, or the number of occupants. Some exceptions permit live, balled trees, if maintained, and trees in locations where automatic sprinkler systems

Δ *TABLE 10.13.1.1 Provisions for Christmas Trees by Occupancy*

Occupancy	No Trees Permitted	Cut Tree Permitted With Automatic Sprinkler Systems	Cut Tree Permitted Without Automatic Sprinkler Systems	Balled Tree Permitted

Lodging and rooming				X
Mercantile		X		X
One and two family		X	X	X
Storage		X	X	X

are installed. Because a living tree needs moisture to stay alive, a balled, living tree should be placed in a container so that the root structure of the tree can be kept moist.

10.13.1.1 Christmas tree placement within buildings shall comply with Table 10.13.1.1.

10.13.2 In any occupancy, limited quantities of combustible vegetation shall be permitted where the AHJ determines that adequate safeguards are provided based on the quantity and nature of the combustible vegetation.

Subsection 10.13.2 permits limited quantities of combustible vegetation if the AHJ determines adequate safeguards are in place. Examples of common combustible vegetation include hay or straw, tree cuttings, flowers, leaves, and other decorative materials based on the particular season or holiday. Adequate safeguards might include sprinkler protection, limited quantities, moisture content, and placement. It is not the intent of the *Code* to permit a Christmas tree to be considered "limited quantity of combustible vegetation" where the display of Christmas trees is otherwise prohibited by Table 10.13.1.1.

10.13.3* Provisions for Fire Retardance for Artificial Vegetation.

Δ **A.10.13.3** One example of acceptable fire retardance is for the individual decorative vegetation item to exhibit a maximum heat release rate of 100 kilowatts (kW) when tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or NFPA 289 using the 20 kW ignition source. Another example of acceptable fire retardance is for the individual artificial Christmas trees, when exposed to the flames from 1 lb of shredded newspaper distributed around the tree, to meet the following three criteria:

(1) To have flames that do not extend more than 3 ft (0.9 m) above the tree
(2) To have no significant lateral flame spread away from the area affected by the ignition source
(3) To have no flaming droplets that continue flaming after reaching the floor

10.13.3.1 Artificial vegetation and artificial Christmas trees shall be labeled or otherwise identified or certified by the manufacturer as being fire retardant.

10.13.3.2 Such fire retardance shall be demonstrated by each individual decorative vegetation item, including any decorative lighting, in an approved manner.

10.13.4 Vegetation and Christmas trees shall not obstruct corridors, exit ways, or other means of egress.

No means of egress is permitted to be obstructed by any combustible vegetation item or Christmas tree. This provision is further reinforced by the requirements of Chapter 14. The preferred location for a Christmas tree from a property owner's perspective is often in the lobby, the reception area, or a similar area. However, trees located in these areas often encroach on the means of egress and present an increased danger.

10.13.5 Only listed electrical lights and wiring shall be used on natural or artificial combustible vegetation, natural or artificial Christmas trees, and other similar decorations.

10.13.6 Electrical lights shall be prohibited on metal artificial trees.

10.13.7 Open flames such as from candles, lanterns, kerosene heaters, and gas-fired heaters shall not be located on or near combustible vegetation, Christmas trees, or other similar combustible materials.

10.13.8 Combustible vegetation and natural cut Christmas trees shall not be located near heating vents or other fixed or portable heating devices that could cause it to dry out prematurely or to be ignited.

When determining where to place combustible vegetation items or Christmas trees, an important consideration is that they might fall over, especially if children or pets come in contact with the tree or vegetation. Placing a portable heater, other heat source, or heating vent near combustible vegetation is prohibited, because the vegetation might fall over and also because the heater will prematurely dry the vegetation, increasing the risk of a fire.

10.13.9 Provisions for Natural Cut Trees.

10.13.9.1 Where a natural cut tree is permitted, the bottom end of the trunk shall be cut off with a straight fresh cut at least ½ in. (13 mm) above the end prior to placing the tree in a stand to allow the tree to absorb water.

10.13.9.2 The tree shall be placed in a suitable stand with water.

10.13.9.3 The water level shall be maintained above the fresh cut and checked at least once daily.

The tree water should be checked daily. Because new trees absorb water more rapidly than trees that have been displayed for some time, a newly displayed tree might need to be checked a few times per day in order to ensure that the water level is adequate. When the tree becomes dry, it should be removed immediately. See the National Institute of Standards and Technology (NIST) Building and Fire Research Laboratory's Fire Research Division website, fire.nist.gov/tree_fire.htm, for tree fire videos, including a video comparing the fire performance of a dry tree with that of a moist tree. In 2015, a live burn event at the U.S. Consumer Product Safety Commission's research lab in Rockville, MD showed just how fast a dried-out Christmas tree will burn. Footage of the burn can be seen at https://community.nfpa.org/community/safety-source/blog/2015/12/10/live-burn-shows-just-how-quickly-christmas-tree-fires-can-turn-devastating-and-deadly.

10.13.9.4* The tree shall be removed from the building immediately upon evidence of dryness.

A.10.13.9.4 A method to check for dryness is to grasp a tree branch with a reasonably firm pressure and pull your hand to you, allowing the branch to slip through your grasp. If the needles fall off readily, the tree does not have adequate moisture content and should be removed.

10.13.10 Exterior Vegetation.

10.13.10.1 Cut or uncut weeds, grass, vines, and other vegetation shall be removed when determined by the AHJ to be a fire hazard.

Exhibit 10.12

Example of vegetation close to a building.

Paragraph 10.13.10.1 is not intended to prohibit landscaping around buildings or in other areas. This requirement addresses unmaintained materials such as weeds, grass, and brush. (See Exhibit 10.12.) In many instances, fire has spread either into an area or a building or between areas or buildings because of vegetation that has grown up around a building. Vegetation should be removed from around buildings, storage areas, and other areas to prevent the spread of fire. Fires have occurred in wood chips and mulch placed around buildings and then extended to the buildings. See Chapter 17 for additional guidance.

10.13.10.2 When the AHJ determines that total removal of growth is impractical due to size or environmental factors, approved fuel breaks shall be established.

10.13.10.3 Designated areas shall be cleared of combustible vegetation to establish the fuel breaks.

10.14 Special Outdoor Events, Carnivals, and Fairs

10.14.1 Permits. Permits, where required, shall comply with Section 1.12.

Per Table 1.12.8(a), permits are required for conducting a carnival or fair; operation of a crop maze; use of a parade float for public performance, presentation, spectacle, entertainment, or parade; and for the location and operation of special outdoor events.

10.14.2 The AHJ shall be permitted to regulate all outdoor events such as carnivals and fairs as it pertains to access for emergency vehicles; access to fire protection equipment; placement of stands, concession booths, and exhibits; and the control of hazardous conditions dangerous to life and property.

10.14.3 Life Safety Evaluation. The AHJ shall be permitted to order a life safety evaluation in accordance with this subsection.

The life safety evaluation (LSE) detailed in 10.14.3 is required by NFPA *101* under any of three conditions:

1. Where the occupant load exceeds 6000 persons — see 12/13.1.7.3 and 12/13.1.7.4 of NFPA *101*
2. Where indoor festival seating (i.e., a form of general admission) is used for more than 250 persons — see 12/13.2.5.4.1(2) NFPA *101*
3. Where a reduction in egress path sizing occurs for the special arrangement known as smoke-protected assembly seating — see 12/13.4.2.2 NFPA *101*

The LSE provisions of 10.14.3 were expanded for the 2015 edition of the *Code* to improve their utility. Historically the LSE was performed, approved by the AHJ, updated for special or unusual conditions as needed, and presented to the AHJ for re-approval on a yearly basis. The LSE was lacking in that it did not tie together, at the time the facility was designed and built, the physical elements and how the facility was to be managed.

For the 2015 edition of the *Code*, a new assembly venue subject to the LSE must be assessed prior to construction to ensure that the needed physical elements are part of the design. Also, facility management must be evaluated prior to building occupancy. The expanded LSE provisions help to facilitate better communication among the designers and those who manage the facilities after construction. The goal is to provide managers with safety systems that are compatible with actual building use.

The LSE provisions of 10.14.3 are intended to apply to both new and existing assembly occupancies, other than those related to preconstruction criteria, which only apply to new assembly occupancies. In addition to the building systems and facility management assessments, the LSE criteria include requirements for a life safety narrative, floor plans, engineering analysis and calculations, operational plans, and systems reference guide.

Δ **10.14.3.1* General.** Where a life safety evaluation is required by other provisions of the *Code*, it shall comply with all of the following:

(1) The life safety evaluation shall be performed by persons acceptable to the AHJ.
(2) The life safety evaluation shall include a written assessment of safety measures for conditions listed in 10.14.3.2 and of the building systems and facility management in accordance with 10.14.3.3.
(3) The life safety evaluation shall be approved annually and shall be updated for special or unusual conditions in accordance with the provisions of 13.4.1 of NFPA *101* for existing assembly occupancies.

[***101:***12.4.1.1]

A.10.14.3.1 Life safety evaluations are examples of performance-based approaches to life safety. In this respect, significant guidance in the form and process of life safety evaluations is provided by Chapter 5 of NFPA *101*, keeping in mind the fire safety emphasis in Chapter 5 of NFPA *101*. Performance criteria, scenarios, evaluation, safety factors, documentation, maintenance, and periodic assessment (including a warrant of fitness) all apply to the broader considerations in a life safety evaluation. A life safety evaluation deals not only with fire but also with storms, collapse, crowd behavior, and other related safety considerations for which a checklist is provided in A.10.14.3.3. Chapter 5 of NFPA *101* provides guidance, based on fire safety requirements, for establishing a documented case showing that products of combustion in all conceivable fire scenarios will not significantly endanger occupants using means of egress in the facility (for example, due to fire detection, automatic suppression, smoke control, large-volume space, or management procedures). Moreover, means of egress facilities plus facility management capabilities should be adequate to cope with scenarios where certain egress routes are blocked for some reason. [***101:***A.12.4.1.1]

In addition to making realistic assumptions about the capabilities of persons in the facility (e.g., an assembled crowd including many disabled persons or persons unfamiliar with the facility), the life safety evaluation should include a factor of safety of not less than 2.0 in all calculations relating to hazard development time and required egress time (the combination of flow time and other time needed to detect and assess an emergency condition, initiate egress, and move along the egress routes). The factor of safety takes into account the possibility that half of the egress routes might not be used (or be usable) in certain situations. [***101:***A.12.4.1.1]

Regarding crowd behavior, the potential hazards created by larger masses of people and greater crowd densities (which can be problematic during ingress, occupancy, and egress) demand that technology be used by designers, managers, and authorities responsible for buildings to compensate for the relaxed egress capacity provisions of Table 12.4.2.3 of NFPA *101*. In very large buildings for assembly use, the hazard of crowd crushes can exceed that of fire or structural failure. Therefore, the building designers, managers, event planners, security personnel, police authorities, and fire authorities, as well as the building construction authorities, should understand the potential problems and solutions, including coordination of their activities. For crowd behavior, this understanding includes factors of space, energy, time, and information, as well as specific crowd management techniques, such as metering. Published guidance on these factors and techniques is found in the *SFPE Handbook of Fire Protection Engineering*, Section 3, Chapter 13, pp. 3-342–3-366 (Proulx, G., "Movement of People"), and the publications referenced therein. [***101:***A.12.4.1.1]

Table 12.2.3.2 and Table 12.4.2.3 of NFPA *101* are based on a linear relationship between number of seats and nominal flow time, with not less than 200 seconds (3.3 minutes) for 2000 seats plus 1 second for every additional 50 seats up to 25,000. Beyond 25,000 total seats, the nominal flow time is limited to 660 seconds (11 minutes). Nominal flow time refers to the flow time for the most able group of patrons; some groups less familiar with the premises or less able groups might take longer to pass a point in the egress system. Although three or more digits are noted in the tables, the resulting calculations should be assumed to provide only two significant figures of precision. [***101:***A.12.4.1.1]

Δ **10.14.3.2 Conditions to Be Assessed.** Life safety evaluations shall include an assessment of all of the following conditions and related appropriate safety measures:

(1) Nature of the events and the participants and attendees
(2) Access and egress movement, including crowd density problems
(3) Medical emergencies
(4) Fire hazards
(5) Permanent and temporary structural systems
(6) Severe weather conditions
(7) Earthquakes
(8) Civil or other disturbances
(9) Hazardous materials incidents within and near the facility
(10) Relationships among facility management, event participants, emergency response agencies, and others having a role in the events accommodated in the facility

[***101:***12.4.1.2]

10.14.3.3* Building Systems and Facility Management Assessments. Life safety evaluations shall include assessments of both building systems and facility management upon which reliance is placed for the safety of facility occupants, and such assessments shall consider scenarios appropriate to the facility. [***101:***12.4.1.3]

A.10.14.3.3 Factors to be considered in a life safety evaluation include the following:

(1) Nature of the events being accommodated, including the following:
  (a) Ingress, intra-event movement, and egress patterns
  (b) Ticketing and seating policies/practices
  (c) Event purpose (e.g., sports contest, religious meeting)
  (d) Emotional qualities (e.g., competitiveness) of event
  (e) Time of day when event is held
  (f) Time duration of single event
  (g) Time duration of attendees' occupancy of the building
(2) Occupant characteristics and behavior, including the following:
  (a) Homogeneity
  (b) Cohesiveness
  (c) Familiarity with building
  (d) Familiarity with similar events
  (e) Capability (as influenced by factors such as age, physical abilities)
  (f) Socioeconomic factors
  (g) Small minority involved with recreational violence
  (h) Emotional involvement with the event and other occupants
  (i) Use of alcohol or drugs
  (j) Food consumption
  (k) Washroom utilization
(3) Management, including the following:
  (a) Clear, contractual arrangements for facility operation/use as follows:
    i. Between facility owner and operator
    ii. Between facility operator and event promoter
    iii. Between event promoter and performer
    iv. Between event promoter and attendee
    v. With police forces
    vi. With private security services
    vii. With ushering services
  (b) Experience with the building
  (c) Experience with similar events and attendees
  (d) Thorough, up-to-date operations manual
  (e) Training of personnel
  (f) Supervision of personnel
  (g) Communications systems and utilization
  (h) Ratios of management and other personnel to attendees
  (i) Location/distribution of personnel
  (j) Central command location
  (k) Rapport between personnel and attendees
  (l) Personnel support of attendee goals
  (m) Respect of attendees for personnel due to the following:
    i. Dress (uniform) standards
    ii. Age and perceived experience
    iii. Personnel behavior, including interaction
    vi. Distinction between crowd management and control
    v. Management concern for facility quality (e.g., cleanliness)
    vi. Management concern for entire event experience of attendees (i.e., not just during the occupancy of the building)
(4) Emergency management preparedness, including the following:
  (a) Complete range of emergencies addressed in operations manual
  (b) Power loss
  (c) Fire
  (d) Severe weather
  (e) Earthquake
  (f) Crowd incident
  (g) Terrorism
  (h) Hazardous materials
  (i) Transportation accident (e.g., road, rail, air)
  (j) Communications systems available
  (k) Personnel and emergency forces ready to respond
  (l) Attendees clearly informed of situation and proper behavior
(5) Building systems, including the following:
  (a) Structural soundness
  (b) Normal static loads
  (c) Abnormal static loads (e.g., crowds, precipitation)
  (d) Dynamic loads (e.g., crowd sway, impact, explosion, wind, earthquake)
  (e) Stability of nonstructural components (e.g., lighting)
  (f) Stability of movable (e.g., telescoping) structures
  (g) Fire protection
  (h) Fire prevention (e.g., maintenance, contents, housekeeping)
  (i) Compartmentation
  (j) Automatic detection and suppression of fire

(k) Smoke control
(l) Alarm and communications systems
(m) Fire department access routes and response capability
(n) Structural integrity
(o) Weather protection
(p) Wind
(q) Precipitation (attendees rush for shelter or hold up egress of others)
(r) Lightning protection
(s) Circulation systems
(t) Flowline or network analysis
(u) Waywinding and orientation
(v) Merging of paths (e.g., precedence behavior)
(w) Decision/branching points
(x) Route redundancies
(y) Counterflow, crossflow, and queuing situations
(z) Control possibilities, including metering
(aa) Flow capacity adequacy
(ab) System balance
(ac) Movement time performance
(ad) Flow times
(ae) Travel times
(af) Queuing times
(ag) Route quality
(ah) Walking surfaces (e.g., traction, discontinuities)
(ai) Appropriate widths and boundary conditions
(aj) Handrails, guardrails, and other rails
(ak) Ramp slopes
(al) Step geometries
(am) Perceptual aspects (e.g., orientation, signage, marking, lighting, glare, distractions)
(an) Route choices, especially for vertical travel
(ao) Resting/waiting areas
(ap) Levels of service (overall crowd movement quality)
(aq) Services
(ar) Washroom provision and distribution
(as) Concessions
(at) First aid and EMS facilities
(au) General attendee services

[***101:***A.12.4.1.3]

A scenario-based approach to performance-based fire safety is addressed in Chapter 5 of NFPA *101*. In addition to using such scenarios and, more generally, the attention to performance criteria, evaluation, safety factors, documentation, maintenance, and periodic assessment required when the Chapter 5 of NFPA *101* option is used, life safety evaluations should consider scenarios based on characteristics important in assembly occupancies. These characteristics include the following:

(1) Whether there is a local or mass awareness of an incident, event, or condition that might provoke egress
(2) Whether the incident, event, or condition stays localized or spreads
(3) Whether or not egress is desired by facility occupants
(4) Whether there is a localized start to any egress or mass start to egress
(5) Whether exits are available or not available

[***101:***A.12.4.1.3]

Examples of scenarios and sets of characteristics that might occur in a facility follow. [***101:***A.12.4.1.3]

Scenario 1. Characteristics: mass start, egress desired (by management and attendees), exits not available, local awareness. [***101:***A.12.4.1.3]

Normal egress at the end of an event occurs just as a severe weather condition induces evacuees at the exterior doors to retard or stop their egress. The backup that occurs in the egress system is not known to most evacuees, who continue to press forward, potentially resulting in a crowd crush. [***101:***A.12.4.1.3]

Scenario 2. Characteristics: mass start, egress not desired (by management), exits possibly not available, mass awareness. [***101:***A.12.4.1.3]

An earthquake occurs during an event. The attendees are relatively safe in the seating area. The means of egress outside the seating areas are relatively unsafe and vulnerable to aftershock damage. Facility management discourages mass egress until the means of egress can be checked and cleared for use. [***101:***A.12.4.1.3]

Scenario 3. Characteristics: local start, incident stays local, egress desired (by attendees and management), exits available, mass awareness. [***101:***A.12.4.1.3]

A localized civil disturbance (e.g., firearms violence) provokes localized egress, which is seen by attendees, generally, who then decide to leave also. [***101:***A.12.4.1.3]

Scenario 4. Characteristics: mass start, egress desired (by attendees), incident spreads, exits not available, mass awareness. [***101:***A.12.4.1.3]

In an open-air facility unprotected from wind, precipitation, and lightning, sudden severe weather prompts egress to shelter, but not from the facility. The means of egress congest and block quickly as people in front stop once they are under shelter while people behind them continue to press forward, potentially resulting in a crowd crush. [***101:***A.12.4.1.3]

These scenarios illustrate some of the broader factors to be taken into account when assessing the capability of both building systems and management features on which reliance is placed in a range of situations, not just fire emergencies. Some scenarios also illustrate the conflicting motivations of management and attendees, based on differing perceptions of danger and differing knowledge of hazards, countermeasures, and capabilities. Mass egress might not be the most appropriate life safety strategy in some scenarios, such as Scenario 2. [***101:***A.12.4.1.3]

Table A.10.14.3.3 summarizes the characteristics in the scenarios and provides a framework for developing other characteristics and scenarios that might be important for a particular facility, hazard, occupant type, event, or management. [***101:***A.12.4.1.3]

10.14.3.3.1 Building Systems. Prior to issuance of the building permit, the design team shall provide the AHJ with building systems documentation in accordance with 10.14.3.4. [***101:***12.4.1.3.1]

[***101:*** Table A.12.4.1.3]

10.14.3.3.2 Facility Management. Prior to issuance of the certificate of occupancy, the facility management shall provide the AHJ with facility management documentation in accordance with 10.14.3.5. [***101:***12.4.1.3.2]

10.14.3.3.3 Life Safety Evaluation.

10.14.3.3.3.1 Prior to issuance of the building permit, the persons performing the life safety evaluation shall confirm that the building systems provide safety measures. [***101:***12.4.1.3.3.1]

10.14.3.3.3.2 Prior to issuance of the certificate of occupancy, the owner shall confirm that the facility management and operational plans provide appropriate safety measures. [***101:***12.4.1.3.3.2]

Δ **10.14.3.3.3.3** The life safety evaluation shall be performed by persons acceptable to the authority having jurisdiction. [***101:***12.4.1.3.3.3]

10.14.3.4 Life Safety Building Systems Document. The AHJ shall be provided with a life safety building systems document providing the information required in 10.14.3.4.2 through 10.14.3.4.4. [***101:***12.4.1.4]

10.14.3.4.1 Document Distribution. The persons performing the life safety evaluation, the AHJ, the A/E design team and the building owner shall receive a copy of the life safety building systems document prior to issuance of the building permit. [***101:***12.4.1.4.1]

Δ **10.14.3.4.2 Life Safety Narrative.** A life safety narrative shall be provided describing the following, as applicable:

(1) Building occupancy, construction type, and intended uses and events
(2) Building area and population capacity of the proposed facility
(3) Principal fire and life safety features/strategies for the building, including the following, as applicable:
 (a) Egress
 (b) Access control
 (c) Fire barriers, smoke barriers, and smoke partitions
 (d) Fire suppression systems
 (e) Smoke control/protection
 (f) Fire detection and alarm
 (g) PA system
 (h) Emergency elevator operation
 (i) Emergency power and lighting
 (j) Provisions for patrons with disabilities
 (k) Fire department access
 (l) Fire/emergency command center
(4) Exterior construction design parameters used/applied

[***101:***12.4.1.4.2]

Δ **10.14.3.4.3 Life Safety Floor Plans.** Life safety floor plans of each level shall be provided, as applicable, with the following:

(1) Occupant load, exit location, egress capacity, main entrance/exit, horizontal exits, travel distance and exit discharge
(2) Fire barriers, smoke barriers, and smoke partitions
(3) Areas of smoke protected assembly occupancy
(4) Separate smoke protected areas or zones
(5) Areas of other occupancy type and separations
(6) Unprotected vertical openings
(7) Event plans for each anticipated type of event depicting the following:
 (a) Seating configuration
 (b) Exhibit booth layout
 (c) Stage location
 (d) Occupant load, egress capacity required, exits provided and travel distance
 (e) Any floor or stage use restrictions
 (f) Plan and/or section drawing indicating where sprinkler protection is omitted
 (g) Areas of refuge — interior and exterior

[***101:***12.4.1.4.3]

Δ **10.14.3.4.4 Engineering Analysis and Calculations.** Where active or passive smoke control is used, an engineering analysis shall be provided and shall include the following:

(1) Smoke protection analysis to substitute the use of smoke-protected assembly seating as follows:
 (1) Performance-based design methods approved by the AHJ
 (2) Smoke control air requirements per NFPA 92

(3) Smoke control assumptions, such as fire scenario description, fire size quantification, and smoke development/smoke movement analysis
(4) Proposed testing protocol for smoke control system and pass/fail criteria
(5) Timed egress analysis
(6) Assumed flow rates and travel speeds

(2) Sprinkler protection calculations, including an engineering analysis substantiating locations in accordance with 12.3.5.3 where sprinkler protection would be ineffective due to height and combustible loading
(3) Load diagram of rigging/load capacity of gridiron, fly loft, or long-span roof structure used for hanging overhead objects

[***101:***12.4.1.4.4]

10.14.3.5 Life Safety Management Document. The AHJ shall be provided with a life safety management document providing the information required in 10.14.3.5.2 through 10.14.3.5.7. [***101:***12.4.1.5]

10.14.3.5.1 Document Distribution. The persons performing the life safety evaluation, the AHJ, the A/E design team and the building owner shall receive a copy of the life safety management document prior to issuance of the certificate of occupancy. [***101:***12.4.1.5.1]

10.14.3.5.2 Facility Management and Operational Plans. Facility management and operational plans shall address the following, as applicable:

(1) Best practices adopted or recognized
(2) Emergency plans
(3) Evacuation plans
(4) Shelter-in-place plans, including capacities and protection considerations
(5) Crowd management training plan
(6) Safety plans, which include the following:
  (a) Training plans
  (b) Safety equipment plans
(7) Fire alarm, smoke control system protocol and testing plans
(8) First aid or medical treatment plans, which include the following:
  (a) Defined levels of service
  (b) Standing orders adopted
  (c) Supply and equipment plan
(9) Housekeeping plans — biological, medical, hazardous materials cleaning
(10) Emergency communication plans, which include the following:
  (a) Chain of authority and incident command system employed
  (b) Contact information for the following:
    (i) Venue personnel
    (ii) Emergency management and response organizations (such as fire, police, medical, utility, transportation, and key stakeholders)
  (c) Communication systems
  (d) Standard announcement for incidents or emergency situations
(11) Risk and threat assessment for venue and surrounding area for the following:
  (a) Severe weather
  (b) Hazardous materials
  (c) Terrorism
  (d) Hostile intruder
(12) Operating procedures and protocols for risks, such as the following:
  (a) Severe weather preparedness and monitoring plans
  (b) Hazardous materials incidence response plans
  (c) Terrorism response plans
  (d) Hostile intruder response plans
(13) First responder response/arrival routes plans
(14) Alcohol management plans
(15) Food safety plans
(16) Rigging and temporary performance structure, which includes the following:
  (a) Design and safety review plans
  (b) Emergency action plans
(17) Chemical and hazardous materials information and data
(18) Barrier and wall protection plans for motor sports or similar events

[***101:***12.4.1.5.2]

Δ **10.14.3.5.3 Records.** Records of the facility management plans, including procedures and location, shall be maintained, for the following:

(1) Crowd management training
(2) Safety training
(3) Fire alarm, smoke control system maintenance, and test records
(4) First aid or medical treatment and regulation compliance

[***101:***12.4.1.5.3]

10.14.3.5.4 Building Systems Reference Guide. A building systems reference guide shall be provided in accordance with 10.14.3.5.4.1 through 10.14.3.5.4.3. [***101:***12.4.1.5.4]

10.14.3.5.4.1 A basic life safety building systems reference guide shall be developed and maintained. [***101:***12.4.1.5.4.1]

10.14.3.5.4.2 The life safety building systems reference guide shall contain the important and key information for the venue management's use when planning events/activities for the safety of patrons, performers/participants, employees and vendors. [***101:***12.4.1.5.4.2]

Δ **10.14.3.5.4.3** The life safety building systems document in accordance with 10.14.3.4 shall be permitted to be used, and additionally the life safety building systems reference guide shall include the following, as applicable:

(1) Occupant capacity of every space/room
(2) Egress flow diagrams, including assumed flow rates, and capacities of all aisles and hallways, including public and nonpublic areas
(3) Capacities of all exterior doors and/or choke points in immediate perimeter areas

(4) Limitations or assumptions for ingress control that could be in place during an emergency egress/evacuation, including control gates, queuing barriers, and turnstiles
(5) Capacities of immediate perimeter exterior walkways, including assumed flow rates for exterior areas
(6) Assumed egress paths for normal conditions — transportation modes
(7) Management-level sequencing charts for alarm and emergency communication systems, the manual, or override options/instructions that include the following:
   (a) List of codes or alarm signals
   (b) Location of manual overrides
   (c) Description of sequence of operations during an alarm, such as exhaust fans operate or doors open
(8) Principal fire and life safety features/strategies, such as sprinklers, smoke control, fire alarm notifications, PA system, emergency power, and fire department access
(9) Assumptions when developing occupancy plans for venue floor, open areas, and nonevent spaces, such as the following:
   (a) Event floor plans/setup diagrams for each typical event/activity
   (b) Fire sprinkler and smoke protection capabilities
(10) Severe weather shelter areas, locations, structure considerations (limitations), capacities (occupancy and density factor)
(11) Command center, which includes the following:
   (a) Location (formal or informal)
   (b) Structural integrity considerations
   (c) Redundant locations and/or capabilities
   (d) Jurisdictional rights — assumed and/or applied
(12) Locations and capacities of wheelchair and mobility-impaired seating
(13) Locations and capacities of areas of refuge and other safe areas
(14) Rigging or structural load capacities of grids, truss structure, fly lofts, ceilings, floors, ramps, and staging
(15) List of locations of emergency equipment such as fire extinguishers, fire hose cabinets, fire hydrants, and AEDs.
(16) Sequencing of electrical service, such as the following:
   (a) Emergency generators and charts of all areas illuminated during power outages
   (b) Multiple electrical feed capabilities
(17) List of mechanical, movable equipment in the facility
(18) Potential hazards in the surrounding neighborhood, including train tracks and propane stations
(19) Assumptions or accommodations considered and used in design

[***101:***12.4.1.5.4.3]

10.14.3.5.5 The facility management plans shall be maintained and adjusted as necessary for changes to the venue structure, operating purposes and style, and event occupancy. [***101:***12.4.1.5.5]

10.14.3.5.6 Facility management and operational plans shall be submitted to the AHJ annually. [***101:***12.4.1.5.6]

Δ **10.14.3.5.7** For events and activities at the venue that are outside the normal operating conditions or vary from the normal facility management plans, the following shall apply:

(1) Facility management shall perform an event/activity specific facility management plan for the AHJ to review.
(2) Approval of the AHJ for the specific facility management plan shall occur prior to such event.

[***101:***12.4.1.5.7]

10.14.4 Standby Fire Personnel. Where required by the AHJ, standby fire personnel shall be provided and comply with 1.7.17.

When needed to provide adequate protection of life and property due to special outdoor events, the AHJ can require that standby fire personnel be in attendance. The number and type of personnel are based on the type of event, the number of people in attendance, and other hazards present. See 1.7.17 for additional guidance.

10.14.5 Portable Fire Extinguishers. A minimum of one portable fire extinguisher shall be provided for each concession stand where required by the AHJ in accordance with Section 13.6.

Each concession stand, regardless of size, is required to be provided with a portable fire extinguisher. This provides easy access to a fire extinguisher without having to determine in which stand the extinguisher is located and avoids placing them in public areas where they could be blocked, tampered with, removed, or damaged.

10.14.6 Smoke Alarms. A minimum of one single station smoke alarm shall be located in all stock or equipment trailers when they are used for sleeping purposes.

Stock and equipment trailers are frequently used for sleeping purposes after they are unloaded. In these cases, as in all residential occupancies, smoke alarms are required to protect sleeping individuals in such trailers.

10.14.7 Electrical Equipment. Electrical equipment and installations shall comply with Section 11.1.

10.14.8 Cooking. Concession stands utilized for cooking shall have a minimum of 10 ft (3 m) of clearance on two sides and shall not be located within 10 ft (3 m) of amusement rides or devices.

Paragraph 10.14.8 requires cooking concession stands to be separated from other structures by a distance of not less than 10 ft (3 m). This distance might need to be increased based on the construction or makeup of the stands, fuels used, and combustible material present. Providing a minimum clearance distance on at least two sides of the concession stand helps to prevent a fire from spreading to adjacent concession stands in multiple directions, which could potentially impact occupant safety, egress, and/or fire department access in addition to the potential for the fire to grow and spread rapidly. Exhibit 10.13 shows a concession stand that is separated from the other concession stands by at least 10 ft (3 m) and also not located within 10 ft (3 m) of amusement rides.

Exhibit 10.13

Concession stands meeting the minimum 10 ft (3 m) clearance.

Exhibit 10.14

Entrance to a crop maze. (Courtesy of Town Stone Management Company, Inc.)

10.14.9 Communications. Where required by the AHJ, a method of notifying the fire department in the event of an emergency shall be provided.

10.14.9.1 Methods of notifying the fire department shall consist of a telephone, an alarm system connected to the fire department or other approved agency, or other approved means.

10.14.9.2 Methods of notifying the fire department shall be readily available to the public.

10.14.10 Internal Combustion Power Sources.

10.14.10.1 Fueling. Fuel tanks shall be of adequate capacity to permit uninterrupted operation during normal operating hours.

Refueling of internal combustion engines, such as generators, creates significant risk of fire. The intent of 10.14.10.1 is to prevent the fueling of generators and other fuel-fired equipment while people are in the area. Having an adequate fuel capacity for equipment that needs to operate for 12 hours or more might be impractical. In these cases, the AHJ should be consulted regarding refueling of equipment that is expected to be in operation for long periods of time, especially during special events or during long power outages.

10.14.10.2 Refueling. Refueling shall be conducted only when not in use.

10.14.10.3 Protection. Internal combustion power sources shall be isolated from contact with the public by either physical guards, fencing, or an enclosure.

Internal combustion power sources such as generators create many hazards, such as fuel, heat, noise, and electrical hazards. They should be located in isolated areas inaccessible to the public to prevent unauthorized access. Fences can serve to isolate these areas.

10.14.10.4 Fire Extinguishers. A minimum of one portable fire extinguisher with a rating of not less than 2-A:10-B:C shall be provided.

Section 10.14.10.4 requires a minimum of one portable fire extinguisher at the internal combustion power source, such as at the location of the generator. Requirements for fire extinguishers for the concession stand are addressed in 10.14.5.

10.14.11 Crop Maze.

Crop mazes pose unique fire safety problems due to their configuration (confusing paths and lack of marked egress) and the inherent combustibility of the maze materials. Exhibit 10.14 depicts the entrance to a crop maze.

10.14.11.1 Permits. Permits, where required, shall comply with Section 1.12.

10.14.11.2 General.

10.14.11.2.1 The owner or operator of a crop maze amusement attraction shall advise all employees of the fire and life safety regulations established in this subsection prior to the employees assuming their respective duties.

Employees need to be trained in the duties they are expected to perform and in emergency procedures, as outlined in 10.14.11.

10.14.11.2.2 The owner or operator of a crop maze or their employees shall provide safety instructions to the visitors and patrons of a crop maze prior to their entrance to the maze.

Safety instructions should be given to patrons visiting the crop maze. Written instructions or a briefing before patrons go into the maze can meet this requirement.

10.14.11.2.3 Employee Monitor.

10.14.11.2.3.1 A minimum of two employees shall be on duty to monitor a crop maze during hours of operation.

The size of a crop maze might dictate the need for more than two employees to monitor conditions effectively. These employees are in addition to other employees such as ticket takers, concession stand personnel, and other employees not directly monitoring the maze.

10.14.11.2.3.2 A minimum of one of the employees shall be located on an elevated platform a minimum of 10 ft (3 m) above the maze.

The requirement for the platform to be at least 10 ft (3 m) above the height of the maze permits employees to view the activity in the maze and where patrons are located. Employees can then direct people away from any hazard, stop unsafe activities, and direct emergency personnel in the event of fire or other emergency. Because most corn crops are 6 ft to 8 ft (1.8 m to 2.4 m) high, the platform will be over 18 ft (5.5 m) from ground level.

10.14.11.2.4 The owner or operator of a crop maze shall contact the local fire department and provide the fire department with the opportunity to prepare a pre-plan of the crop maze amusement attraction prior to the start of seasonal operations.

The fire department should be contacted prior to the opening of the attraction so it can prepare an incident preplan for the crop maze in the event it needs to respond to an emergency. In those instances where the fire department does not provide emergency medical service (EMS), the EMS provider should be contacted and should participate in the preplanning. Preplanning should consider severe weather events, since crop mazes are located outdoors.

10.14.11.2.5 Motorized vehicles shall not be parked within 75 ft (23 m) of a crop maze.

10.14.11.2.6 A fuel break of a minimum of 20 ft (6 m) wide shall be cleared between a crop maze and any vehicles or vegetation outside the maze.

10.14.11.2.7 Public Address System.

A means to communicate with crop maze patrons must be provided. This requirement is fairly easy and inexpensive to meet, since the *Code* permits portable bullhorns and loud speakers. Multiple bullhorns can be placed strategically around the maze for staff use.

10.14.11.2.7.1 A public address system shall be readily available to employees at a crop maze to assist them in making announcements to the visitors or patrons of a crop maze in the event of an emergency.

10.14.11.2.7.2 A bull horn or loud speaker shall suffice as a public address system.

10.14.11.2.8 The entrance and exit from a crop maze shall not be blocked or obstructed at any time the maze is open for business and occupied by the public.

10.14.11.2.9 No more than 200 persons per acre, including adults and children, shall occupy the crop maze at any one time.

Paragraph 10.14.11.2.9 provides an occupant load limitation for the crop maze. The occupant load should be determined before the maze opens to the public. A means to determine the number of patrons in the maze at any time needs to be established. Counters or tags, which are given to each person upon entry and collected upon leaving, can be used to meet this requirement. Such accountability also assists the fire department in the event of an emergency.

10.14.11.3 Prohibited.

10.14.11.3.1* No open flame-producing devices or equipment shall be permitted within the confines of the crop maze.

A.10.14.11.3.1 Visitors to the crop maze should only use flashlights, chemical lights, or similar devices to illuminate their travel through the maze. Candles, gas-fired lanterns, cigarette lighters, or similar open flame or flame-producing devices are prohibited for use inside a crop maze at all times.

10.14.11.3.2 No smoking shall be permitted within the confines of the crop maze.

Due to the combustible nature of crop mazes, all open flames, including lit cigarettes, machinery, candles, and lanterns, are prohibited from crop mazes and surrounding areas. The use of signage can assist in communicating the rules and regulations of the corn maze to patrons. Exhibit 10.15 shows a sign in a crop maze reminding patrons that smoking is prohibited.

10.14.11.4 Fireworks.

10.14.11.4.1 Fireworks shall not be discharged within a minimum of 300 ft (91 m) of any crop maze at any time.

Exhibit 10.15

"No Smoking" sign in a corn maze.

The requirement of 10.14.11.4.1 does not override the distance requirements in NFPA 1123, *Code for Fireworks Display*, which might require greater distances, based on shell size.

10.14.11.4.2 The use of display fireworks shall comply with Chapter 65 in addition to the requirements of 10.14.11.4.

10.15* Outside Storage

A.10.15 For additional guidance, see Chapter 34 for provisions for indoor and outdoor storage of material. Chapter 33 contains provisions for outside storage of tires.

For requirements on combustible waste and refuse stored outside, see Chapter 19.

10.15.1 Outside storage of combustible materials shall not be located within 10 ft (3 m) of a property line.

10.15.2 The separation distance shall be allowed to be reduced to 3 ft (0.9 m) for storage not exceeding 6 ft (1.8 m) in height.

10.15.3 The separation distance shall be allowed to be reduced where the AHJ determines that no hazard to the adjoining property exists.

10.15.4 Combustible material shall not be stored beneath a building or structure unless specifically constructed or protected for this purpose.

10.15.5 Combustible storage in the open shall not exceed 20 ft (6.1 m) in height.

10.16 Parade Floats

10.16.1 Permits. Permits, where required, shall comply with Section 1.12.

10.16.2 Fire Protection. Motorized parade floats and towing apparatus shall be provided with a minimum 2-A:10-B:C-rated portable fire extinguisher readily accessible to the operator.

Δ 10.17 Powered Industrial Trucks

Powered industrial trucks shall be operated and maintained in accordance with NFPA 505.

NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations*, applies to fork trucks, tractors, platform lift trucks, motorized hand trucks, and other specialized industrial trucks powered by electric motors or internal combustion engines. NFPA 505 does not apply to compressed air–operated or nonflammable compressed gas–operated industrial trucks, farm vehicles, or automotive vehicles for highway use. For the design and installation of the compressed natural gas (CNG) fuel systems on CNG-powered and dual fuel–powered (gasoline and CNG) industrial trucks, see NFPA 52, *Vehicular Natural Gas Fuel Systems Code*. For the design and installation of LP-Gas fuel systems on LP-Gas–powered and dual fuel–powered (gasoline and LP-Gas) industrial trucks, see NFPA 58, *Liquefied Petroleum Gas Code*.

10.18* Storage of Combustible Materials

A.10.18 See A.10.15.

10.18.1 General. Storage of combustible materials shall be orderly.

10.18.2 Permits. Permits, where required, shall comply with Section 1.12.

10.18.3 Ceiling Clearance.

10.18.3.1 Storage shall be maintained 2 ft (0.61 m) or more from the ceiling in nonsprinklered areas of buildings.

The 2 ft (0.61 m) clearance requirements for nonsprinklered buildings permits fire department hose streams to reach the ceiling. The 2 ft (0.61 m) clearance requirement does not apply to storage against walls.

10.18.3.2 The clearance between the deflector and the top of storage shall be 18 in. (450 mm) or greater. [**13:**8.6.6.1]

Sprinklers installed near wall-mounted shelves or piled storage located against a wall are not intended to be governed by the requirements of 10.18.3.2 (see Exhibit 10.16, left). The clear space beneath the sprinkler is needed for the spray pattern to fully develop to allow proper wetting of the floor and not the wall (see Exhibit 10.16, right).

Δ **10.18.3.3** The 18 in. (450 mm) dimension shall not limit the height of shelving on a wall or shelving against a wall in accordance with 10.18.3, of this *Code*, and 8.7.6, 8.8.6, and Section 8.9 of NFPA 13. [**13:**8.6.6.2]

10.18.3.3.1 Where shelving is installed on a wall and is not directly below sprinklers, the shelves, including storage thereon, shall be permitted to extend above the level of a plane located 18 in. (450 mm) below ceiling sprinkler deflectors. [**13:**8.6.6.2.1]

10.18.3.3.2 Shelving, and any storage thereon, directly below the sprinklers shall not extend above a plane located 18 in. (450 mm) below the ceiling sprinkler deflectors. [**13:**8.6.6.2.2]

The discharge pattern of upright and pendent spray sprinklers takes a parabolic shape. To ensure the distribution of water over the area that the sprinkler was designed to protect, the spray pattern must encounter minimal obstructions. Rack storage fire tests, other tests with solid-piled storage, and field experience

Exhibit 10.16

Examples of storage room clearances: (left) room with storage against wall extending to ceiling with sprinklers and (right) storage room with proper clearance below sprinklers.

have shown that standard spray sprinklers are effective with a minimum 18 in. (450 mm) clearance.

One example of the need to observe the clearance provisions required for special sprinklers or special design features is specified in the design provisions for miscellaneous storage in Chapter 13 of NFPA 13, *Standard for the Installation of Sprinkler Systems,* for Group A plastics. The design criteria for storage of Group A plastics vary as the clearance increases.

10.18.3.4 Where other standards specify greater clearance to storage minimums, they shall be followed. [**13:**8.6.6.3]

10.18.4 Means of Egress. Combustible material shall not be stored in exits.

An exit enclosure shall not be used for any purpose that has the potential to interfere with its use as an exit and, if so designated, as an area of refuge. See 14.3.3.

10.18.5 Equipment Rooms.

10.18.5.1 Combustible material shall not be stored in boiler rooms, mechanical rooms, or electrical equipment rooms.

10.18.5.2 Materials and supplies for the operation and maintenance of the equipment in the room shall be permitted.

The use of equipment rooms to store items, such as those needed for the equipment in the room, is normal. The storage of materials and supplies related to the operation of the equipment is permitted in accordance with 10.18.5.2. Equipment should be stored in cabinets or other protected areas to limit the hazard. Materials not associated with the equipment are not permitted to be stored within equipment rooms.

10.18.6 Attic, Under-Floor, and Concealed Spaces. Attic, under-floor, and concealed spaces used for storage of combustible materials shall comply with the protection from hazards requirements for storage rooms in NFPA *101*.

Areas not designed or protected as storage areas should not be used as storage areas unless provided with the proper protection, typically automatic sprinklers, rated separation, or both, as specified by Section 8.7 of NFPA *101* and the applicable occupancy chapters of NFPA *101*.

10.18.7 Fueled Equipment. Fueled equipment, including but not limited to motorcycles, mopeds, lawn-care equipment, and portable cooking equipment, shall not be stored, operated, or repaired within a building except under one of the following conditions:

(1) The building or room has been constructed for such use in accordance with the building code.
(2) The use is allowed by other provisions of this *Code*.

Buildings or areas within buildings that have not been designed to accommodate the storage and/or use of fueled equipment such as motorcycles, lawn mowers, and portable cooking equipment will not have the necessary construction or protection features necessary to accommodate for the hazards presented by that type of equipment. A building code will prescribe the minimum construction type as well as required protection from adjacent areas and other fire protection features, as necessary, to account for the presence of this type of equipment.

10.19 Indoor Children's Playground Structures

Δ **10.19.1** Structures intended as children's playgrounds installed indoors and exceeding 10 ft (3.1 m) in height or 160 ft^2 (14.9 m^2) in area shall comply with the specifications in 10.19.1.1 through 10.19.1.4.

Δ **10.19.1.1** Indoor children's playground structures shall be constructed of noncombustible materials or of combustible materials that comply with the following:

(1) Fire retardant–treated wood.
(2) Light-transmitting plastics complying with the requirements in 10.19.1.2.
(3) Foam plastics (including the pipe foam used in soft-contained play equipment structures) having a maximum heat-release rate not greater than 100 kW when tested in accordance with UL 1975 or NFPA 289 using the 20 kW ignition source.
(4) Aluminum composite material (ACM) meeting the requirements of Class A interior finish in accordance with Chapter 10 of NFPA *101* when tested as an assembly in the maximum thickness intended for use.
(5) Textiles and films complying with the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701.
(6) Plastic materials used to construct rigid components of soft-contained play equipment structures (such as tubes, windows, panels, junction boxes, pipes, slides, and decks) exhibiting a peak rate of heat release not exceeding 400 kW/m^2 when tested in accordance with ASTM E1354 at an incident heat flux of 0.24 in. 50 kW/m^2 in the horizontal orientation at a thickness of 0.24 in. (6 mm).
(7) Balls used in ball pools, in soft-contained play equipment structures, shall have a maximum heat release rate not greater than 100 kW when tested in accordance with UL 1975 or NFPA 289 using the 20 kW ignition source. The minimum specimen test size shall be 36 in. × 36 in. (0.91 m × 0.91 m) by an average of 21 in. (0.56 m) deep, and the balls shall be held in a box constructed of galvanized steel poultry netting wire mesh.
(8) Foam plastics shall be covered by fabric, coating, or film meeting the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701.
(9) The floor covering within the children's playground structure shall exhibit a Class I interior floor finish classification, as described in Chapter 10 of NFPA *101*, when tested in accordance with NFPA 253 or with ASTM E648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*.

10.19.1.2* Light-transmitting plastics used for children's playgrounds shall meet all of the following criteria:

(1) They shall have a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D1929.
(2) They shall have a smoke developed index not greater than 450 when tested in the manner intended for use in accordance with ASTM E84, *Standard Test Method of Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, or not greater than 75 when tested in the thickness intended for use in accordance with ASTM D2843, *Standard Test Method for Density of Smoke from the Burning or Decomposition of Plastics*.
(3) They shall meet the criteria of one of the following classifications:
   (a) CC1 — Plastic materials that have a burn length of 1 in. (25 mm) or less and flame extinguishment when tested at a nominal thickness of 0.060 in. (1.5 mm), or in the thickness intended for use, in accordance with ASTM D635, *Standard Test Method for Rate of Burning and/or Extent and Time of Burning of Plastics in a Horizontal Position*
   (b) CC2 — Plastic materials that have a burning rate of 2½ in./min (64 mm/min) or less when tested at a nominal thickness of 0.060 in. (1.5 mm), or at a thickness intended for use, in accordance with ASTM D635

Δ **A.10.19.1.2** The flame-retardant requirements for light-transmitting plastics can also be found in Chapter 48 of *NFPA 5000*.

10.19.1.3 Indoor children's playground structures shall have a minimum horizontal separation from other structures of 20 ft (6.1 m).

10.19.1.4 Indoor children's playground structures shall not exceed 300 ft^2 (28 m^2) in area, unless approved by the AHJ.

The requirements of Section 10.19 regulate the fire properties of materials used in the construction of indoor children's playground structures. The mazelike configuration will hinder evacuation in the event of a fire. Multilevel play structures are also considered special amusement buildings where they exceed 10 ft (3050 mm) in height and have aggregate horizontal projections exceeding 160 ft^2 (15 m^2) (see 20.1.4). Exhibit 10.17 depicts an indoor children's playground structure.

Exhibit 10.17

Indoor children's play structure. (Courtesy of Amazing Adventures Playland, Ontario, Canada)

Building Services

11

Chapter 11 addresses electrical fire safety; heating, ventilation, and air-conditioning (HVAC) equipment; elevators and escalators; utilities; heating appliances; waste and laundry chutes and incinerators; stationary generators and standby power systems; smoke control; emergency command centers; two-way radio communication enhancement systems; medical gas and vacuum systems; and photovoltaic systems.

11.1 Electrical Fire Safety

The approval of new electrical installations or approval of modifications to an existing electrical system is a function typically performed by an electrical inspector or other building code enforcement official using the requirements of *NFPA 70®*, *National Electrical Code®*. However, in many cases, prior to a building or other facility being constructed or occupied, fire marshals or fire inspectors perform periodic inspections to ensure that the safety systems and features of the premises are in place, are in proper working order, and have not been compromised or adversely modified. Electrical systems are often subject to this type of periodic safety inspection. In general, the focus of this type of inspection is compliance with fundamental electrical safety provisions that have long been required by *NFPA 70*. Requirements covering the integrity of enclosures housing electrical wiring and equipment, the proper use of electrical appliances, the proper application and use of flexible cords, the complete and up-to-date identification of circuit disconnecting means, and the proper maintenance and operation of electrically powered emergency features, such as battery-operated emergency lighting units, are among the items typically included in these periodic safety inspections.

11.1.1 General. Section 11.1 shall apply to permanent and temporary electrical appliances, equipment, fixtures, and wiring.

11.1.2 Permanent Wiring, Fixtures, and Equipment.

Δ **11.1.2.1** All new electrical wiring, fixtures, appliances and equipment shall be installed in accordance with *NFPA 70*.

Δ **11.1.2.2** Unless determined to present an imminent danger, existing electrical wiring, fixtures, appliances, and equipment shall be permitted to be maintained in accordance with the edition of *NFPA 70* in effect at the time of the installation.

11.1.2.3 Permanent wiring abandoned in place shall be tagged or otherwise identified at its termination and junction points as "Abandoned in Place" or removed from all accessible areas and insulated from contact with other live electrical wiring or devices.

No wiring should be abandoned unless it has been physically disconnected at its power source. Wiring that is disconnected should be tagged, noting that it is disconnected. The removal of the wiring is better practice because, in most cases, the wiring will never be reused and if left in place for extended periods will increase the fire load.

11.1.3 Multiplug Adapters.

11.1.3.1 Multiplug adapters, such as multiplug extension cords, cube adapters, strip plugs, and other devices, shall be listed and used in accordance with their listing.

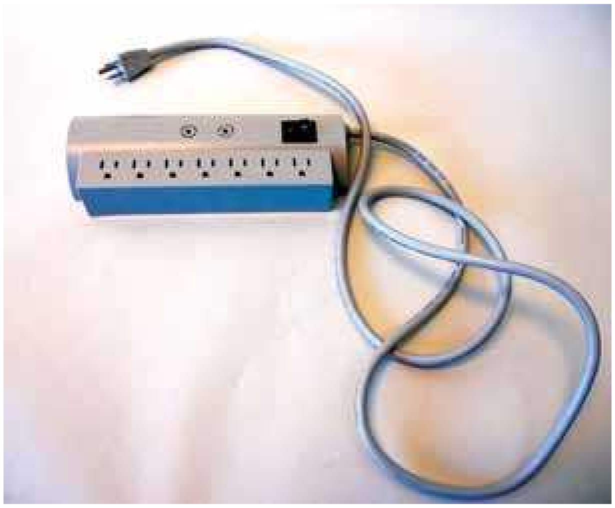
11.1.3.2 Multiplug adapters shall not be used as a substitute for permanent wiring or receptacles.

11.1.4 Relocatable Power Taps.

Relocatable power taps, commonly known as power strips or surge suppressors, are commonly used for computers, printers, and other peripherals at workstations, offices, and dormitories, where additional electrical power receptacles are needed. During inspections, power taps that are plugged into other power taps (daisy-chained) should be removed, because such arrangement is prohibited. Relocatable power taps are for temporary use and should not take the place of permanently installed receptacles. Exhibit 11.1 shows an example of a listed relocatable power tap.

Δ **11.1.4.1** Relocatable power taps shall be listed to UL 1363, *Standard for Relocatable Power Taps,* or UL 1363A, *Outline of Investigation for Special Purpose Relocatable Power Taps,* where applicable.

Exhibit 11.1



Listed relocatable power tap.

11.1.4.2 The relocatable power taps shall be directly connected to a permanently installed receptacle.

Mandating that relocatable power taps be listed is not a new *Code* provision, but references to the specific listing standards, UL 1363, *Standard for Relocatable Power Taps*, and UL 1363A, *Outline of Investigation for Special Purpose Relocatable Power Taps,* are new for the 2018 edition of the *Code*. In addition to the current *Code* requirements for relocatable power taps to be polarized or grounded type with overcurrent protection, which is covered in Sections 13 and 14 of UL 1363, requiring the relocatable power taps to be listed in accordance with UL 1363 will also address all other applicable safety requirements for relocatable power taps used in occupancies other than health care occupancies.

The addition of UL 1363A addresses the specific requirements for relocatable power taps used in general care space or critical care space as defined by Article 517, Health Care Facilities, of the *National Electrical Code*. UL 1363A requires compliance with UL 1363, with additional requirements specific to the use, such as the use of hospital-grade receptacle outlets and plugs, and verification of electrical and mechanical integrity where used with medical equipment.

Relocatable power taps are not to be plugged into extension cords to extend their reach. Where extension cords are used for other than temporary purposes, additional permanent receptacles should be installed in accordance with Section 11.1 and 11.1.5.6.

11.1.4.3 Relocatable power tap cords shall not extend through walls, ceilings, or floors; under doors or floor coverings; or be subject to environmental or physical damage.

Where relocatable power taps extend through walls and floors or under doors or rugs, the installation of permanent receptacles should be required in accordance with 11.1.2.

11.1.5 Extension Cords.

11.1.5.1 Extension cords shall be plugged directly into an approved receptacle, power tap, or multiplug adapter and shall, except for approved multiplug extension cords, serve only one portable appliance.

Extension cords should not be used in place of permanent wiring. Where extension cords are used to permanently power equipment, the fire official should require the installation of permanent wiring in accordance with 11.1.2.

11.1.5.2* The ampacity of the extension cords shall not be less than the rated capacity of the portable appliance supplied by the cord.

A.11.1.5.2 See Table A.11.1.5.2.

11.1.5.3 The extension cords shall be maintained in good condition without splices, deterioration, or damage.

11.1.5.4 Extension cords shall be grounded when servicing grounded portable appliances.

11.1.5.5 Extension cords and flexible cords shall not be affixed to structures; extend through walls, ceilings, or floors, or under doors or floor coverings; or be subject to environmental or physical damage.

Where extension cords extend through walls and floors or under doors or rugs, the installation of permanent receptacles should be required in accordance with 11.1.2.

11.1.5.6 Extension cords shall not be used as a substitute for permanent wiring.

11.1.6 Temporary Installations.

11.1.6.1 Scope. The provisions of 11.1.6 shall apply to temporary electric power and lighting installations. [***70:***590.1]

11.1.6.2 All Wiring Installations.

11.1.6.2.1 Other Articles. Except as specifically modified in Article 590 of *NFPA 70*, all other requirements of *NFPA 70* for permanent wiring shall apply to temporary wiring installations. [***70:***590.2(A)]

Temporary installations of electrical equipment must be installed in accordance with all applicable permanent installation requirements, except as modified by 11.1.6. For example, the requirements of Section 300.15 of *NFPA 70* specify that a box or other enclosure must be used where splices are made. *NFPA 70* permits exceptions to the enclosure requirement for certain applications such as construction sites. Consult *NFPA 70* for additional guidance.

11.1.6.2.2 Approval. Temporary wiring methods shall be acceptable only if approved based on the conditions of use and any special requirements of the temporary installation. [***70:***590.2(B)]

All temporary wiring methods must be approved based on criteria such as (1) length of time in service, (2) severity of physical

TABLE A.11.1.5.2 Recommended Extension Cord Sizes for Portable Electric Tools

Extension Cord Length (ft)	Nameplate Ampere Rating											
	0–2.0		2.1–3.4		3.5–5.0		5.1–7.0		7.1–12.0		12.1–16.0	
	115 V	230 V	115 V	230 V	115 V	230 V	115 V	230 V	115 V	230 V	115 V	230 V

1000	8	12	6	10	4	8	2	6	1	4	0	2

Notes:

(1) Size is based on current equivalent to 150 percent of full load of tool and a loss in voltage of not over 5 volts.

(2) If voltage is already low at the source (outlet), voltage should be increased to standard, or a larger cord than listed should be used to minimize the total voltage drop.

[**70B:** Table 29.5.1]

abuse, (3) exposure to weather, and (4) other special requirements. Special requirements might range from tunnel construction projects and tent cities constructed after a natural disaster to flammable hazardous reclamation projects.

11.1.6.3 Time Constraints.

11.1.6.3.1 During the Period of Construction. Temporary electric power and lighting installations shall be permitted during the period of construction, remodeling, maintenance, repair, or demolition of buildings, structures, equipment, or similar activities. [***70:***590.3(A)]

11.1.6.3.2 90 Days. Temporary electric power and lighting installations shall be permitted for a period not to exceed 90 days for holiday decorative lighting and similar purposes. [***70:***590.3(B)]

Note that the 90-day time limit applies only to temporary electrical installations associated with holiday displays. Construction, emergency, and test temporary wiring installations are not bound by this time limit.

11.1.6.3.3 Emergencies and Tests. Temporary electric power and lighting installations shall be permitted during emergencies and for tests, experiments, and developmental work. [***70:***590.3(C)]

11.1.6.3.4 Removal. Temporary wiring shall be removed immediately upon completion of construction or purpose for which the wiring was installed. [***70:***590.3(D)]

Permitted temporary wiring installations might not meet all the requirements for a permanent installation. Therefore, all temporary wiring must be not only disconnected but also removed from the building, structure, or other location of installation.

11.1.7 Building Disconnect.

11.1.7.1* Means shall be provided for the fire department to disconnect the electrical service to a building, structure, or facility when the electrical installation is covered under the scope of *NFPA 70*.

Δ **A.11.1.7.1** Section 230.70 of *NFPA 70* (*NEC*), includes requirements for the location and marking of service disconnect means. *NFPA 70* applies to most public and private buildings, structures, yards, parking lots, and similar installations. It does not apply to certain electrical installations under the exclusive control of communications utilities or electric utilities, and other specific installations. *(See NFPA 70, Section 90.2.)* Multiple service disconnect means could be provided as allowed by *NFPA 70*.

The building disconnecting means should be in a location accessible to the fire department in the event of an emergency. A disconnecting means located in the center of the building interior requires fire fighters to enter the building to disconnect power. Disconnects should be located in rooms with access either directly to the outside or in close proximity to an outside door. Shunt trips or other devices might be permitted if approved by the fire department.

11.1.7.2 The disconnecting means shall be maintained accessible to the fire department.

11.1.7.3 Identification of Disconnecting Means.

11.1.7.3.1 Each disconnecting means shall be legibly marked to indicate its purpose unless located and arranged so the purpose is evident. The marking shall be of sufficient durability to withstand the environment involved. [***70:***110.22(A)]

Proper identification needs to be specific. For example, the marking should indicate not simply "motor" but, rather, "motor, water pump," or not simply "lights" but, rather, "lights, front lobby." Consideration also should be given to the form of identification. Marking often fades or is covered by paint after installation. See Section 408.4 of *NFPA 70* for further information on circuit directories for switchboards and panelboards.

11.1.8 Covers. All panelboard and switchboards, pull boxes, junction boxes, switches, receptacles, and conduit bodies shall be provided with covers compatible with the box or conduit body construction and suitable for the conditions of use.

11.2 Heating, Ventilation, and Air-Conditioning

Δ **11.2.1 Air-Conditioning, Heating, Ventilating Ductwork, and Related Equipment.** Air-conditioning, heating, ventilating ductwork, and related equipment shall be in accordance with NFPA 90A or NFPA 90B as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101:***9.2.1]

For the proper installation of HVAC systems, 11.2.1 refers the *Code* user to NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems.* For occupancies with small overall volumes, such as one- and two-family dwellings, the *Code* refers the user to NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems.*

For example, NFPA 90A addresses fire damper requirements for both ductwork and air-transfer grilles that penetrate fire barriers. NFPA 90A also prohibits means of egress corridors in health care, detention and correctional, and residential occupancies from being used as a portion of a supply-, return-, or exhaust-air system serving adjoining areas. Exhibit 11.2 identifies some of the areas where fire dampers and smoke dampers would be required by NFPA 90A.

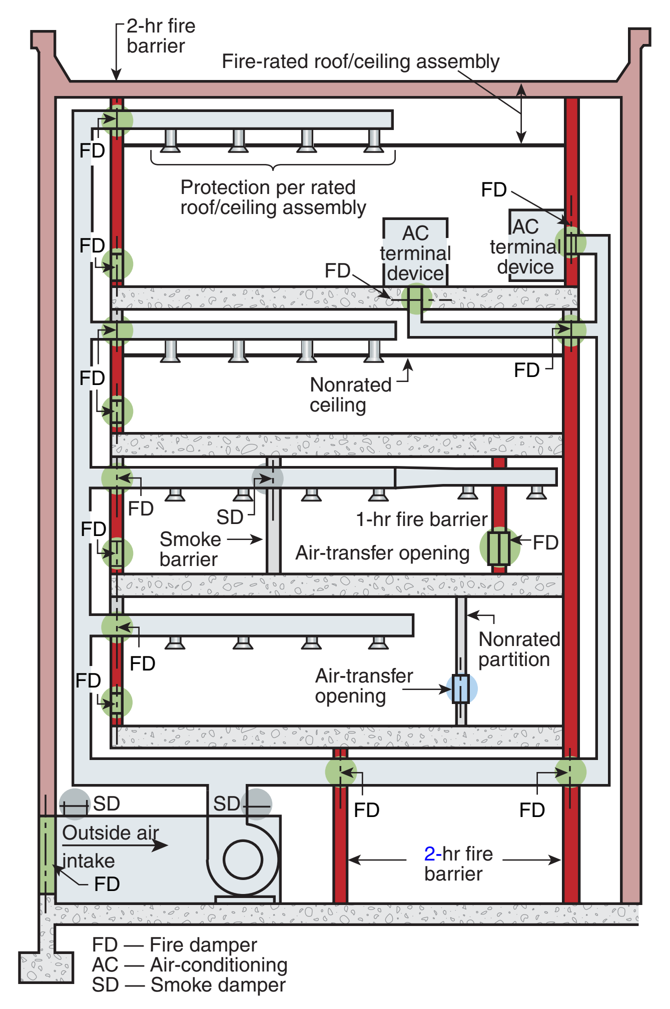
Δ **11.2.2 Ventilating or Heat-Producing Equipment.** Ventilating or heat-producing equipment shall be in accordance with NFPA 91, NFPA 211, NFPA 31, NFPA 54, or *NFPA 70*, as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101:***9.2.2]

11.3 Elevators, Escalators, and Conveyors

11.3.1 Fire Fighters' Emergency Operations.

Because an elevator stopping at a fire floor (intentionally or unintentionally) is an extreme hazard, the *Code* mandates compliance with the fire fighters' emergency operations requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators,* and ASME A17.3, *Safety Code for Existing Elevators and Escalators,* for new and existing elevators, respectively. The fire fighters' emergency operations requirements establish elevator recall activated by smoke detection in each elevator lobby and in associated elevator machine rooms. A three-position, key-operated switch, normally located in the main lobby at the elevator, controls the recall function. The requirements mandate specific functions for the "RESET," "OFF," and "ON" positions of this switch. The requirements also provide for emergency in-car operations or what is often referred to as fire fighters' service. Fire fighters' service requires a three-position, key-operated switch in each elevator car. The functions of the "ON," "OFF," and "HOLD" positions are specified in the elevator code. For specific details, refer to ASME A17.1/CSA B44. Explanatory material on these rules can be found in the ASME A17.1/CSA B44 *Handbook on Safety Code for Elevators and Escalators.*

Exhibit 11.2



Partition and fire barrier penetration protection.

11.3.1.1 All new elevators shall conform to the fire fighters' emergency operations requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. [***101:***9.4.3.1]

11.3.1.2 All existing elevators having a travel distance of 25 ft (7620 mm) or more above or below the level that best serves the needs of emergency personnel for fire-fighting or rescue purposes shall conform to the fire fighters' emergency operations requirements of ASME A17.3, *Safety Code for Existing Elevators and Escalators*. [***101:***9.4.3.2]

11.3.2 Number of Cars. The number of elevator cars permitted in a hoistway shall be in accordance with 8.6.9.4 of NFPA *101*. [***101:***9.4.4]

11.3.3* Elevator Machine Rooms. Elevator machine rooms that contain solid-state equipment for elevators, other than existing elevators, having a travel distance exceeding 50 ft (15 m) above the level of exit discharge or exceeding 30 ft (9.1 m) below the level of exit discharge shall be provided with independent ventilation or air-conditioning systems to maintain temperature during fire fighters' emergency operations for elevator operation *(see 11.3.1)*. The operating temperature shall be established by the elevator equipment manufacturer's specifications. When standby power is connected to the elevator, the machine room ventilation or air-conditioning shall be connected to standby power. [***101:***9.4.5]

A.11.3.3 Continued operation of solid-state elevator equipment is contingent on maintaining the ambient temperature in the range specified by the elevator manufacturer. If the machine room ventilation/air conditioning is connected to the general building system, and that system is shut down during a fire, the fire department might lose the use of elevators due to excessive heat in the elevator machine room. [***101:***A.9.4.5]

The intent of the requirement for a ventilation or an air-conditioning system to help keep the elevator controls operable is explained in 11.3.3 and A.11.3.3. For many typical installations, this requirement can be met by the installation of an independent, through-the-wall air-conditioning unit. Regardless of shutdown of the building's HVAC system, the independent unit will continue to run, provided that its power supply is not interrupted.

11.3.4 Elevator Testing.

Because emergency responders might use elevators to move personnel and equipment and potentially to assist in the evacuation of mobility-impaired occupants, it is important to routinely test elevators to help ensure they can be used when needed under fire and other emergency conditions.

11.3.4.1 Elevators shall be subject to periodic inspections and tests as specified in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. [***101:***9.4.6.1]

11.3.4.2 All elevators equipped with fire fighters' emergency operations in accordance with 11.3.1 shall be subject to a monthly operation with a written record of the findings made and kept on the premises as required by ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. [***101:***9.4.6.2]

Δ **11.3.4.3** The elevator inspections and tests required by 11.3.4.1 shall be performed at frequencies complying with one of the following:

(1) Inspection and test frequencies specified in Appendix N of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*
(2) Inspection and test frequencies specified by the AHJ

[***101:***9.4.6.3]

11.3.5 Openings to Exit Enclosures. Conveyors, elevators, dumbwaiters, and pneumatic conveyors serving various stories of a building shall not open to an exit enclosure. [***101:***9.4.7]

Openings to exit enclosures are strictly limited by the provisions of 14.3.1(9) to doors that provide access to the exit from normally occupied spaces or corridors and means to leave the exit enclosure. Elevators and other conveyors are not considered normally occupied areas. Additionally, an elevator, with its associated cables, controls, and mechanical equipment, would introduce combustibles into an exit enclosure, which conflicts with the objective of making the exit enclosure a safe place free of combustibles.

11.3.6 Standardized Fire Service Elevator Keys.

11.3.6.1 Buildings with elevators equipped with Phase I emergency recall, Phase II emergency in-car operation, or a fire service access elevator shall be equipped to operate with a standardized fire service key complying with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, except as otherwise permitted by 11.3.6.

11.3.6.2 Existing buildings with elevators equipped with Phase I emergency recall or Phase II emergency in-car operation shall be permitted to comply with 11.3.6.3.

11.3.6.3 Existing Buildings. Existing buildings shall be in compliance with the provisions of 11.3.6.3.1 one year after adoption by the AHJ.

11.3.6.3.1 Where a standardized key cylinder cannot be installed in an existing elevator key switch assembly, the building's nonstandardized fire service elevator keys shall be provided in an access box in accordance with 11.3.6.3.1.1 through 11.3.6.3.1.6.

11.3.6.3.1.1 The access box shall be compatible with an existing rapid-entry access box system in use in the jurisdiction and approved by the AHJ.

11.3.6.3.1.2 The front cover shall be permanently labeled with the words "Fire Department Use Only — Elevator Keys."

11.3.6.3.1.3 The access box shall be mounted at each elevator bank at the lobby nearest to the lowest level of fire department access.

11.3.6.3.1.4 The access box shall be mounted at a location approved by the AHJ.

11.3.6.3.1.5 Contents of the access box shall be limited to the fire service elevator key. Additional elevator access tools, keys, and information pertinent to emergency planning or elevator access shall be permitted when authorized by the AHJ.

11.3.6.3.1.6 In buildings with two or more elevator banks, a single access box shall be permitted to be used where such elevator banks are separated by not more than 30 ft (9140 mm). Additional access boxes shall be provided for each individual elevator or elevator bank separated by more than 30 ft (9140 mm).

11.3.6.3.1.7 A single access box shall be permitted to be located adjacent to a fire command center, or the nonstandard fire service elevator key shall be secured in an access box used for other purposes and located in accordance with 18.2.2.1 when approved by the AHJ.

The requirements of 11.3.6 mandate the standardization of fire service elevator keys to reduce the number of keys necessary for accessing elevators in an emergency. All new elevators must be equipped to use standard keys as approved by the authority having jurisdiction (AHJ), and all existing elevators with fire fighters' emergency operations must be retrofitted to use standard keys within 1 year of the adoption of the *Code* by the jurisdiction. Where the physical limitations of existing elevators do not permit such retrofit, the *Code* permits the installation of access boxes opened by standard fire department keys for the housing of nonstandard elevator keys. It is noted that the 2012 edition of the *Code* prescribed requirements for the standardized fire service key that differed from the requirements of ASME A17.1/CSA B44. The 2015 edition was revised to simply reference the standardized key requirements of ASME A17.1/CSA B44 to eliminate any potential conflicts.

Δ **11.3.7 Elevators for Occupant-Controlled Evacuation Prior to Phase I Emergency Recall Operations and Fire Service Access Elevators.** An approved method to prevent automatic sprinkler water from infiltrating into the hoistway enclosure from the operation of the automatic sprinkler system outside the enclosed occupant evacuation elevator lobby shall be provided where the hoistway serves elevators in accordance with any of the following:

(1) Occupant-controlled evacuation elevators in accordance with Section 7.14 of NFPA *101*
(2) Occupant-controlled evacuation elevators in accordance with the building code
(3) Fire service access elevators in accordance with the building code

The provisions of 11.3.7, which were new to the 2015 edition of the *Code*, do not mandate that elevators comply with the provisions for occupant-controlled evacuation or fire service access in accordance with NFPA *101* or the applicable building code. Rather, they specify that the means of preventing sprinkler water infiltration into the hoistway must be maintained over the life of the building. See A.7.15.9.6 of NFPA *101* for additional guidance.

Δ 11.4 Utilities

Equipment using fuel gas and related gas piping shall be in accordance with NFPA 54 or NFPA 58. *(See Chapter 69 for LP-Gas fuel supply and storage installations.)*

11.4.1 Existing installations shall be permitted to be continued in service, subject to approval by the AHJ.

11.4.2 Aboveground gas meters, regulators, and piping exposed to vehicular damage shall be protected in accordance with 60.5.1.9.

See Chapter 69 for additional requirements involving NFPA 58, *Liquefied Petroleum Gas Code*, and LP-Gas.

11.5 Heating Appliances

11.5.1 General.

Δ **11.5.1.1** The installation of stationary liquid fuel–burning appliances, including but not limited to industrial-, commercial-, and residential-type steam, hot water, or warm air heating appliances; domestic-type range burners; space heaters; and portable liquid fuel–burning equipment shall comply with Section 11.5 and NFPA 31.

NFPA 31, *Standard for the Installation of Oil-Burning Equipment*, is the standard for the safe, efficient design and installation of heating appliances that use a liquid fuel, typically No. 2 heating oil, but also lighter fuels, such as kerosene and diesel fuel, and heavier fuels, such as No. 4 fuel oil. NFPA 31 applies to the installation of these systems in residential, commercial, and industrial occupancies.

Δ **11.5.1.2** Section 11.5 shall also apply to all accessories and control systems, whether electric, thermostatic, or mechanical, and all electrical wiring connected to liquid fuel–burning appliances. [**31:**1.1.2]

Δ **11.5.1.3** Section 11.5 shall also apply to the installation of liquid fuel storage and supply systems connected to liquid fuel–burning appliances. [**31:**1.1.3]

11.5.1.4 Section 11.5 shall also apply to those multifueled appliances in which a liquid fuel is one of the standard or optional fuels. [**31:**1.1.4]

11.5.1.5* Section 11.5 shall not apply to internal combustion engines, oil lamps, or portable devices not specifically covered in NFPA 31. *(See Chapter 11 of NFPA 31 for portable devices that are covered in NFPA 31.)* [**31:**1.1.5]

A.11.5.1.5 Examples of portable devices not covered by NFPA 31 are blowtorches, melting pots, and weed burners. [**31:**A.1.1.5]

11.5.1.6 The installation of gas-fired heating appliances shall comply with Section 11.5 and NFPA 54. *(See Chapter 69 for LP-Gas fuel supply and storage installations.)*

NFPA 54, *National Fuel Gas Code*, addresses the installation of fuel gas piping systems, fuel gas utilization equipment, and related accessories, including piping systems, operating pressure, installation, combustion, ventilation air, and venting. The use of unvented fuel-fired heaters is prohibited by this *Code* and NFPA *101*®, *Life Safety Code*®, in numerous occupancies, unless they are approved units that comply with NFPA 54. The use of such equipment is prohibited in all residential board and care occupancies regardless of compliance with NFPA 54.

11.5.1.7 All heating appliances shall be approved or listed.

11.5.1.8 Permits. Permits, where required, shall comply with Section 1.12.

This *Code* requires that a permit be obtained in order to store, use, or handle LP-Gas or Class I, Class II, or Class IIIA flammable or combustible liquids.

11.5.1.9 Electrical wiring and utilization equipment used in connection with oil-burning appliances or equipment shall be installed in accordance with Section 11.1. [**31:**4.4.1]

11.5.1.10 Acceptable Liquid Fuels.

Δ **11.5.1.10.1*** The type and grade of liquid fuel used in a liquid fuel–burning appliance shall be that liquid fuel for which the appliance is listed and approved or is stipulated by the manufacturer. Liquid fuels shall meet one of the following specifications and shall not contain gasoline or any other flammable liquid:

(1) ASTM D396, *Standard Specification for Fuel Oils*
(2) ASTM D3699, *Standard Specification for Kerosene*
(3) ASTM D6448, *Industrial Burner Fuels from Used Lube Oils*
(4) ASTM D6751, *Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuel*
(5) ASTM D6823, *Commercial Burner Fuels from Used Lube Oils*

[**31:**4.5.1]

A.11.5.1.10.1 See Chapter 11 of NFPA 31 for additional requirements for oil-burning stoves, kerosene-burning room heaters, and kerosene-burning portable heaters. See Chapter 12 of NFPA 31 for additional requirements for used oil–burning appliances. See Chapter 13 of NFPA 31 for additional requirements for combination oil-and-gas–burning appliances. [**31:**A.4.5.1]

Δ **11.5.1.10.2** Appliances that burn crankcase oil or used oil shall not be used in a residential occupancy. Such appliances shall only be used if all of the following conditions are met:

(1) The installation is in a commercial or industrial occupancy.
(2) The oil-burning appliance is designed to burn crankcase oil or used oil and is listed for such use.
(3) The appliance is installed in accordance with the manufacturer's instructions and with the terms of its listing.
(4) The installation meets the applicable requirements of Section 4.6 and Chapter 12 of NFPA 31.

[**31:**4.5.2]

Δ **11.5.1.10.3*** Where heavy oils are used, the following shall be required:

(1) The oil-burning appliance shall be designed to burn such fuels.
(2) Means shall be provided to maintain the oil at its proper atomizing temperature.
(3) Automatically operated burners that require preheating of oil shall be arranged so that no oil can be delivered for combustion until the oil is at the proper atomizing temperature.
(4)* Use of an oil-fired appliance that is listed in accordance with ANSI/UL 296A, *Standard for Waste Oil-Burning Air-Heating Appliances*, shall be deemed as meeting the intent of 11.5.1.10.3(1) through 11.5.1.10.3(3).

[**31:**4.5.3]

A.11.5.1.10.3 Where heavy oils are used, provisions should be made to maintain the oil within the recommended temperature range indicated in Table A.11.5.1.10.3 so that proper atomization is maintained. [**31:**A.4.5.3]

A.11.5.1.10.3(4) ANSI/UL 296A, *Standard for Waste Oil-Burning Air Heating Appliances*, specifies that a burner provided with preheating means for the fuel oil can be provided with an oil temperature interlock device to prevent delivery of the fuel oil to the firing portion of the burner until the fuel oil has reached a predetermined minimum temperature. On a burner that is not equipped

Δ ***TABLE A.11.5.1.10.3*** *Recommended Temperature Range for Proper Atomization of Heavy Oils*

Fuel No.	Viscosity in SSU at 100°F	Low Temperature Limit (°F)	High Temperature Limit (°F)
4	45	35*	50
	50	35*	65
	60	45*	85
	75	62	105
	100	80	125
5	150	100	145
	200	112	160
	300	130	180
	400	140	190
	500	150	200
6	1,000	170	225
	2,000	190	245
	3,000	205	260
	4,000	212	270
	5,000	218	275
	10,000	240	290

*At these temperatures, proper operation of the appliance might not be attained because of unsatisfactory atomization of the fuel. For this reason, the fuel oil should be kept at the high end of the recommended temperature range.

[**31:** Table A.4.5.3]

with oil-preheating equipment, an oil temperature interlock device should not be provided on the burner and should be bypassed during any firing tests of the burner. [**31:**A.4.5.3(4)]

11.5.1.10.4 A properly sized and rated oil filter or strainer shall be installed in the oil supply line to an oil burner. [**31:**4.5.4]

Section 4.6 of NFPA 31, *Standard for the Installation of Oil-Burning Equipment,* provides the applicable requirements for the use of crankcase oil and used oil as a fuel. Typical locations are burner areas, fuel-handling areas, fuel storage areas, pits, sumps, and low spots where fuel leakage or vapors can accumulate. Chapter 5 of *NFPA 70* provides information for classifying such areas and defines requirements for electrical installations in areas so classified.

Crankcase oil and used oil properties can vary considerably, and light volatile materials can be released during storage or handling or upon heating. Because of this characteristic, appropriate and adequate provisions should be made to safely handle, store, and burn crankcase oil and used oil. Flexibility built into the facility is desirable to accommodate the expected range of properties of the fuels in use. Failure to observe the necessary design, installation, and operating and maintenance procedures can result in fire, explosion, or personal injury.

Extensive treatment of this subject is beyond the scope of this *Code*. The AHJ should be responsible for classifying areas where fuel is stored, handled, or burned and for revising the classification if conditions are changed. Installation of electrical equipment in such areas must conform to *NFPA 70*. Additional guidance can be obtained from NFPA 30, *Flammable and Combustible Liquids Code,* and NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*.

11.5.1.11 Clothes Dryers.

11.5.1.11.1 Clothes dryers shall be cleaned to maintain the lint trap and keep the mechanical and heating components free from excessive accumulations of lint.

11.5.1.11.2 The requirements of 11.5.1.11.1 shall not apply to clothes dryers in individual dwelling units of residential occupancies.

11.5.2 Kerosene Burners and Oil Stoves.

Kerosene stoves are self-contained, self-supporting, kerosene-burning ranges, room heaters, or water heaters not connected to chimneys but equipped with integral fuel supply tanks with a maximum capacity of 2 gal (7.6 L). Kerosene room heaters are often referred to as cabinet heaters and space heaters. See Exhibit 11.3 for an example of a kerosene heater.

Because these heaters are not connected to chimneys, they can be moved rather easily, although they generally are not considered portable. Each year, many serious fires result from the improper use of these heaters. Because of their mobility, these stoves pose a hazard when placed near combustible materials or where they can block a means of egress.

Exhibit 11.3

Kerosene heater.

Exhibit 11.4

Kerosene fuel container. (Courtesy of Blitz USA)

Another fire hazard is the use of gasoline instead of kerosene fuel. Kerosene fuel should be stored in an approved container. See Exhibit 11.4 for an example of a kerosene fuel container. These containers are of a blue color to distinguish them from other flammable liquid containers that might be in the home.

11.5.2.1 Kerosene burners and oil stoves shall be equipped with a primary safety control furnished as an integral part of the appliance by the manufacturer to stop the flow of oil in the event of flame failure. Barometric oil feed shall not be considered a primary safety control.

11.5.2.2 A conversion range oil burner shall be equipped with a thermal (heat-actuated) valve in the oil supply line, located in the burner compartment of the stove.

Conversion range oil burners consist of a single-sleeve or double-sleeve burner assembly, regulating valves, and an oil supply assembly with a suitable supporting stand and seamless connecting tubing. A thermal valve located in the burner compartment of the stove adjacent to the burner is installed in the oil supply line.

Range oil burners, which are found most frequently in the northeastern United States, are designed to burn kerosene, range oil, or similar fuel. They are primarily installed in stoves or ranges originally designed to use solid fuel. Range oil burners should not be mistaken for vaporizing-pot conversion oil burners that are designed for the conversion of central heating appliances.

Δ **11.5.2.3** Kerosene heaters shall be listed and labeled in accordance with UL 647, *Standard for Unvented Kerosene-Fired Room Heaters and Portable Heaters,* and their use shall meet all of the following:

(1) Adequate ventilation shall be provided.
(2) Kerosene heaters shall not be placed on carpeting.
(3) Kerosene heaters shall be located not less than 3 ft (0.9 m) from combustible furnishings and drapes.
(4) Only approved Type 1-K water clear kerosene shall be used.
(5) Kerosene heaters shall be allowed to cool before refueling.

Portable kerosene heaters pose a hazard similar to that of kerosene stoves, since they are not connected to a chimney. However, the hazard is increased by their greater portability and subsequent misuse and improper placement. They are also subject to improper fueling, substitution of gasoline or other inappropriate liquid fuel, and refueling when hot, which can produce and ignite flammable vapors. The safest heaters incorporate fire safety features, such as special types of latching devices and integral sheet-metal trays under the burners to catch oil drips. They usually employ wick-type burners that are integral with the oil reservoir. Portable kerosene heaters should include a tip-over switch that automatically snuffs the burner if the unit is jostled or tipped. Also see 11.5.2.1.

UL 647, *Standard for Unvented Kerosene-Fired Room Heaters and Portable Heaters,* provides requirements for unvented kerosene-fired room heaters, including either requiring automatic primary safety controls or for the heater to be inherently constructed to prevent abnormal discharge of fuel at the burner in case of ignition failure or premature flame extinguishment. Reference to UL 647 as the specific listing standard is new for the 2018 edition of the *Code*. Kerosene stoves listed by testing laboratories incorporate fire protection features that might be missing from stoves that are not listed. Important features of listed stoves include substantial construction materials, provision of primary control valves, and use of drip pans to catch any leaking fuel, confining it to the stove.

11.5.3 Portable Electric Heater.

11.5.3.1 The AHJ shall be permitted to prohibit use of portable electric heaters in occupancies or situations where such use or operation would present an undue danger to life or property.

During cold weather, portable electric space heaters are used in many locations, including under desks. Although placing a heater under a desk or table lessens the chance of the heater being easily overturned, the heater also can easily be forgotten. A heater that is left on for an extended time can overheat combustible materials that might also be stored under the desk or table. Managers of facilities that allow the use of electric space heaters should be instructed to remind employees to shut them off at the end of the day and keep combustible material away from the heater.

In addition, because of the amount of electric current drawn by space heaters, electric heaters should be used only where they can be plugged directly into appropriate receptacles or extension cords of adequate current capacity. See 11.1.5 for requirements addressing extension cords.

The AHJ is permitted to prohibit the use of space heaters where an undue danger to life or property exists. The AHJ can use past inspection findings, such as portable heaters that were left turned on and unattended, fire incidents, and other reasons to prohibit the use of such heaters.

11.5.3.2 Portable electric heaters shall be designed and located so that they cannot be easily overturned.

11.5.3.3 All portable electric heaters shall be listed.

11.5.4 Vents. All chimneys, smokestacks, or similar devices for conveying smoke or hot gases to the outer air and the stoves, furnaces, incinerators, boilers, or any other heat-producing devices or appliances shall be installed and maintained in accordance with NFPA 54 and NFPA 211.

11.6 Waste Chutes, Incinerators, and Laundry Chutes

11.6.1 Enclosure.

11.6.1.1 Waste chutes and laundry chutes shall be separately enclosed by walls or partitions in accordance with the provisions of Section 12.7. [***101:***9.5.1.1]

11.6.1.2 Chute intake openings shall be protected in accordance with Section 12.7. [***101:***9.5.1.2]

11.6.1.3 The doors of chutes specified in 11.6.1.2 shall open only to a room that is designed and used exclusively for accessing the chute opening. [***101:***9.5.1.3]

11.6.1.4 Chute service opening rooms shall be separated from other spaces in accordance with Section 8.7 of NFPA *101*. [***101:***9.5.1.4]

Δ **11.6.1.5** The requirements of 11.6.1.1 through 11.6.1.4 shall not apply where otherwise permitted by the following:

(1) Existing installations having properly enclosed service chutes and properly installed and maintained chute intake doors shall be permitted to have chute intake doors open to a corridor or normally occupied space.
(2) Waste chutes and laundry chutes shall be permitted to open into rooms not exceeding 400 ft² (37 m²) that are used for storage, provided that the room is protected by automatic sprinklers.

[***101***:9.5.1.5]

Waste chutes are often associated with a trash collection room, and laundry chutes are often associated with a laundry/storage room. The provision of 11.6.1.5(2) permits chutes to open into such rooms, provided that the area of the room does not exceed 400 ft² (37 m²). Without this provision, the user might interpret the words "used exclusively" in 11.6.1.3 as limiting the use of that room to serving the chute only.

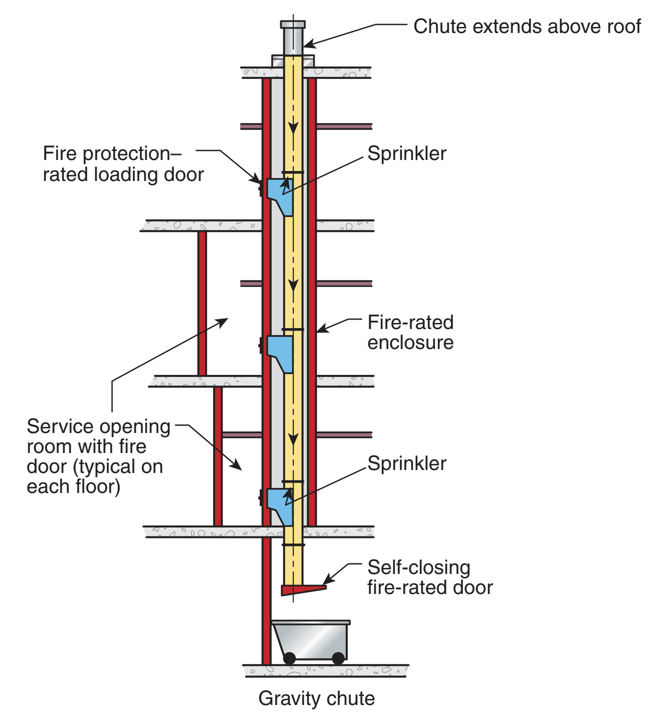
Δ **11.6.2 Installation and Maintenance.** Waste chutes, laundry chutes, and incinerators shall be installed and maintained in accordance with NFPA 82 unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101***:9.5.2]

Shafts containing waste and linen chutes must be enclosed according to the requirements for the protection of vertical openings found in Section 11.6. The installation of the chute itself must meet the requirements of NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment.*

Additional concerns regarding chutes opening to other parts of the building need to be addressed. For convenience, service openings for loading are usually located to be accessible from corridors on the upper floors of the building. However, these corridors also serve as exit access, and a fire in the chute with an open loading door could result in the obstruction of the corridor by smoke and other products of combustion. To address this hazard, the *Code* and NFPA 82 require the construction of service opening rooms to form a buffer between the chute and the building space. The special hazard protection provisions in Section 8.7 of NFPA *101* for the separation of the service opening are referenced in 11.6.1.4. The result is a room that is separated from the rest of the building by construction with a 1-hour fire resistance rating or protected with an automatic extinguishing system. The door to this room is required to have a ¾-hour fire protection rating. Exhibit 11.5 illustrates the protection arrangement required for waste and linen chutes by NFPA 82.

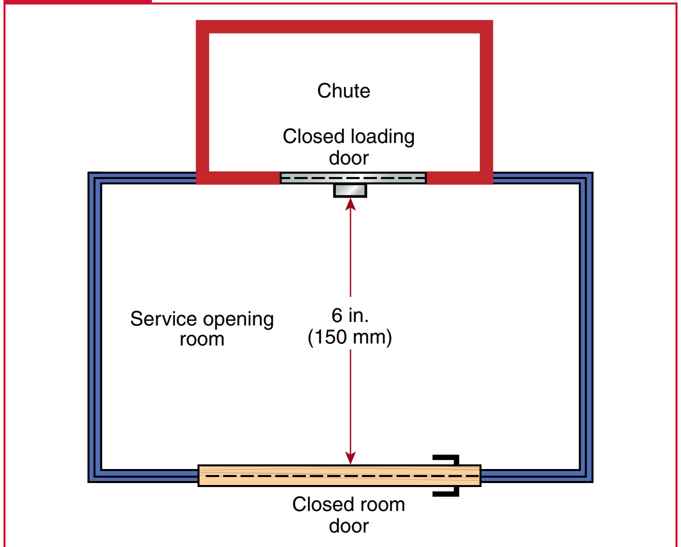
Additionally, NFPA 82 requires the service opening room to be sized to maintain a minimum 6 in. (150 mm) clearance between the closed chute loading door and the closed room door. Exhibit 11.6 illustrates the measurement of this clearance.

Exhibit 11.5



Protection of waste and linen chutes.

Exhibit 11.6



Clearance in service opening room.

11.7 Stationary Generators and Standby Power Systems

11.7.1 Stationary Combustion Engines and Gas Turbines Installation. Stationary generator sets shall be installed in accordance with NFPA 37 and *NFPA 70*.

NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines,* applies to stationary combustion engines and gas turbines, portable engines that remain connected for use in the same location for a period of 1 week or more, new installations, and those portions of existing equipment and installations that are changed or modified.

11.7.2 Portable Generators.

11.7.2.1* Portable generators shall not be operated or refueled within buildings, on balconies, or on roofs.

A.11.7.2.1 It is not the intent of this section to prohibit the installation or use of portable generators within outside structures such as lean-tos or sheds intended solely to provide weather protection for the generator.

11.7.2.1.1 Portable generators shall be permitted to be operated or refueled in a building or room that has been constructed for such use in accordance with the building code.

11.7.2.1.2 Fueling from a container shall be permitted when the engine is shut down and engine surface temperature is below the autoignition temperature of the fuel.

11.7.2.2 Portable generators shall be positioned so that the exhaust is directed as follows:

(1) At least 5 ft (1.5 m) in any direction away from any openings or air intakes
(2) Away from the building

Portable generators have been a life safety problem for years, especially when storms knock out power for extended periods of time, such as during hurricanes or snowstorms. Each year, many people are killed or injured by carbon monoxide due to improper placement and use of portable generators. People often purchase generators to provide power during power outages without knowing the associated risks and end up using them improperly or wiring them incorrectly. Portable generators should never be run or fueled indoors unless the room has the proper fire protection and ventilation required in the building code. Wiring should never be directly tied into the distribution panel where it could potentially feed back into the electrical distribution system, endangering electrical company workers who are restoring power. A properly installed transfer switch should be provided.

Portable generator exhaust should be pointed away from the building and be placed no closer than 5 ft (1.5 m) from any openings, including doors, windows, and vents.

11.7.3 Emergency and Legally Required Standby Power Systems.

Δ **11.7.3.1 General.** New stationary generators for emergency use or for legally required standby power required by this *Code*, the building code, or other codes and standards shall be installed in accordance with NFPA 110.

NFPA 110, *Standard for Emergency and Standby Power Systems,* covers performance requirements for emergency and standby power systems providing an alternative source of electrical power to loads in buildings and facilities in the event that the primary power source fails. Power systems covered in NFPA 110 include power sources, transfer equipment, controls, supervisory equipment, and all related electrical and mechanical auxiliary and accessory equipment needed to supply electrical power to the load terminals of the transfer equipment.

NFPA 110 covers installation, maintenance, operation, and testing requirements as they pertain to the performance of the emergency power supply system (EPSS). NFPA 110 does not cover the following:

1. Application of the EPSS
2. Emergency lighting unit equipment
3. Distribution wiring
4. Utility service, when such service is permitted as the EPSS
5. Parameters for stored energy devices
6. Equipment of systems not classed as Level 1 or Level 2 systems in accordance with Chapter 4 of NFPA 110

11.7.3.2 Acceptance. Newly installed stationary generators for emergency use or for legally required standby power for fire protection systems and features shall demonstrate the capacity of the energy converter, with its controls and accessories, to survive without damage from common and abnormal disturbances in actual load circuits by any of the following means:

(1) By tests on separate prototype models
(2) By acceptance tests on the system components as performed by the component suppliers
(3) By listing for emergency service as a completely factory-assembled and factory-tested apparatus

11.7.4 Stored Electrical Energy Emergency and Legally Required Standby Power System Installation. Stored electrical energy systems required by this *Code*, the building code, or other NFPA codes and standards shall be installed in accordance with NFPA 111 and *NFPA 70*.

NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems,* covers the performance requirements for stored electrical energy systems providing an alternative source of electrical power in buildings and facilities in the event that the normal electrical power source fails.

Systems covered by NFPA 111 include power sources, transfer equipment, controls, supervisory equipment, and accessory equipment, including integral accessory equipment, needed to supply electrical power to the selected circuits. NFPA 111 also covers the installation, maintenance, operation, and testing requirements as they pertain to the performance of the stored emergency power supply system (SEPSS). NFPA 111 does not cover the following:

1. Application of the SEPSS
2. Distribution wiring

3. Systems having total outputs less than 500 volt-amperes or less than 24 volts, or systems less than Class 0.033
4. Unit equipment
5. Nuclear sources, solar systems, and wind energy systems
6. Uninterruptible power supply systems (UPS) supplied by an emergency power supply system (EPSS)

11.7.5 Maintenance and Testing.

11.7.5.1 Stationary generators used for emergency or legally required standby power shall be tested and maintained in accordance with NFPA 110 and NFPA 37.

11.7.5.2 Stationary generators required by this *Code*, the building code, or other NFPA codes and standards shall be maintained in accordance with NFPA 110.

Paragraph 11.7.5.2 does not require the installation of emergency generators, but it mandates that, where required and where such systems are installed for *Code* compliance, an approved maintenance and testing program must be provided to ensure operational integrity. Routine maintenance and operational testing are covered in Chapter 8 of NFPA 110.

11.7.5.3 Stored electrical energy systems required by this *Code*, the building code, or other NFPA codes and standards shall be maintained in accordance with NFPA 111.

Paragraph 11.7.5.3 does not require the installation of standby power systems, but it mandates that, where required and where such systems are installed for *Code* compliance, an approved maintenance and testing program must be provided to ensure operational integrity.

11.8* Smoke Control

Δ **A.11.8** NFPA 92 provides guidance in implementing systems using pressure differentials to accomplish one or more of the following:

(1) Maintain a tenable environment in the means of egress during the time required for evacuation
(2) Control and reduce the migration of smoke from the fire area
(3) Provide conditions outside the fire zone that assist emergency response personnel to conduct search and rescue operations and to locate and control the fire
(4) Contribute to the protection of life and reduction of property loss

Section 11.8 does not require smoke control systems but mandates that, where such systems are installed for *Code* compliance, an approved maintenance and testing program must be provided to ensure operational integrity. A smoke control system dedicated to emergency use only will not be subject to daily use, and, therefore, maintenance and testing of smoke control systems are necessary.

Some requirements of NFPA *101*, such as those applicable to atriums, mandate smoke control systems via performance-based language that requires tenable smoke conditions during egress.

11.8.1 Newly installed smoke-control systems shall be inspected by the AHJ and tested in accordance with the criteria established in the approved design documents, NFPA 204 and NFPA 92.

NFPA 204, *Standard for Smoke and Heat Venting,* applies to the design of venting systems for the emergency venting of products of combustion from fires in buildings. The provisions of Chapters 4 through 10 of NFPA 204 apply to the design of venting systems for the emergency venting of products of combustion from fires in nonsprinklered, single-story buildings using both hand calculations and computer-based solution methods. Chapter 11 of NFPA 204 applies to venting in sprinklered buildings.

NFPA 204 does not specify under which conditions venting is to be provided or required. It also does not specify or require ventilation within a building designed for regulation of environmental air for personnel comfort, regulation of commercial cooking operations, regulation of odor or humidity in toilet and bathing facilities, regulation of cooling of production equipment, or venting for explosion pressure relief.

NFPA 92, *Standard for Smoke Control Systems,* serves as a resource for the design, installation, acceptance testing, operation, and ongoing periodic testing of mechanical smoke control systems. It establishes requirements for smoke control systems that use pressure differences across barriers that accomplish one or more of the following:

1. Inhibit smoke from entering stairwells, means of egress, smoke refuge areas, elevator shafts, or similar areas
2. Maintain a tenable environment in smoke refuge areas and means of egress during the time required for evacuation
3. Inhibit the migration of smoke from the smoke zone
4. Provide conditions outside the smoke zone that enable emergency response personnel to conduct search and rescue operations and to locate and control the fire
5. Contribute to the protection of life and to the reduction of property loss

Other codes and standards specify the conditions under which a smoke control system must be provided.

An engineered smoke control system or smoke removal system acceptable to the AHJ has been required since the atrium provisions were first introduced in the 1981 edition of NFPA *101*. As advisory, but nonmandatory, information, the appendix of earlier editions suggested that, depending on atrium height and volume, either four or six air changes per hour could provide the smoke exhaust rate needed to meet the tenability conditions intended by the requirement for atrium smoke control.

The guideline for six air changes per hour came to be considered law by many AHJs and was thus accepted as the norm by many system designers. The AHJs then subjected such systems to acceptance testing using smoke bombs that produce cold smoke, which does not have the heat, buoyancy, and entrainment of air from a real fire. The acceptance criteria were further complicated by those who mistakenly believed that the intent of the smoke control requirement was, for example, that no smoke be visible within the atrium at the end of a 10-minute test. Designers found that, to ensure that the acceptance test could be passed, the system should provide approximately 10 to 12 air changes per hour. In effect, atrium smoke control systems were typically designed to pass the acceptance test with no consideration or assurance of effective smoke control under real fire conditions. NFPA 92 warns that a system designed in accordance with that standard and capable of providing the intended smoke management might not pass smoke bomb tests. Conversely, it is possible for a system that is incapable of providing the intended smoke management to pass smoke bomb tests. Because of the impracticality of conducting real fire tests within an atrium, the acceptance tests described in NFPA 92 are directed at those aspects of smoke management systems that can be verified through direct measurement (e.g., pressure differences across smoke zones as defined by the smoke control system's engineered design).

The smoke control system's performance objectives and acceptance criteria should be approved by the AHJ prior to its installation. In some cases, the code mandating the system specifies the performance objectives. For example, in accordance with NFPA *101*, atriums require an engineering analysis to demonstrate that smoke will be managed for the time necessary to evacuate the building. The analysis must prove that the smoke layer will be maintained above the highest unprotected opening to adjoining spaces, or 6 ft (1830 mm) above the highest floor level of exit access open to the atrium for a time equal to 1½ times the calculated egress time or 20 minutes, whichever is greater. (See the *Life Safety Code® Handbook* for additional details on atrium smoke control.) Where the system designers and the AHJ lack a documented agreement of the system's objectives and acceptance criteria, change orders following the system's installation can prove extremely costly.

11.8.2 Smoke-control systems shall have an approved maintenance and testing program to ensure operational integrity in accordance with this section. Components of such systems shall be operated, maintained, and tested in accordance with their operation and maintenance manuals.

11.8.2.1 Testing. Operational testing of the smoke-control system shall be in accordance with NFPA 92, and shall include all equipment related to the system including, but not limited to, initiating devices, fans, dampers, controls, doors, and windows.

11.8.2.1.1 An approved written schedule for such operational tests shall be established.

11.8.2.2 Test records shall be maintained on the premises and must indicate the date of such testing, the qualified service personnel, and any corrective measures needed or taken.

11.8.3 All smoke-control systems and devices shall be maintained in a reliable operating condition and shall be replaced or repaired where defective.

11.8.4 The AHJ shall be notified when any smoke-control system is out of service for more than 4 hours in a 24-hour period and again upon restoration of service of such systems.

11.8.5 The AHJ shall be permitted to require the building to be evacuated or an approved fire watch to be provided for all portions left unprotected by the fire protection system shutdown until the fire protection system has been returned to service.

11.9 Emergency Command Center

Where required, emergency command centers shall comply with Section 11.9.

11.9.1 The location, design, content, and fire department access of the emergency command center shall be approved by the fire department.

Approval by the fire department is required with regard to the location of, design of, and access to the emergency command center. As the primary user of the space, the fire department's input is important. The emergency command center should be easily accessible from the outside without requiring entrance into the building. The emergency command center can be either located in a room near an entrance or exit or accessible from outside the building.

11.9.2 The emergency command center shall be separated from the remainder of the building by a fire barrier having a fire resistance rating of not less than 1 hour.

11.9.3 New emergency command center rooms shall be a minimum of 200 ft² (19 m²) with a minimum dimension of 10 ft (3050 mm).

N **11.9.3.1** Existing emergency command center rooms shall be maintained with the minimum square footage and dimensions previously approved by the AHJ.

The emergency command center should be sized to accommodate all the equipment and supplies outlined in 11.9.4 and 11.9.5. It should also be large enough to provide fire department personnel with adequate room to work and store additional supplies required by the fire department. If the emergency command center is not large enough to store needed supplies, the room size should be increased or an additional room should be provided.

The minimum dimensions for the emergency command center have been revised for the 2018 edition of the *Code*. New emergency command centers are required to be a minimum of 200 ft² (19 m²). This change was for consistency with building code requirements. So that this change does not put an undue burden on existing emergency command centers that might not meet the minimum 200 ft² (19 m²) size, a new 11.9.3.1 has been added to address existing emergency command centers and to ensure that the square footage and dimensions of such centers are not reduced unless approved by the AHJ.

11.9.4 The following shall be provided in the emergency command center:

(1) The fire department communication unit
(2) A telephone for fire department use with controlled access to the public telephone system

(3) Schematic building plans indicating the typical floor plan and detailing the building core means of egress, fire protection systems, fire-fighting equipment, and fire department access
(4) Work table
(5) If applicable, hazardous material management plans for the building

11.9.5 Where otherwise required, the following devices or functions shall be provided within the emergency command center:

(1) The emergency voice/alarm communication system unit
(2) Fire detection and alarm system annunciator unit
(3) Annunciator visually indicating the location of the elevators and whether they are operational
(4) Status indicators and controls for air-handling systems
(5) Controls for unlocking stairway doors simultaneously
(6) Sprinkler valve and waterflow detector display panels
(7) Emergency and standby power status indicators
(8) Fire pump status indicators
(9) Generator supervision devices and manual start and transfer features
(10) Public address system, where specifically required by other sections of this *Code*
(11) Controls required for smoke control

The emergency command center gives the fire department access to valuable communication, control, and protection system annunciators. According to 11.9.1, the fire department must approve the design and layout of the emergency command center, including the layout of those devices and functions outlined in 11.9.4 and 11.9.5.

11.9.6 Emergency Command Center Acceptance Testing. Devices, equipment, components, and sequences shall be individually tested in accordance with appropriate standards and manufacturers' documented instructions.

The devices, equipment, controls, and other items installed or provided in the emergency command center need to be tested to ensure they function properly. Testing should be performed on the initial installation and at varying intervals as required by the AHJ or applicable standards.

11.10* Two-Way Radio Communication Enhancement Systems

A.11.10 Two-way radio communication enhancement systems provide for greater flexibility and safety for emergency responders during in-building operations.

11.10.1 In all new and existing buildings, minimum radio signal strength for fire department communications shall be maintained at a level determined by the AHJ.

11.10.2 Where required by the AHJ, two-way radio communication enhancement systems shall comply with NFPA 1221.

11.10.3 Where a two-way radio communication enhancement system is required and such system, components, or equipment has a negative impact on the normal operations of the facility at which it is installed, the AHJ shall have the authority to accept an automatically activated responder system.

The 2009 edition of *the Code* provided guidance on the design of two-way radio communication enhancement systems in Annex O. Annex O was deleted for the 2012 edition, because much of its criteria was incorporated into *NFPA 72®*, *National Fire Alarm and Signaling Code®*. For the 2012 edition of this *Code*, the mandatory reference to *NFPA 72* was added to Section 11.10 for enforcement where the AHJ determines that a building requires such a system to facilitate fire department communications in the building. For the 2018 edition, the reference to *NFPA 72* in Section 11.10.2 was replaced with a reference to NFPA 1221, *Standard for the Installation, Maintenance and Use of Emergency Services Communications Systems*. The 2016 edition of NFPA 1221 added requirements regarding two-way communications enhancement systems from NFPA 72.

Fire department radio systems might not operate properly where concrete and steel construction interfere with radio traffic. One means of enhancing fire department radio communication within a building is to install antennae and repeaters at strategic locations, typically called bi-directional amplifier systems. This method is often preferred by fire departments because it allows them to use their normal radio equipment and communication procedures within the building. See Exhibit 11.7 and Exhibit 11.8 for examples of two-way in-building radio communication enhancement systems.

Δ 11.11 Medical Gas and Vacuum Systems

Medical gas and vacuum systems shall comply with NFPA 99.

Section 11.11 references NFPA 99, *Health Care Facilities Code*, for medical gas and vacuum systems. NFPA 99 establishes criteria to minimize the hazards of fire, explosion, and electricity in health care facilities providing services to human beings. NFPA 99 defines the term *health care facilities* as "buildings, portions of buildings, or mobile enclosures in which medical, dental, psychiatric, nursing, obstetrical, or surgical care is provided."

Health care facilities as defined by NFPA 99 include, but are not limited to, hospitals, nursing homes, limited care facilities, clinics, medical and dental offices, and ambulatory health care centers, whether permanent or movable. This definition applies to normal, regular operations and does not pertain to facilities during declared local or national disasters. A health care facility is not a type of occupancy classification as defined by this *Code* or NFPA *101*. Therefore, the term *health care facility* should not be confused with the term *health care occupancy*. All health care occupancies (and ambulatory health care occupancies) are considered health care facilities; however, not all health care facilities are considered health care occupancies, since health care facilities also include ambulatory health care occupancies and business occupancies.

For additional details on medical gas and piping systems, refer to the *Medical Gas and Vacuum Systems Installation Handbook*, which includes the relevant portions of NFPA 99 as referenced by this *Code*.

11.12 Photovoltaic Systems

Many new and existing buildings are being provided with photovoltaic (PV) systems, which produce electrical power from sunlight but present unique hazards to building occupants and fire fighters. Such electrical systems carry voltages of up to 600 volts (dc) and currents of up to 8 amperes in residential applications. Exhibit 11.9 depicts a roof-mounted PV system. There is no way to isolate the power at the PV modules during daytime hours. Because of the life-threatening voltage and current, these systems pose significant risks to people on the roofs of buildings — particularly fire fighters conducting ventilation operations (among others) during fire suppression operations. PV system installations should take into consideration the tactics employed by the fire service by providing safe roof access and means for identification of the presence of a PV system. The provisions of Section 11.12 are intended to address fire fighter safety during fire suppression operations.

Section 11.12 is revised for the 2018 edition of the Code. The 2012 edition of NFPA 1 and the 2011 edition of *NFPA 70* contained matching requirements to aid emergency responders when interacting with live PV power systems. As the provisions were further developed, it was understood that the electrical requirements would be deleted from NFPA 1 and retained in *NFPA 70* as appropriate. First, the 2018 edition of this *Code* deletes the electrical provisions (existing 11.12.2.1) and replaces it with a new section establishing labeling requirements for the rapid shutdown markings for PV systems, which is within the scope of NFPA 1. Second, the existing provision for roof access (11.12.2.2) is replaced with updated provisions for roof access that include language for the AHJ to permit a reduction or modification to roof access based upon fire department ventilation procedures or alternative methods to ensure adequate fire department access, pathways, and smoke ventilation. Additional clarifications to ventilation options, pathway dimensions, and terminology are

Exhibit 11.9

Roof-mounted photovoltaic system. (Thinkstock) also included in the revisions. Third, 11.12.3 is updated to provide flexibility to the AHJ to enforce provisions appropriate to the scale of a ground-mounted PV installation. Where previous editions of the *Code* required a gravel base or other noncombustible base acceptable to the AHJ to be installed and maintained under and around all ground-mounted PV installations, the new provisions require a vegetation management plan or other noncombustible base acceptable to the AHJ be maintained under and around the installation only where required by the AHJ. The rate of ground-mounted PV system installations is increasing, but for many jurisdictions nationwide, this is still considered a new or first-time development. The risks and hazards also differ widely when the installation is ground mounted rather than rooftop mounted. As a result, many AHJs do not have much familiarity with large-scale ground-mounted installations, nor are they as familiar with applying the appropriate interpretations when the *Code* does not clearly address this topic.

Another impacting concern is the environmental aspect. There are a variety of environmental factors considered as development and permitting challenges as ground-mount projects undergo environmental studies. Environmental requirements that would directly conflict with the literal requirement for only gravel or noncombustible bases underneath the system installation include, but are not limited to:

- Dust control (air)
- Water usage limitations in dry areas (water)
- Logistics to transport/haul/lay gravel (water/sustainability/air emissions)
- Native revegetation (flora)
- Natural habitat preservation (flora/fauna)

A project plan requiring a "noncombustible" or gravel base for a large-scale PV installation would never be permitted because of these reasons. All project permits for large PV installations require minimally invasive surface preparation techniques and natural vegetation recruitment or revegetation to greater or lesser extents during the operation of the power plant as a default requirement.

11.12.1 Photovoltaic systems shall be in accordance with Section 11.12 and *NFPA 70*.

11.12.2 Building-Mounted Photovoltaic Installations.

11.12.2.1* Marking. Photovoltaic systems shall be permanently marked as specified in this subsection.

A.11.12.2.1 Marking is needed to provide emergency responders with appropriate warning and guidance with respect to working around and isolating the solar electric system. This can facilitate identifying energized electrical lines that connect the solar modules to the inverter, which should not be cut when venting for smoke removal during fire-fighting operations.

• *N* **11.12.2.1.1* Rapid Shutdown Marking.** Buildings with a PV system shall be provided with permanent labels as described in 11.12.2.1.1.1 through 11.12.2.1.1.7.

N **A.11.12.2.1.1** To clarify what the labels described in the text of 11.12.2.1.1 should look like, this annex information provides a pictorial depiction of the sign to be similarly replicated for compliance with 11.12.2.1.1. Figure A.11.12.2.1.1(a) depicts the sign required by 11.12.2.1.1.1. Figure A.11.12.2.1.1(b) depicts the sign required by 11.12.2.1.1.2.

N **11.12.2.1.1.1 Rapid Shutdown Type.** The type of PV system rapid shutdown shall be labeled as described in 11.12.2.1.1.1.1 or 11.12.2.1.1.1.2.

N **11.12.2.1.1.1.1** For PV systems that shut down the array and conductors leaving the array:

EMERGENCY RESPONDER:
THIS SOLAR PV SYSTEM IS EQUIPPED
WITH RAPID SHUTDOWN

TURN RAPID SHUTDOWN SWITCH TO THE "OFF"
POSITION TO SHUT DOWN ENTIRE PV SYSTEM

N **11.12.2.1.1.1.2** For PV systems that only shut down conductors leaving the array:

EMERGENCY RESPONDER:
THIS SOLAR PV SYSTEM IS EQUIPPED
WITH RAPID SHUTDOWN

TURN RAPID SHUTDOWN SWITCH TO
THE "OFF" POSITION.
ONLY CONDUCTORS INSIDE BUILDING OR
OFF THE ROOF WILL SHUT DOWN

N **11.12.2.1.1.2** The label shall be reflective, with all letters capitalized and having a minimum height of ⅜ in. (9.5 mm), in white on a red background.

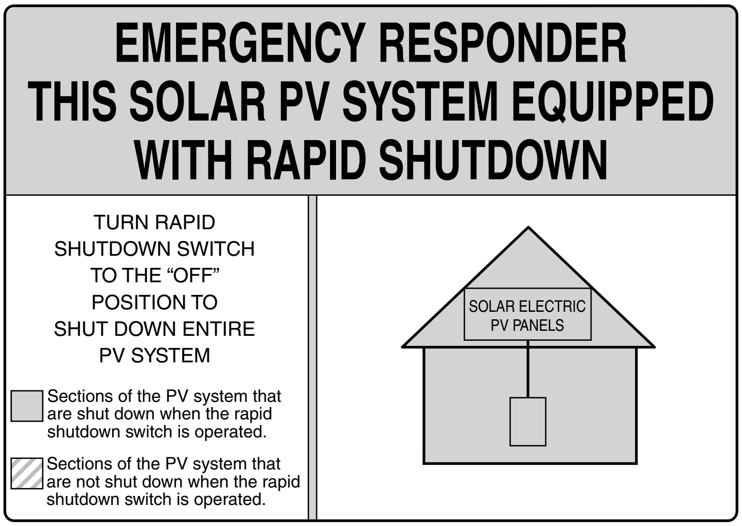
N **11.12.2.1.1.3** The label shall include a simple diagram of a building with a roof. Diagram sections in red shall signify sections of the PV system that are not shut down when the rapid shutdown switch is operated. Sections of the diagram in green shall signify sections of the PV system that are shut down when the rapid shutdown switch is operated.

N **11.12.2.1.1.4** The rapid shutdown label shall be located on or no more than 3 ft (1 m) from the service disconnecting means to which the PV systems are connected, and the label shall indicate the location of the rapid shutdown switch if it is not at the same location.

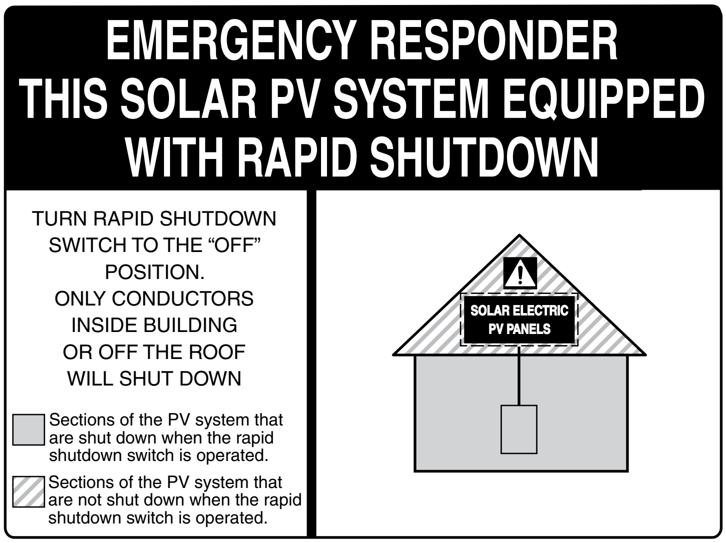
N **11.12.2.1.1.5 Buildings with More Than One Rapid Shutdown Type.** For buildings that have PV systems with both rapid shutdown types, or a rapid shutdown type and a PV system with no rapid shutdown, a detailed plan view diagram of the roof shall be provided showing each PV system and a dotted line around areas that remain energized after the rapid shutdown switch is operated.

N **11.12.2.1.1.6 Rapid Shutdown Switch.** The rapid shutdown switch shall have a label located on or no more than 3 ft (1 m) from the switch that includes the following words:

RAPID SHUTDOWN SWITCH FOR SOLAR PV SYSTEM



Δ *FIGURE A.11.12.2.1.1(a) Sign Required by 11.12.2.1.1.1.*



Δ *FIGURE A.11.12.2.1.1(b) Sign Required by 11.12.2.1.1.2.*

N **11.12.2.1.1.7** The label required by 11.12.2.1.1.6 shall be reflective, with all letters capitalized and having a minimum height of ⅜ in. (9.5 mm), in white on red background. [***70:***690.56(C)]

N **11.12.2.1.2** Each PV system disconnecting means shall be permanently marked to identify it as a PV system disconnect and shall indicate whether in the open or closed position. [***70:***690.13(B)]

N **11.12.2.1.3 Markings for Direct-Current Photovoltaic Source and Direct-Current Output Circuits on or Inside a Building.** The following wiring methods and enclosures that contain PV power source conductors shall be marked with the words WARNING: PHOTOVOLTAIC POWER SOURCE by means of permanently affixed labels or other approved permanent marking:

(1) Exposed raceways, cable trays, and other wiring methods
(2) Covers or enclosures of pull boxes and junction boxes
(3) Conduit bodies in which any of the available conduit openings are unused

[***70:***690.31(G)(3)]

N **11.12.2.1.3.1 Marking Locations and Methods.** The labels or markings shall be visible after installation. The labels shall be reflective and shall have all letters capitalized with a minimum height of ⅜ in. (9.5 mm) white on red background. PV power circuit labels shall appear on every section of the wiring system that is separated by enclosures, walls, partitions, ceilings, or floors. Spacing between labels or markings, or between a label and a marking, shall not be more than 10 ft (3 m). Labels required by this section shall be suitable for the environment where they are installed. [*70:*690.31(G)(4)]

N **11.12.2.1.4 Secondary Power Source Markings.** A permanent plaque or directory, denoting all electric power sources on or in the premises, shall be installed at each service equipment location and at locations of all electric power production sources capable of being interconnected. [*70:*705.10]

N **11.12.2.1.5 Installer Information.** A label shall be installed adjacent to the main disconnect indicating the name and emergency telephone number of the company currently servicing the PV system.

•

N **11.12.2.2 Roof Access.**

N **11.12.2.2.1 General.** Access and spacing requirements shall be required to provide emergency access to the roof, provide pathways to specific areas of the roof, provide for smoke ventilation opportunity areas, and to provide emergency egress from the roof. The AHJ shall be permitted to reduce or modify roof access based upon fire department ventilation procedures or alternative methods that ensure adequate fire department access, pathways, and smoke ventilation.

N **11.12.2.2.2 One- and Two-Family Dwellings and Townhouses.** Photovoltaic systems installed in one- and two-family dwellings and townhouses shall provide roof access in accordance with 11.12.2.2.2. Designation of ridges shall not apply to roofs with 2 in 12 or less pitch.

N **11.12.2.2.2.1 Pathways.** Not less than two 36 in. (914 mm) wide pathways on separate roof planes, from gutter to ridge, shall be provided on all buildings. One pathway shall be provided on the street or driveway side of the roof. For each roof plane with a PV array, a 36 in. (914 mm) wide pathway from gutter to ridge shall be provided on the same roof plane as the PV array, on an adjacent roof plane or straddling the same and adjacent roof planes. Pathways shall be located in areas with minimal obstructions such as vent pipes, conduit, or mechanical equipment.

N **11.12.2.2.2.2** For PV arrays occupying up to 33 percent of the plan view roof area, a minimum 18 in. (457 mm) pathway shall be provided on either side of a horizontal ridge. For PV arrays occupying more than 33 percent of the plan view roof area, a minimum of 36 in. (914 mm) pathway shall be provided on either side of a horizontal ridge.

N **11.12.2.2.2.3 Buildings Other Than One- and Two-Family Dwellings and Townhouses.** Photovoltaic systems installed on any building other than one- and two-family dwellings and townhouses shall provide roof access in accordance with 11.12.2.2.2.3. Where the AHJ determines that the roof configuration is similar to a one- and two-family dwelling or townhouse, the AHJ shall allow the roof access requirements of 11.12.2.2.2. Detached, nonhabitable structures including, but not limited to, parking shade structures, carports, solar trellises, and similar structures shall not be required to provide roof access.

N **11.12.2.2.2.3.1 Perimeter Pathways.** A minimum 4 ft (1219 mm) wide perimeter pathway shall be provided around the edges of the roof for buildings with a length or width of 250 ft (76.2 m) or less along either axis. A minimum 6 ft (1829 mm) wide perimeter pathway shall be provided around the edges of the roof for buildings having length or width greater than 250 ft (76.2 m) along either axis.

N **11.12.2.2.2.3.2 Other Pathways.** Pathways shall be over areas capable of supporting fire fighters accessing the roof and shall be provided between array sections as follows:

(1) Pathways shall be provided in a straight line 48 in. (1219 mm) or greater in width to all ventilation hatches, and roof standpipes.
(2) Pathways shall be provided 48 in. (1219 mm) or greater in width around roof access hatches with at least one 48 in. (1219 mm) or greater in width pathway to the parapet or roof edge.
(3) Pathways shall be provided at intervals no greater than 150 ft (46 m) throughout the length and width of the roof.

N **11.12.2.2.2.3.3 Smoke Ventilation.** A pathway shall be provided 48 in. (1219 mm) or greater in width bordering all sides of nongravity-operated smoke and heat vents. Ventilation options between array sections shall be one of the following:

(1) A pathway 96 in. (2438 mm) or greater in width
(2) A pathway 48 in. (1219 mm) or greater in width and bordering on existing roof skylights or gravity-operated dropout smoke and heat vents on not less than one side
(3) A pathway 48 in. (1219 mm) or greater in width and bordering 48 in. (1219 mm) by 96 in. (2438 mm) venting cutouts options every 20 ft (6096 mm)

N **11.12.2.2.2.3.4 Minimizing Obstructions in Pathways.** Pathways shall be located in areas with minimal obstructions such as vent pipes, conduit, or mechanical equipment to reduce trip hazards and maximize ventilation opportunities.

11.12.3 Ground-Mounted Photovoltaic System Installations. Ground-mounted photovoltaic systems shall be installed in accordance with 11.12.3.1 through 11.12.3.3.

11.12.3.1* Clearances. A clear area of 10 ft (3048 mm) around ground-mounted photovoltaic installations shall be provided.

A.11.12.3.1 The zoning regulations of the jurisdiction setback requirements between buildings or property lines, and accessory structures may apply.

11.12.3.2* Vegetation Management Plan. A vegetation management plan or noncombustible base acceptable to the AHJ shall be approved and maintained under and around the installation where required by the AHJ.

A.11.12.3.2 Though dirt with minor growth is not considered noncombustible, the AHJ might approve dirt bases as long as any growth is maintained under and around the installation to reduce the risk of ignition from the electrical system. This could be a serious consideration for large ground-mounted photovoltaic systems. Not only should the base be considered under the systems, but also around the systems to the point that the risk of fire from growth or other ignition sources will be reduced.

11.12.3.3* Security Barriers. Fencing, skirting, or other suitable security barriers shall be installed when required by the AHJ.

A.11.12.3.3 Security barriers are intended to protect individuals and animals from contact with energized conductors or other components.

Features of Fire Protection

12

Chapter 12 discusses features of fire protection and addresses the topics of construction types, fire-resistive materials and construction, fire doors and other opening protectives, interior finish, contents and furnishings, fire barriers, smoke partitions, and smoke barriers.

12.1 General

This chapter shall apply to new, existing, permanent, or temporary buildings.

12.2* Construction

A.12.2 Table A.12.2 provides a cross reference from the NFPA construction types to the model building codes.

Δ **12.2.1*** Where required by this *Code*, a type of building construction shall comply with NFPA 220.

Δ **A.12.2.1** Building construction types are defined in NFPA 220. The following material is extracted verbatim from NFPA 220 and is included here as a convenience for users of this *Code*. Any requests for Formal Interpretations (FIs) or Tentative Interim Amendments (TIAs) on the following material should be directed to the Technical Committee on Building Construction. See Table A.12.2.1 for fire resistance ratings for each building construction type.

Type I and Type II Construction. Type I (442 or 332) and Type II (222, 111, or 000) construction shall be those types in which the fire walls, structural elements, walls, arches, floors, and roofs are of approved noncombustible or limited-combustible materials. [**220:**4.3.1]

Type III Construction. Type III (211 or 200) construction shall be that type in which exterior walls and structural elements that are portions of exterior walls are of approved noncombustible or limited-combustible materials, and in which fire walls, interior structural elements, walls, arches, floors, and roofs, are entirely or partially of wood of smaller dimensions than required for Type IV construction or are of approved noncombustible, limited-combustible, or other approved combustible materials. [**220:**4.4.1]

Type IV Construction. Type IV (2HH) construction shall be that type in which fire walls, exterior walls, and interior bearing walls and structural elements that are portions of such walls are of approved

[b]See *NFPA 5000,* Section 7.3.

[c]See 4.3.2.12, 4.4.2.3, and 4.5.6.8 of NFPA 220.

[**220:** Table 4.1.1]

noncombustible or limited-combustible materials, except as allowed for exterior walls in 4.5.6.7 of NFPA 220. Other interior structural elements, arches, floors, and roofs shall be of solid or laminated wood or cross-laminated timber without concealed spaces or with concealed spaces conforming to 4.5.4 of NFPA 220 and shall comply with the allowable dimensions of 4.5.5 of NFPA 220. [**220:**4.5.1]

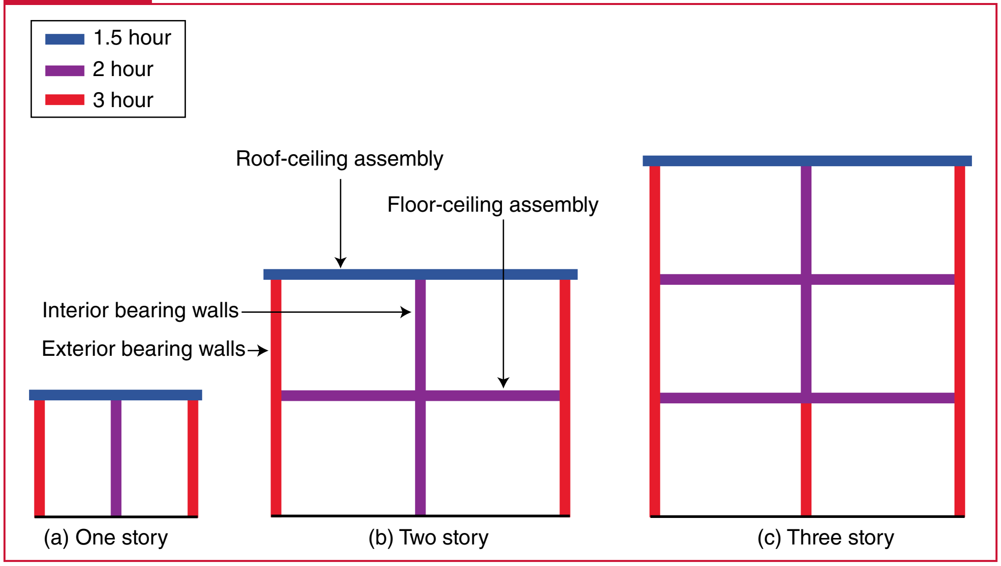
Type V (111 or 000) Construction. Type V (111 or 000) construction shall be that type in which structural elements, walls, arches, floors, and roofs are entirely or partially of wood or other approved material. [**220:**4.6]

NFPA 220, *Standard on Types of Building Construction*, is the reference document used throughout this *Code* to define specific types of building construction.

Table A.12.2.1 identifies the minimum fire resistance rating of certain building components. Typically the shorthand notation, such as Type I (332), provides the minimum hourly fire resistance ratings required to meet the definition of that construction type for three components of the building — exterior bearing walls, structural frame/columns/girders, and floor construction. In the example of Type I (332) construction, the exterior bearing walls would have a 3-hour fire resistance rating, the structural frame/columns/girders, and floor construction would have a 3-hour fire resistance rating, and the floor construction would have a 2-hour fire resistance rating. To fully meet the construction type, other building components, such as roof construction and interior bearing walls, need to meet the minimum fire resistance ratings outlined in Table A.12.2.1. Occasionally the required fire resistance rating may be less than the shorthand notation states if the building element supports just the roof, or one floor only. Exhibit 12.1 shows how to use the table and how fire resistance rating requirements can vary depending on what the building component supports.

The three parts of Exhibit 12.1 are examples of requirements for a Type I (332) building. The first step in evaluating the

Exhibit 12.1



Examples of requirements for a Type I (332) building.

required fire resistance rating is to determine what the building element supports. For many components Table A.12.2.1 lists three different options, "supporting a roof only," "supporting one floor only," "supporting more than one floor, columns, or other bearing walls." Typically, the building elements on the top floor of a building will fall into the "supporting a roof only" category. Those building elements on the floor below the top floor will fall into the "supporting one floor only" category, and everything below that would fall into the "supporting more than one floor, columns, or other bearing walls" category.

Part (a) of Exhibit 12.1 shows a one-story building of Type I (332) construction. Since there are no additional floors, all building components are supporting the roof only. To determine the required fire resistance rating of the columns for a Type I (332) construction type, follow the bottom row ("supporting roof only") of the "Columns" section, over to where it intersects with the row for Type I (332) construction. At the intersection point, there is a 2. This means that the columns would only require a 2-hour fire resistance rating. Following the same procedure for the exterior bearing walls, we find that a 3-hour fire resistance rating would be required even when those walls only support the roof.

Part (b) shows a two-story building of Type I (332) construction. To determine the fire resistance rating for the interior bearing walls on the bottom floor, you would look at the middle row, "Supporting one floor only," under the "Interior Bearing Walls" section. There, you would find that a 2-hour fire resistance rating is required. The 2-hour fire resistance rating also applies to the interior bearing walls on the top floor, where the walls are only supporting the roof.

Part (c) shows a three-story building of Type I (332) construction. To determine the fire resistance rating for the interior bearing walls on the bottom floor, you would look at the top row ("Supporting more than one floor, columns, or other bearing walls") under the "Interior Bearing Walls" section. Following the row over to Type I (332) we find that a 3-hour fire resistance rating is required. The interior bearing walls on the second floor would only require a 2-hour fire resistance rating since they are supporting one floor only. The interior bearing walls on the top floor would also only require a 2-hour fire resistance rating. Another useful reference is the "Guideline on Fire Ratings of Archaic Materials and Assemblies," which is Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*. This annex can assist in the determination of the fire resistance ratings of materials used in older construction.

Exhibit 12.2 shows some examples of different construction types. Part (a) shows an example of Type I construction which is typically associated with concrete and steel structures. An example of Type II construction is shown in part (b). Type III construction is a mixture of masonry and wood construction. Type II is typically made of steel and may or may not have fireproofing. Part (c) shows an example of Type III construction which usually consists of masonry exterior walls and a wood interior and roof. Type IV construction is sometimes referred to as "heavy timber" or "mass timber" construction. Typically, it is constructed of large wood beams similar to old mill building construction. Part (d) shows an example of Type IV construction. Type V construction, or "stick-built" construction is made of combustible materials, usually dimensional lumber. Part (e) shows an example of Type V construction.

12.2.2 Fire safety construction features for new and existing occupancies shall comply with this *Code* and the referenced edition of NFPA *101*.

Subsection X.1.6 of each occupancy chapter in NFPA *101*®, *Life Safety Code*®, where X is the applicable occupancy chapter number, specifies the minimum type of construction for those occupancy classifications that regulate construction type. For example, construction is regulated in assembly and health care occupancies because the construction serves as a life safety feature — the building must remain structurally stable during a fire to allow for extended evacuation times in the case of assembly occupancies and the defend-in-place strategy associated with health care occupancies. Other occupancies, such as business and residential occupancies, specify no minimum construction types because it is assumed that occupants will quickly evacuate upon notification of a fire in the building.

NFPA *101* also requires other construction features, such as protection of vertical openings and protection of hazards. Other referenced codes and standards might also require specific construction types or features.

12.3 Fire-Resistive Materials and Construction

Δ **12.3.1** The design and construction of fire walls and fire barrier walls that are required to separate buildings or subdivide a building to prevent the spread of fire shall comply with Section 12.3 and NFPA 221.

NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls,* prescribes minimum requirements for the design and construction of high challenge fire walls, fire walls, and fire barrier walls for use in providing safety to life and protection of property from fire. These requirements apply to walls that are required to separate buildings or subdivide a building to prevent the spread of fire. The minimum fire resistance rating of a wall assembly is outside the scope of NFPA 221. This *Code* and referenced codes and standards might require the installation of a fire wall or fire barrier wall for a specific application. High challenge fire walls are not specifically required by the *Code*. It is up to the designer/engineer to determine when a fire wall needs to be a high challenge fire wall. The intended use of a high challenge fire wall is in areas where an explosion is expected. The additional requirements for a high challenge fire wall allow it to remain stable after a structural collapse due to fire on either side of the wall. NFPA 221 provides the requirements necessary to evaluate the design and construction of high challenge fire walls, fire walls, and fire barrier walls.

12.3.2* Quality Assurance for Penetrations and Joints. In new buildings three stories or greater in height, a quality assurance program for the installation of devices and systems installed to protect penetration and joints shall be prepared and monitored by the RDP responsible for design. Inspections of firestop systems and fire-resistive joint systems shall be in accordance with 12.3.2.1 and 12.3.2.2.

Δ **A.12.3.2** The scoping provision of 12.3.2 is extracted from *NFPA 5000*, but limited to new buildings that are three or more stories in height. Such threshold is reasonable from the fire inspection perspective.

12.3.2.1 Inspection of firestop systems of the types tested in accordance with ASTM E814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*, or /UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*, shall be conducted in accordance with ASTM E2174, *Standard Practice for On-Site Inspection of Installed Fire Stops*. [***5000:***40.9.1]

12.3.2.2 Inspection of fire-resistive joint systems of the types tested in accordance with ASTM E1966, *Standard Test Method for Fire-Resistive Joint Systems*, or UL 2079, *Standard for Tests for Fire Resistance of Buildings Joint Systems*, shall be conducted in accordance with ASTM E2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*. [***5000:***40.9.2]

Quality assurance for the proper design, installation, and inspection of through-penetrations and joint systems in fire walls and fire barrier walls is critically important to controlling fire spread in multistory buildings. The provisions of 12.3.2, which are extracted from *NFPA 5000®*, *Building Construction and Safety Code®*, mandate the establishment of a quality assurance program for such penetrations and joint systems in new buildings. The authority having jurisdiction (AHJ) should verify that inspections are conducted in accordance with the standards mandated by 12.3.2.1 and 12.3.2.2. Such inspections should occur before any penetrations or joint systems, for example, above a gypsum board ceiling, are permanently concealed.

12.3.3* Maintenance of Fire-Resistive Construction, Draft-Stop Partitions, and Roof Coverings.

A.12.3.3 Fire-resistive construction also includes fire-resistive coatings and sprayed fire-resistive materials, as well as membrane and through-penetration firestops and fire-resistive joint systems. It is important to conduct periodic inspections of fire-resistive construction, especially these elements and components that are directly visible or readily accessible for inspection.

Inspections of sprayed fire-resistive materials and coatings are especially important since they can be subject to delamination, removal, physical abuse, deterioration, and degradation over time. Periodic inspections should be able to identify apparent deficiencies, especially where they crumble or fall off when touched. When such conditions are identified, they should be further inspected or tested by qualified third parties to verify their integrity and effectiveness. Where they are found to be deficient, appropriate corrective action should be taken to restore them to their original condition.

Tested and listed firestop systems should be installed to the listing in order to perform as expected. Systems installed in accordance with an engineering judgment (EJ) should be installed in accordance with the EJ. The firestop systems should be inspected periodically to assure continued performance. To inspect firestops, the listed system design or EJ should be accessible. Firestop installations are only able to be identified by the listing design, the listing references, the materials to be used, and installation parameters. Without the listing, neither the inspector, building owner, nor building management company has any idea how to inspect or repair the firestop systems.

Firestop systems can be marked at the location of the installation using a variety of methods from paper labels to complex plastic tear-away labels, ceramic fiber, or metal tags. These can be attached to the assembly or to the penetrating item(s). A variety of marking methods can be used and they should provide important information, such as the listing number, date, manufacturer, and installing contractor.

12.3.3.1 Required fire-resistive construction, including fire barriers, fire walls, exterior walls due to location on property, fire-resistive requirements based on type of construction, draft-stop partitions, and roof coverings, shall be maintained and shall be properly repaired, restored, or replaced where damaged, altered, breached, penetrated, removed, or improperly installed.

Returning any damaged fire resistance–rated construction to its original condition is important. Damage or breaches to such materials or the creation of unprotected penetrations through them reduces or eliminates their fire-resistive characteristics, making them ineffective in the event of a fire. Inspectors should ensure that fire resistance–rated construction is maintained. Damage might not always be obvious, because penetrations and breaches sometimes occur above ceilings. Therefore, areas above ceilings must be carefully inspected where such areas can be accessed without damaging the building. See 1.7.13 for additional guidance.

Exhibit 12.3 illustrates cable penetrations through a fire barrier.

12.3.3.2 Where required, fire-rated gypsum wallboard walls or ceilings that are damaged to the extent that through openings exist, the damaged gypsum wallboard shall be replaced or returned to the required level of fire resistance using a listed repair system or using materials and methods equivalent to the original construction.

Where holes exist in gypsum wallboard, the damaged sections must be replaced or, if possible, repaired in an approved manner with a listed material or system.

Exhibit 12.3

Cable penetrations through a fire barrier.

12.3.3.3 Where readily accessible, required fire-resistance-rated assemblies in high-rise buildings shall be visually inspected for integrity at least once every 3 years.

12.3.3.3.1 The person responsible for conducting the visual inspection shall demonstrate appropriate technical knowledge and experience in fire-resistance-rated design and construction acceptable to the AHJ.

12.3.3.3.2 A written report prepared by the person responsible for conducting the visual inspection shall be submitted to the AHJ documenting the results of the visual inspection.

The fire resistance of high-rise building structural components is of paramount importance for building occupants and fire fighters, given the potential for prolonged evacuation times. The requirements of 12.3.3.3 mandate visual inspections of readily accessible structural components every 5 years to ensure that the fire resistance has not been diminished due to construction projects, environmental conditions, or any other reason. The AHJ should periodically review the inspection reports provided by the owner to verify the qualifications of the inspectors and to ensure that, where any issues were located, they were properly remedied.

12.4 Fire Doors and Other Opening Protectives

Δ **12.4.1*** The installation and maintenance of assemblies and devices used to protect openings in walls, floors, and ceilings against the spread of fire and smoke within, into, or out of buildings shall comply with Section 12.4 and NFPA 80. [**80:**1.1]

A.12.4.1 See Annex K of NFPA 80 for general information about fire doors. [**80:**A.1.1]

New installations of fire doors and fire windows should be in accordance with NFPA 80, *Standard for Fire Doors and Other Opening Protectives*. Chapter 5 of NFPA 80 covers the care and maintenance of new and existing fire doors and fire windows.

12.4.2* With the exception of fabric fire safety curtain assemblies, Section 12.4 addresses assemblies that have been subjected to standardized fire tests. *(See Chapter 20 of* NFPA 80.*)* [**80:**1.1.1]

A.12.4.2 No fire test standard requirement currently exists to which fabric fire safety curtain assemblies can be tested. Only the curtain fabric is tested in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. The perimeter and internal framework and all supporting, guide, and operating components used in specific applications are not tested. Variations in size of proscenium openings and the amount of side and head clearances available for individual stages dictate the number of variations in design of the assemblies. [**80:**A.1.1.1]

12.4.3* Incinerator doors, record room doors, and vault doors are not covered in Section 12.4. [**80:**1.1.2]

Δ **A.12.4.3** For requirements on their installation, see NFPA 82 and NFPA 232. [**80:**A.1.1.2]

NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment,* addresses fire doors on incinerators and waste handling systems. NFPA 232, *Standard for the Protection of Records*, addresses fire doors for record rooms and vaults.

12.4.4* Requirements for horizontally sliding, vertically sliding, and swinging doors as used in this *Code* do not apply to hoistway doors for elevators and dumbwaiters. [**80:**1.1.3]

A.12.4.4 For requirements on the installation of hoistway doors for elevators and dumbwaiters, see the applicable sections of ASME A17.1 CSA B44-2010, *Safety Code for Existing Elevators and Escalators*, or ASME A17.3/CSA B44-13, *Safety Code for Existing Elevators and Escalators*. [**80:**A.1.1.3]

12.4.5* Section 12.4 shall not cover fire resistance glazing materials and horizontally sliding accordion or folding assemblies fabricated for use as walls and tested as wall assemblies in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. [**80:**1.1.4]

Δ **A.12.4.5** The fire performance evaluation of these assemblies is tested in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, for horizontal access doors, NFPA 252 for fire doors and shutters, NFPA 257 for fire windows and glass block, and NFPA 288 for doors in horizontal fire-rated assemblies. It is not the intent of this section to establish the degree of protection required or to constitute the approval of any product. These are determined by the AHJ. [**80:**A.1.1.4]

Currently doors and windows are being used that are tested and listed in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials,* as wall assemblies. When evaluating fire doors and fire windows, the listing obtained from the testing laboratory should be carefully reviewed to ensure compliance with the applicable requirements.

12.4.6 Care and Maintenance of Fire Doors and Other Opening Protectives.

12.4.6.1 Subsection 12.4.6 shall cover the inspection, testing, and maintenance of fire doors, fire shutters, fire windows, and opening protectives other than fire dampers and fabric fire safety curtains. [**80:**5.1.1.1]

N **12.4.6.2** The requirements of Section 12.4 shall apply to new and existing installations. [**80:**5.1.1.2]

NFPA 80 is an installation standard and is applicable to new installations. It is not intended to be applied retroactively. The exception to that rule is Chapter 5, which is applicable to new *and* existing installations. One very important point regarding

Chapter 5 is that older fire door assemblies need to be inspected with the code requirements that were applicable at the time of installation. It is not the intent that existing installations meet the provisions for new installations, unless the AHJ has determined that the existing situation involves a distinct hazard to life or property. For example, for many years, ¼ in. (6.35 mm) clear wire glass was the only type of glazing material permitted to be installed in fire doors. Today, however, ¼ in. (6.35 mm) clear wire glass is severely restricted as to where it can be used, due to the invention of newer and better fire-rated glazing products. When older fire doors are inspected, inspectors should not cite the presence of ¼ in. (6.35 mm) wire glass as a deficiency since that was permitted at the time of installation. On the other hand, if the clear wire glass is damaged and needs to be replaced, the replacement glazing material needs to comply with the edition of NFPA 80 that is enforced at the time of replacement.

12.4.6.3 Operability.

12.4.6.3.1 Doors, shutters, and windows shall be operable at all times. [**80:**5.1.2.1]

Paragraph 12.4.6.3.1 requires that fire doors, shutters, and windows be operable throughout the life of their installation, which is why the provisions of Chapter 5 of NFPA 80 are applicable to new and existing assemblies. Operability includes opening, closing, and, where required, latching in the closed position, as specified elsewhere in NFPA 80. Fire doors, shutters, and windows are not required to be operable after exposure to the elevated temperatures of a fire, but will require replacement.

12.4.6.3.2 Doors, shutters, and windows shall be kept closed and latched or arranged for automatic closing. [**80:**5.1.2.2]

N **12.4.6.3.3 Prevention of Door Blockage.**

The subparagraphs of 12.4.6.3.3 require the area leading to and away from door openings to be unobstructed and clear of anything (e.g., furniture, boxes, and other equipment) that might prevent doors from opening and closing. Swinging door leaves need to move freely to their full open and closed positions. In applications where materials and equipment might interfere with sliding doors, barriers need to be constructed to ensure that the doors are free to open and close. Blocking or wedging doors in the open position is expressly prohibited by 12.4.6.3.3.3. Kickdown door stops and wood/rubber wedges used to hold open swinging fire doors are frequently cited by AHJs as code violations.

N **12.4.6.3.3.1** Door openings and their surrounding areas shall be kept clear of anything that could obstruct or interfere with the free operation of the door. [**80:**5.1.2.3.2]

N **12.4.6.3.3.2** Where necessary, a barrier shall be built to prevent the piling of material against sliding doors. [**80:**5.1.2.3.2]

N **12.4.6.3.3.3** Blocking or wedging of doors in the open position shall be prohibited. [**80:**5.1.2.3.3]

12.4.6.4 Replacement. Where it is necessary to replace fire doors, shutters, windows or their frames, glazing materials, hardware, and closing mechanisms, replacements shall meet the requirements for fire protection and shall be installed and tested as required by this section for new installations. [**80:**5.1.3]

When fire door assemblies need new components (e.g., hinges, rollers, closing devices, glass, and latching hardware) or complete replacement, the new items must comply with the requirements for new installations. Paragraph 12.4.6.4 applies directly to provisions and requirements of 12.4.6.11, Maintenance.

N **12.4.6.5 Field Labeling.**

The requirements in 12.4.6.5.1 through 12.4.6.5, which cover field labeling of existing fire doors, shutters, and windows, were new to the 2016 edition of NFPA 80. Nationally recognized testing laboratories (e.g., Underwriters Laboratories, Intertek/Warnock Hersey, and FM Global) have offered field labeling services for installed assemblies for many years.

Field labeling is used to replace labels on door frames and doors where the original labels have been painted over, removed, or incorrectly labeled or where modifications have been made to the door frames or doors. Previous editions of NFPA 80 did not address the long-standing industry practice of field labeling.

Paragraph 12.4.6.5.3 lists the minimum information to be printed on the field labels for fire doors and fire door frames.

Paragraphs 12.4.6.5.4 and 12.4.6.5.6 cover situations concerning converting non–fire-rated assemblies into fire-rated assemblies. Paragraph 12.4.6.5.4 requires modifications to non–fire-rated door assemblies to be completed in compliance with 12.4.6.6. In these cases, the manufacturer of the modified component(s) will need to seek approval from one of the nationally recognized testing laboratories. Most likely, that testing lab will follow up the modifications with a field inspection to confirm that the work resulted in creating a fire-rated door assembly and, where the modifications comply with NFPA 80 and the respective manufacturer's published listings, the testing lab will field label the modified assemblies.

Paragraph 12.4.6.5.6 applies to all the fire door assemblies covered in NFPA 80, with the possible exception of swinging doors with builders hardware, which are covered in Chapter 6. Unlike the other types of fire door assemblies, swinging doors with builders hardware are component-based systems; each component is required to be labeled or listed. Because they are component-based systems, converting non–fire-rated assemblies into fire-rated assemblies could be accomplished by replacing door leaves with ones that are labeled and, where necessary, upgrading hardware components — provided door frames are labeled or capable of being labeled. Where existing door frames are not capable of being labeled, replacing entire assemblies is necessary.

Other types of door assemblies are unit-based systems, and the label on the door covers the entire assembly. For example, the label on the curtains of rolling steel fire doors covers the curtain, tracks, guides, rollers, cables, fusible links, pulleys, springs, hoods, and all other components. Consequently, converting non–fire-rated unit-based door assemblies such as these is not possible and requires new fire-rated door assemblies to be installed in their stead.

N **12.4.6.5.1** Field labeling shall be performed only by individuals or companies that have been certified or listed, or by individuals or companies that are representatives of a labeling service that maintains periodic inspections of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner. [**80:**5.1.4.1]

N **12.4.6.5.2** Individuals performing the service shall provide proof of qualifications to the authority having jurisdiction prior to performing work, as described in 12.4.6.5.1. [**80:**5.1.4.2]

N **12.4.6.5.3** At a minimum, field labels shall contain the following information:

(1) The words "field inspected" or "field labeled"
(2) The words "fire door" or "fire door frame"
(3) The marking of a third-party certification agency
(4) The fire protection rating
(5) A unique serial number (if provided by the listing agency)
(6) The fire test standard designation to which the assembly was tested

[**80:**5.1.4.3]

N **12.4.6.5.4** Field modifications shall not be permitted to be made to a non-fire-rated door assembly to achieve a fire rating unless the field modification is completed under label service. [**80:**5.1.4.4]

N **12.4.6.5.5** Doors in which a field modification in accordance with 5.1.4.4 has been completed shall be labeled. [**80:**5.1.4.5]

N **12.4.6.5.6** When an opening with a non-fire-rated door requires a fire door, the door assembly shall be replaced. [**80:**5.1.4.6]

12.4.6.6 Field Modifications.

Any work performed on fire door assemblies that requires drilling into or cutting material needs to be carefully considered beforehand. Chapter 4 of NFPA 80 explicitly identifies work that can be done in the field as part of the installation process. When the work about to be performed is not explicitly permitted by 4.1.3.2 through 4.1.3.2.5 of NFPA 80, the work falls under the category of a field modification and is subject to the requirements of 12.4.6.6 of this *Code*.

One of the main requirements to bear in mind is that each component attached to a swinging fire door with builders hardware needs to be labeled for use on fire door assemblies. For example, very few door contact switches are labeled and/or listed for use on swinging fire doors. Some models of contact switches require a round hole to be drilled into the rabbets of door frames that is larger than the 1 in. (25.4 mm) permitted in 4.1.3.2.2 and 4.1.3.2.3 of NFPA 80. Just as important, it needs to be confirmed with the manufacturer of the doors and frames that their specific products are listed for use with the components that are intended to be installed on them. Not all fire-rated components can be used together — some components are restricted to very specific applications.

The unfortunate reality is that the fire protection ratings of many swinging fire doors have been compromised in the field by the installation of electrified hardware and access control devices by persons who were not aware of the requirements before they modified the fire door assemblies. Inspections based on NFPA 80 will eventually find and correct these problems, but the costs for repairing or replacing the damaged door assemblies could be expensive.

One frequently asked question regards painting a door. Generally, fire doors are permitted to be painted by the facility/building owner. The one caveat to painting fire doors is that moving parts (e.g., hinges, latches, and door closer arms) need to be able to move freely. Layers of accumulated paint can inhibit the operation of such items and prevent door leaves from functioning properly. In those cases, the old layers of paint have to be removed to restore the moving parts to their proper operation. Paragraph 12.4.6.8.3.8 has a specific requirement regarding the accumulation of paint on moving parts.

12.4.6.6.1* In cases where a field modification to a fire door or a fire door assembly is desired and is not permitted by 4.1.3.2 through 4.1.3.42.5 of NFPA 80, the laboratory with which the product or component being modified is listed shall be contacted through the manufacturer and a written or graphic description of the modifications shall be presented to that laboratory. [**80:**5.1.5.1]

A.12.4.6.6.1 Field modifications beyond the scope of the prescriptive allowances permitted by 4.1.3.2 through 4.1.3.42.5 of NFPA 80 typically result in voiding the fire rating of the assembly. Paragraph 5.1.4.1 of NFPA 80 provides an alternative method whereby proposed modifications can be documented and presented to the labeling agency prior to work commencing. Where the proposed modification(s) are within the parameters of the manufacturer's procedures and will not degrade the fire resistance of the assembly, the labeling agency is permitted to authorize such modifications without a requirement for a subsequent field inspection. [**80:**A.5.1.4.1]

Generally, the replacement of hardware components on swinging doors (hinges, pivots, door closers, etc.) is not considered to be a field modification, provided the replacement hardware does not require additional cutting, mortising, or boring into the doors and frames and the hardware meets the criteria specified elsewhere in NFPA 80. Likewise, the installation of surface-mounted items like protection plates is not considered to be field modifications. Cutting doors for vision panels, enlarging existing cutouts for vision panels, and trimming doors in height or width are examples of field modifications. Similarly, installing hardware components that require additional cutting and mortising of the doors or frames are examples of field modifications.

12.4.6.6.2 Field modifications shall be permitted without a field visit from the laboratory upon written authorization from that laboratory. [**80:**5.1.5.2]

12.4.6.6.3 When the manufacturer is no longer available, the laboratory shall be permitted to provide an engineering evaluation supporting the field modification. [**80:**5.1.5.3]

12.4.6.7 Removal of Door or Window. Where a fire door or fire window opening no longer functions as an opening, or the door or window is removed and not replaced, the opening shall be filled to maintain the required rating of the wall assembly. [**80:**5.1.6]

Where a door or window opening is no longer in use, the opening must be filled with construction materials equivalent to those of the wall to maintain the required rating of the wall assembly. Many times, doors are no longer used as doors and functionally become walls. For example, an office (or similar space) might have two doors installed for convenience. Over time, one of the doors is no longer needed or used and has items placed in front of it to prevent its use. When the door no longer functions as a door and has materials placed against it or in close proximity to it, the effectiveness and rating of the fire barrier are reduced. The fire testing requirements differ for a wall and a door, and care should be taken when a fire door or a fire window is no longer used as a door or window.

12.4.6.8* Inspection and Testing.

Section 5.2 contains all the provisions related to inspection and test procedures for fire doors, fire windows, and fire shutters. Paragraphs 12.4.6.8.1 and 12.4.6.8.2 address general inspection and testing criteria, including record keeping, that is applicable to all fire door, fire window, and fire shutter inspections. Paragraph 12.4.6.8.2 also includes the requirements for inspections and testing upon completion of installation of the assembly and after maintenance work. Paragraph 12.4.6.8.3 addresses acceptance tests and provides all the minimum requirements that must be met during these tests, including a visual inspection. Finally, 12.4.6.8.4 addresses periodic inspection and testing and provides the minimum required frequency for inspections and makes a reference back to 12.4.6.8.3 for the criteria that must be met.

There are at least three occurrences when an inspection and test of fire door, fire window, and fire shutter assemblies must be performed:

1. Upon completion of installation of a fire door, fire window, or fire shutter assembly (12.4.6.8.3)
2. Periodically, but not less than annually (12.4.6.8.4)
3. Upon completion of maintenance work (12.4.6.8.3)

A.12.4.6.8 Doors, shutters, and windows are of no value unless they are properly maintained and closed or are able to close at the time of fire. A periodic inspection and maintenance program is generally the responsibility of the building owner. [**80:**A.5.2]

12.4.6.8.1* Upon completion of the installation, door, shutters, and window assemblies shall be inspected and tested in accordance with 5.2.4 of NFPA 80. [**80:**5.2.1]

A.12.4.6.8.1 Hinges, catches, closers, latches, and stay rollers are especially subject to wear. [**80:**A.5.2.1]

Once the installation of a fire door, fire window, or fire shutter assembly has been completed, the assembly must be tested to ensure that it works properly. This includes verifying that the door closes and latches and that all closing devices are working properly and effectively. It should be verified that no floor coverings or obstructions interfere with the proper operation of the door or window assembly at the time of installation. In addition to this initial visual and functional test, a written record must be retained and made available to the AHJ if necessary.

12.4.6.8.2* A record of all inspections and testing shall be signed by the inspector and kept for inspection by the AHJ. [**80:**5.2.2]

A.12.4.6.8.2 Newer technology includes use of barcodes and other electronic devices. This section recognizes that completed and filed barcode reports should be considered signed by the inspector. [**80:**A.5.2.2]

In past editions of NFPA 80, records of fire door, fire window, and fire shutter inspections have been required. For the 2013 edition of NFPA 80, the significant details of those records were added to address the length of time to retain the records at a facility and the type of information that the records should include.

Maintaining records of inspection, testing, and maintenance is critical for the performance and the condition of the opening protectives. Records ensure not only that the inspections and testing have occurred, but that they have occurred on a timely basis and by a person with the appropriate qualifications.

12.4.6.8.2.1 Records of acceptance tests shall be retained for the life of the assembly. [**80:**5.2.2.1]

12.4.6.8.2.2* Unless a longer period is required by Section 5.4 of NFPA 80, records shall be retained for a period of at least 3 years. [**80:**5.2.2.2]

Δ **A.12.4.6.8.2.2** In many cases, AHJs are not able to inspect each building in their jurisdiction each year. Inspection and testing records need to be retained during the intervening periods between the AHJ's formal visits to provide evidence that the inspections and testing were performed as required by NFPA 80. Additionally, maintenance records documenting that the necessary corrective actions have been made in accordance with this standard should be stored with the inspection and testing records for the same period of time. Retaining the records for 7 years allows the AHJ the ability to look back over an extended period of time to verify that the fire door assemblies are being properly maintained. [**80:**A.5.2.2.2]

12.4.6.8.2.3* The records shall be on a medium that will survive the retention period. Paper or electronic media shall be permitted. [**72:**14.6.2.3]

With the tremendous growth of technology and the move from paper to electronic resources in many industries, the need to retain electronic records of fire door, fire window, and fire shutter inspections is also growing. A number of companies are producing systems that allow fire doors, fire windows, and fire shutters in a building to be scanned electronically, using either a barcode or another code on the door, window, or shutter. An inspection form can be filled out either on a mobile device or on a computer, and all records can be updated, signed, and tracked electronically. This technology allows for a quicker inspection procedure and minimizes the risk of records being lost or destroyed. NFPA 80 and this *Code* recognize records in both paper and electronic formats.

A.12.4.6.8.2.3 Installation of new fire door assemblies should be documented in the same manner and level of detail as the periodic inspections and testing of fire door assemblies required by 12.4.6.8.3 and 12.4.6.8.4. Records of new fire door assemblies should be retained with the periodic inspections and testing records for the facility. [**80:**A.5.2.2.3]

12.4.6.8.2.4 A record of all inspections and testing shall be provided that includes, but is not limited to, the following information:

(1) Date of inspection
(2) Name of facility
(3) Address of facility
(4) Name of person(s) performing inspections and testing
(5) Company name and address of inspecting company
(6) Signature of inspector of record
(7) Individual record of each inspected and tested fire door assembly
(8)* Opening identifier and location of each inspected and tested fire door assembly

The information required by 12.4.6.8.2.4 is a minimum. Other information can be included as part of the inspection and testing records. Items 8 through 11 apply to each door, shutter, and window assembly subject to NFPA 80's inspections and testing. For example, each assembly needs to have its own identifier code. Identifier codes can be as simple as a door number, but they can be a barcode, a radio-frequency identification (RFID) chip, or some other unique code that can be tracked in the inspection records. Item 10 documents the inspection and operational testing of the assemblies. Item 11 captures the deficiencies discovered during the inspection and testing.

A.12.4.6.8.2.4(8) Each fire door assembly inspected and tested should be assigned a unique identifier code (e.g., door number as assigned by the facility) that can be used to track the assembly's compliance and maintenance records throughout the lifetime of its installation. Identifier codes could be a door assembly number, barcode, or other code that is unique to each fire door assembly. [**80:**A.5.2.2.4(8)]

(9)* Type and description of each inspected and tested fire door assembly

A.12.4.6.8.2.4(9) To aid the AHJ during the review of the inspections and testing reports, the records should include a description of the type of fire door assembly as follows:

Type 6: Swinging door with builders hardware

Type 7: Swinging fire door with fire door hardware

Type 8: Horizontally sliding fire door

Type 9: Special purpose horizontally sliding accordion or folding door

Type 10: Vertically sliding fire door

Type 11: Rolling steel door

Type 12: Fire shutter

Type 13: Service counter fire door

Type 14: Hoistway doors for elevators and dumbwaiter

Type 15: Chute door

Type 16: Access door

Type 17: Fire window

[**80:**A.5.2.2.4(9)]

(10)* Verification of visual inspection and functional operation

A.12.4.6.8.2.4(10) Functional operation of fire door assemblies should include testing of the closing device, complete closure of the fire door, and full engagement of latch(es) where required by door type. Functional testing of automatic-closing or power-operated fire door assemblies and electrically controlled latching hardware or release devices might need to be coordinated with the facility during other electrically controlled system tests. [**80:**A.5.2.2.4(10)]

(11) Listing of deficiencies in accordance with 12.4.6.8.3, 12.4.6.9, and 12.4.6.10

[**80:**5.2.2.4]

Δ **12.4.6.8.2.5*** Upon completion of maintenance work, fire door assemblies shall be inspected and tested in accordance with 12.4.6.8.3. [**80:**5.2.2.5]

Δ **A.12.4.6.8.2.5** Existing fire door assemblies that have been repaired should be inspected and tested immediately upon completion of the repair work to ensure that they are in compliance with NFPA 80. [**80:**A.5.2.2.5]

12.4.6.8.3 Acceptance Testing.

12.4.6.8.3.1* Acceptance testing of fire door and window assemblies shall be performed by a qualified person with knowledge and understanding of the operating components of the type of assembly being subject to testing. [**80:**5.2.3.1]

A.12.4.6.8.3.1 Visual inspection and functional testing of fire door and fire window assemblies require the persons performing the inspections and testing to be thoroughly knowledgeable of the various components and systems that are used to create fire-rated assemblies. In the case of swinging doors with builders hardware, these assemblies are comprised of labeled and listed components from several manufacturers. Often, the listing of the door leaf determines which products are permitted to be installed on an assembly. Inspectors of swinging doors with builders hardware need be able to recognize which components can or cannot be used on specific assemblies, which requires training and experience on behalf of the persons performing the inspections. Additionally, AHJs need to be able to rely on the competency, expertise, experience, and knowledge of the fire door inspectors in their jurisdiction. [**80:**A.5.2.3.1]

The *Code* is not explicit with regard to the qualifications of persons performing fire door inspections and testing, nor does the *Code* mandate that the inspections be performed by third-party inspectors. While the *Code* does not require professional certification, professional certification might assure AHJs that the persons performing the inspections are properly trained. In addition, the *Code* does not distinguish the persons who perform the inspections from the persons who perform the corrective actions.

A commonly asked question is whether building owners can use their own personnel to perform these inspections. The issue is the need to satisfy the AHJ's concern that the persons performing the inspections be qualified and trained to perform the inspections. Large facilities and institutions (e.g., universities) that have an established maintenance program with appropriately trained personnel will most likely rely on their own personnel for the inspections. The *Code* does not require professional certification, but professional certification can help assure the AHJ that the persons performing the inspections are properly trained. In addition, the *Code* does not distinguish between the persons who perform the inspections and the persons who perform the corrective actions. Ultimately, it is up to the local AHJ to determine if the person(s) performing the required inspections and test meet the definition of *qualified person* according to Chapter 3 of NFPA 80.

12.4.6.8.3.2* Before testing, a visual inspection shall be performed to identify any damaged or missing parts that can create a hazard during testing or affect operation or resetting. [**80:**5.2.3.2]

A.12.4.6.8.3.2 Any fire door or fire window assembly or component that has a history of reoccurring failures should be evaluated for possible replacement or other corrective measures. [**80:**A.5.2.3.2]

12.4.6.8.3.3 Acceptance testing shall include the closing of the door by all means of activation. [**80:**5.2.3.3]

An important requirement of operational testing is that assemblies arranged for automatic closing must be tested by all means of activation. For example, automatic-closing cross-corridor swinging doors might be held open by wall-mounted magnetic door holders or by electrically controlled door closers. In either case, the hold-open devices are required to release the doors upon actuation of the fire alarm system, actuation of local smoke/heat detectors, or loss of power. Upon release, the doors must close completely and latch. These same doors must also operate as self-closing doors when they are not electrically held open.

Operational testing of door assemblies with fusible links (e.g., horizontal sliding doors and rolling steel doors) include removing one or more of the fusible links to verify that the doors close correctly. Paragraph 12.4.6.8.3.3 requires operational testing of the doors to include "all means of activation." Operational testing of automatic-closing and power-operated assemblies requires coordination of testing with other building systems (e.g., fire alarm) to verify that the doors release and close as designed.

Δ **12.4.6.8.3.4** A record of these inspections and testing shall be made in accordance with 12.4.6.8.2. [**80:**5.2.3.4]

12.4.6.8.3.5 Swinging Doors with Builders Hardware or Fire Door Hardware.

12.4.6.8.3.5.1 Fire door assemblies shall be visually inspected from both sides to assess the overall condition of door assembly. [**80:**5.2.3.5.1]

12.4.6.8.3.5.2 As a minimum, the following items shall be verified:

(1) Labels are clearly visible and legible.
(2) No open holes or breaks exist in surfaces of either the door or frame.
(3) Glazing, vision light frames, and glazing beads are intact and securely fastened in place, if so equipped.
(4) The door, frame, hinges, hardware, and noncombustible threshold are secured, aligned, and in working order with no visible signs of damage.
(5) No parts are missing or broken.
(6) Door clearances do not exceed clearances listed in 4.8.4 and 6.3.1.7 of NFPA 80.
(7) The self-closing device is operational; that is, the active door completely closes when operated from the full open position.
(8) If a coordinator is installed, the inactive leaf closes before the active leaf.
(9) Latching hardware operates and secures the door when it is in the closed position.
(10) Auxiliary hardware items that interfere or prohibit operation are not installed on the door or frame.
(11) No field modifications to the door assembly have been performed that void the label.
(12) Meeting edge protection, gasketing and edge seals, where required, are inspected to verify their presence and integrity.
(13) Signage affixed to a door meets the requirements listed in 4.1.4 of NFPA 80.

[**80:**5.2.3.5.2]

It is important to remember that the list of inspection items in 12.4.6.8.3.5.2 is a minimum list. In many cases, the requirements of Chapters 4 and 6 of NFPA 80 also need to be applied to correctly assess the condition of the fire door assembly. For example, NFPA 80 does not explicitly address the maintenance, inspection, and testing of fire pins. However, because fire pins are a critical component on pairs of swinging fire doors without active bottom latch or bolt assemblies, the inspectors should include them in their assessment of the complete fire door assembly.

The application of fire pins on pairs of doors is governed by the listing of the door leaves — not all door leaves, especially older existing door leaves, are listed for use with fire pins. When fire pins were first introduced in the 1990s, very few types of door construction were tested for use with fire pins. Fire pins have become a common component on many of today's pairs of fire doors.

There really is no practical way to test fire pins in the field; once the pins release and engage, the door leaves are basically fixed in place. The door leaves would need to be removed from the frame in order to replace the fire pins — fire pins cannot be reset or reused after they have been activated/released.

The labels, per 12.4.6.8.3.5.2(1), on door frames, doors, and, where required, individual components need to be visible after installation. Labels contain important information regarding the assembly. For example, the level of fire protection rating (or fire resistance rating) is stated on the label. Some labels contain additional information regarding the dimension of latch throw, the requirement for fire exit hardware, temperature-rise rating, and "S" markings for smoke door assemblies. Painted labels on doors and frames are one of the most commonly cited deficiencies during inspections and testing. Where labels show signs of tampering, they should be captured in the inspection reports; follow-up field labeling services to replace the labels correctly might be required. Many hollow metal (e.g., steel) door frames have labels that are embossed into the soffit area of the hinge and strike jambs (the vertical jamb members). When the door frames are painted, embossed labels are difficult to read. For that reason, it might be necessary for owners to periodically strip built-up layers of paint covering the embossed labels to make them legible.

Paragraph 12.4.6.11.7 provides instructions for how to properly repair holes, as referenced by 12.4.6.8.3.5.2(2), that are left in a door or frame due to changes or removal of plant-on hardware. Exhibit 12.4 shows a fire door where the holes were drilled in preparation for installing the closing device. The set of four holes was actually drilled twice, thus leaving four exposed open holes in the fire door that were not filled properly.

Exhibit 12.4

Fire door with an extra set of holes for installation of closing device. (Courtesy of Lori Greene)

Glazing materials used in fire door assemblies include ¼ in. (6.35 mm) clear wire glass and glass ceramic products. Clear wire glass installed prior to the enforcement of the 1992 edition of NFPA 80 was not required to be individually labeled. Since then, each individual piece of glazing material (including clear wire glass) is required to have a visible label. Glazing materials installed in fire door frames and doors installed in accordance with recent model building codes are also required to be marked with the coding system given in Table 4.2.2 of NFPA 80. There are two categories of glazing materials, fire protection–rated and fire resistance–rated. Depending on the location of the fire door assembly, the model building codes designate which type of glazing material is needed in door assemblies. *Glazing bead*, as referenced in 12.4.6.8.3.5.2(3), is a term used to identify the removable piece of trim, usually made of metal, that holds the glazing material securely in the door or frame. Glazing beads can be snap-in or screw-in designs.

Damage to a door leaf or frame, as referenced in 12.4.6.8.3.5.2(4), varies. In the case of hollow metal doors and frames, a dent that prevents the door from closing completely or causes the door to rub the frame is one example. A dent that penetrates the face of the door is another example. Rust-through is one more example. In the case of wood fire doors (including plastic laminate–faced doors), any damage that penetrates the skin or face of the door needs to be repaired. Older wood fire doors were constructed with salt-treated stiles (vertical) and rails (horizontal), which were infamous for splitting if the installers did not drill the proper sized pilot holes for the screws. Edge stiles on modern wood fire doors are somewhat less susceptible to splitting, but it does occur.

Delamination, the separation of the door face or edges from the core construction of the door leaves, is a common type of damage that can occur on wood, plastic laminate–faced, and hollow metal fire doors.

In all of the above-mentioned cases, the actual repair work needs to be performed under authorized licensed service, which will require the door leaves to be removed from the building and worked on in a dedicated shop that is authorized by a testing lab and licensed by the door leaf manufacturer. Work that needs to be done in place in the building falls under the category of field modifications and is subject to the requirements of 12.4.6.6. The *Code* does not require the door assemblies to be maintained in like-new condition; rather, it requires the door assemblies to be maintained in working condition. Minor scuffs, scratches, dents, and dings are acceptable.

Exhibit 12.5 is an example of a fire door with a hinge pin not secured in the proper position. Exhibit 12.6 shows a fire door where the top corner is broken and there are cracks in the door.

Clearances between the doors and the frames, as referenced in 12.4.6.8.3.5.2(6), affect latch bolt engagement in the strike plates and other types of strikes. For example, latching hardware devices that extend from the bottom of the door need to fully engage in floor-mounted strikes. In fact, many bottom-mounted flush bolts are not correctly adjusted or aligned to fit into their

Exhibit 12.5

Fire door with hinge pin not secured in proper position.

Exhibit 12.6

Fire door with broken corner and cracks. (Courtesy of Lori Greene)

strikes. In other words, it is possible to have a door with a bottom clearance that complies with 4.8.4 of NFPA 80 [meaning it has ¾ in. (19 mm) clearance] but does not latch correctly.

Where clearance dimensions between door frames and doors or meeting stiles of paired doors exceed NFPA 80's maximum dimensions, latch bolt projection into the strike plates is proportionately reduced. Latching hardware cannot be expected to perform as tested if latch bolts do not project far enough into their strike plates.

NFPA 80's clearance dimensions also ensure that the doors overlap the door frames sufficiently to form a barrier that resists the passage of smoke, gases, and flames through the assembly. If the clearance dimensions are greater than those allowed by NFPA 80, the assemblies cannot be expected to provide their intended level of fire protection. Note that Chapter 7 of NFPA 80 does not specify clearance dimensions between door frames and doors for swinging doors. Exhibit 12.7 and Exhibit 12.8 are examples of pairs of fire doors where the clearance is in excess of that permitted by 6.3.1.7 of NFPA 80. It should be noted that in Exhibit 12.6 the installed kickdown is also in violation of NFPA 80.

Self-closing mechanisms, as referenced in 12.4.6.8.3.5.2(7), are perhaps one of the most important pieces of hardware on a fire door or window. Closing mechanisms ensure that the door will close and protect the opening at the time of fire. Without closing mechanisms or with damaged or improperly installed closing mechanisms, the risk is that an opening could be exposed and unprotected during a fire, thus leaving a path open for fire and smoke to spread to multiple fire compartments. In the case of swinging doors, closing devices need to be adjusted so that they close doors completely when doors are opened to *any* position. Swinging doors covered in Chapter 6 of NFPA 80 need to reliably latch in the closed position, regardless of how far the doors are opened. Accordingly, closing devices should be adjusted to overcome HVAC pressures (e.g., stack pressure) and resistance/friction of latching hardware devices every time the doors return to the closed position. Some door closers do

Exhibit 12.7

Pair of swing fire doors with vertical clearance between the doors in excess of ⅛ in. (3.18 mm). (Courtesy of the Door Security & Safety Foundation, Door and Hardware Institute)

Exhibit 12.8

Pair of swing fire doors with noncompliant vertical clearance.

not have sufficient closing power to reliably close fire doors, due to their reduced-opening force designs to meet accessibility standards.

Door coordinators are required on pairs of swinging fire doors when there is an overlapping astragal or an extended latch bolt that prevents one of the doors from closing completely. In some cases, an auxiliary item referred to as a carry-open bar is needed to ensure that both doors reliably close. Carry-open bars mount to the push side of the inactive door leaf and force (e.g., stiff-arm) open the active leaf, engaging the coordinator. When the inactive leaf closes it releases the coordinator, allowing the active leaf to close, thereby ensuring that both door leaves are completely closed.

Auxiliary items, as referenced in 12.4.6.8.3.5.2(10), include kickstops, wooden wedges, chains, ropes, and other items that would interfere with the operation of the door. Kickstops are not permitted to be installed on fire doors. Even if the door is self-closing or automatic closing while the kickstop is disengaged, human intervention cannot be relied upon to release the kickstop and close the door. All fire doors must be self-closing or automatic closing, and kickstops not only interfere with the operation of the door, they also do not allow the door to be the required self-closing or automatic closing.

According to 12.4.6.8.3.5.2(12), gasketing materials (including intumescent materials) that are required by code (in this case, a building code) must be inspected. If the edges of the doors become damaged to the point that the damage compromises the intumescent material, most likely the door leaf will need to be replaced. While auxiliary surface-mounted intumescent gasketing could be installed, if the construction of the door leaf is compromised, the door leaf will need to be replaced. Smoke and intumescent gasketing products mounted to door frames need to form a continuous (unbroken) seal along the vertical and horizontal jambs. Because the gasketing is one of the last items installed, installers frequently cut and notch gasketing materials to fit around soffit-mounted hardware (e.g., parallel arm closer brackets and strikes for rim/surface vertical rod fire exit hardware devices). Gaps and notches in gasketing compromise its ability to resist the passage of smoke and gases around the assemblies.

Signage attached to doors is permitted, provided the total area of the signage is no more than 5 percent of the nominal area of the faces of the doors. Signage is not permitted to be attached to doors by fasteners that penetrate the doors (see 4.1.4 of NFPA 80). Classroom doors in schools and patient room doors in hospitals are frequently covered with papers, posters, and other decorations. While these decorations are not necessarily signage, they can pose a problem on fire-rated doors.

12.4.6.8.3.6 Horizontally Sliding, Vertically Sliding, and Rolling Doors.

12.4.6.8.3.6.1 Fire door assemblies shall be visually inspected from both sides to assess the overall condition of door assembly. [**80:**5.2.3.6.1]

12.4.6.8.3.6.2 At a minimum, the following items shall be verified:

(1) Labels are clearly visible and legible.
(2) No open holes or breaks exist in surfaces of either the door or frame.
(3) Slats, endlocks, bottom bar, guide assembly, curtain entry hood, and flame baffle are correctly installed and intact for rolling steel fire doors.
(4) Glazing, vision light frames, and glazing beads are intact and securely fastened in place, if so equipped.
(5) Curtain, barrel, and guides are aligned, level, plumb, and true for rolling steel fire doors.
(6) Expansion clearance is maintained in accordance with manufacturer's listing.
(7) Drop release arms and weights are not blocked or wedged.
(8) Mounting and assembly bolts are intact and secured.
(9) Attachment to jambs are with bolts, expansion anchors, or as otherwise required by the listing.
(10) Smoke detectors, if equipped, are installed and operational.
(11) No parts are missing or broken.
(12)* Fusible links, if equipped, are in the location; chain/cable, s-hooks, eyes, and so forth, are in good condition; the cable or chain are not kinked, pinched, twisted, or inflexible; and links are not painted or coated with dust or grease.
(13) Auxiliary hardware items that interfere or prohibit operation are not installed on the door or frame.

(14) No field modifications to the door assembly have been performed that void the label.
(15) Doors have an average closing speed of not less than 6 in./sec (152 mm/sec) or more than 24 in./sec (610 mm/sec).
[**80:**5.2.3.6.2]

A.12.4.6.8.3.6.2(12) Fusible links should not be coated with any materials such as fireproofing, drywall compound, or spray texturing. [**80:**A.5.2.3.6.2(12)]

The list in 12.4.6.8.3.6.2 includes many of the items that were listed for swinging doors but also contains items that are specific to sliding and rolling doors. Slats, endlocks, bars and guides, and hoods are some of the main components of a rolling steel fire door assembly. It must be verified that these components are installed correctly and are intact to ensure proper operation of the door assembly.

Much like kickstops for swinging doors, blocking the release arms or counterweights for sliding and rolling doors could mean that the door will not close and protect the opening during fire conditions. According to 12.4.6.8.3.6.2(7), it is critical that no obstructions interfere with the proper closing mechanisms that are part of the door assembly.

The use of fusible link hold-open door closers, as referenced in 12.4.6.8.3.6.2(12), has been restricted to a very few specific applications. Paragraph 12.4.6.8.3.8 specifically prohibits the painting of fusible links on all types of fire door assemblies, which means that painted fusible links will need to be replaced. When the fusible links are replaced, the manufacturer must be consulted to ensure that the replacement fusible link is the correct type and has the correct melting point. See also Section 4.7 of NFPA 80 for additional information on the installation of fusible links and sleeves.

12.4.6.8.3.7 Closing Devices.

12.4.6.8.3.7.1 All fire doors, fire shutters, and fire window assemblies shall be inspected and tested to check for proper operation and full closure. [**80:**5.2.3.7.1]

12.4.6.8.3.7.2 Resetting of the automatic-closing device shall be done in accordance with the manufacturer's instructions. [**80:**5.2.3.7.2]

12.4.6.8.3.7.3 Rolling Steel Fire Doors.

12.4.6.8.3.7.3.1 Rolling steel fire doors shall be drop-tested twice. [**80:**5.2.3.7.3.1]

12.4.6.8.3.7.3.2 The first test shall be to check for proper operation and full closure. [**80:**5.2.3.7.3.2]

12.4.6.8.3.7.3.3 A second test shall be done to verify that the automatic-closing device has been reset correctly. [**80:**5.2.3.7.3.3]

12.4.6.8.3.8* Fusible links, release devices, and any other movable parts shall not be painted or coated with other materials that could interfere with the operation of the assembly. [**80:**5.2.3.8]

A.12.4.6.8.3.8 Movable parts of the door assembly can include, but are not limited to, stay rollers, gears, and closing mechanisms. [**80:**A.5.2.3.8]

12.4.6.8.4 Periodic Inspection and Testing.

12.4.6.8.4.1* Periodic inspections and testing shall be performed not less than annually. [**80:**5.2.4.1]

A.12.4.6.8.4.1 Doors subject to high-volume use and abuse might warrant an increased frequency of inspection. Components including, but not limited to, hinges, catches, closers, latches, and stay rollers are especially subject to wear. [**80:**A.5.2.4.1]

12.4.6.8.4.2 As a minimum, the provisions of 12.4.6.8.3 shall be included in the periodic inspection and testing procedure. [**80:**5.2.4.2]

12.4.6.8.4.3 Inspection shall include an operational test for automatic-closing doors and windows to verify that the assembly will close under fire conditions. [**80:**5.2.4.3]

12.4.6.8.4.4 The assembly shall be reset after a successful test. [**80:**5.2.4.4]

12.4.6.8.4.5 Resetting of the release mechanism shall be done in accordance with the manufacturer's instructions. [**80:**5.2.4.5]

12.4.6.8.4.6* Hardware shall be examined, and inoperative hardware, parts, or other defective items shall be replaced without delay. [**80:**5.2.4.6]

A.12.4.6.8.4.6 The determination of the time required for corrective action should be based on a risk analysis and availability of replacement materials. [**80:**A.5.2.4.6]

12.4.6.8.4.7 Tin-clad and kalamein doors shall be inspected for dry rot of the wood core. [**80:**5.2.4.7]

12.4.6.8.4.8 Chains or cables employed shall be inspected for excessive wear, stretching, and binding. [**80:**5.2.4.8]

12.4.6.9 Retrofit Operators.

12.4.6.9.1 The operator, governor, and automatic-closing device on rolling steel fire doors shall be permitted to be retrofitted with a labeled retrofit operator under the conditions specified in 12.4.6.9.2 through 12.4.6.9.5. [**80:**5.3.1]

12.4.6.9.2 The retrofit operator shall be labeled as such. [**80:**5.3.2]

12.4.6.9.3 The retrofit operator shall be installed in accordance with its installation instructions and listing. [**80:**5.3.3]

12.4.6.9.4 The installation shall be acceptable to the AHJ. [**80:**5.3.4]

12.4.6.9.5 The retrofit operator shall be permitted to be provided by a manufacturer other than the original manufacturer of the rolling steel fire door on which it is retrofitted, provided its listing allows it to be retrofitted on that manufacturer's doors. [**80:**5.3.5]

12.4.6.10* Performance-Based Option.

Δ **A.12.4.6.10** See Annex J of NFPA 80 for information regarding performance-based inspection, testing, and maintenance options for fire door assemblies. [**80:**A.5.4]

12.4.6.10.1 As an alternate means of compliance with 12.4.6.8.4, subject to the AHJ, fire door assemblies shall be permitted to be inspected, tested, and maintained under a written performance-based program. [**80:**5.4.1]

12.4.6.10.2 Goals established under a performance-based program shall provide assurance that the fire door assembly will perform its intended function when exposed to fire conditions. [**80:**5.4.2]

12.4.6.10.3 Technical justification for inspection, testing, and maintenance intervals shall be documented in writing. [**80:**5.4.3]

12.4.6.10.4 The performance-based option shall include historical data acceptable to the AHJ. [**80:**5.4.4]

Using the performance-based option detailed in 12.4.6.10 is an alternative means for complying with the prescriptive requirements mandating the annual inspection of fire doors and fire windows. The concept of a performance-based program is to establish the type and frequency of inspection to demonstrate that the assembly is operational. The goal is to balance the inspection frequency with the proven reliability of the assembly. The goal is also to adjust the test and inspection frequencies corresponding with the documented history of equipment performance and desired reliability. See Annex J of NFPA 80 for additional information regarding the performance-based option for the inspection, testing, and maintenance of fire door assemblies.

12.4.6.11 Maintenance.

12.4.6.11.1* Repairs shall be made, and defects that could interfere with operation shall be corrected without delay. [**80:**5.5.1]

A.12.4.6.11.1 The determination of the time required for corrective action should be based on a risk analysis and availability of replacement materials. [**80:**A.5.5.1]

NFPA 80 requires the corrective actions to be made "without delay." It is up to the AHJ to decide what constitutes a reasonable time frame, because there needs to be some allowance for the time it takes to place orders, receive the materials, and perform the work. It is likely that owners could demonstrate compliance to the AHJ if they could show that the process has started and that the corrective actions will be completed in a reasonable time frame. The time it takes the corrective actions to be made should be commensurate with the size and complexity of the needed repairs.

Δ **12.4.6.11.2** Damaged glazing material shall be replaced with labeled glazing. [**80:**5.5.2]

12.4.6.11.3 Replacement glazing materials shall be installed in accordance with their individual listing. [**80:**5.5.3]

12.4.6.11.4 Any breaks in the face covering of doors shall be repaired without delay. [**80:**5.5.4]

Δ **12.4.6.11.5** Where a fire door, frame, or any part of its appurtenances is damaged to the extent that it could impair the door's proper emergency function, the following actions shall be performed:

(1) The fire door, frame, door assembly, or any part of its appurtenances shall be repaired with labeled parts or parts obtained from the original manufacturer.
(2) The door shall be tested to ensure emergency operation and closing upon completion of the repairs.

[**80:**5.5.5]

12.4.6.11.6 If repairs cannot be made with labeled components or parts obtained from the original manufacturer or retrofitted in accordance with Section 5.3 of NFPA 80, the fire door frame, fire door assembly, or appurtenances shall be replaced. [**80:**5.5.6]

12.4.6.11.7 When fastener holes are left in a door or frame due to changes or removal of hardware or plant-ons, the holes shall be repaired by the following methods:

(1) Install steel fasteners that completely fill the holes
(2) Fill the screw or bolt holes with the same material as the door or frame
(3) Fill holes with material listed for this use and installed in accordance with the manufacturer's procedures

[**80:**5.5.7]

This paragraph covers the repairing of round holes left in doors and door frames due to reinstallation and replacement of hardware components. Paragraph 4.1.3.2 of NFPA 80 describes the types and sizes of holes that are permitted to be made during the installation process; these are the types of holes covered by 12.4.6.11.7. Repairing round holes larger than 1 in. (25.4 mm) in diameter or holes of other shapes (of any size) falls under the category of field modification.

If the door leaves are hollow metal, any holes and cutouts will need to be filled with the same material as the door leaf. This type of work might not be permitted to be completed in the field since it would fall into the category of field modification. At a minimum, the laboratory whose label is attached to the door leaf will need to be contacted for more specific instruction, but most likely the actual door manufacturer will need to be consulted for direction. Depending on the number of door leaves that are left with open holes or cutouts, it might be less expensive to replace the door leaves. Note that the frame will need to be repaired if open holes or cutouts are in it as well — this might be as simple as installing a solid steel filler plate attached with steel screws.

If the door leaves are wood, most likely the best way to resolve the issue is to replace the door. It may be difficult to determine a satisfactory method for making such a substantial repair/modification. The AHJ must determine if the repair to the wood door is in compliance with the *Code*.

The use of fire caulk or other such putties or fillers is not an acceptable method for repairing fire doors, and neither places a protection plate over the holes in doors and frames. This type of work could easily fall under the field modification category, which requires the test laboratory to be contacted. It is important to research the construction of the door in question and seek direction as to how to correctly repair it before attempting to repair a damaged fire door.

New products designed to repair fire door assemblies have been labeled and listed by the testing laboratories. In most cases, these new products have specific limitations as to what types of doors they can be used on. For example, some products are limited for use on fire-rated wood composite doors with ratings up to 1½ hours.

Other such products can be used on doors rated up to ⅓ hour. Some products can be used to fill in round holes only up to ¾ in. (19 mm) in diameter in wood fire doors. It is likely that more products designed to repair fire doors will be on the market in the future. Accordingly, item (3) in 12.4.6.11.7 provides for the application of these new products when they are used in accordance with the manufacturer's procedures.

N **12.4.6.11.8** Holes, other than those as described by 12.4.6.9.7, shall be treated as a field modification in accordance with 12.4.6.4. [**80:**5.5.8]

N **12.4.6.11.9*** Upon completion of maintenance work, fire door assemblies shall be inspected and tested in accordance with 12.4.6.6.3. A record of these inspections and testing shall be made in accordance with 12.4.6.6.2. A record of maintenance performed on existing fire door assemblies shall be provided that includes the following information:

(1) Date of maintenance
(2) Name of facility
(3) Address of facility
(4) Name of person(s) performing maintenance
(5) Company name and address of maintenance personnel
(6) Signature of maintenance personnel performing the work
(7) Individual listings of each inspected and tested fire door assembly
(8) Opening identifier and location of each repaired fire door assembly
(9) Type and description of each repaired fire door assembly
(10) Description or listing of the work performed on each fire door assembly

[**80:**5.5.9]

N **A.12.4.6.11.9** Existing fire door assemblies that have been repaired should be inspected and tested immediately upon completion of the repair work to ensure that they are in compliance with this standard. Records of maintenance work should be maintained with the periodic inspections and testing records for the facility. [**80:**A.5.5.9]

The text in 12.4.6.11.9 is new to the 2016 edition of NFPA 80, from which it is extracted. Like acceptance testing and periodic inspection reports, maintenance reports must include the information listed in 12.4.6.11.9. When the work performed corrects deficiencies recorded during acceptance testing or periodic inspection and testing, the maintenance records should reference the corresponding inspection and testing records. Ideally, the maintenance records documenting corrective work should be kept with the inspection and testing records.

12.5* Interior Finish

A.12.5 The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building. [***101:***A.10.2]

The requirements are based on fire testing to NFPA 286 (with the criteria of 12.5.4.2), which apply to all interior finish materials. Many interior finish materials are permitted to be tested based on other fire tests, such as ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, or NFPA 265 as provided in the relevant subsection of Section 10.2. [***101:***A.10.2]

12.5.1 Interior finish in buildings and structures shall meet the requirements of NFPA *101* and this *Code*.

12.5.2* General.

A.12.5.2 The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building. The presence of multiple paint layers has the potential for paint delamination and bubbling or blistering of paint. Testing (NFPA Fire Technology, August 1974, "Fire Tests of Building Interior Covering Systems," David Waksman and John Ferguson, Institute for Applied Technology, National Bureau of Standards) has shown that adding up to two layers of paint with a dry film thickness of about 0.007 in. (0.18 mm) will not change the fire properties of surface-covering systems. Testing has shown that the fire properties of the surface-covering systems are highly substrate dependent and that thin coatings generally take on the characteristics of the substrate. When exposed to fire, the delamination, bubbling, and blistering of paint can result in an accelerated rate of flame spread. [***101:***A.10.2.1]

Δ **12.5.2.1** Classification of interior finish materials shall be in accordance with tests made under conditions simulating actual installations, provided that the authority having jurisdiction is permitted to establish the classification of any material for which classification by a standard test is not available. [***101:***10.2.1.1]

Paragraph 12.5.2.1 presents two concepts. First, for interior finish materials to be classified properly based on performance under a standardized test, the test needs to be indicative of the conditions under which the material will actually be installed. For example, thin wood paneling applied directly to wall framing studs can be expected to spread flame differently than does thin wood paneling applied to gypsum wallboard. This concept is explained, in part, in A.12.5.2.

Second, the AHJ is responsible for classifying interior finish materials for which standardized test data are not available. The AHJ is free to use whatever tools are available (such as experience, intuition, comparative field testing) and will generally take the conservative approach of banning the use of suspect materials for which there are no supporting data. The regulation of interior finish materials is an important part of the total package of life safety offered by compliance with the *Code*.

12.5.2.2 Fixed or movable walls and partitions, paneling, wall pads, and crash pads applied structurally or for decoration, acoustical correction, surface insulation, or other purposes shall be considered interior finish and shall not be considered decorations or furnishings. [***101:***10.2.1.2]

Prior to the 2006 edition of NFPA *101,* there was significant confusion among users on how to address materials placed on walls after construction and occupancy of the building. Often when materials were brought into an occupied building and attached to the walls, the AHJ was petitioned to treat such materials as decorations or furnishings. If the AHJ agreed to the classifying of such materials as decorations or furnishings, the materials might go unregulated or, at best, would be tested per NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films* (see 12.6.1), which is not the appropriate test for interior finish materials. The criteria in 12.5.2.2 provide the needed clarification.

Pads are often attached to walls in school gymnasiums to cushion the impact if a student collides with the wall. Such pads applied to or placed against walls need to be treated as interior wall finish. Similar pads placed on the floor should be considered contents and furnishings.

Δ **12.5.2.3** Lockers shall be considered interior finish. [***101:***10.2.1.3]

Historically, lockers in occupancies such as schools have been constructed of metal and have not posed a significant fire hazard. More recently, however, lockers constructed of wood and plastic have been made available. It is typical for lockers to line the walls of corridors; therefore, where they are constructed of combustible materials, they need to be regulated as interior wall finish materials in accordance with 12.5.2.3. See 12.6.7 for further details on lockers.

Δ **12.5.2.4** Washroom water closet partitions shall be considered interior finish. [***101:***10.2.1.4]

12.5.2.5 Fire-retardant coatings shall be in accordance with 12.5.7. [***101:***10.2.1.5]

• **12.5.3* Use of Interior Finishes.**

Δ **A.12.5.3** Table A.12.5.3 provides a compilation of the interior finish requirements of 7.1.4 of *NFPA 101* and the occupancy chapters (Chapters 12 through 42) of *NFPA 101*. [***101:***A.10.2.2]

Δ **12.5.3.1** Requirements for interior wall and ceiling finish shall apply as follows:

(1) Where specified elsewhere in this *Code* for specific occupancies *(see Chapter 7 and Chapters 11 through 43 of NFPA 101)*
(2) As specified in 12.5.4 through 12.5.7

[***101:***10.2.2.1]

12.5.3.2* Interior floor finish shall comply with 12.5.8 under any of the following conditions:

(1) Where floor finish requirements are specified elsewhere in this *Code*
(2) Where the fire performance of the floor finish cannot be demonstrated to be equivalent to floor finishes with a critical radiant flux of at least 0.1 W/cm²

[***101:***10.2.2.2]

A.12.5.3.2 This paragraph recognizes that traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings, have not proved to present an unusual hazard. [***101:***A.10.2.2.2]

Traditional floor coverings, such as wood flooring and resilient tile, do not contribute to the early growth of fire. Paragraph 12.5.3.2 has the effect of exempting traditional floor coverings from the restrictions that would otherwise be applicable. However, the AHJ can require substantiation of the performance of any unfamiliar floor covering. For example, imitation wood floors made of plastic, artificial turf, artificial surfaces of athletic fields, and certain types of carpeting are products that might merit substantiation. If the AHJ judges that a floor covering warrants testing and substantiation, or if an occupancy chapter imposes restrictions, the floor covering must be treated as interior floor finish. It would, therefore, be regulated on the basis of tests conducted in accordance with the flooring radiant panel test required in 12.5.8.

Δ **12.5.4* Interior Wall or Ceiling Finish Testing and Classification.** Where interior wall or ceiling finish is required elsewhere in this *Code* to be classified for fire performance and smoke development, it shall be classified in accordance with 12.5.4.1 or 12.5.4.3, except as indicated in 12.5.5. [***101:***10.2.3]

A.12.5.4 ASTM E84, *Standard Test Method of Surface Burning Characteristics of Building Materials*, and UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, are considered nationally recognized consensus standard test methods for determining the flame spread index and smoke developed index of building materials and are likely to yield equivalent test results. *(See also A.12.5.5.4.1.)* [***101:***A.10.2.3]

The provisions of 12.5.4 were reorganized for the 2018 edition of the *Code* for user friendliness. Any interior wall or ceiling finish material is permitted to be tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth,* as indicated in 12.5.4.1.1. Materials meeting the acceptance criteria in 12.5.4.2 are permitted to be used wherever a Class A, Class B, or Class C material is required as described in 12.5.4.1.2. Alternatively, flame spread and smoke development characteristics can be both quantified and recorded in the results of a test conducted in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building*

N *TABLE A.12.5.3 Interior Finish Classification Limitations*

Occupancy	Exits	Exit Access Corridors	Other Spaces
Assembly — new			
>300 occupant load	A	A or B	A or B
	I or II	I or II	NA
≤300 occupant load	A	A or B	A, B, or C
	I or II	I or II	NA
Assembly — existing			
>300 occupant load	A	A or B	A or B
≤300 occupant load	A	A or B	A, B, or C
Educational — new	A	A or B	A or B; C on low partitions*
	I or II	I or II	NA
Educational — existing	A	A or B	A, B, or C
Day-care centers — new	A	A	A or B
	I or II	I or II	NA
Day-care centers — existing	A or B	A or B	A or B
Day-care homes — new	A or B	A or B	A, B, or C
	I or II		NA
Day-care homes — existing	A or B	A, B, or C	A, B, or C
Health care — new	A	A	A
	NA	B on lower portion of corridor wall*	B in small individual rooms*
	I or II	I or II	NA
Health care — existing	A or B	A or B	A or B
Detention and correctional — new (sprinklers mandatory)	A or B	A or B	A, B, or C
	I or II	I or II	NA
Detention and correctional — existing	A or B	A or B	A, B, or C
	I or II	I or II	NA
One- and two-family dwellings and lodging or rooming houses	A, B, or C	A, B, or C	A, B, or C
Hotels and dormitories — new	A	A or B	A, B, or C
	I or II	I or II	NA
Hotels and dormitories — existing	A or B	A or B	A, B, or C
	I or II*	I or II*	NA
Apartment buildings — new	A	A or B	A, B, or C
	I or II	I or II	NA
Apartment buildings — existing	A or B	A or B	A, B, or C
	I or II*	I or II*	NA
Residential board and care — (See Chapters 32 and 33.)			
Mercantile — new	A or B	A or B	A or B
	I or II		NA
Mercantile — existing			
Class A or class B stores	A or B	A or B	Ceilings — A or B; walls — A, B, or C
Class C stores	A, B, or C	A, B, or C	A, B, or C
Business and ambulatory health care — new	A or B	A or B	A, B, or C
	I or II		NA
Business and ambulatory health care — existing	A or B	A or B	A, B, or C
Industrial	A or B	A, B, or C	A, B, or C
	I or II	I or II	NA
Storage	A or B	A, B, or C	A, B, or C
	I or II		NA

*See corresponding chapters for details.

NA: Not applicable.

Notes:

(1) Class A interior wall and ceiling finish — flame spread index, 0–25 (new applications); smoke developed index, 0–450.

(2) Class B interior wall and ceiling finish — flame spread index, 26–75 (new applications); smoke developed index, 0–450.

(3) Class C interior wall and ceiling finish — flame spread index, 76–200 (new applications); smoke developed index, 0–450.

(4) Class I interior floor finish — critical radiant flux, not less than 0.45 W/cm^2.

(5) Class II interior floor finish — critical radiant flux, not more than 0.22 W/cm^2, but less than 0.45 W/cm^2.

(6) Automatic sprinklers — where a complete standard system of automatic sprinklers is installed, interior wall and ceiling finish with a flame spread rating not exceeding Class C is permitted to be used in any location where Class B is required, and Class B interior wall and ceiling finish is permitted to be used in any location where Class A is required; similarly, Class II interior floor finish is permitted to be used in any location where Class I is required, and no interior floor finish classification is required where Class II is required. These provisions do not apply to new detention and correctional occupancies.

(7) Exposed portions of structural members complying with the requirements for heavy timber construction are permitted.

Materials, as described in 12.5.4.3. The test is also commonly referred to as the "Steiner tunnel test" (named after its inventor, Al Steiner, who developed the test at Underwriters Laboratories in 1944) and, generically, as the "tunnel test."

12.5.4.1 Interior Wall and Ceiling Finish Materials Tested in Accordance with NFPA 286.

N **12.5.4.1.1** Interior wall and ceiling finish materials shall be classified in accordance with NFPA 286 and comply with 12.5.4.2. [***101:***10.2.3.1.1]

N **12.5.4.1.2** Materials tested in accordance with 12.5.4.1.1 and complying with 12.5.4.2 shall be considered also to comply with the requirements of a Class A, Class B, or Class C in accordance with 12.5.4.3. [***101:***10.2.3.1.2]

Paragraph 12.5.4.1.2 permits materials that meet the criteria specified in 12.5.4.2, where tested in accordance with NFPA 286, to be used as both interior wall finish and interior ceiling finish, even where other *Code* provisions require interior wall and ceiling finish to be Class A in accordance with 12.5.4.3. Testing in accordance with NFPA 286, combined with performance criteria specified by 12.5.4.2, represents an improvement over testing in accordance with ASTM E84 or ANSI/UL 723 and classification in accordance with 12.5.4.3. ASTM E84 and ANSI/UL 723 test a sample that is mounted in a horizontal orientation to cover the 18 in. (455 mm) wide by 24 ft (7.3 m) long ceiling of the test tunnel. NFPA 286 tests a sample that fully covers three walls of the 8 ft (2440 mm) wide by 12 ft (3660 mm) long by 8 ft (2440 mm) high test chamber — and the ceiling as well if the results are to be applied to interior ceiling finish. See the commentary following 12.5.4.2.

Note that 12.5.4.1.2 does not require testing per NFPA 286; rather, it offers that test procedure as an alternative to meeting the Class A classification criteria of 12.5.4.3, based on results from the more traditional ASTM E84 or ANSI/UL 723 test protocol.

12.5.4.2 Acceptance Criteria for NFPA 286. The interior finish shall comply with the following:

(1) During the 40 kW exposure, flames shall not spread to the ceiling.
(2) The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
(3) Flashover, as described in NFPA 286, shall not occur.
(4) The peak heat release rate throughout the test shall not exceed 800 kW.
(5) For new installations, the total smoke released throughout the test shall not exceed 1000 m^2.

[***101:***10.2.3.2]

NFPA 286 was developed specifically to measure the following:

1. Extent of flame spread and burning relative to the realistically sized and mounted sample
2. Whether flashover occurs
3. Peak rate of heat release
4. Total smoke released throughout the test

The peak heat release rate of 800 kW, as specified by 12.5.4.2(4), was new to the 2006 edition of NFPA *101*. It was added because 12.5.4.1.2 permits materials that meet the criteria specified in 12.5.4.2, where tested in accordance with NFPA 286, to be used as both interior wall finish and interior ceiling finish, even where other *Code* provisions require interior wall and ceiling finish to be Class A in accordance with 12.5.4.3. Some interior finish materials can be produced less expensively, albeit somewhat less fire safe, if they need to meet only the criteria of 12.5.4.2 (based on testing per NFPA 286) without a peak heat release rate criterion, instead of having to pass the flame spread criteria for Class A required by 12.5.4.3 (based on testing per ASTM E84 or ANSI/UL 723). The peak heat release rate criterion associated with testing per NFPA 286 helps equalize the anomaly in the test methods.

Materials that meet the criteria for Class A interior finish when tested per ASTM E84 or ANSI/UL 723 and that do not flashover the test room when tested per NFPA 286, typically have a peak heat release rate of less than 400 kW. The 800 kW peak heat release rate criterion of 12.5.4.2(4) was chosen to help ensure that materials that have already been tested are not unnecessarily penalized.

The test room used for NFPA 286 testing is the same size as that used for NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls,* testing. If the test results are to be applied only to interior wall finish, then the test specimens are mounted to cover fully both 8 ft × 12 ft (2440 mm × 3660 mm) walls and the 8 ft × 8 ft (2440 mm × 2440 mm) rear wall. If the test results are to be applied both to interior wall finish and to interior ceiling finish, then the test specimen also is mounted to cover the ceiling. If the test results are to be applied only to interior ceiling finish, the test specimen is mounted to cover the ceiling only.

12.5.4.3* Interior Wall and Ceiling Finish Materials Tested in Accordance with ASTM E84 or ANSI/UL 723. Interior wall and ceiling finish materials shall be classified in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard Test Method for Surface Burning Characteristics of Building Materials*, except as indicated in 12.5.4.4 and 12.5.4.5, and shall be grouped in the following classes in accordance with their flame spread and smoke developed indexes:

(1) Class A: Flame spread index 0–25; smoke developed index 0–450.
(2) Class B: Flame spread index 26–75; smoke developed index 0–450.
(3) Class C: Flame spread index 76–200; smoke developed index 0–450.

[***101:***10.2.3.3]

N **A.12.5.4.3** It has been shown that the method of mounting interior finish materials usually affects actual performance. The use of standard mounting methods will be helpful in determining appropriate fire test results. Where materials are tested in intimate contact with a substrate to determine a classification, such materials should be installed in intimate contact with a similar substrate. Such details are especially important for "thermally thin" materials. For further information, see ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*. [***101:***A.10.2.3.3]

Some interior wall and ceiling finish materials, such as fabrics not applied to a solid backing, do not lend themselves to a test made in accordance with ASTM E84. In such cases, the large-scale test outlined in NFPA 701 is permitted to be used. In 1989 the NFPA Technical Committee on Fire Tests eliminated the so-called "small-scale test" from NFPA 701 because the results had been shown not to represent a fire performance that corresponded to what happened in real scale. Since then, NFPA 701 no longer contains a "small-scale test" but it now contains two tests (Test 1 and Test 2), which apply to materials as a function of their areal density. Thus NFPA 701 Test 1 applies to fabrics (other than vinyl-coated fabric blackout linings) having an areal density less than or equal to 21 oz/yd^2 (700 g/m^2), while NFPA 701 Test 2 applies to fabrics with an areal density greater than 21 oz/yd^2 (700 g/m^2), vinyl-coated fabric blackout linings, decorative objects, and films. Representations that materials or products have been tested to the small-scale test in NFPA 701 normally refer to the pre-1989 small-scale test, which no longer exists and which does not represent acceptable fire performance. [***101:***A.10.2.3.3]

Prior to 1978, the test report described by ASTM E84 included an evaluation of the fuel contribution as well as the flame spread index and the smoke developed index. However, it is now recognized that the measurement on which the fuel contribution is based does not provide a valid measure. Therefore, although the data are recorded during the test, the information is no longer normally reported. Classification of interior wall and ceiling finish thus relies only on the flame spread index and smoke developed index. [***101:***A.10.2.3.3]

The 450 smoke developed index limit is based solely on obscuration. (*See A.10.2.4.4 of NFPA 101)* [***101:***A.10.2.3.3]

N **12.5.4.3.1** Existing interior finish shall be exempt from the smoke developed index criteria of 12.5.4.3. [***101:***10.2.3.3.1]

Samples are tested in accordance with ASTM E84 or ANSI/UL 723, as mandated by 12.5.4.3, using a noncombustible, fiber cement board backing. Specimens are tested with adhesives and joints and under other conditions that simulate the actual installation of a product in a building. These fire test standards provide a general indication of product performance only if the product is installed in a fashion similar to that which has been tested. Available data demonstrate that the performance of interior finish materials varies, depending on mounting conditions. For example, a product installed over a combustible substrate tends to propagate fire more readily than would be typical of the same product installed over a noncombustible substrate.

Further, a wall covering installed with air space behind the covering tends to spread flame more readily than one installed in contact with a noncombustible substrate. Therefore, mounting techniques must be carefully considered in the evaluation of probable product performance.

Exhibit 12.9

ASTM E84 tunnel test apparatus. (Photo courtesy of Herbert Blenstein)

Exhibit 12.9 illustrates the ASTM E84 tunnel test apparatus. The same apparatus is required for testing per ANSI/UL 723.

Interior wall and ceiling finish classifications in accordance with 12.5.4.3 are based mainly on flame spread indices, with an additional requirement that the smoke developed index not exceed a common value of 450, regardless of the class into which the material falls based on flame spread. Flame spread classifications offer a general indication of the speed with which fire might spread across the surface of a material. In assessing the hazard posed by a material on the basis of flame spread, it is assumed that a person might be close to the fire and would be directly exposed to the energy associated with the actual flames. By contrast, the purpose of the smoke developed index is to address visual obscuration of the egress path by smoke. Thus, an interior wall and ceiling finish material with a low smoke developed index should provide better visibility in a given egress route than a material with a relatively high smoke developed index. Given that the smoke developed index is a cumulative measurement over the prescribed test duration, it is based on both quantity and rate of smoke liberation.

The *Code* requires the use of specific classes of interior wall and ceiling finish materials, which are differentiated by their allowable flame spread index, based on consideration of their installed location within the building, the building's egress paths, and the occupancy in question. Different classes of interior finish materials are specified for an office area, for example, as opposed to an exit stair enclosure or exit access corridor. The different classes recognize that, when escaping a building, people must move away from the flames while traveling through the means of egress toward an exit. The classes of interior finishes that are considered acceptable within an open office, therefore, are different from those that are required for exit enclosures. Similarly, occupancies used by those who have decreased capabilities of self-preservation have stricter interior finish requirements than occupancies used by fully ambulatory occupants. For example, although both hospitals and hotels provide sleeping accommodations, interior finish requirements for hospitals are more stringent, because hospital patients are less capable of self-preservation.

The same smoke developed index limit is used for all three flame spread classifications. This limit recognizes that smoke generated during a fire might affect visibility both in the vicinity of and remote from the fire. Large buildings can quickly fill with smoke as a result of a fire. An upper limit has been established, therefore, that applies to new interior finish materials, regardless of their location.

According to 12.5.4.3.1, existing wall and ceiling finish materials are exempt from the smoke development limitation. In existing buildings, existing interior finish materials are restricted only on the basis of flame spread. Prior to the 1976 edition, the *Code* did not regulate interior finish materials based on smoke development. As a general rule, the replacement of existing materials only because they were previously approved exclusively on the basis of flame spread is not warranted.

The smoke developed index limit of 450 was determined on the basis of research conducted by Underwriters Laboratories Inc. A 5000 ft^3 (140 m^3) room equipped with illuminated exit signs was filled with smoke from the tunnel test chamber. The time required to reach various stages of exit sign obscuration was recorded and compared to the smoke developed indices for the different materials involved. The report states that "materials having smoke developed ratings above 325 showed 'good' to 'marginal' visibility — scale readings of 3 to 4.8 — in a few cases; other materials produced conditions of 'marginal' to obscuration in the six-minute period."

Considering both time and smoke levels, the limit of 450 on smoke development as used in the *Code* has been judged to be reasonable. There is no direct relationship between flame spread and smoke development. For example, in the report referenced in the preceding paragraph, one material had a flame spread index of 490 and a smoke developed index of 57, while another had a flame spread index of 44 and a smoke developed index of 1387.

The smoke development limit of 450 is based solely on the level of visual obscuration. Although not addressed by the requirements for interior finishes, other important factors used in evaluating materials on the basis of smoke generation are the effects of irritability and toxicity caused by gases. Smoke might also act as an irritant, further reducing visibility, and might, in addition, have a debilitating physiological effect on people attempting to escape from a building. Such effects are not evaluated by the current smoke development limit. The adverse physiological effects on the human body caused by exposure to heat and the effects of inhaling hot gases also should be considered as part of an overall hazard risk assessment and should be considered separately from the interior finish requirements of Section 12.5.

N **12.5.4.3.2** The classification of interior finish specified in 12.5.4.3 shall be that of the basic material used by itself or in combination with other materials. [***101:***10.2.3.3.2]

N **12.5.4.3.3** Wherever the use of Class C interior wall and ceiling finish is required, Class A or Class B shall be permitted, and where Class B interior wall and ceiling finish is required, Class A shall be permitted. [***101:***10.2.3.3.3]

•

Paragraph 12.5.4.3.3 recognizes that the *Code* sets minimum criteria. An interior finish material that performs better than that specifically prescribed by the *Code* is always permitted.

N **12.5.4.4** Materials complying with the requirements of 12.5.4.1 shall not be required to be tested in accordance with 12.5.4.3. [***101:***10.2.3.4]

N **12.5.4.5** Materials described in 12.5.5 shall be tested as described in the corresponding sections. [***101:***10.2.3.5]

N **12.5.5* Interior Wall and Ceiling Finish Materials with Special Requirements.** The materials indicated in 12.5.5.1 through 12.5.5.16 shall be tested as indicated in the corresponding sections. [***101:***10.2.4]

N **A.12.5.5** Surface nonmetallic raceway products, as permitted by *NFPA 70* are not interior finishes and are not subject to the provisions of Chapter 10 of *NFPA 101*. [***101:***A.10.2.4]

N **12.5.5.1 Thickness Exemption.** The provisions of 12.5.2.1 shall not apply to materials having a total thickness of less than 1⁄28 in. (0.9 mm) that are applied directly to the surface of walls and ceilings where both of the following conditions are met:

(1) The wall or ceiling surface is a noncombustible or limited combustible material.
(2) The materials applied meet the requirements of Class A interior wall or ceiling finish when tested in accordance with 12.5.4, using fiber cement board as the substrate material.

[***101:***10.2.4.1]

Paragraph 12.5.5.1 addresses the issue of thin coverings, which was covered in earlier editions of the *Code* by a simply worded, performance-based criterion that was difficult to use and enforce. The *Code* recognized that thin coverings [those less than 1⁄28 in. (0.9 mm) in thickness] with surface-burning characteristics not greater than that of paper would not significantly affect the fire performance of the basic wall or ceiling material. If assurance was provided that such a thin covering had surface-burning characteristics not greater than those of paper, the thin material would not be subject to regulation as an interior finish. Therefore, the material's flame spread rating was not needed, which, in turn, meant that no fire testing was required. The problem was that, without running fire tests, it was impossible to determine whether a thin material had surface-burning characteristics that were greater than those of paper.

The wording of 12.5.5.1 does not exempt newly installed thin materials from testing, but it does exempt thin materials from testing with the actual substrate or backing material that will be used in the final installed state, provided that the material is installed on a noncombustible or limited-combustible surface (e.g., gypsum wallboard). If there were no exemption, thin materials, such as paint (whose liquid suspension state dries to become a thin layer of material) and wallpaper, would be required to be fire tested in combination with numerous backing materials. A complete set of test results, representative of the many forms of substrates in common use, would be prohibitively expensive to collect. Paragraph 12.5.5.1 permits the material to be tested only with fiber cement board as the substrate material. If the material, where tested in that configuration, meets the requirements for Class A interior finish (see 12.5.4.3), no further regulation by Section 12.5 is required.

Thermally thin coverings, such as paint and wallpaper coverings, where secured to a noncombustible substrate such as fiber cement board, will not significantly alter the performance of the substrate during a fire. However, thicker coverings, such as multiple layers of wallpaper, can contribute to rapid fire growth.

The provision of 12.5.5.1 has the effect of requiring any wall or ceiling covering (or multiple layers of such covering) of more than 1⁄28 in. (0.9 mm) in thickness to undergo the full test series required of other interior finish materials so as to be representative of actual installations. Painted surfaces might be evaluated using the following steps:

1. Determine the classification of the interior finish material (e.g., wood wainscoting) in its unpainted configuration and verify that it complies with the applicable limits.
2. Obtain a paint product for which the manufacturer has documented that it achieves a Class A rating when applied to a substrate of cement fiber board and tested in accordance with ASTM E84 or ANSI/UL 723.
3. Apply the paint to the substrate described in step 1 such that the thickness is less than 1⁄28 in. (0.9 mm).
4. Where steps 1 through 3 are followed, the paint is exempt from being tested on the substrate on which it is actually installed.

Where the thickness of an interior finish material is 1⁄28 in. (0.9 mm) or greater, it must be tested as it will actually be installed. For example, according to research presented in "Fire Tests of Building Interior Covering Systems" from the journal *Fire Technology,* the performance of thermally thin coverings is altered by the nature of the substrate over which they are installed. Adhesives might also be an important factor in performance. In the case of composites (such as textile wall coverings over gypsum board), the adhesive should be sufficient to maintain a bond between the "finish" and the substrate. However, excess adhesive might contribute to a fire. According to research from the Fire Research Laboratory, University of California, tests of textile wall coverings have shown that changing adhesives or simply changing the application rate for the same adhesive might significantly alter product performance. Tests to qualify assemblies should use adhesives and application rates similar to actual installations.

Similarly, a product that undergoes testing in intimate contact with a mineral board should be installed in contact with a mineral board or similar substrate. Also, where products are tested in intimate contact with a substrate, results might be altered if the product is installed with air space behind the covering.

N **12.5.5.1.1** If a material having a total thickness of less than 1⁄28 in. (0.9 mm) is applied to a surface that is not noncombustible or not limited-combustible, the provisions of 12.5.4 shall apply. [***101:***10.2.4.1.1]

N **12.5.5.1.2** Approved existing installations of materials applied directly to the surface of walls and ceilings in a total thickness of less than 1⁄28 in. (0.9 mm) shall be permitted to remain in use, and the provisions of 12.5.4 shall not apply. [***101:***10.2.4.1.2]

The provision of 12.5.5.1.2 exempts existing interior wall and ceiling finish materials having a thickness of less than 1⁄28 in. (0.9 mm) from the testing requirements of 12.5.4, provided that they are acceptable to the AHJ. See the definition of *approved existing* in 3.3.84.1 of NFPA *101.* The intent of the exemption is to permit existing finishes such as a single layer of paint or wallpaper to remain in place without documentation of their flame spread characteristics, since determination of their classification might be impractical. It is expected that such finish materials have a finite service life, and, upon replacement, tested products can be applied or installed. Where the AHJ determines that the finish material is of such character that regulation is necessary, use of the exemption provided by 12.5.5.1.2 can be denied.

N **12.5.5.2* Exposed Portions of Structural Members.** In other than new interior exit stairways, new interior exit ramps, and new exit passageways, exposed portions of structural members complying with the requirements for Type IV (2HH) construction in accordance with NFPA 220 or with the building code shall be exempt from testing and classification in accordance with 12.5.4. [***101:***10.2.4.2]

N **A.12.5.5.2** Paragraph 12.5.5.2 does not require Type IV (2HH), heavy timber, other than that used in interior exit stairs, interior exit ramps, and exit passageways be tested by either ASTM E84 or ANSI/UL 723 to determine a flame spread rating. Taller wood buildings and new technology, primarily new "mass timber," make taller buildings of Type IV possible. To that end, the requirements for Type IV have been changed to require the testing for components in the egress system such that they too need to be tested and meet the appropriate classification required in this section. This means that Type IV is "presumed" to comply with the finish requirements in this section for the purpose of meeting the requirements of this section for any wall or ceiling finish of elements other than interior exit stairways, interior exit ramps, and exit passageways. [***101:***A.10.2.4.2]

Paragraph 12.5.5.2 recognizes that exposed surfaces of heavy timber structural members can be safely used where Class A, Class B, or Class C interior wall and ceiling finish is required in other than exit enclosures, as explained in A.12.5.5.2, the text of which is new to the 2018 edition of NFPA *101*. Such wood members often have flame spread indices in the range of 76 to 200 and, therefore, are typically classified as Class C interior finish. The exemption is based on the fact that the structural members are located at intervals and do not constitute a continuous surface that allows flame to spread, for example, across a ceiling.

N **12.5.5.3 Cellular or Foamed Plastic.**

N **12.5.5.3.1** Cellular or foamed plastic materials shall not be used as interior wall and ceiling finish unless specifically permitted by 12.5.5.3.2 or 12.5.5.3.4. [***101:***10.2.4.3.1]

N **12.5.5.3.2** The requirements of 12.5.5.3 shall apply both to exposed foamed plastics and to foamed plastics used in conjunction with a textile or vinyl facing or cover. [***101:***10.2.4.3.2]

N **12.5.5.3.3*** Cellular or foamed plastic materials shall be permitted where subjected to large-scale fire tests that substantiate their combustibility and smoke release characteristics for the use intended under actual fire conditions. [***101:***10.2.4.3.3]

N **A.12.5.5.3.3** See A.12.5.5.3.3.2. [***101:***A.10.2.4.3.3]

N **12.5.5.3.3.1** One of the following fire tests shall be used for assessing the combustibility of cellular or foamed plastic materials as interior finish:

(1) NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, with the acceptance criteria of 12.5.4.2
(2) ANSI/UL 1715, *Standard for Fire Test of Interior Finish Material* (including smoke measurements, with total smoke release not to exceed 1000 m^2)
(3) ANSI/UL 1040, *Standard for Fire Test of Insulated Wall Construction*
(4) ANSI/FM Approval 4880, *Approval Standard for Class 1 Rating of Insulated Wall or Wall and Roof/Ceiling Panels, Interior Finish Materials or Coatings, and Exterior Wall Systems*

[***101:***10.2.4.3.3.1]

N **12.5.5.3.3.2*** The tests shall be performed on a finished foamed plastic assembly related to the actual end-use configuration, including any cover or facing, and at the maximum thickness intended for use. [***101:***10.2.4.3.3.2]

N **A.12.5.5.3.3.2** Both NFPA 286 and ANSI/UL 1715, *Standard for Fire Test of Interior Finish Material*, contain smoke obscuration criteria. ANSI/UL 1040, *Standard for Fire Test of Insulated Wall Construction*, and FM 4880, *Approval Standard for Class I Insulated Wall or Wall and Roof/Ceiling Panels; Plastic Interior Finish Materials; Plastic Exterior Building Panels; Wall/Ceiling Coating Systems; Interior or Exterior Finish Systems*, do not. Smoke obscuration is an important component of the fire performance of cellular or foamed plastic materials. [***101:***A. 10.2.4.3.3.2]

N **12.5.5.3.4** Cellular or foamed plastic shall be permitted for trim not in excess of 10 percent of the specific wall or ceiling area to which it is applied, provided that it is not less than 20 lb/ft³ (320 kg/m³) in density, is limited to ½ in. (13 mm) in thickness and 4 in. (100 mm) in width, and complies with the requirements for Class A or Class B interior wall and ceiling finish as described in 12.5.4.3; however, the smoke developed index shall not be limited. [***101:***10.2.4.3.4]

The prohibition of 12.5.5.3.1 on the use of foamed plastics within buildings is based on actual fire experience in which foamed plastics have contributed to very rapid fire development, as presented in "Foamed Plastic Fire: Fire Spreads 430 Feet in Eight Minutes," from *Fire Journal*. It also acknowledges that tunnel testing per ASTM E84 (see 12.5.4.4) might not accurately assess the potential hazard of plastics in general. Therefore, if cellular or foamed plastics are to be used within a building, their use needs to be substantiated on the basis of large-scale fire tests that simulate conditions of actual use. Four such tests are offered in 12.5.5.3.3.1(1) through (4).

Note that the provisions of 12.5.5.3 apply not only to exposed foamed plastics but also to foamed plastics used as backings for textile or vinyl facings or cover materials. An assembly comprising foamed plastic backings in conjunction with a textile or vinyl facing or cover is expected to behave differently under fire tests than if just the textile or vinyl facing were tested alone.

Paragraph 12.5.5.3.4 permits the limited use of cellular or foamed plastics as a substitute for traditional wood trim, assuming their performance under fire exposure will be comparable to that of wood. To control the mass of the material that can be used, limits have been established on width and thickness. The intent in establishing a minimum density of 20 lb/ft³ (320 kg/m³) is to prohibit the use of lightweight [1 lb/ft³ to 3 lb/ft³ (16 kg/m³ to 48 kg/m³)], readily available, foamed plastics as trim.

Limiting plastic trim to Class A or Class B materials, in combination with the 10 percent area limit for walls and ceilings, imposes a greater restriction than that which applies to wood. This limitation ensures that the performance of the plastic trim will be equivalent or superior to that of more traditional materials.

In establishing the 10 percent limit, it is intended that the trim will be used around doors and windows or at the junction of walls and ceilings. Therefore, the trim will be somewhat uniformly distributed throughout the room. There would be a significant difference in the probable performance of wall and ceiling finish if the 10 percent limit were concentrated in one area.

N **12.5.5.4* Textile Wall Coverings.** Where used as interior wall finish materials, textile materials shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall comply with the requirements of either, 12.5.4.1, 12.5.5.4.1, or 12.5.5.4.3. [***101:***10.2.4.4]

N **A.12.5.5.4** Previous editions of the *Code* have regulated textile materials on walls and ceilings using ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Full-scale room/corner fire test research has shown that flame spread indices produced by ASTM E84 or ANSI/UL 723 might not reliably predict all aspects of the fire behavior of textile wall and ceiling coverings. [***101:***A.10.2.4.4]

NFPA 265 and NFPA 286, both known as room/corner tests, were developed for assessing the fire and smoke obscuration performance of textile wall coverings and interior wall and ceiling finish materials, respectively. As long as an interior wall or ceiling finish material is tested by NFPA 265 or NFPA 286, as appropriate, using a mounting system, substrate, and adhesive (if appropriate) that are representative of actual use, the room/corner test provides an adequate evaluation of a product's flammability and smoke obscuration behavior. Manufacturers, installers, and specifiers should be encouraged to use NFPA 265 or NFPA 286, as appropriate (but not both), because each of these standard fire tests has the ability to characterize actual product behavior, as opposed to data generated by tests using ASTM E84 or ANSI/UL 723, which only allow comparisons of one product's performance with another. If a manufacturer or installer chooses to test a wall finish in accordance with NFPA 286, additional testing in accordance with ASTM E84 or ANSI/UL 723 is not necessary. [***101:***A.10.2.4.4]

The test results from ASTM E84 or ANSI/UL 723 are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations. Actual test results for heat, smoke, and combustion product release from NFPA 265, and from NFPA 286, are suitable for use as input into fire models for performance-based design. [***101:***A.10.2.4.4]

N **12.5.5.4.1*** Products tested in accordance with NFPA 265 shall comply with the criteria of 12.5.5.4.2. [**101:**10.2.4.4.1]

N **A.12.5.5.4.1** The methodology specified in NFPA 265 includes provisions for measuring smoke obscuration. [***101:***A.10.2.4.4.1]

N **12.5.5.4.2*** The interior finish shall comply with all of the following when tested using method B of the test protocol of NFPA 265:

(1) During the 40 kW exposure, flames shall not spread to the ceiling.
(2) The flame shall not spread to the outer extremities of the samples on the 8 ft × 12 ft (2440 mm × 3660 mm) walls.
(3) Flashover, as described in NFPA 265, shall not occur.
(4) For new installations, the total smoke released throughout the test shall not exceed 1000 m^2.

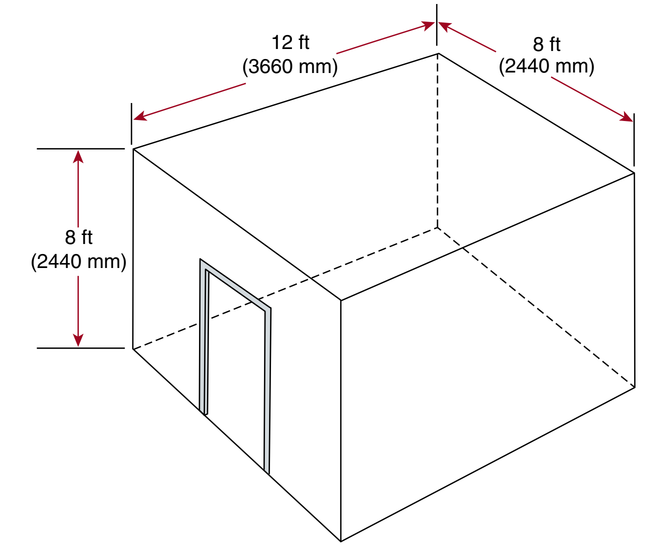
[***101:***10.2.4.4.2]

N **A.12.5.5.4.2** See A.12.5.5.4.1 and A.12.5.5.4. [***101:***A.10.2.4.4.2]

The *Code* recognizes the use of Method B of NFPA 265, but not Method A. Method B is the more rigorous test and requires that the test specimens be mounted to cover fully both 8 ft × 12 ft (2440 mm × 3660 mm) walls and the 8 ft × 8 ft (2440 mm × 2440 mm) rear wall. Method A is a screening test for which the test specimen is mounted as 24 in. (610 mm) wide strips at the intersection of two adjacent walls and along the tops of those two walls where they meet the ceiling.

The NFPA 265 test compartment is depicted in Exhibit 12.10.

Exhibit 12.10



Test compartment required by NFPA 265.

N **12.5.5.4.3** Textile materials meeting the requirements of Class A when tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard Test Method for Surface Burning Characteristics of Building Materials*, using the specimen preparation and mounting method of ASTM E2404, *Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics*, shall be permitted as follows:

(1) On the walls of rooms or areas protected by an approved automatic sprinkler system.
(2) On partitions that do not exceed three-quarters of the floor-to-ceiling height or do not exceed 8 ft (2440 mm) in height, whichever is less.
(3) On the lower 48 in. (1220 mm) above the finished floor on ceiling-height walls and ceiling-height partitions.
(4) Previously approved existing installations of textile material meeting the requirements of Class A when tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials* or ANSI/UL 723, *Standard Test Method for Surface Burning Characteristics of Building Materials*, shall be permitted to be continued to be used.

[***101:***10.2.4.4.3]

The provisions addressing textile wall coverings were editorially reorganized for the 2018 edition of the *Code* to be more user friendly; no technical changes were intended. Textile materials are permitted to be used as interior wall finish only where such materials meet 12.5.4.1, 12.5.5.4.1, or 12.5.5.4.3. See the *Life Safety Code® Handbook* for further details on the use of textile wall and ceiling coverings.

N **12.5.5.5* Expanded Vinyl Wall Coverings.** Where used as interior wall finish materials, expanded vinyl wall coverings shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall comply with the requirements of either 12.5.4.1, 12.5.5.4.1, or 12.5.5.4.3. [***101:***10.2.4.5]

N **A.12.5.5.5** Expanded vinyl wall covering consists of a woven textile backing, an expanded vinyl base coat layer, and a nonexpanded vinyl skin coat. The expanded base coat layer is a homogeneous vinyl layer that contains a blowing agent. During processing, the blowing agent decomposes, which causes this layer to expand by forming closed cells. The total thickness of the wall covering is approximately 0.055 in. to 0.070 in. (1.4 mm to 1.8 mm). [***101:***A.10.2.4.5]

The provisions of 12.5.5.5, which address expanded vinyl wall coverings, are similar to those of 12.5.5.4, which are applicable to textile wall coverings. It is the intent of the *Code* to require compliance with 12.5.5.5 wherever expanded vinyl wall finish materials are installed, regardless of occupancy classification.

N **12.5.5.6 Textile Ceiling Coverings.** Where used as interior ceiling finish materials, textile materials shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall meet one of the following:

(1) Comply with the requirements of 12.5.4.1
(2) Meet the requirements of Class A when tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials* or ANSI/UL 723, *Standard Test Method for Surface Burning Characteristics of Building Materials* using the specimen preparation and mounting method of ASTM E2404, *Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics*, and used on the ceilings of rooms or areas protected by an approved automatic sprinkler system

[**101:**10.2.4.6]

N **12.5.5.7 Expanded Vinyl Ceiling Coverings.** Where used as interior ceiling finish materials, expanded vinyl materials shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall meet one of the following:

(1) Comply with the requirements of 12.5.4.1
(2) Meet the requirements of Class A when tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials* or ANSI/UL 723, *Standard Test Method for Surface Burning Characteristics of Building Materials*, using the specimen preparation and mounting method of ASTM E2404, *Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics*, and used on the ceilings of rooms or areas protected by an approved automatic sprinkler system

[***101:***10.2.4.7]

N **12.5.5.8 Lockers.**

N **12.5.5.8.1 Combustible Lockers.** Where lockers constructed of combustible materials other than wood are used, the lockers shall be considered interior finish and shall comply with 12.5.4, except as permitted by 12.5.5.8.2. [***101:***10.2.4.8.1]

N **12.5.5.8.2 Wood Lockers.** Lockers constructed entirely of wood and of noncombustible materials shall be permitted to be used in any location where interior finish materials are required to meet a Class C classification in accordance with 12.5.4. [***101:***10.2.4.8.2]

N **12.5.5.9 Solid Thermoplastics.**

N **12.5.5.9.1** Solid thermoplastics including, but not limited to, polypropylene, high-density polyethylene (HDPE), solid polycarbonate, solid polystyrene, and solid acrylic materials that melt and drip when exposed to flame shall not be permitted as interior wall or ceiling finish unless the material complies with the requirements of 12.5.4.1. [***101:***10.2.4.9.1]

N **12.5.5.9.2** The tests shall be performed on a finished assembly and on the maximum thickness intended for use. [***101:***10.2.4.9.2]

Polypropylene (PP) and high-density polyethylene (HDPE) are thermoplastic materials that, when exposed to fire, have a tendency to melt and form pool fires that can potentially burn vigorously. The requirement of 12.5.5.9.1 specifies that products, such as toilet room privacy dividers constructed of PP or HDPE, are considered interior finish materials and must comply with the performance criteria of 12.5.4.1 when tested in accordance with NFPA 286. Testing such materials for their flame spread and smoke development characteristics using the tunnel test of ASTM E84 or ANSI/UL 723 does not sufficiently characterize their fire performance. The NFPA 286 room-corner test provides a more realistic determination of their contribution to fire development in a room.

N **12.5.5.10 Site-Fabricated Stretch Systems.**

N **12.5.5.10.1** For new installations, site-fabricated stretch systems containing all three components described in the definition in Chapter 3 shall be tested in the manner intended for use and shall comply with the requirements of 12.5.4.1 or 12.6.7. [***101:***10.2.4.10.1]

N **12.5.5.10.2** If the materials are tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, specimen preparation and mounting shall be in accordance with ASTM E2573, *Standard Practice for Specimen Preparation and Mounting of Site-Fabricated Stretch Systems to Assess Surface Burning Characteristics*. [***101:***10.2.4.10.2]

Site-fabricated stretch systems comprise the following three components, as described in the definition of the term in 3.3.284.2 of NFPA *101*:

1. A frame (constructed of plastic, wood, metal, or other material) used to hold fabric in place
2. A core material (infill, with the correct properties for the application)
3. An outside layer, comprising a textile, fabric, or vinyl, that is stretched taut and held in place by tension or mechanical fasteners via the frame

Although many AHJs might have previously regulated site-fabricated stretch systems as interior finish, the requirements of 12.5.5.10 make it clear that such systems are, in fact, interior finish and must be tested accordingly. Additionally, where such systems are tested using the Steiner tunnel test in accordance with ASTM E84 or ANSI/UL 723, they must be mounted in the tunnel using the procedure specified by ASTM E2573, *Standard Practice for Specimen Preparation and Mounting of Site-Fabricated Stretch Systems to Assess Surface Burning Characteristics.*

N **12.5.5.11 Reflective Insulation Materials.**

N **12.5.5.11.1** Reflective insulation materials shall be tested in the manner intended for use and shall comply with the requirements of 12.5.4 or 12.5.4.3. [***101:***10.2.4.11.1]

N **12.5.5.11.2** If the materials are tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, specimen preparation and mounting shall be in accordance with ASTM E2599, *Standard Practice for Specimen Preparation and Mounting of Reflective Insulation, Radiant Barrier, and Vinyl Stretch Ceiling Materials for Building Applications to Assess Surface Burning Characteristics*. [***101:***10.2.4.11.2]

N **12.5.5.12 Metal Ceiling and Wall Panels.**

N **12.5.5.12.1** Listed factory finished metal ceiling and wall panels meeting the requirements of Class A in accordance with 12.5.4, shall be permitted to be finished with one additional application of paint. [***101:***10.2.4.12.1]

N **12.5.5.12.2** Such painted panels shall be permitted for use in areas where Class A interior finishes are required. The total paint thickness shall not exceed 1⁄28 in. (0.9 mm). [***101:***10.2.4.12.2]

N **12.5.5.13 Laminated Products Factory Produced with a Wood Substrate.**

N **12.5.5.13.1** Laminated products factory produced with a wood substrate shall be tested in the manner intended for use and shall comply with the requirements of 12.5.4.1 or 12.5.4.3. [***101:***10.2.4.13.1]

N **12.5.5.13.2** If the materials are tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, specimen preparation and mounting shall be in accordance with ASTM E2579, *Standard Practice for Specimen Preparation and Mounting of Wood Products to Assess Surface Burning Characteristics*, using the product-mounting system, including adhesive, of actual use. [***101:***10.2.4.13.2]

N **12.5.5.14 Facings or Wood Veneers Intended to be Applied on Site over a Wood Substrate.**

N **12.5.5.14.1** Facings or veneers intended to be applied on site over a wood substrate shall be tested in the manner intended for use and shall comply with the requirements of 12.5.4.1 or 12.5.4.3. [***101:***10.2.4.14.1]

N **12.5.5.14.2** If the materials are tested in accordance with NFPA 286 they shall use the product-mounting system, including adhesive, described in Section 5.8.9 of NFPA 286. [***101:***10.2.4.14.2]

N **12.5.5.14.3** If the materials are tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, specimen preparation and mounting shall be in accordance with ASTM E2404, *Standard Practice for Specimen Preparation and Mounting of Textile, Paper or Polymeric (Including Vinyl) and Wood Wall or Ceiling Coverings, Facings and Veneers, to Assess Surface Burning Characteristics*. [***101:***10.2.4.14.3]

N **12.5.5.15* Light-Transmitting Plastics.** Light-transmitting plastics shall be permitted to be used as interior wall and ceiling finish shall be permitted based on large-scale fire tests per 12.5.5.3.3.1, which substantiate the combustibility characteristics of the plastics for the use intended under actual fire conditions. [***101:***10.2.4.15]

N **A.12.5.5.15** Light-transmitting plastics are used for a variety of purposes, including light diffusers, exterior wall panels, skylights, canopies, glazing, and the like. Previous editions of the *Code* have not addressed the use of light-transmitting plastics. Light-transmitting plastics will not normally be used in applications representative of interior finishes. Accordingly, ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials,* can produce test results that might or might not apply. [***101:***A.10.2.4.15]

Light-transmitting plastics are regulated by model building codes such as *NFPA 5000*. Model building codes provide adequate regulation for most applications of light-transmitting plastics. Where an authority having jurisdiction determines that a use is contemplated that differs from uses regulated by model building codes, light-transmitting plastics in such applications can be substantiated by fire tests that demonstrate the combustibility characteristics of the light-transmitting plastics for the use intended under actual fire conditions. [***101:***A.10.2.4.15]

For additional information on light transmitting plastics, see Section 48.7 of *NFPA 5000*. [***101:***A.10.2.4.15]

N **12.5.5.16 Decorations and Furnishings.** Decorations and furnishings that do not meet the definition of interior finish, as defined in 3.3.116.2, shall be regulated by the provisions of Section 12.6. [***101:***10.2.4.16]

N **12.5.6 Trim and Incidental Finish.**

N **12.5.6.1 General.** Interior wall and ceiling trim and incidental finish, other than wall base in accordance with 12.5.6.2 and bulletin boards, posters, and paper in accordance with 12.5.6.3, not in excess of 10 percent of the specific wall and ceiling areas of any room or space to which it is applied shall be permitted to be Class C materials in occupancies where interior wall and ceiling finish of Class A or Class B is required. [***101:***10.2.5.1]

N **12.5.6.2 Wall Base.** Interior floor trim material used at the junction of the wall and the floor to provide a functional or decorative border, and not exceeding 6 in. (150 mm) in height, shall meet the requirements for interior wall finish for its location or the requirements for Class II interior floor finish as described in 12.5.8.4 using the test described in 12.5.8.3. [***101:***10.2.5.2]

N **12.5.6.2.1** If a Class I floor finish is required, the interior floor trim shall be Class I. [***101:***10.2.5.2.1]

N **12.5.6.3 Bulletin Boards, Posters, and Paper.**

N **12.5.6.3.1** Bulletin boards, posters, and paper attached directly to the wall shall not exceed 20 percent of the aggregate wall area to which they are applied. [***101:***10.2.5.3.1]

N **12.5.6.3.2** The provision of 12.5.6.3.1 shall not apply to artwork and teaching materials in sprinklered educational or day-care occupancies in accordance with 20.2.4.4.3 and 20.3.4.2.3.5.3. [***101:***10.2.5.3.2]

Subsection 12.5.6 is intended to permit the use of wood trim around doors and windows as a decoration or as functional molding (such as for chair rails). Wood trim must meet the criteria for Class C materials. See 12.5.5.3.4 for restrictions applicable to plastic trim. Where such trim is used in rooms or spaces requiring the use of Class A or Class B materials, the trim is permitted to constitute not more than 10 percent of the aggregate wall or ceiling area to ensure that the trim will be more or less uniformly distributed throughout the room or space. If the trim is concentrated in a single, sizable, continuous pattern (e.g., on one wall of a room), the materials could contribute to rapid fire growth.

The wall base provisions of 12.5.6.2 regulate the common practice of running flooring up onto the lowest portion of a wall where it meets the floor. The 6 in. (150 mm) maximum height criterion recognizes the limitations of judging an interior wall finish material based on a test method developed to evaluate flame spread for interior floor finish materials exposed to a flaming radiant heat source. Note that, even where the interior floor finish of a room or space is not required to be Class I or Class II in accordance with 12.5.8.4, the flooring material wrapped up onto the wall is required to be tested and classified per 12.5.8.3 and 12.5.8.4.

The educational and day-care occupancies regulate artwork and teaching materials that are attached directly to walls for many editions of that *Code* — see 20.2.4.4.3 and 20.3.4.2.3.5.3. The provisions of 12.5.6.3 codify the subject for all other occupancies. Bulletin boards, posters, and paper attached directly to a wall serve as de facto interior finish materials with the potential for spreading flame. The 20 percent maximum aggregate wall area criterion of 12.5.6.3.1 helps ensure that there are not sufficient expanses of such materials, for which classification per 12.5.4.3 is unfeasible and unenforceable, that could spread flame more quickly than would occur with wall finish materials complying with applicable interior finish requirements based on testing per ASTM E84 or ANSI/UL 723.

N **12.5.7* Fire-Retardant Coatings.**

N **A.12.5.7** Fire-retardant coatings need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings. [***101:***A.10.2.6]

N **12.5.7.1*** The required flame spread index or smoke developed index of existing surfaces of walls, partitions, columns, and ceilings shall be permitted to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread index values than permitted. [***101:***10.2.6.1]

N **A.12.5.7.1** It is the intent of NFPA 1 to mandate interior wall and ceiling finish materials that obtain their fire performance and smoke developed characteristics in their original form. However, in renovations, particularly those involving historic buildings, and in changes of occupancy, the required fire performance or smoke developed characteristics of existing surfaces of walls, partitions, columns, and ceilings might have to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread ratings than permitted. Such treatments should comply with the requirements of NFPA 703. When fire-retardant coatings are used, they need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings, but permanency must be assured in some appropriate fashion. Fire-retardant coatings must possess the desired degree of permanency and be maintained so as to retain the effectiveness of the treatment under the service conditions encountered in actual use. [***101:***A.10.2.6.1]

N **12.5.7.1.1** Such treatments shall be tested, or shall be listed and labeled for application to the material to which they are applied, and shall comply with the requirements of NFPA 703. [***101:***10.2.6.1.1]

N **12.5.7.2*** Surfaces of walls, partitions, columns, and ceilings shall be permitted to be finished with factory-applied fire-retardant-coated products that have been listed and labeled to demonstrate compliance with the requirements of ASTM E2768, *Standard Test Method for Extended Duration Surface Burning Characteristics of Building Materials,* on the coated surface. [***101:***10.2.6.2]

N **A.12.5.7.2** The intent of this section is that factory-applied fire-retardant-coated products, such as panels or tiles applied to walls or ceilings, replace the existing finish and are not applied on top of the existing finish. [***101:***A.10.2.6.2]

N **12.5.7.3** Fire-retardant coatings or factory-applied fire-retardant-coated assemblies shall possess the desired degree of permanency and shall be maintained so as to retain the effectiveness of the treatment under the service conditions encountered in actual use. [***101:***10.2.6.3]

Fire-retardant paints, coatings, and penetrants are sometimes used to improve the flame spread ratings of materials or assemblies used as interior finishes within buildings. Fire-retardant treatments are permitted to be used to satisfy the flame spread requirements only for existing interior finish materials within existing buildings.

Fire retardants are generally surface treatments that — through intumescence or other chemical reaction — delay the ignition and slow the flame spread of a material. The nature of the material to which the treatment has been applied is not changed. Fire exposures of sufficient duration or intensity can ultimately cause a treated material to burn. Therefore, as a rule, materials with favorable intrinsic performance characteristics are preferred over those that achieve a satisfactory level of performance through the use of externally applied treatments. However, external treatments, where properly applied and maintained, can be effective in achieving reasonable fire performance.

Note that 12.5.7.1.1 permits fire-retardant coatings to be either tested or listed, since the product might have been tested with adequate results but not yet listed when being considered for application. Additionally, such products must comply with NFPA 703, *Standard for Fire-Retardant–Treated Wood and Fire-Retardant Coatings for Building Materials* which contains criteria related to testing.

Fire-retardant paints, coatings, and penetrants must be applied in strict accordance with the manufacturer's instructions. Most fire-retardant coatings require an application rate that is three to four times greater than that of ordinary paints. Application is usually done by brush, spray, immersion, or pressure treatment. The treatment should be reapplied or renewed at regular intervals. Treatments that might be removed by regular maintenance, washing, or cleaning procedures will require periodic examination and reapplication to maintain the required level of performance.

The use of fire retardants can improve the performance of some materials from Class C to Class B; similarly, Class B materials can, in some cases, be upgraded to Class A. Likewise, materials having flame spread ratings in excess of 200 can sometimes be upgraded to Class C.

In approving fire-retardant treatments, the AHJ should take into consideration the fact that, in reducing flame spread, some fire-retardant treatments increase a material's capacity for smoke generation.

The provision of 12.5.7.2 is intended to permit assemblies with factory-applied coatings, provided that they are listed and labeled by an approved testing laboratory to indicate compliance with the noted test standard.

N 12.5.8* Interior Floor Finish Testing and Classification.

N **A.12.5.8** The flooring radiant panel provides a measure of a floor covering's tendency to spread flames when located in a corridor and exposed to the flame and hot gases from a room fire. The flooring radiant panel test method is to be used as a basis for estimating the fire performance of a floor covering installed in the building corridor. Floor coverings in open building spaces and in rooms within buildings merit no further regulation, provided that it can be shown that the floor covering is at least as resistant to spread of flame as a material that meets the U.S. federal flammability standard 16 CFR 1630, "Standard for the Surface Flammability of Carpets and Rugs" (FF 1-70). All carpeting sold in the United States since 1971 is required to meet this standard and, therefore, is not likely to become involved in a fire until a room reaches or approaches flashover. Therefore, no further regulations are necessary for carpet, other than carpet in exitways and corridors. [***101:***A.10.2.7]

It has not been found necessary or practical to regulate interior floor finishes on the basis of smoke development. [***101:***A.10.2.7]

Full-scale fire tests and fire experience have shown that floor coverings in open building spaces merit no regulation beyond the U.S. federally mandated DOC FF 1-70 "pill test." This is because floor coverings meeting the pill test will not spread flame significantly until a room fire approaches flashover. At flashover, the spread of flame across a floor covering will have minimal impact on the already existing hazard. The minimum critical radiant flux of a floor covering that will pass the FF 1-70 test has been determined to be approximately 0.04 W/cm^2 (Tu, King-Mon and Davis, Sanford, "Flame Spread of Carpet Systems Involved in Room Fires," NFSIR 76-1013, Center for Fire Research, National Bureau of Standards, June 1976). The flooring radiant panel is only able to determine critical radiant flux values to 0.1 W/cm^2. This provision will prevent use of a noncomplying material, which can create a problem, especially when the *Code* is used outside the United States where U.S. federal regulation FF 1-70 (16 CFR 1630) is not mandated. [***101:***A.10.2.7]

N **12.5.8.1*** Carpet and carpet-like interior floor finishes shall comply with ASTM D2859, *Standard Test Method for Ignition Characteristics of Finished Textile Floor Covering Materials.* [***101:***10.2.7.1]

N **A.12.5.8.1** Compliance with 16 CFR 1630, "Standard for the Surface Flammability of Carpets and Rugs" (FFI-70), is considered equivalent to compliance with ASTM D2859, *Standard Test Method for Ignition Characteristic of Finished Textile Floor Covering Materials.* [***101:***A.10.2.7.1]

N **12.5.8.2** Floor coverings, other than carpet for which 12.5.3.2 establishes requirements for fire performance, shall have a minimum critical radiant flux of 0.1 W/cm^2. [***101:***10.2.7.2]

N **12.5.8.3*** Interior floor finishes shall be classified in accordance with 12.5.8.4, based on test results from NFPA 253 or ASTM E648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source.* [***101:***10.2.7.3]

N **A.12.5.8.3** ASTM E648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, and NFPA 253 are considered nationally recognized consensus standard test methods for determining the critical radiant flux from floor covering systems and are likely to yield equivalent test results. [***101:***A.10.2.7.3]

Experience and full-scale fire test data have shown that floor coverings of modest resistance to flame spread are unlikely to become involved in the early growth of a fire. The testing of flooring materials in accordance with 12.5.8.1 and 12.5.8.2 is relatively easy to accomplish. The testing helps to identify floor finish materials that have a modest resistance to flame spread.

Where floor coverings are regulated by the occupancy chapters in NFPA *101*, the evaluation is based on tests conducted in accordance with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, or ASTM E648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*. The flooring radiant panel test was specifically developed to evaluate the tendency of a floor covering to propagate flame. It measures a floor covering's tendency to spread flames where located in a corridor and exposed to flame and hot gases from a room fire.

Interior floor finishes must be tested as proposed for use. For example, if a carpet is to be used with a separate underlayment, the carpet must be tested as such. The flooring radiant panel test specifies that a carpet is permitted to be tested using either the standard underlayment specified in NFPA 253 or ASTM E648 or the actual underlayment proposed for use. Data generated using the standard underlayment is intended to permit the tested carpet to be used over any other underlayment. Where assembly tests are conducted with other than the standard underlayment, the results of such tests are valid only for the specific combination tested.

Floor coverings are not regulated on the basis of smoke generation. Smoke development limits are not believed to be practical or necessary, because floor coverings generally will not contribute to a fire until the fire has grown to large proportions. The minimal benefits achieved by imposing smoke development limits do not usually warrant such regulation. In addition, it is not considered practical to regulate on the basis of smoke development, because no regulatory test method that exists has been shown to be capable of producing data that correlate with the performance of products in actual fires.

N **12.5.8.4** Interior floor finishes shall be grouped in the classes specified in 12.5.8.4.1 and 12.5.8.4.2 in accordance with the critical radiant flux requirements. [***101:***10.2.7.4]

N **12.5.8.4.1 Class I Interior Floor Finish.** Class I interior floor finish shall have a critical radiant flux of not less than 0.45 W/cm^2, as determined by the test described in 12.5.8.3. [***101:***10.2.7.4.1]

N **12.5.8.4.2 Class II Interior Floor Finish.** Class II interior floor finish shall have a critical radiant flux of not less than 0.22 W/cm^2, but less than 0.45 W/cm^2, as determined by the test described in 12.5.8.3. [***101:***10.2.7.4.2]

The greater its critical radiant flux value, the greater the resistance of a floor finish to flame propagation. Thus, a Class I interior floor finish with a critical radiant flux of 0.45 W/cm^2 or greater should perform better under fire conditions than a Class II interior floor finish material with its lesser critical radiant flux value range of 0.22 W/cm^2 to less than 0.45 W/cm^2. Compare this classification with that of interior wall and ceiling interior finish materials in 12.5.4.3, in which higher flame spread indices generally denote poorer performance under fire conditions.

N **12.5.8.5** Wherever the use of Class II interior floor finish is required, Class I interior floor finish shall be permitted. [***101:***10.2.7.5]

N **12.5.9 Automatic Sprinklers.**

N **12.5.9.1** Other than as required in 12.5.5, where an approved automatic sprinkler system is installed in accordance with Section 13.3, Class C interior wall and ceiling finish materials shall be permitted in any location where Class B is required, and Class B interior wall and ceiling finish materials shall be permitted in any location where Class A is required. [***101:***10.2.8.1]

N **12.5.9.2** Where an approved automatic sprinkler system is installed in accordance with Section 13.3, throughout the fire compartment or smoke compartment containing the interior floor finish, Class II interior floor finish shall be permitted in any location where Class I interior floor finish is required, and where Class II is required, the provisions of 12.5.8.2 shall apply. [***101:***10.2.8.2]

Fire testing and actual fire experience have shown that automatic sprinklers prevent flame spread across the surface of a wall, ceiling, or floor covering so as to prevent flashover. Flame spread limits (applicable to interior wall and ceiling finishes) and critical radiant flux limits (applicable to interior floor finishes) are more lenient in areas protected by an automatic sprinkler system. However, there is a value beyond which the potential for flame spread becomes unacceptably high. For example, in occupancies with the most lenient interior finish requirements, which include fully sprinklered buildings, interior wall and ceiling finishes must meet the criteria for Class C materials. Note that the provisions of 12.5.9.1 and 12.5.9.2 apply unless specifically prohibited elsewhere in the *Code*. New detention and correctional occupancies are an example of an occupancy prohibiting the interior finish requirements from being further relaxed based on sprinkler protection, see 20.7.3.2. All new detention and correctional occupancies are required to be sprinklered (see 13.3.2.13.1). The interior finish limitations established in 20.7.3.2 and 20.7.3.4.2 are based on the presence of sprinklers. The prohibition on use of 12.5.9.1 and 12.5.9.2 keeps the user from taking a second, unjustified credit for the sprinklers.

N 12.6 Contents and Furnishings

N **12.6.1*** Where required by the applicable provisions of this *Code*, draperies, curtains, and other similar loosely hanging furnishings and decorations shall meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701. [***101:***10.3.1]

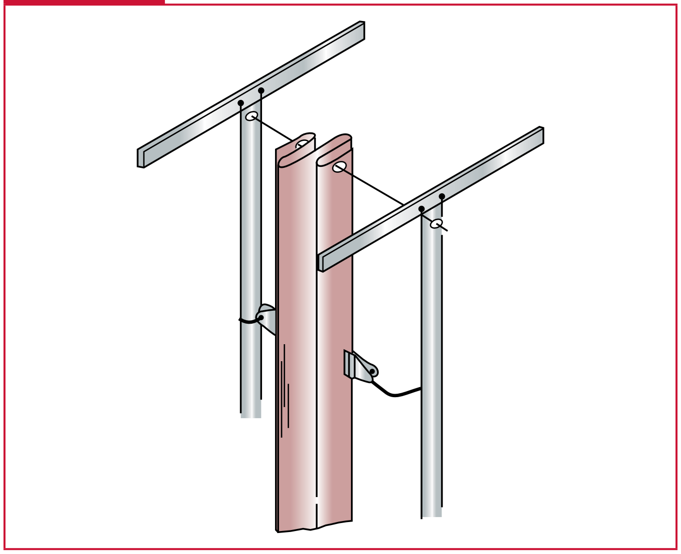
N **A.12.6.1** Testing per NFPA 701 applies to textiles and films used in a hanging configuration. If the textiles are to be applied to surfaces of buildings or backing materials as interior finishes for use in buildings, they should be treated as interior wall and ceiling finishes in accordance with Section 12.5.2 of this *Code*, and they should then be tested for flame spread index and smoke developed index values in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, or for flame spread and flashover in accordance with NFPA 265. Films and other materials used as interior finish applied to surfaces of buildings should be tested for flame spread index and smoke developed index values in accordance with ASTM E84 or ANSI/UL 723 or for heat and smoke release and flashover in accordance with NFPA 286. [***101:***A.10.3.1]

The test results from NFPA 701 are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations. [***101:***A.10.3.1]

The testing requirements of NFPA 701 measure the level of hazard posed by draperies and other loosely hanging fabrics and films. NFPA 701 describes procedures for an intermediate-scale test (referred to as Test Method 1) and a large-scale test (referred to as Test Method 2). The applicable test method is determined, in part, by the weight of the material per unit area (i.e., areal density). Both tests involve applying a flame to a vertically positioned sample for a specified time. Upon removal of the flame-producing burner, the sample must self-extinguish and must not have charred beyond a specified distance in order to pass the test. Additionally, with the intermediate-scale test, a specified maximum percent weight loss must not be exceeded.

Exhibit 12.11 illustrates a representative setup for a folded test sample for the large-scale test (Test Method 2) from NFPA 701. The hanging textile sample is approximately 47 in. (1200 mm) long.

Exhibit 12.11



NFPA 701 test sample in folds.

N 12.6.2 Smoldering Ignition of Upholstered Furniture and Mattresses.

N **12.6.2.1* Upholstered Furniture.** Newly introduced upholstered furniture, except as otherwise permitted by Chapters 11 through 43 of NFPA *101*, shall be resistant to a cigarette ignition (i.e., smoldering) in accordance with one of the following:

(1) The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.
(2) Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1½ in. (38 mm) when tested in accordance with NFPA 261.

[***101:***10.3.2.1]

N **A.12.6.2.1** The Class I requirement associated with testing in accordance with NFPA 260 and the char length of not more than 1½ in. (38 mm) required with testing in accordance with NFPA 261 are indicators that the furniture item or mattress is resistant to a cigarette ignition. A fire that smolders for an excessive period of time without flaming can reduce the tenability within the room or area of fire origin without developing the temperatures necessary to operate automatic sprinklers. [***101:***A.10.3.2.1]

The test results from NFPA 260 and from NFPA 261 are suitable for classification purposes but should not be used as input into fire models because they are not generated in units suitable for engineering calculations. [***101:***A.10.3.2.1]

Until recently, NFPA 260 was equivalent to ASTM E1353, *Standard Test Methods for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and NFPA 261 was equivalent to ASTM E1352, *Standard Test Method for Cigarette Ignition Resistance of Mock-Up Upholstered Furniture Assemblies*. However, that changed when NFPA 260 and NFPA 261 adopted the new NIST standard reference material (SRM 1196) as the igniting cigarette and ASTM E1352 and ASTM E1353 did not, meaning that ASTM E1352 and ASTM E1353 use commercial cigarettes that are low-ignition propensity and have a low likelihood of properly assessing smoldering potential. [***101:***A.10.3.2.1]

N **12.6.2.2* Mattresses.** Newly introduced mattresses, except as otherwise permitted by Chapters 11 through 43 of *NFPA 101*, shall have a char length not exceeding 2 in. (51 mm) when tested in accordance with 16 CFR 1632, “Standard for the Flammability of Mattresses and Mattress Pads” (FF 4-72). [**101:**10.3.2.2]

N **A.12.6.2.2** The char length of not more than 2 in. (51 mm) required in 16 CFR 1632, “Standard for the Flammability of Mattresses and Mattress Pads” (FF 4-72), is an indicator that the mattress is resistant to a cigarette ignition. United States federal regulations require mattresses in this country to comply with 16 CFR 1632. [***101:***A.10.3.2.2]

The provisions of 12.6.2 address ignition by cigarettes or other smoldering sources in an attempt to reduce the incidence of fires involving upholstered furniture and mattresses. Such ignition sources can smolder for considerable periods before producing flaming ignition.

Note that the provisions of 12.6.2.1 and 12.6.2.2 require cigarette ignition testing of newly introduced upholstered furniture and newly introduced mattresses for all occupancies unless "otherwise permitted by Chapters 11 through 43 of NFPA *101*."

The following fire test methods address the cigarette ignition resistance of upholstered furniture:

1. NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*
2. NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*

NFPA 260 tests individual components of upholstered furniture, such as cover fabric, interior fabric, welt cord, filling/padding, decking materials, and barrier materials. Specimens of the component to be tested are assembled with specimens of standardized materials to create a miniature horizontal base panel and vertical panel tester, a mocked-up arrangement that simulates the junction and surrounding area of a seat cushion and back cushion in a piece of upholstered furniture. Standardizing all the components of the mocked-up tester, except the component being tested, allows the test to measure the ignition resistance of the test component. Components that meet the test criteria are designated as Class I materials. Components that do not meet the test criteria are designated as Class II materials. Upholstered furniture constructed from components that individually received a Class I designation is judged to be resistant to cigarette ignition without testing of the actual combination of materials. Cigarette ignition–resistant upholstered furniture can also be constructed using Class II cover fabric materials over conventional polyurethane foam cushions if a Class I barrier material is used between the Class II fabric and the conventional foam cushion.

NFPA 261 tests a mocked-up assembly consisting of all the actual components that will be used to construct the piece of upholstered furniture, rather than testing the components individually. The test procedure specifies that a char length is to be measured and reported. There are no pass/fail criteria within the document, so 12.6.2.1(2) specifies that the char length not exceed 1½ in. (38 mm) if the mocked-up assembly is to be considered resistant to cigarette ignition.

NFPA 260 and NFPA 261 address the cigarette ignition resistance of upholstered furniture; 16 CFR 1632, "Standard for the Flammability of Mattresses and Mattress Pads," addresses the cigarette ignition resistance of mattresses. For this test method, 12.6.2.2 establishes that a char length not exceeding 2 in. (51 mm) qualifies the mattress as resistant to cigarette ignition.

N **12.6.3* Rate of Heat Release Testing of Upholstered Furniture and Mattresses.**

N **A.12.6.3** The intent of the provisions of 12.6.3 is as follows:

(1) The peak heat release rate of not more than 80 kW by a single upholstered furniture item was chosen based on maintaining a tenable environment within the room of fire origin, and the sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions, even if the single upholstered furniture item were to have a peak rate of heat release in excess of 80 kW.
(2) The total heat release of not more than 25 MJ by the single upholstered furniture item during the first 10 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by an upholstered furniture item that released its heat in other than the usual measured scenario, and the following should also be noted:
    (a) During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off, so as to create a triangle-shaped curve.
    (b) In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 80 kW limit would not ensure safety.
    (c) Only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E1537, *Standard Test Method for Fire Testing of Upholstered Furniture*, might be suitable for use as input into fire models for performance-based design. Furthermore, California Technical Bulletin 133, "Flammability Test Procedure for Seating Furniture for Use in Public Occupancies," includes pass/fail criteria for a single upholstered furniture item of 80 kW peak heat release rate and 25 MJ total heat release over the first 10 minutes of the test.

[***101:***A.10.3.3]

N **12.6.3.1** Where required by the applicable provisions of this *Code*, upholstered furniture and other seating furniture, unless the furniture is located in a building protected throughout by an approved automatic sprinkler system, shall have limited rates of heat release when tested in accordance with ASTM E1537, *Standard Test Method for Fire Testing of Upholstered Furniture*, as follows:

(1) The peak rate of heat release for the single furniture item shall not exceed 80 kW.
(2) The total heat released by the single furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

[***101:***10.3.3.1]

N **12.6.3.2*** Where required by the applicable provisions of this *Code*, mattresses shall comply with 12.6.3.2.1 or 12.6.3.2.2, unless the mattress is located in a building protected throughout by an approved automatic sprinkler system. [***101:***10.3.3.2]

N **A.12.6.3.2** The intent of the provisions of 12.6.3.2 is as follows:

(1) The peak heat release rate of not more than 100 kW by a single mattress was chosen based on maintaining a tenable environment within the room of fire origin, and the sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions, even if the single mattress were to have a peak rate of heat release in excess of 100 kW.
(2) The total heat release of not more than 25 MJ by the single mattress during the first 10 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by a mattress that released its heat in other than the usual measured scenario, and the following should also be noted:
   (a) During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off, so as to create a triangle-shaped curve.
   (b) In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 100 kW limit would not ensure safety.
   (c) Only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E1590, *Standard Test Method for Fire Testing of Mattresses*, might be suitable for use as input into fire models for performance-based design. Furthermore, California Technical Bulletin 129, "Flammability Test Procedure for Mattresses for Use in Public Buildings," includes pass/fail criteria for a single mattress of 100 kW peak heat release rate and 25 MJ total heat release over the first 10 minutes of test.

[***101:***A.10.3.3.2]

N **12.6.3.2.1** The mattress shall have limited rates of heat release when tested in accordance with ASTM E1590, *Standard Test Method for Fire Testing of Mattresses*, as follows:

(1) The peak rate of heat release for the mattress shall not exceed 100 kW.
(2) The total heat released by the mattress during the first 10 minutes of the test shall not exceed 25 MJ.

[***101:***10.3.3.2.1]

N **12.6.3.2.2** The mattress shall have a mass loss not exceeding 15 percent when tested in accordance with the fire test in Appendix A3 of ASTM F1085, *Standard Specification for Mattress and Box Springs for Use in Berths and Marine Vessels*. [***101:***10.3.3.2.2]

Paragraph 12.6.3.2.2, which is new to the 2018 edition, offers an alternative to the ASTM E1590, *Standard Test Method for Fire Testing of Mattresses,* test. This test is relatively simple and does not require the use of an instrumented fire test lab. It involves rolling up a mattress, placing it at an angle (e.g., by holding it with a brick), introducing newspaper into the volume surrounding the rolled-up mattress and igniting the newspaper with a match. One of the advantages of using the test noted in 12.6.3.2.2 is that if the mattress materials melt away from the flame with flaming drips, they might "pass" the ASTM E1590 test, but melting will not allow a mattress to pass this test. In this test, flaming material on the floor will keep burning the mattress itself.

N **12.6.4*** Furnishings or decorations of an explosive or highly flammable character shall not be used. [***101:***10.3.4]

N **A.12.6.4** Christmas trees that are not effectively flame-retardant treated, ordinary crepe paper decorations, and pyroxylin plastic decorations might be classified as highly flammable. [***101:***A.10.3.4]

The *Code* relies on the AHJ to exercise judgment in determining whether materials are of an explosive or highly flammable nature.

N **12.6.5** Fire-retardant coatings shall be maintained to retain the effectiveness of the treatment under service conditions encountered in actual use. [***101:***10.3.5]

See NFPA 703.

N **12.6.6*** Where required by the applicable provisions of this *Code*, furnishings and contents made with foamed plastic materials that are unprotected from ignition shall have a heat release rate not exceeding 100 kW when tested in accordance with ANSI/UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or when tested in accordance with NFPA 289 using the 20 kW ignition source. [***101:***10.3.6]

N **A.12.6.6** Neither UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, nor NFPA 289 is intended for evaluating interior wall and ceiling finish materials. Actual test results for heat, smoke, and combustion product release from UL 1975 or from NFPA 289 might be suitable for use as input into fire models intended for performance-based design. [***101:***A.10.3.6]

N **12.6.7 Lockers.**

N **12.6.7.1 Combustible Lockers.** Where lockers constructed of combustible materials other than wood are used, the lockers shall be considered interior finish and shall comply with Section 12.5, except as permitted by 12.6.7.2. [***101:***10.3.7.1]

N **12.6.7.2 Wood Lockers.** Lockers constructed entirely of wood and of noncombustible materials shall be permitted to be used in any location where interior finish materials are required to meet a Class C classification in accordance with 12.5.3. [***101:***10.3.7.2]

The provisions of 12.6.7 correspond with the provision of 12.5.2.3, which specifies that lockers are considered interior finish. Where lockers comprise combustible materials other than wood, they must be tested as required by 12.5.4. Where lockers are made of wood or a combination of wood and noncombustible materials, they are permitted to be installed wherever the *Code* permits Class C wall and ceiling finish materials with no additional testing.

N **12.6.8 Containers for Waste, or Linen.**

N **12.6.8.1** Where required by Chapters 11 through 43 of NFPA *101*, newly introduced containers for waste or linen, with a capacity of 20 gal (75.7 L) or more, shall meet both of the following:

(1) Such containers shall be provided with lids.
(2) Such containers and their lids shall be constructed of noncombustible materials or of materials that meet a peak rate of heat release not exceeding 300 kW/m^2 when tested at an incident heat flux of 50 kW/m^2 in the horizontal orientation and at a thickness as used in the container but not less than ¼ in. (6.3 mm), in accordance with ASTM E1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*.

[***101:***10.3.8.1]

N **12.6.8.2** Where required by Chapters 11 through 43 of NFPA *101*, newly introduced metal wastebaskets and other metal waste, or linen containers with a capacity of 20 gal (75.7 L) or more shall be listed in accordance with ANSI/UL 1315, *Standard for Safety for Metal Waste Paper Containers*, and shall be provided with a noncombustible lid. [***101:***10.3.8.2]

12.7 Fire Barriers

Δ **12.7.1 General.** Fire barriers used to provide enclosure, subdivision, or protection under NFPA *101* and this *Code* shall be classified in accordance with one of the following fire resistance ratings:

(1) 3-hour fire resistance rating
(2) 2-hour fire resistance rating
(3) 1-hour fire resistance rating
(4) ½-hour fire resistance rating

[***101:***8.3.1.1]

N **12.7.2*** Fire barriers shall comply with one of the following:

(1) The fire barriers are continuous from outside wall to outside wall or from one fire barrier to another, or a combination thereof, including continuity through all concealed spaces, such as those found above a ceiling, including interstitial spaces.
(2) The fire barriers are continuous from outside wall to outside wall or from one fire barrier to another, and from the floor to the bottom of the interstitial space, provided that the construction assembly forming the bottom of the interstitial space has a fire resistance rating not less than that of the fire barrier.

[***101:***8.3.1.2]

N **A.12.7.2** To ensure that a fire barrier is continuous, it is necessary to seal completely all openings where the fire barrier abuts other fire barriers, the exterior walls, the floor below, and the floor or ceiling above. In 12.7.2(2), the fire resistance rating of the bottom of the interstitial space is provided by that membrane alone. Ceilings of rated floor/ceiling and roof/ceiling assemblies do not necessarily provide the required fire resistance. [***101:***A.8.3.1.2]

N **12.7.3** Walls used as fire barriers shall comply with Chapter 7 of NFPA 221. The NFPA 221 limitation on percentage width of openings shall not apply. [***101:***8.3.1.3]

N **12.7.4 Smoke Barrier Used as a Fire Barrier.** A smoke barrier shall be permitted to be used as a fire barrier, provided that it meets the requirements of Section 8.3 of NFPA *101*. [***101:***8.3.1.4]

Subsection 12.7.4 is new to the 2018 edition of the *Code*, and it reminds users that smoke barriers that are also required to be constructed as fire barriers must also meet the fire barrier provisions of Section 12.7. Conversely, Section 12.9 currently contains similar text for fire barriers used as smoke barriers. Many occupancies that require smoke barriers with a fire-resistance rating also contain their own criteria for the construction and protection of the smoke barriers. Users should consult the occupancy chapter provisions where smoke barriers are required prior to following all the requirements in Section 12.7.

12.7.5 Walls.

12.7.5.1 The fire-resistive materials, assemblies, and systems used shall be limited to those permitted in this *Code* and this subsection. [***101:***8.3.2.1]

12.7.5.1.1* Fire resistance–rated glazing tested in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, shall be permitted. [***101:***8.3.2.1.1]

A.12.7.5.1.1 Fire resistance–rated glazing complying with 12.7.5, where not installed in a door, is considered a wall, not an opening protective. [***101:***A.8.3.2.1.1]

12.7.5.2 The construction materials and details for fire-resistive assemblies and systems for walls described shall comply with all other provisions of this *Code*, except as modified herein. [***101:***8.3.2.2]

12.7.5.3 Interior walls and partitions of nonsymmetrical construction shall be evaluated from both directions and assigned a fire resistance rating based on the shorter duration obtained in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials* or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. When the wall is tested with the least fire-resistive side exposed to the furnace, the wall shall not be required to be subjected to tests from the opposite side. [***101:***8.3.2.3]

12.7.6 Opening Protectives.

Subsection 12.7.6 was completely revised and reorganized for the 2018 edition of the *Code*. In previous editions, requirements for fire doors and windows and other opening protectives in fire barriers were presented in a manner that was not logical to users of the *Code*. Most provisions were retained and relocated, while other provisions were updated to reflect consistent terminology. Some sections from previous editions were deleted because they were repeated elsewhere or addressed by other provisions in the *Code*, but minimal significant technical changes were made.

Δ **12.7.6.1 General.** Every opening in a fire barrier shall be protected to limit the spread of fire from one side of the fire barrier to the other. [***101:***8.3.3.1]

12.7.6.2 Minimum Fire Protection Rating.

N **12.7.6.2.1** Fire protection ratings for products required to comply with 12.7.6 shall be as determined and reported by a nationally recognized testing agency in accordance with NFPA 252; ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*; or ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*; NFPA 257; or ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*. [***101:***8.3.3.2.1]

Δ **12.7.6.2.2*** The fire rating for opening protectives in fire barriers, fire-rated smoke barriers, and fire-rated smoke partitions shall be in accordance with Table 12.7.6.2.2, except as otherwise permitted in 12.7.6.2.3 or 12.7.6.2.4. [***101:***8.3.3.2.2].

Table 12.7.6.2.2 does not mandate fire resistance ratings for the components listed; rather, it specifies the fire protection rating needed for openings where the listed components are required to be rated by another section of the *Code*. For example, not all exit access corridors are required to be rated. However, where corridor walls are required by another section of the *Code* to have a 1-hour rating, the doors therein must have a ⅓-hour (or 20-minute) fire protection rating. The table also specifies the maximum sizes of fire-rated door vision panels and glazing markings for various applications; the minimum fire protection or fire resistance rating for doorway sidelights or transoms and glazing markings for various applications; and the minimum fire protection ratings for fire window assemblies and associated markings for various applications. Table 12.7.6.2.2 was revised for the 2015 edition; however, no technical changes were intended. The revisions were intended to clarify its application to fire protection–rated glazing and fire resistance–rated glazing used in rated window assemblies.

Table 12.7.6.2.2 was further revised for the 2018 edition of the *Code*. The row for fire barriers within the table was relocated to the end of the table, before the entry for smoke barriers. This change helps clarify that this row addresses only fire barriers not otherwise addressed within the table. The table also contains a new row for 1-hour smoke partitions and 1-hour smoke barriers that previously were not included within the table.

Δ **A.12.7.6.2.2** Longer ratings might be required where opening protectives are provided for property protection as well as life safety. NFPA 80 should be consulted for standard practice in the selection and installation of fire door assemblies and fire window assemblies.

A vision panel in a fire door is not a fire window, and, thus, it is not the intent of the "NP" notations in the "Fire Window Assemblies" column of Table 12.7.6.2.2 to prohibit vision panels in fire doors. [***101:***A.8.3.3.2.2]

12.7.6.2.3 Existing fire door assemblies having a minimum 1¾-hour fire protection rating shall be permitted to continue to be used in vertical openings and in exit enclosures in lieu of the minimum 1-hour fire protection rating required by Table 12.7.6.2.2. [***101:***8.3.3.2.3]

12.7.6.2.4 Where a 20-minute fire protection–rated door is required in existing buildings, an existing 1¾ in. (44 mm) solid-bonded wood-core door, an existing steel-clad (tin-clad) wood door, or an existing solid-core steel door with positive latch and closer shall be permitted, unless otherwise specified by Chapters 11 through 43 of NFPA *101*. [***101:***8.3.3.2.4]

Fire barriers have fire *resistance* ratings, as addressed in 12.7.1; opening protectives, such as fire doors, have fire *protection* ratings, as discussed in 12.7.6.

In general, 1-hour fire barriers for the protection of vertical openings (e.g., the walls enclosing maximum three-story exit stairs) require doors with a 1-hour fire protection rating. One-hour fire barriers for other than vertical opening protection, such as those used to isolate a hazardous contents room, require doors with a ¾-hour fire protection rating.

In some cases, other sections of the *Code* modify the general rules stated in the preceding paragraph. Table 12.7.6.2.2 permits a 1-hour or ½-hour fire resistance–rated corridor wall or 1-hour fire resistance–rated smoke barrier to have a door with a 20-minute fire protection rating. Health care and ambulatory health care occupancies permit the omission of the self-closing devices on patient room doors installed in corridor walls. This provision recognizes the functional needs for open doors in these facilities, and a true fire protection–rated patient room door assembly is not required.

The fire protection ratings of the opening protectives are sometimes permitted to be of a lower rating than the fire resistance rating of the fire barrier openings to be protected. For example, a 2-hour fire barrier is permitted to have its openings protected by 1½-hour fire protection–rated door assemblies. The perceived mismatch of ratings actually accomplishes a reasonable, practical match — as explained in the paragraphs that follow.

The test procedures on which the ratings are based, that is, ASTM E119 and ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials,* for fire barriers and NFPA 252, *Standard Methods of Fire Tests of Door* Assemblies; ANSI/UL 10B, *Standard for Fire Tests of Door* Assemblies; and ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*, for fire doors, are different.

Although combustibles placed against a fire resistance–rated wall expose the wall to a considerable fire challenge, a fire protection–rated door assembly does not usually have combustibles placed against it, because the opening must be clear to use the door and kept free of obstructions for proper operation of the door. Such a scenario suggests that if a door — for example, a second door to a storage room that is no longer needed — is not to be used and combustible storage is to be placed at the door opening, the door should be removed and the opening replaced with solid construction to restore the wall to its required fire resistance rating.

Δ ***TABLE 12.7.6.2.2*** *Minimum Fire Protection Ratings for Opening Protectives in Fire Resistance–Rated Assemblies and Fire-Rated Glazing Markings*

Component	Walls and Partitions (hr)	Fire Door Assemblies (hr)	Door Vision Panel Maximum Size (in.^{2})	Fire-Rated Glazing Marking Door Vision Panel	Minimum Side Light/Transom Assembly Rating (hr)		Fire-Rated Glazing Marking Side Light/Transom Panel		Minimum Fire-Rated Windows Rating[a,b] (hr)		Fire Window Marking	
					Fire Protection	Fire Resistance	Fire Protection	Fire Resistance	Fire Protection	Fire Resistance	Fire Protection	Fire Resistance
Elevator hoistways	2	1½	155 in.^{2}[c,e]	D-H-90 or D-H-W-90	NP	2	NP	D-H-W-120	NP	2	NP	W-120

For SI units, 1 in.^{2} = .00064516 m^2.

NP: Not permitted.

[a]Fire resistance–rated glazing tested to ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, shall be permitted in the maximum size tested. *(See 12.7.6.6.8.)*

[b]Fire-rated glazing in exterior windows shall be marked in accordance with Table 12.7.6.6.3.

[c]See ASME A17.1, *Safety Code for Elevators and Escalators*, for additional information.

[d]See ASME A17.3, *Safety Code for Existing Elevators and Escalators*, for additional information.

[e]Maximum area of individual exposed lights shall be 1296 in.^{2} (0.84 m^2) with no dimension exceeding 54 in. (1.37 m) unless otherwise tested. [**80:** Table 4.4.5, Note b, and **80:**4.4.5.1]

[f]Fire doors are not required to have a hose stream test per ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*; or ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*.

[g]For residential board and care, see 32.2.3.1 and 33.2.3.1 of NFPA *101*.

[***101:***Table 8.3.3.2.2]

N **12.7.6.2.5** Openings required to have a fire protection rating by Table 12.7.6.2.2 shall be protected by approved, listed and labeled fire door assemblies and fire window assemblies and their accompanying hardware, including all frames, closing devices, anchorage, and sills in accordance with the requirements of NFPA 80, except as otherwise specified in NFPA *101*. [***101:***8.3.3.2.5]

12.7.6.3* Fire Doors.

Fire protection–rated door assemblies are tested in accordance with NFPA 252. Such assemblies must be installed in accordance with the requirements of NFPA 80. Where the *Code* uses the term *door*, it refers to the fire door assembly, which includes not only the door leaf or slab but also the doorway, frame, and necessary hardware, including hinges. Where describing a fire door, the applicable standards similarly define a fire protection–rated assembly as including all these components, as well as a listed door closer and positive latching.

If they are to be effective, fire doors must be not only closed but also held closed. Building fires are capable of generating pressures sufficient to force fire doors open if they are not held closed with positive latching, thereby rendering the doors incapable of protecting the opening in which they are installed and potentially allowing the fire to spread to an adjacent space and beyond the compartment of origin.

The acceptance criteria for fire protection–rated assemblies, such as fire doors, differ from those for fire resistance–rated construction, such as a wall or floor/ceiling assembly. The limitation of temperature rise through the fire door is not normally a measure of acceptance, although it is a measure of acceptance for a fire resistance–rated assembly such as a wall. In addition, during the course of the fire test, fire doors will expand on the exposed side and, as a result, will warp — sometimes expanding through the door opening at the top of the door. This expansion and warping can result in some flaming through the top of the door openings. The test standards recognize this phenomenon, and a certain amount of such flaming is permitted under the acceptance criteria. This does not adversely affect safety, given that fire protection–rated assemblies are intended to protect relatively small openings in larger fire resistance–rated barriers. Also, to maintain the door as usable, combustible materials are not typically stored in front of the door opening. Exhibit 12.12 shows the effects of a successful fire door assembly installation from the non-fire side. Exhibit 12.13 shows the same fire door assembly from the fire side.

N **A.12.7.6.3** Some door assemblies have been tested to meet the conditions of acceptance of ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. Where such assemblies are used, the provisions of 12.7.5 should be applied instead of those of 12.7.6.3.

In existing installations, steel door frames that are well set in the wall might be judged as acceptable even if the frame label is not legible. [***101:***A.8.3.3.3]

Exhibit 12.12

Fire door assembly from non-fire side.

Exhibit 12.13

Fire door assembly from fire side.

N **12.7.6.3.1** Fire door assemblies shall be installed, inspected, tested, and maintained in accordance with NFPA 80. [***101:***8.3.3.3.1]

Δ **12.7.6.3.2** All fire door assemblies shall be labeled. [***101:***8.3.3.3.2]

• **12.7.6.3.3** Labels on fire door assemblies shall be maintained in a legible condition. [***101:***8.3.3.3.3]

NFPA 80 mandates that fire door assemblies be tested and inspected not less than annually by a qualified person. Annual inspections and testing should be documented and retained for review by the local AHJ. Any deficiencies found during inspection and testing should be documented and a corrective action plan developed to fix the deficiencies. Annual testing of the fire door assembly should verify proper operation of the door by closing the door by all means of activation. This verifies that there are no obstructions to door operation that would interfere with its ability to be self-closing and positive latching and that any device connected to the door, such as smoke detectors, are integrated properly and will close the door during an emergency.

The provisions for the annual inspection of fire doors were new to the 2007 edition of NFPA 80; thus, they became applicable to this *Code*, by reference, in the 2009 edition. Since then, as more jurisdictions move to adopting newer editions of this *Code*, they are becoming more aware for the need to properly care for and maintain fire door assemblies, a fire protection system that was often overlooked in earlier editions. Occupancies such as health care modify the application of NFPA 80 in certain conditions such as corridor fire door assemblies. The extent to which NFPA 80 is applied should be verified through the occupancy chapter.

Paragraphs 12.7.6.3.2 and 12.7.6.3.3 require that all fire door assemblies be labeled and that the label must be maintained in legible condition, as shown in Exhibit 12.14. A label is the identifier that a door is fire protection rated and that it has met the applicable testing criteria and has been certified by an accredited testing laboratory. Without the presence of a label on a fire door assembly, it is extremely difficult, if not impossible, to identify the door as a fire protection–rated door and the necessary criteria cannot be confirmed. The labeling requirement is a repetition of the provision from NFPA 80. Because it is such an important and fundamental concept for fire door assemblies, it is being repeated in this *Code* for emphasis and as a reminder to the users of the importance of labels on these products. Labels are permitted to be of metal, paper, or plastic or to be stamped onto or diecast into the item; the labels should not be removed, defaced, or made illegible while the door is in service. If the label on an existing fire door has been removed or is no longer legible, it might be acceptable to have the rating of the fire door verified by other means acceptable to the AHJ, such as an inspection or certification service that provides acceptable documentation.

Exhibit 12.14

Fire door label.

12.7.6.3.4* In existing installations, steel door frames without a label shall be permitted where approved by the AHJ. [***101:***8.3.3.3.4]

A.12.7.6.3.4 In existing installations, it is important to be able to determine the fire protection rating of the fire door. However, steel door frames that are well set in the wall might be judged as acceptable even if the frame label is not legible. [***101:***A.8.3.3.3.4]

12.7.6.3.5 Unless otherwise specified, fire doors shall be self-closing or automatic-closing in accordance with 14.5.4. [***101:***8.3.3.3.6]

12.7.6.4 Floor Fire Door Assemblies.

N **12.7.6.4.1** Floor fire door assemblies used to protect openings in fire resistance-rated floors shall be tested in accordance with NFPA 288 and shall achieve a fire resistance rating not less than the assembly being penetrated. [***101:***8.3.3.4.1]

N **12.7.6.4.2** Floor fire doors assemblies shall be listed and labeled. [***101:***8.3.3.4.2]

N **12.7.6.5 Fire Windows.**

N **12.7.6.5.1** Fire window assemblies shall be installed, inspected, tested, and maintained in accordance with NFPA 80. [***101:***8.3.3.5.1]

N **12.7.6.5.2** All fire window assemblies be labeled. [***101:***8.3.3.5.2]

12.7.6.5.3* Fire window assemblies shall be permitted in fire barriers having a required fire resistance rating of 1 hour or less and shall be of an approved type with the appropriate fire protection rating for the location in which they are installed. [***101:***8.3.3.5.3]

N **A.12.7.6.5.3** Some doors and glazing assemblies have been tested to meet the conditions of acceptance of ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. Where such assemblies are used, the provisions of 12.7.5 should be applied instead of those of 12.7.6.6.6. [***101:***A.8.3.3.5.3]

N **12.7.6.6 Glazing.**

N **12.7.6.6.1** Glazing materials that have been tested, listed, and labeled to indicate the type of opening to be protected for fire protection purposes shall be permitted to be used in approved opening protectives in accordance with Table 12.7.6.2.2 and NFPA 80. [***101:***8.3.3.6.1]

N **12.7.6.6.2** Fire-rated glazing assemblies shall be permitted as follows:

(1) Those marked as complying with hose stream requirements (H) shall be permitted in applications that do not require compliance with hose stream requirements.
(2) Those marked as complying with temperature rise requirements (T) shall be permitted in applications that do not require compliance with temperature rise requirements.
(3) Those marked with ratings that exceed the ratings required by NFPA *101* shall be permitted.

[***101:***8.3.3.6.2]

TABLE 12.7.6.6.3 Marking Fire-Rated Glazing Assemblies

Fire Test Standard	Marking	Definition of Marking
ASTM E119 or ANSI/UL 263	W	Meets wall assembly criteria
NFPA 257	OH	Meets fire window assembly criteria, including the hose stream test
NFPA 252	D	Meets fire door assembly criteria
	H	Meets fire door assembly hose stream test
	T	Meets 450°F (232°C) temperature rise criteria for 30 minutes
	XXX	The time, in minutes, of fire resistance or fire protection rating of the glazing assembly

N **12.7.6.6.3** New fire protection-rated glazing shall be marked in accordance with Table 12.7.6.6.3 and Table 12.7.6.2.2, and such marking shall be permanently affixed. [***101:***8.3.3.6.3]

New glazing for use in fire barriers and fire doors is regulated by performance-oriented criteria, which refer to fire-rated glazing, in lieu of the more traditional but prescriptive requirements previously applicable to wired glass.

N **12.7.6.6.4** New fire resistance–rated glazing shall be marked in accordance with Table 12.7.6.6.3 and Table 12.7.6.2.2, and such marking shall be permanently affixed. [***101:***8.3.3.6.4]

N **12.7.6.6.5** Fire protection–rated glazing shall be permitted in fire barriers having a required fire resistance rating of 1 hour or less and shall be of an approved type with the appropriate fire protection rating for the location in which the barriers are installed. [***101:***8.3.3.6.5]

N **12.7.6.6.6*** Glazing in fire window assemblies, other than in existing fire window installations of wired glass and other fire-rated glazing material, shall be of a design that has been tested to meet the conditions of acceptance of NFPA 257 or ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*. [***101:***8.3.3.6.6]

N **A.12.7.6.6.6** Some window assemblies have been tested to meet the conditions of acceptance of ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. Where such assemblies are used, the provisions of 12.7.5 should be applied instead of those of 12.7.6.6.6. [***101:***A.8.3.3.6.6]

N **12.7.6.6.7** Fire protection–rated glazing in fire door assemblies, other than in existing fire-rated door assemblies, shall be of a design that has been tested to meet the conditions of acceptance of NFPA 252, ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*, or ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*. [***101:***8.3.3.6.7]

N **12.7.6.6.8** Fire resistance–rated glazing tested in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, shall be permitted in fire doors and fire window assemblies in accordance with their listings. [***101:***8.3.3.6.8]

The provisions of 12.7.6.6.4 and 12.7.6.6.8 recognize that glazing material that has been tested as a wall assembly in accordance with ASTM E119 or ANSI/UL 263 is permitted to be used in fire barrier walls with no limitations other than those imposed by the product's listing. New glazing material tested and used as such must be appropriately labeled as specified in 12.7.6.6.3.

N **12.7.6.6.9** Nonsymmetrical fire protection–rated glazing systems shall be tested with each face exposed to the furnace, and the assigned fire protection rating shall be that of the shortest duration obtained from the two tests conducted in compliance with NFPA 257; or ANSI/UL 9, *Standard for Fire Tests of Window Assemblies*. [***101:***8.3.3.6.9]

N **12.7.6.6.10** The total combined area of glazing in fire-rated window assemblies and fire-rated door assemblies used in fire barriers shall not exceed 25 percent of the area of the fire barrier that is common with any room, unless the installation meets one of the following criteria:

(1) The installation is an existing fire window installation of wired glass and other fire-rated glazing materials in approved frames.
(2) The fire protection–rated glazing material is installed in approved existing frames.

[***101:***8.3.3.10]

N **12.7.6.6.11** Existing installations of wired glass of ¼ in. (6.3 mm) thickness and labeled for fire protection purposes shall be permitted to be used in approved opening protectives, provided that the maximum size specified by the listing is not exceeded. [***101:***8.3.3.6.11]

The requirements of 12.7.6.6.10 limit the installation of fire windows used in fire barriers to not more than 25 percent of the area of the fire barrier that is common with any room. However, 12.7.6.6.10 continues to recognize the current practice of using greater percentages of wired glass for existing fire windows if the material is installed in approved frames. Paragraph 12.7.6.6.11 recognizes the use of any existing installations of wired glass of ¼ in (6.3 mm) thickness and labeled for fire protection purposes in approved opening protectives if the maximum size specified in the listing is not exceeded. This recognizes a common application of wired glass used in vision panels in door assemblies. The language of 12.7.6.6.11 does not permit new installations of wired glazing in opening protectives; it simply permits existing installations to remain in use. Per the installation requirements in

NFPA 80, newer glazing installations require the glazing materials used in fire doors, windows, sidelights, and commercial lights to also meet applicable safety standards if they are subject to human impact.

The marking requirements for fire protection–rated glazing in 12.7.6.6.3 and Table 12.7.6.6.3 vary, depending on whether the glazing is installed in a door or a wall, and the table provides details on the test criteria at a glance. The prescribed marking scheme is consistent with the requirements of *NFPA 5000* and other model building codes.

N **12.7.6.7 Sidelights and Transoms.** Glazing used in sidelights and transoms adjacent to 20-minute doors in 1-hour corridor fire barriers shall be tested in accordance with 12.7.6.2, including hose stream, and shall attain a minimum 45-minute fire protection rating. [***101:***8.3.3.7]

12.7.7 Opening Protectives.

12.7.7.1 Every opening in a fire barrier shall be protected to limit the spread of fire and restrict the movement of smoke from one side of the fire barrier to the other. [***101:***8.3.4.1]

12.7.8 Penetrations.

N **12.7.8.1 General.**

N **12.7.8.1.1** The provisions of 12.7.8 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations in fire walls, fire barrier walls, and fire resistance–rated horizontal assemblies. [***101:***8.3.4.1.1]

N **12.7.8.1.2** The provisions of 12.7.8 shall not apply to approved existing materials and methods of construction used to protect existing through-penetrations and existing membrane penetrations in fire walls, fire barrier walls, or fire resistance–rated horizontal assemblies, unless otherwise required by Chapter 11 through 43 of NFPA *101*. [***101:***8.3.4.1.2]

N **12.7.8.1.3** Penetrations shall be protected in accordance with a tested system, and installed and maintained in accordance with the manufacturer's instructions. [***101:***8.3.4.1.3]

12.7.8.2* Firestop Systems and Devices Required.

A.12.7.8.2 Firestop materials become systems when installed to the listed firestop system design from an accredited testing laboratory. Installation of firestop materials to the listed system should meet all limitations of the system. [***101:***A.8.3.4.2]

There are management system–based contractor approval or qualification programs offered by third-party, independent companies that quantifiably qualify a company to install firestop materials that become systems after proper installation. In each program, there is an industry firestop exam that gives the company a basis to appoint a "Designated Responsible Individual." [***101:***A.8.3.4.2]

Then, the third party firm audits the firestop company's product and systems documentation records in conjunction with the company's management system operational policies and procedures to verify company compliance does as it says it does. An audit also takes place on a project site to verify that the management system is working. [***101:***A.8.3.4.2]

Where the configuration of a penetrating item or group of items is such that a listed system is determined to be nonexistent and reconfiguration of the penetrations or fire resistance–rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire resistance rating of the assembly should be permitted to be established using an engineering analysis based on a comparison of listed systems prepared by a manufacturer's technical representative of the systems specified, by the laboratory that conducted the original test, or by a professional engineer. [***101:***A.8.3.4.2]

ASTM E2174, *Standard Practice for On-Site Inspection of Installed Fire Stops*, provides guidance for the inspection of through-penetration firestop systems tested in accordance with ASTM E814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*, and ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*. [***101:***A.8.3.4.2]

Independent inspection paid for by owner is in many specifications and referenced in this appendix using ASTM E2174 and ASTM E2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*. As a result, there is an accreditation program available for firestop special inspection agencies. [***101:***A.8.3.4.2]

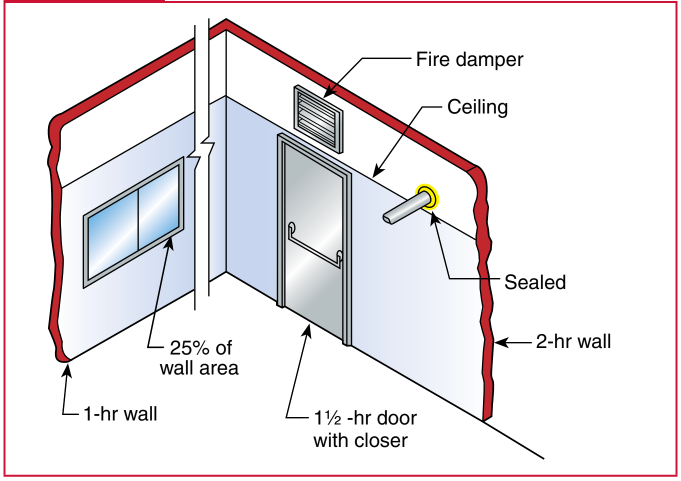
One source of information on tested materials, devices, and systems for protecting through-penetrations of fire resistance–rated barriers is Volume 2 of the UL *Fire Resistance Directory*. Such devices and systems are designed to resist the spread of fire through openings in fire resistance–rated floor or wall barriers that accommodate penetrating items, such as electrical cables, cable trays, conduits, and pipes. Underwriters Laboratories classifies such devices and systems with respect to installation in a wall only, installation in a floor only, or installation in a wall or floor. The basic standard used by UL to investigate products in this category is ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*, which is similar to ASTM E814, Standard Test Method for Fire Tests of Through-Penetration Fire Stops. A sampling of the currently classified devices includes the use of the following:

1. Ceramic fibers
2. Foamed silicones
3. Mineral wool batts
4. Intumescent sheets
5. Sealing blankets and plugs
6. Fittings and couplings
7. Various caulks, putties, and mastics
8. Spring-loaded guillotine blades

Over the life of a building, it is important to maintain the integrity of barriers to protect against fire penetration. Renovations or any changes to building utilities tend to violate the compartmentation provided when a building is first occupied.

Exhibit 12.15 illustrates some of the typical fire barrier penetrations addressed by 12.7.8.

Exhibit 12.15



Typical penetrations of a fire barrier.

N **12.7.8.2.1** Penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a wall, floor, or floor/ceiling assembly constructed as a fire barrier shall be protected by a firestop system or device. [***101:***8.3.4.2.1]

N **12.7.8.2.2 Testing.** The firestop system or device shall be tested in accordance with ASTM E814, *Standard Test Method for Fire Tests of Through Penetration Fire Stops*, or ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*, at a minimum positive pressure differential of 0.01 in. water column (2.5 Pa) between the exposed and the unexposed surface of the test assembly. [***101:***8.3.4.2.2]

12.7.8.2.3 F Ratings. Firestop systems and devices shall have a minimum 1-hour F rating, but not less than the required fire resistance rating of the fire barrier penetrated. [***101:***8.3.4.2.3]

12.7.8.2.4 T Ratings.

N **12.7.8.2.4.1** Penetrations in fire resistance–rated horizontal assemblies shall have a T rating of not less than 1 hour, and not less than the fire resistance rating of the horizontal assembly. [***101:***8.3.4.2.4.1]

N **12.7.8.2.4.2** A T rating shall not be required for either of the following:

(1) Floor penetrations contained within the cavity of a wall assembly
(2) Penetrations through floors or floor assemblies where the penetration is not in direct contact with combustible material [***101:***8.3.4.2.4.2]

12.7.8.2.5 Alternative Firestop Requirements.

N **12.7.8.2.5.1** The requirements of 12.7.8.2 shall not apply where otherwise permitted by any one of the following:

(1) Where penetrations are tested and installed as part of an assembly tested and rated in accordance with ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials* or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*
(2) Where penetrations through floors are enclosed in a shaft enclosure designed as a fire barrier
(3) Where concrete, grout, or mortar has been used to fill the annular spaces around cast-iron, copper, or steel piping, conduit or tubing that penetrates one or more concrete or masonry fire resistance–rated assemblies and all of the following applies:
   (a) The nominal diameter of each penetrating item does not exceed 6 in. (150 mm),
   (b) The opening size does not exceed 1 ft² (0.09 m²).
   (c) The thickness of the concrete, grout, or mortar is the full thickness of the assembly.
(4) Where penetration is limited to one floor, the firestopping material is capable of preventing the passage of flame and hot gases sufficient to ignite cotton waste when subjected to the time–temperature fire conditions of ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Materials* under a minimum positive pressure differential of 0.01 in. water column (2.5 Pa) at the location of the penetration for the time period equivalent to the required fire resistance rating of the assembly penetrated, and the firestopping materials are used with the following penetrating items:
   (a) Steel, ferrous, or copper cables
   (b) Cable or wire with steel jackets
   (c) Cast-iron, steel, or copper pipes
   (d) Steel conduit or tubing

[***101:***8.3.4.2.5.1]

Δ **12.7.8.2.5.2** The maximum nominal diameter of the penetrating item, as indicated in 12.7.8.2.5.1(4)(a) through (d), shall not be greater than 4 in. (100 mm) and shall not exceed an aggregate 100 in.² (64,520 mm²) opening in any 100 ft² (9.3 m²) of floor or wall area. [***101:***8.3.4.2.5.2]

12.7.8.3 Sleeves. Where the penetrating item uses a sleeve to penetrate the wall or floor, the sleeve shall be securely set in the wall or floor, and the space between the item and the sleeve shall be filled with a material that complies with 12.7.8.2. [***101:***8.3.4.3]

12.7.8.4 Insulation and Coverings. Insulation and coverings for penetrating items shall not pass through the wall or floor unless the insulation or covering has been tested as part of the firestop system or device. [***101:***8.3.4.4]

12.7.8.5 Vibration Isolation Equipment or Systems. Where vibration isolation of equipment or systems is employed, the vibration restraint(s) shall be located outside of the partition, wall, or floor assembly for which the equipment or systems pass through. [***101:***8.3.4.5]

12.7.8.6 Transitions.

12.7.8.6.1 Where piping penetrates a fire resistance–rated wall or floor assembly, combustible piping shall not connect to noncombustible piping within 36 in. (915 mm) of the firestop system or device unless it can be demonstrated that the transition will not reduce the fire resistance rating, except in the case of previously approved installations. [*101:*8.3.4.6.1]

12.7.8.6.2 Unshielded couplings shall not be used to connect noncombustible piping to combustible piping unless it can be demonstrated that the transition complies with the fire-resistive requirements of 12.7.8.2. [*101:*8.3.4.6.2]

12.7.8.7 Membrane Penetrations.

The term *membrane penetration* refers to openings for penetrations made through one side only of a fire resistance–rated assembly, as defined in *NFPA 5000*. The provisions of 12.7.8.7 address such penetrations, which, if not properly protected, would compromise the fire-resistive integrity of the barrier. The term *through-penetration*, on the other hand, refers to openings for penetrations that pass through both sides of a fire barrier.

12.7.8.7.1 Membrane penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a membrane of a wall, floor, or floor/ceiling assembly constructed as a fire barrier shall be protected by a firestop system or device and shall comply with 12.7.8.2 through 12.7.8.6.2. [*101:*8.3.4.7.1]

Δ **12.7.8.7.2** The firestop system or device shall be tested in accordance with ASTM E814, *Standard Test Method for Fire Tests of Through Penetration Fire Stops*, or ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*, at a minimum positive pressure differential of 0.01 in. water column (2.5 Pa) between the exposed and the unexposed surface of the test assembly, unless one of the following conditions applies:

(1) Membrane penetrations of ceilings that are not an integral part of a fire resistance–rated floor/ceiling or roof/ceiling assembly.
(2) Membrane penetrations of steel, ferrous, or copper conduits, piping, or tubing, and steel electrical outlet boxes and wires, or combustion vents or exhaust vents where the annular space is protected with an approved material, and the aggregate area of the openings does not exceed 100 in.^{2} (64,520 mm^2) in any 100 ft^2 (9.3 m^2) of ceiling area.
(3) Electrical outlet boxes and fittings, provided that such devices are listed for use in fire resistance–rated assemblies and are installed in accordance with their listing.
(4) The annular space created by the membrane penetration of a fire sprinkler shall be permitted, provided that the space is covered by a metal escutcheon plate.

[*101:*8.3.4.7.2]

Δ **12.7.8.7.3** Where walls or partitions are required to have a minimum 1-hour fire resistance rating, recessed fixtures shall be installed in the wall or partition in such a manner that the required fire resistance is not reduced, unless one of the following criteria is met:

(1) Any steel electrical box not exceeding 16 in.^{2} (10,300 mm^2) in area shall be permitted where the aggregate area of the openings provided for the boxes does not exceed 100 in.^{2} (64,520 mm^2) in any 100 ft^2 (9.3 m^2) of wall area, and, where outlet boxes are installed on opposite sides of the wall, the boxes shall be separated by one of the following means:
   (a) Horizontal distance of not less than 24 in. (610 mm)
   (b) Horizontal distance of not less than the depth of the wall cavity, where the wall cavity is filled with cellulose loose-fill, rock wool, or slag wool insulation
   (c)* Solid fireblocking
   (d) Other listed materials and methods
(2) Membrane penetrations for any listed electrical outlet box made of any material shall be permitted, provided that such boxes have been tested for use in fire resistance–rated assemblies and are installed in accordance with the instructions included in the listing.
(3) The annular space created by the membrane penetration of a fire sprinkler shall be permitted, provided that the space is covered by a metal escutcheon plate.
(4) Membrane penetrations by electrical boxes of any size or type, which have been listed as part of a wall opening protective material system for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the listing shall be permitted.

[*101:*8.3.4.7.3]

A.12.7.8.7.3(1)(c) Criteria associated with fireblocking can be found in the building code. [*101:*A.8.3.4.7.3(1)(c)]

12.7.8.8 Ducts and Air-Transfer Openings. Openings in fire barriers for air-handling ductwork or air movement shall be protected in accordance with 11.2.1. [*101:*8.3.4.8]

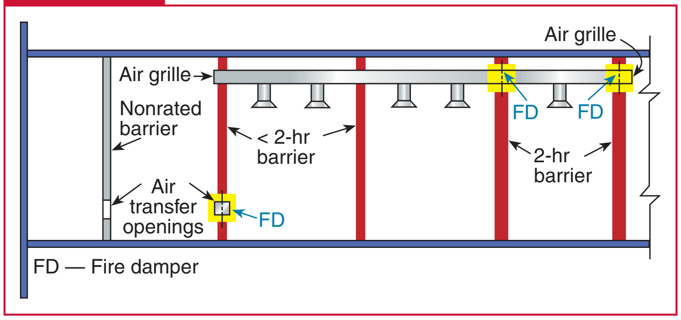
In referencing 11.2.1 for the protection of openings in fire barriers for air-handling ductwork or air movement, 12.7.8.8 mandates that the requirements of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, and not the usual *Life Safety Code* requirements for opening protectives (contained in 12.7.6), apply to heating, ventilating, and air-conditioning (HVAC) system penetrations of fire barriers. NFPA 90A requires that approved fire dampers be provided in all air-transfer openings in barriers that are required to have a fire resistance rating. It also requires that approved fire dampers be provided where ducts penetrate barriers that are required to have a fire resistance rating of 2 hours or more. Thus, although any air-transfer opening would have to be provided with a fire damper in a required fire barrier of any rating, penetrations by ducts would not have to be provided with fire dampers if the required rating of the fire barrier is less than 2 hours. These requirements are depicted in Exhibit 12.16.

12.7.9 Joints.

12.7.9.1 General.

N **12.7.9.1.1** The provisions of 12.7.9 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of fire barriers or, where fire barriers meet other

Exhibit 12.16



Fire damper requirements of NFPA 90A for HVAC penetrations of fire barriers.

fire barriers, the floor or roof deck above, or the outside walls. [***101:***8.3.5.1.1]

N **12.7.9.1.2** The provisions of 12.7.9 shall not apply to approved existing materials and methods of construction used to protect existing joints in fire barriers, unless otherwise required by Chapters 11 through 43 of NFPA *101*. [***101:***8.5.1.2]

12.7.9.2* **Joint System Requirements.**

N **A.12.7.9.2** Materials used to protect joints become systems when installed to the listed joint system design from an accredited testing laboratory. Installation of joint materials to the listed system should meet all limitations of the system. [***101:***A.8.3.5.2.1]

There are management system–based contractor approval or qualification programs offered by third-party, independent companies that quantifiably qualify a company to install firestop materials that become systems after proper installation. In each program, there is an industry firestop exam that gives the company a basis to appoint a "Designated Responsible Individual." [***101:***A.8.3.5.2.1]

Then, the third-party firm audits the firestop company's product and systems documentation records in conjunction with the company's management system operational policies and procedures to verify company compliance. An audit also takes place on a project site to verify that the management system is working. [***101:***A.8.3.5.2.1]

Where the configuration of a joint is such that a listed system is determined to be nonexistent and reconfiguration of the joint or fire resistance–rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire resistance rating of the assembly should be permitted to be established using an engineering analysis based on a comparison of listed systems prepared by a manufacturer's technical representative of the systems specified, by the laboratory that conducted the original test, or by a professional engineer. [***101:***A.8.3.5.2.1]

On-site inspection of firestopping is important in maintaining the integrity of any vertical or horizontal fire barrier. Two standard practice documents were developed with the ASTM process to allow inspections of through-penetration firestops, joints, and perimeter fire barrier systems. ASTM E2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*, provides guidance for the inspection of fire-resistive joints and perimeter fire barrier joint systems tested in accordance with the requirements of ASTM E1966, *Standard Test Method for Fire-Resistive Joint Systems*, or with ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*. ASTM E2393 contains a standardized report format, which would lead to greater consistency for inspections. [***101:***A.8.3.5.2.1]

Independent inspection paid for by the owner is in many specifications and referenced in this annex using ASTM E2393. As a result, there is an accreditation program available for firestop special inspection agencies. [***101:***A.8.3.5.2.1]

N **12.7.9.2.1** Joints made within or at the perimeter of fire barriers, between fire resistance–rated assemblies, or where fire barriers meet other fire barriers, the floor or roof deck above, or the outside walls shall be protected with a joint system that is designed and tested to prevent the spread of fire for a time period equal to that of the assembly in which the joint is located. [***101:***8.3.5.2.1]

12.7.9.2.2 Joints made within or at the perimeter of fire barriers used as smoke barriers shall be capable of restricting the transfer of smoke in accordance with 8.5.7.4 of NFPA *101*. [***101:***8.3.5.2.2]

N **12.7.9.2.3** Joints shall be installed in accordance with a tested system, and installed and maintained in accordance with the manufacturer's instructions. [***101:***8.3.5.2.3]

12.7.9.2.4 Testing of the joint system in a fire barrier shall be representative of the actual installation suitable for the required engineering demand without compromising the fire resistance rating of the assembly or the structural integrity of the assembly. [***101:***8.3.5.2.4]

Δ **12.7.9.2.5** Such materials, systems, or devices shall be tested as part of the assembly in accordance with the requirements of ASTM E1966, *Standard Test Method for Fire-Resistive Joint Systems*, or ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*. [***101:***8.3.5.2.5]

Δ **12.7.9.2.6** All joint systems shall be tested at their maximum joint width in accordance with the requirements of ASTM E1966 or ANSI/UL 2079, under a minimum positive pressure differential of 0.01 in. water column (2.5 N/m^2) for a time period equal to that of the assembly. [***101:***8.3.5.2.6]

N **12.7.9.2.7** All test specimens shall comply with the minimum height or length required by the standard. [***101:***8.3.5.2.7]

N **12.7.9.2.8** Wall assemblies shall be subjected to a hose stream test in accordance with ASTM E119 or ANSI/UL 263. [***101:***8.3.5.2.8]

N **12.7.9.3** Joints made between a fire barrier and a non-fire-resistance-rated floor or roof sheathing, slab, or deck above shall be protected by an approved continuity head of wall joint system installed as tested in accordance with ASTM E2837, *Standard Test Method for Determining the Fire Resistance of Continuity Head-of-Wall Joint Systems Installed Between Rated Wall Assemblies and Nonrated Horizontal Assemblies*, and the system shall have an F rating and T rating of not less than the required fire resistance rating of the fire barrier. [***101:***8.3.5.3]

The extension of the fire barrier to the next horizontal assembly needs to be tested as the assembly itself. ASTM E2387, *Standard Test Method for Determining the Fire Resistance of Continuity Head-of-Wall Joint Systems Installed Between Rated Wall Assemblies and Nonrated Horizontal Assemblies,* measures the performance of the system and provides the continuity to protect the system consistent with the barrier. Joints between and within fire barriers must be protected by materials tested to ensure the integrity of the barrier. Like a weak link in a chain, an improperly protected joint in a fire barrier is likely to be the point of failure when exposed to fire.

12.7.9.4* Exterior Curtain Walls and Perimeter Joints.

N **A.12.7.9.4** The provisions of 12.7.9.4 are intended to restrict the interior vertical passage of flame and hot gases from one floor to another at the location where the floor intersects the exterior wall assembly. The requirements of 8.3.5.4 mandate sealing the opening between a floor and an exterior wall assembly to provide the same fire performance as that required for the floor. ASTM E2307, *Standard Test Method for Determining Fire Resistance of Perimeter Fire Barrier Systems Using Intermediate-Scale, Multi-Story Test Apparatus*, is a test method for evaluating the performance of perimeter fire barrier systems. Some laboratories have tested and listed perimeter fire barrier systems essentially in accordance with the ASTM method. The ASTM test method evaluates the performance of perimeter fire barrier systems in terms of heat transfer and fire spread inside a building through the floor/exterior wall intersection. The current test method does not assess the ability of perimeter fire barrier systems to prevent the spread of fire from story to story via the exterior. However, some laboratories have included additional temperature measurement criteria in their evaluation of the exterior wall and evaluation of vision glass breakage as additional pass/fail criteria in an attempt to at least partially address this "leapfrog" effect. [***101:***A.8.3.5.4]

12.7.9.4.1 Voids created between the fire resistance–rated floor assembly and the exterior curtain wall shall be protected with a perimeter joint system that is designed and tested in accordance with ASTM E2307, *Standard Test Method for Determining Fire Resistance of Perimeter Fire Barriers Using Intermediate-Scale, Multi-story Apparatus*. [***101:***8.3.5.4.1]

12.7.9.4.2 The perimeter joint system shall have an F rating equal to the fire resistance rating of the floor assembly. [***101:***8.3.5.4.2]

12.8 Smoke Partitions

12.8.1* General. Where required elsewhere in this *Code*, smoke partitions shall be provided to limit the transfer of smoke. [***101:***8.4.1]

A.12.8.1 The provision for terminating the smoke partition at the ceiling is not intended to prevent the wall from extending above the ceiling.

Although a smoke partition is intended to limit the free movement of smoke, it is not intended to provide an area that would be free of smoke. [***101:***A.8.4.1]

Chapter 12 does not require the installation of smoke partitions but does provide detailed criteria for smoke partitions where required by other sections of the *Code*. A smoke partition is a continuous membrane designed to form a barrier to limit the transfer of smoke.

The smoke partition provisions offer options not available prior to the 2000 edition of the *Code* under the provisions for fire barriers and smoke barriers. For example, a smoke partition is not always required to have a fire resistance rating, but all fire barriers must have a rating. Also, a smoke partition is not required to have a smoke damper where ductwork penetrates the partition, but a duct penetration of a smoke barrier typically is required to do so.

Δ **12.8.2 Continuity.** Smoke partitions shall comply with the following:

(1) They shall extend from the floor to the underside of the floor or roof deck above, through any concealed spaces, such as those above suspended ceilings, and through interstitial structural and mechanical spaces.
(2)* They shall be permitted to extend from the floor to the underside of a monolithic or suspended ceiling system where all of the following conditions are met:
  (a) The ceiling system forms a continuous membrane.
  (b) A smoke-tight joint is provided between the top of the smoke partition and the bottom of the suspended ceiling.
  (c) The space above the ceiling is not used as a plenum.
(3) Smoke partitions enclosing hazardous areas shall be permitted to terminate at the underside of a monolithic or suspended ceiling system where all of the following conditions are met:
  (a) The ceiling system forms a continuous membrane.
  (b) A smoke-tight joint is provided between the top of the smoke partition and the bottom of the suspended ceiling.
  (c) Where the space above the ceiling is used as a plenum, return grilles from the hazardous area into the plenums are not permitted.

[***101:***8.4.2]

A.12.8.2(2) An architectural, exposed, suspended-grid acoustical tile ceiling with penetrations for sprinklers, ducted HVAC supply and return-air diffusers, speakers, and recessed light fixtures is capable of limiting the transfer of smoke. [***101:***A.8.4.2(2)]

A smoke partition should be thought of as a barrier that reasonably limits, but does not necessarily prevent, smoke transfer. As such, there are suspended ceiling systems and monolithic surfaced ceilings that provide resistance to smoke transfer that is approximately equal to that of the traditional, nonrated corridor wall or partition. Smoke partitions are permitted to terminate tightly against the underside of such ceilings in accordance with 12.8.2(2). The concept is further described in A.12.8.2(2). The provision for terminating the smoke partition at the ceiling is not intended to prevent the wall from extending above the ceiling.

The list of acceptable penetrating items (e.g., speakers, recessed light fixtures, and ducted HVAC air diffusers) makes it clear that a smoke partition is not intended to prevent all smoke transfer; rather, it limits the transfer of smoke to an acceptable level to provide for occupant life safety.

12.8.3 Opening Protectives.

12.8.3.1 Doors in smoke partitions shall comply with 12.8.3.2 through 12.8.3.6. [***101:***8.4.3.1]

12.8.3.2 Doors shall comply with the provisions of 7.2.1 of NFPA *101*. [***101:***8.4.3.2]

12.8.3.3 Doors shall not include louvers. [***101:***8.4.3.3]

12.8.3.4* Door clearances shall be in accordance with NFPA 80. [***101:***8.4.3.4]

A.12.8.3.4 Gasketing of doors should not be necessary, as the clearances in NFPA 80 effectively achieve resistance to the passage of smoke if the door is relatively tight-fitting. [***101:***A.8.4.3.4]

For swinging doors with builders hardware, NFPA 80 permits clearances of not more than ⅛ in. (3.2 mm) [±1⁄16 in. (±1.6 mm) for steel doors] between the top and the vertical edges of the door and the frame and between the meeting edges of doors in swinging pairs. The clearance under the bottom of a fire door is permitted to be not more than ¾ in. (19 mm).

With the permitted clearances, some smoke will pass to the opposite side of a closed door. It is important to remember that the intent of the smoke partition is not to prevent all smoke transfer but, rather, to limit the transfer of smoke to an acceptable level.

12.8.3.5 Doors shall be self-closing or automatic-closing in accordance with 14.5.4. [***101:***8.4.3.5]

12.8.4 Penetrations. The provisions of 12.8.4 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations of smoke partitions. [***101:***8.4.4]

12.8.4.1 Penetrations for cables, cable trays, conduits, pipes, tubes, vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a smoke partition shall be protected by a system or material that is capable of limiting the transfer of smoke. [***101:***8.4.4.1]

12.8.4.2 Vibration Isolation Equipment or Systems. Where vibration isloation of equipment or systems is employed, the vibration restraint(s) shall be located outside of the partition, wall or floor assembly for which the equipment or systems pass through. [***101:***8.4.4.2]

12.8.5 Joints.

12.8.5.1 The provisions of 12.8.5 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of smoke partitions or, where smoke partitions meet other smoke partitions, the floor or roof deck above, or the outside walls. The provisions of 12.8.5 shall not apply to approved existing materials and methods of construction used to protect existing joints in smoke partitions, unless otherwise required by Chapters 11 through 43 of NFPA *101*. [***101:***8.4.5.1]

12.8.5.2 Joints made within or at the perimeter of smoke partitions shall be protected with a joint system that is capable of limiting the transfer of smoke. [***101:***8.4.5.2]

12.8.6 Air-Transfer Openings.

12.8.6.1 General. The provisions of 12.8.6 shall govern the materials and methods of construction used to protect air-transfer openings in smoke partitions. [***101:***8.4.6.1]

12.8.6.2* Smoke Dampers. Air-transfer openings in smoke partitions shall be provided with approved smoke dampers designed and tested in accordance with the requirements of ANSI/UL 555S, *Standard for Smoke Dampers*, to limit the transfer of smoke. [***101:***8.4.6.2]

A.12.8.6.2 An air-transfer opening, as defined in NFPA 90A, is an opening designed to allow the movement of environmental air between two contiguous spaces. [***101:***A.8.4.6.2]

12.8.6.3 Smoke Damper Ratings. Smoke damper leakage ratings shall be not less than Class II. Elevated temperature ratings shall be not less than 250°F (140°C). [***101:***8.4.6.3]

Δ **12.8.6.4 Smoke Detectors.** Dampers in air-transfer openings shall close upon detection of smoke by approved smoke detectors installed in accordance with *NFPA 72*. [***101:***8.4.6.4]

Where ductwork extends to a smoke partition, pierces the partition, and continues its run on the other side of the partition, no transfer opening exists. Given that no transfer opening is present, there is no requirement for a smoke damper. If such ducted HVAC systems without dampers are to spread smoke, such smoke spread will occur due to the buoyant forces of the hot fire gases, because the provisions of NFPA 90A require the automatic shutdown of most of the fans that would otherwise circulate smoke through the ductwork.

12.9 Smoke Barriers

12.9.1* General. Where required by Chapters 11 through 43 of NFPA *101*, smoke barriers shall be provided to subdivide building spaces for the purpose of restricting the movement of smoke. [***101:***8.5.1]

A.12.9.1 Wherever smoke barriers and doors therein require a degree of fire resistance, as specified by requirements in the various occupancy chapters (Chapter 12 through Chapter 42 of NFPA *101*), the construction should be a fire barrier that has been specified to limit the spread of fire and restrict the movement of smoke. [***101:***A.8.5.1]

Although a smoke barrier is intended to restrict the movement of smoke, it might not result in tenability throughout the adjacent smoke compartment. The adjacent smoke compartment should be safer than the area on the fire side, thus allowing building occupants to move to that area. Eventually, evacuation from the adjacent smoke compartment might be required. [***101:***A.8.5.1]

It is imprecise to refer to a "1-hour smoke barrier," because smoke barriers are not classified based on the duration for which they resist the transfer of smoke. It is more accurate to refer to a "smoke barrier that additionally has a 1-hour fire resistance rating." A barrier with only a fire resistance rating does not necessarily make an effective smoke barrier. For example, a fire barrier, if rated at less than 2 hours, would not be required to have either a fire damper or a smoke damper where ductwork penetrates the barrier. A smoke barrier, in accordance with Section 12.9, would generally have ducted penetrations protected by smoke dampers per 12.9.5.2.

12.9.2* Continuity.

A.12.9.2 To ensure that a smoke barrier is continuous, it is necessary to seal completely all openings where the smoke barrier abuts other smoke barriers, fire barriers, exterior walls, the floor below, and the floor or ceiling above. It is not the intent to prohibit a smoke barrier from stopping at a fire barrier if the fire barrier meets the requirements of a smoke barrier (that is, the fire barrier is a combination smoke barrier/fire barrier). [***101:***A.8.5.2]

12.9.2.1 Smoke barriers required by NFPA *101* shall be continuous from an outside wall to an outside wall, from a floor to a floor, or from a smoke barrier to a smoke barrier, or by use of a combination thereof. [***101:***8.5.2.1]

12.9.2.2 Smoke barriers required by NFPA *101* shall be continuous through all concealed spaces, such as those found above a ceiling, including interstitial spaces. [***101:***8.5.2.2]

12.9.2.3 A smoke barrier required for an occupied space below an interstitial space shall not be required to extend through the interstitial space, provided that the construction assembly forming the bottom of the interstitial space provides resistance to the passage of smoke equal to that provided by the smoke barrier. [***101:***8.5.2.3]

In occupancies where evacuation is a last resort or is expected to be otherwise delayed, smoke barriers and doors require a degree of fire resistance, as specified by the requirements found in the occupancy sections (Chapter 20).

Other openings in smoke and fire barriers must be protected as well. HVAC ducts provide a ready path for smoke and fire to travel from one area to another unless appropriately protected. Penetrations in walls and ceiling construction for utilities and other building services must be firestopped to prevent fire spread. The hidden spaces above suspended ceilings and attic spaces are out of sight and can be easily overlooked.

The provision of 12.9.2.3 must be used with care. Several occupancy chapters require smoke barriers to be fire resistance rated and, therefore, the smoke barrier is permitted to terminate at the ceiling only if the ceiling is of the same rating. Also, even where no fire resistance rating is required, it is difficult to ensure that a ceiling is smoketight, unless it is of monolithic construction without air-handling penetrations. This kind of construction is often found in apartment buildings, hotels, and dormitories; consequently, the provision of 12.9.2.3 can be useful.

12.9.3 Fire Barrier Used as Smoke Barrier. A fire barrier shall be permitted to be used as a smoke barrier, provided that it meets the requirements of Section 12.9. [***101:***8.5.3]

12.9.4 Opening Protectives.

12.9.4.1* Doors in smoke barriers shall close the opening, leaving only the minimum clearance necessary for proper operation, and shall be without louvers or grilles. For other than previously approved existing doors, the clearance under the bottom of the doors shall be a maximum of ¾ in. (19 mm). [***101:***8.5.4.1]

A.12.9.4.1 For additional information on the installation of smoke-control door assemblies, see NFPA 105. [***101:***A.8.5.4.1]

NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*, acknowledges that no nationally recognized test standard for the measurement of hot smoke temperature leakage exists. However, NFPA 105 notes that ANSI/UL 1784, *Standard for Air Leakage Tests of Door Assemblies*, can be used to measure ambient and warm air leakage rates of door assemblies.

ANSI/UL 1784, which is also referenced in 8.2.2.4 of NFPA *101*, should determine satisfactory performance if recognized design features are also taken into account, such as close-fitting assemblies, limited deflections, and the use of gasketing and sealing materials. ANSI/UL 1784 then provides performance criteria for determining maximum air leakage rates expressed in air volume per time per area of door opening.

12.9.4.2 Where required by Chapters 11 through 43 of NFPA *101*, doors in smoke barriers that are required to be smoke leakage–rated shall comply with the requirements of 8.2.2.4 of NFPA *101*. [***101:***8.5.4.2]

12.9.4.3 Latching hardware shall be required on doors in smoke barriers unless specifically exempted by Chapters 11 through 43 of NFPA *101*. [***101:***8.5.4.3]

12.9.4.4* Doors in smoke barriers shall be self-closing or automatic-closing in accordance with 14.5.4 and shall comply with the provisions of 7.2.1 of NFPA *101*. [***101:***8.5.4.4]

A.12.9.4.4 Where, because of operational necessity, it is desired to have smoke barrier doors that are usually open, such doors should be provided with hold-open devices that are activated to close the doors by means of the operation of smoke detectors and other alarm functions. [***101:***A.8.5.4.4]

Doors in smoke barriers are not generally required to have a fire protection rating, unless the applicable occupancy chapter in NFPA *101* requires the smoke barrier itself to have a fire resistance rating. Therefore, any door that resists the passage of smoke, even a hollow-core wood door or a glass door, is acceptable, provided that it is tight-fitting, unless the door is required to be smoke leakage–rated as specified by 12.9.4.2. Stops at the head and sides of the door help resist the passage of smoke. Where a pair of doors is used, it is recommended (and required for cross-corridor door assemblies in new health care occupancies) that they open in opposite directions from each other so that rabbets, bevels, or astragals can be provided at the meeting edges without the use of coordinators. See 18.3.7.6 through 18.3.7.10 of NFPA *101* for details on smoke barrier doors in new health care occupancies.

Doors in smoke barriers, although not the equivalent of fire doors and not completely smoketight, are effective in restricting the spread of smoke and reducing drafts, which might otherwise spread fire rapidly. Where an occupancy chapter in NFPA *101* requires the smoke barrier to have a fire resistance rating, a 20-minute fire protection–rated door assembly should provide a reasonable degree of protection. It has been shown through tests presented in *"The 20-Minute Door and Other Considerations"* from the journal *Building Standards* that the commonly used 1¾ in. (44 mm) thick solid-bonded wood-core door assembly can be expected to fail in fire tests in 22 minutes to 24 minutes, but it has performed well in actual fires when closed. The maximum clearance under the bottom of new smoke barrier doors is limited to ¾ in. (19 mm) as indicated in 12.9.4.1; this limit is intended to be consistent with the clearance permitted by NFPA 80 for fire doors.

Doors in a fire barrier, horizontal exit, or smoke barrier should be closed at all times to impede the spread of smoke and fire gases. Functionally, however, keeping the doors closed can decrease the operational efficiency of the occupancy. In a health care occupancy, for example, closed doors limit patient observation by staff. To accommodate such situations, it is practical to presume that the door will be kept open, even with the use of wood chocks or other makeshift devices. Where operational necessity dictates that smoke barrier doors normally are to be kept open, such doors should be provided with hold-open devices that release by the operation of smoke detectors (see Exhibit 12.17). Smoke detectors for door releasing service are not necessarily required to activate a building evacuation alarm — see 13.7.1.9.2.3 for details.

12.9.4.5 Fire window assemblies shall comply with 12.7.6. [***101:***8.5.4.5]

12.9.5 Ducts and Air-Transfer Openings.

12.9.5.1 General. The provisions of 12.9.5 shall govern the materials and methods of construction used to protect ducts and air-transfer openings in smoke barriers. [***101:***8.5.5.1]

12.9.5.2 Smoke Dampers.

12.9.5.2.1 Where a smoke barrier is penetrated by a duct or air-transfer opening, a smoke damper designed and tested in accordance with the requirements of ANSI/UL 555S shall be installed. [***101:***8.5.5.2.1]

12.9.5.2.2 Where a smoke barrier is also constructed as a fire barrier, a combination fire/smoke damper designed and tested in accordance with the requirements of ANSI/UL 555 and ANSI/UL 555S shall be installed. [***101:***8.5.5.2.2]

Exhibit 12.17

Hold-open mechanism on automatic-closing door.

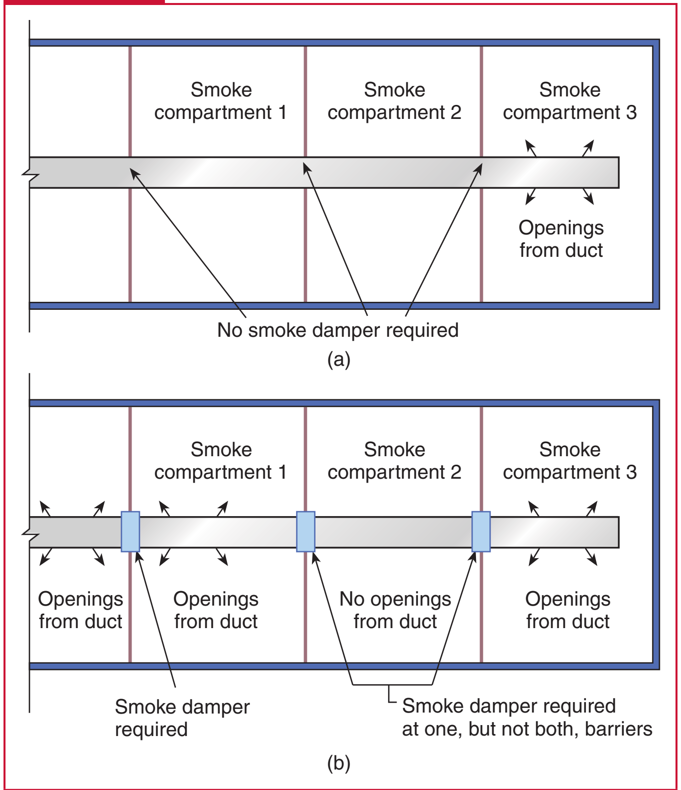
12.9.5.3 Smoke Damper Exemptions. Smoke dampers shall not be required under any of the following conditions:

(1) Where specifically exempted by provisions in Chapters 11 through 43 of NFPA *101*
(2) Where ducts or air-transfer openings are part of an engineered smoke control system and the smoke damper will interfere with the operation of a smoke control system
(3) Where the air in ducts continues to move and the air-handling system installed is arranged to prevent recirculation of exhaust or return air under fire emergency conditions

Item (2) of 12.9.5.3 addresses the omission of dampers in ducts that must remain open so that an engineered smoke control system can operate. The provision of item (3) applies only in very limited cases. It can be used only on small ventilation systems, because NFPA 90A requires that systems with an air-handling capacity over 15,000 ft^3/min (7080 L/s) that are not part of a smoke control system shut down upon detection of smoke.

Even without the restriction of NFPA 90A, it is difficult to ensure that the air-handling system will be in continuous operation. Because of increased awareness of energy conservation, many systems are cycled or shut down during parts of the day. The cycling or shutdown feature might be added later without recognizing its potential detriment to occupant life safety. However, the provisions of 12.9.5.3(3) can be useful for ductwork for small ventilation systems, such as those for toilet rooms or small suites.

Exhibit 12.18



Position of smoke dampers in air-handling ductwork.

(4) Where the air inlet or outlet openings in ducts are limited to a single smoke compartment

Item (4) of 12.9.5.3 addresses situations where an "express" duct has no openings other than in a single smoke compartment. This provision can reasonably be extended to situations illustrated in Exhibit 12.18. According to the requirements of NFPA 90A, only a single floor can be penetrated by ductwork not enclosed within a rated shaft, and such an installation requires a fire damper at the plane of the floor where the penetration is located. Ducts penetrating more than one floor must be enclosed within an appropriately fire-rated shaft. Thus, where a smoke damper is exempted by 12.9.5.3(5), the resulting openings can potentially act as a minor route for smoke migration from one floor to another before the actuation of a fire damper. The floor, as a whole, serves as an adequate smoke barrier in accordance with the requirements of 8.6.1 of NFPA *101*.

(5) Where ducts penetrate floors that serve as smoke barriers
(6) Where ducts penetrate smoke barriers forming a communicating space separation in accordance with 8.6.6(4)(a) of NFPA *101* [***101:***8.5.5.3]

12.9.5.4 Installation, Testing, and Maintenance.

Δ **12.9.5.4.1** Air-conditioning, heating, ventilating ductwork, and related equipment, including smoke dampers and combination fire and smoke dampers, shall be installed in accordance with NFPA 90A, NFPA 90B, NFPA 105, or NFPA 80, as applicable. [***101:***8.5.5.4.1]

12.9.5.4.2 Smoke dampers and combination fire and smoke dampers required by this code shall be inspected, tested, and maintained in accordance with NFPA 105. [***101:***8.5.5.4.2]

12.9.5.4.3 The equipment specified in 12.9.5.4.1 shall be installed in accordance with the requirements of 12.9.5, the manufacturer's installation instructions, and the equipment listing. [***101:***8.5.5.4.3]

12.9.5.5 Access and Identification.

12.9.5.5.1 Access to the dampers shall be provided for inspection, testing, and maintenance. [***101:***8.5.5.5.1]

12.9.5.5.2 Smoke and combination fire and smoke dampers in new construction shall be provided with an approved means of access, as follows:

(1) The means of access shall be large enough to allow inspection and maintenance of the damper and its operating parts.
(2) The access shall not affect the integrity of fire resistance–rated assemblies or smoke barrier continuity.
(3) The access openings shall not reduce the fire resistance rating of the assembly.
(4) Access doors in ducts shall be tight-fitting and suitable for the required duct construction.
(5) Access and maintenance shall comply with the requirements of the mechanical code. [***101:***8.5.5.5.2]

12.9.5.5.3 Identification. Access points to fire and smoke dampers in new construction shall be permanently identified by one of the following:

(1) A label having letters not less than ½ in. (13 mm) in height and reading as one of the following:
 (1) FIRE/SMOKE DAMPER
 (2) SMOKE DAMPER
 (3) FIRE DAMPER
(2) Symbols as approved by the AHJ [***101:***8.5.5.5.3]

Requirements for access to, and identification of, fire dampers, smoke dampers, and combination fire and smoke dampers were revised for the 2015 edition of NFPA *101*, to be consistent with the requirements of *NFPA 5000*. In new construction, access locations must be labeled to facilitate the required inspection, testing, and maintenance of dampers.

12.9.5.6 Smoke Damper Ratings. Smoke damper leakage ratings shall be not less than Class II. Elevated temperature ratings shall be not less than 250°F (140°C). [***101:***8.5.5.6]

12.9.5.7 Smoke Detectors.

12.9.5.7.1 Required smoke dampers in ducts penetrating smoke barriers shall close upon detection of smoke by approved smoke detectors in accordance with *NFPA 72*, unless one of the following conditions exists:

(1) The ducts penetrate smoke barriers above the smoke barrier doors, and the door release detector actuates the damper.

(2) Approved smoke detector installations are located within the ducts in existing installations. [***101:***8.5.5.7.1]

12.9.5.7.2 Where a duct is provided on one side of the smoke barrier, the smoke detectors on the duct side shall be in accordance with 12.9.5.7.1. [***101:***8.5.5.7.2]

12.9.5.7.3 Required smoke dampers in air-transfer openings shall close upon detection of smoke by approved smoke detectors in accordance with *NFPA 72*. [***101:***8.5.5.7.3]

NFPA 72®, National Fire Alarm and Signaling Code®, provides information on the installation of smoke detectors that close smoke dampers. The damper is permitted to be closed by the same detector that closes the door in a smoke barrier if the duct penetrates the wall above the door. Existing installations of detectors installed within ducts, which might not be in total compliance with *NFPA 72*, continue to be recognized.

12.9.6 Penetrations.

12.9.6.1 The provisions of 12.9.6 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations of smoke barriers. [***101:***8.5.6.1]

12.9.6.2 Penetrations for cables, cable trays, conduits, pipes, tubes, vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a wall, floor, or floor/ceiling assembly constructed as a smoke barrier, or through the ceiling membrane of the roof/ceiling of a smoke barrier assembly, shall be protected by a system or material capable of restricting the transfer of smoke. [***101:***8.5.6.2]

12.9.6.3 Where a smoke barrier is also constructed as a fire barrier, the penetrations shall be protected in accordance with the requirements of 12.7.8 to limit the spread of fire for a time period equal to the fire resistance rating of the assembly and the requirements of 12.9.6 to restrict the transfer of smoke, unless the requirements of 12.9.6.4 are met. [***101:***8.5.6.3]

12.9.6.4 Where sprinklers penetrate a single membrane of a fire resistance–rated assembly in buildings equipped throughout with an approved automatic fire sprinkler system, noncombustible escutcheon plates shall be permitted, provided that the space around each sprinkler penetration does not exceed ½ in. (13 mm), measured between the edge of the membrane and the sprinkler. [***101:***8.5.6.4]

12.9.6.5 Where the penetrating item uses a sleeve to penetrate the smoke barrier, the sleeve shall be securely set in the smoke barrier, and the space between the item and the sleeve shall be filled with a listed system or with a material capable of restricting the transfer of smoke. [***101:***8.5.6.5]

12.9.6.6 Vibration Isolation Equipment or Systems. Where vibration isloation of equipment or systems is employed, the vibration restraint(s) shall be located outside of the partition, wall or floor assembly for which the equipment or systems pass through. [***101:***8.5.6.7]

12.9.7 Joints.

12.9.7.1 The provisions of 12.9.7 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of smoke barriers or, where smoke barriers meet other smoke barriers, the floor or roof deck above, or the outside walls. The provisions of 12.9.7 shall not apply to approved existing materials and methods of construction used to protect existing joints in smoke barriers, unless otherwise required by Chapters 11 through 43 of NFPA *101*. [***101:***8.5.7.1]

12.9.7.2 Joints made within or at the perimeter of smoke barriers shall be protected with a joint system that is capable of limiting the transfer of smoke. [***101:***8.5.7.2]

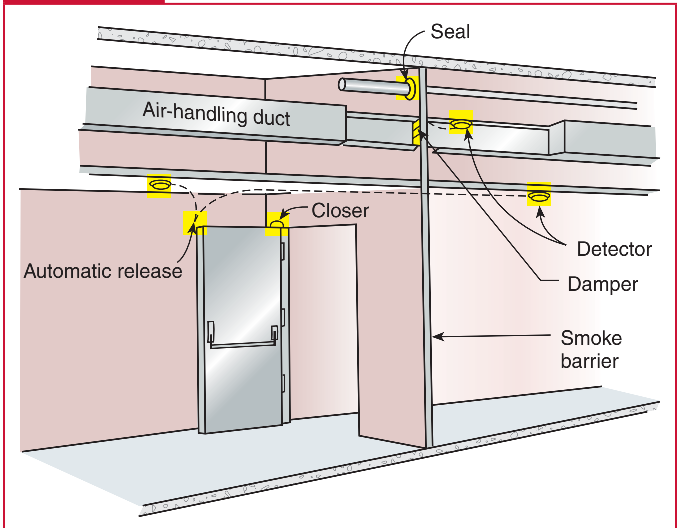
12.9.7.3 Joints made within or between smoke barriers shall be protected with a smoke-tight joint system that is capable of limiting the transfer of smoke. [***101:***8.5.7.3]

12.9.7.4 Smoke barriers that are also constructed as fire barriers shall be protected with a joint system that is designed and tested to resist the spread of fire for a time period equal to the required fire resistance rating of the assembly and restrict the transfer of smoke. [***101:***8.5.7.3]

12.9.7.5 Testing of the joint system in a smoke barrier that also serves as fire barrier shall be representative of the actual installation. [***101:***8.5.7.4]

As in the case of fire barriers, it is important to maintain the integrity of smoke barriers over the life of a building. Exhibit 12.19 illustrates some of the key items regarding smoke barrier penetrations discussed in 12.9.3 through 12.9.7.

Exhibit 12.19



Typical penetrations of a smoke barrier.

Fire Protection Systems

13

Chapter 13 addresses fire protection systems, including requirements for standpipe systems, automatic sprinklers, fire pumps, water supply, portable fire extinguishers, and fire alarms.

13.1 General

13.1.1 The AHJ shall have the authority to require that construction documents for all fire protection systems be submitted for review and approval and a permit be issued prior to the installation, rehabilitation, or modification. *(For additional information concerning construction documents, see Section 1.14.)* Further, the AHJ shall have the authority to require that full acceptance tests of the systems be performed in the AHJ's presence prior to final system certification.

It is recommended that the authority having jurisdiction (AHJ) review plans for fire protection systems to ensure compliance with this *Code* and applicable referenced standards. The approval process ensures that systems are complete and fully functional. The presence of the AHJ during final testing is highly recommended to ensure that, in the event of a fire, fire protection systems operate as intended.

13.1.1.1 Permits. Permits, where required, shall comply with Section 1.12.

13.1.2 The property owner shall be responsible for the proper testing and maintenance of the equipment and systems.

N **13.1.3* Integrated Fire Protection and Life Safety System Test.** Where required by Chapters 11 through 43 of NFPA *101*, and where two or more fire protection or life safety systems are integrated, the integrated system shall be tested to verify the proper operation and function of such systems in accordance with NFPA 4. [***101:***9.11.4]

N **A.13.1.3** NFPA 4 requires that integrated fire protection and life safety systems be periodically retested as specified in the integrated system test plan. In addition, for existing systems, an integrated system test plan must be developed within 5 years of adoption of NFPA 4. [***101:***A.9.11.4]

The provisions of 13.1.3, which are new to the 2018 edition of the *Code*, address the testing of integrated fire protection and life safety systems and mandate compliance with NFPA 4, *Standard for Integrated Fire Protection and Life Safety System Testing*, where required by another section of the *Code*. The integrated systems test addressed by NFPA 4 verifies and documents the operation and function of all interconnected fire protection and life safety systems, including performance in accordance with applicable codes and standards, sequence of operation, performance in accordance with manufacturers' published instructions, and accuracy of record documents.

Where individual systems are needed to function together to provide the intended level of protection, it is important to test the systems together. For example, an engineered smoke control system might depend on the signals from a fire alarm system to activate; the fire alarm system might depend on the activation of an automatic sprinkler system waterflow to initiate an alarm condition. Traditionally, the fire alarm contractor would test only the fire alarm system. The sprinkler system contractor would test only the sprinkler system; and the HVAC contractor would test only the operation of the ventilation system. The provisions of NFPA 4 ensure that the integrated system is tested as whole, with representatives of all the applicable contractors present, to ensure that, for example, a water flow condition initiates an alarm condition on the fire alarm system, which in turn initiates the proper smoke control system operating mode based on the location of the sprinkler activation.

Occupancies and special structures that require the testing of integrated fire protection and life safety systems in accordance with NFPA 4 include the following:

1. High-rise buildings (11.8.9.1 of NFPA *101*)
2. Assembly occupancies (20.1.5.13)
3. New educational occupancies (20.2.4.6)
4. New day-care occupancies (20.3.4.2.3.7)
5. Health care occupancies (20.4.2.7)
6. Ambulatory health care occupancies (20.6.2.7)
7. Detention and correctional occupancies (20.7.2.8)
8. New hotels and dormitories (20.8.2.7)
9. New apartment buildings (20.9.2.4)
10. Mercantile occupancies (20.12.2.6)
11. Industrial occupancies (20.14.3.2)
12. Storage occupancies (20.15.3.2)

Exhibit 13.1

Example of an obstructed fire hydrant. (Source: Abra Staffin Wiebe/ photos.com)

13.1.4 Obstructions shall not be placed or kept near fire hydrants, fire department inlet connections, or fire protection system control valves in a manner that would prevent such equipment or fire hydrants from being immediately visible and accessible.

Obstructions are a common problem and require extra vigilance on the part of the fire inspector and building owner. The AHJ should review site plans to ensure that no obstructions exist. In addition, contacting the local water authority and providing a policy for installation can prevent some common obstruction issues.

See Exhibit 13.1 for an example of an obstructed fire hydrant. Adequate space needs to be provided to gain access and for proper setup and use of fire protection systems and equipment. Where the fire department is not the AHJ, it should be consulted for guidance, because it will require access to the equipment during a fire incident.

13.1.5 A minimum 36 in. (915 mm) of clear space shall be maintained to permit access to and operation of fire protection equipment, fire department inlet connections, or fire protection system control valves. The fire department shall not be deterred or hindered from gaining immediate access to fire protection equipment.

A clear space should be maintained around all fire alarm panels, hose connections, and portable fire extinguishers and any other fire protection equipment. Building and fire department personnel should be able to easily locate and gain access to fire protection equipment at all times. It might be necessary to provide signs indicating the location of fire protection equipment and mark those areas to prevent materials from being placed where they will obstruct access to such equipment.

13.1.5.1 An approved clear and unobstructed path shall be provided and maintained for access to the fire department inlet connections.

13.1.6 Detailed records documenting all systems and equipment testing and maintenance shall be kept by the property owner and shall be made available upon request for review by the AHJ.

Where the AHJ requires documentation regarding fire protection systems to be maintained for review during inspections, the property owner should be notified as part of the approval process. Such notification ensures that the property owner is aware of the documentation requirements.

13.1.7 Existing systems shall be in accordance with 1.3.6.2 and 10.3.2.

13.1.8 All fire protection systems and devices shall be maintained in a reliable operating condition and shall be replaced or repaired where defective or recalled.

N **13.1.9** Whenever impairments, critical deficiencies, or non-critical deficiencies are identified in water-based fire protection systems maintained in accordance with NFPA 25, they shall be corrected in a time frame approved by the AHJ.

13.1.10 The AHJ shall be notified when any fire protection system is out of service and on restoration of service.

•

The AHJ must be notified when a fire protection system is out of service for any reason. The fire department should also be notified so it can respond accordingly to a particular incident. For example, fire-fighting tactics might vary significantly in a building with a fully operational automatic sprinkler system from those in a building in which the automatic sprinkler system is impaired.

13.1.11 In the event of a failure of a fire protection system or an excessive number of accidental activations, the AHJ shall be permitted to require an approved fire watch until the system is repaired.

13.1.12* For occupancies of an especially hazardous nature or where special hazards exist in addition to the normal hazard of the occupancy, or where access for fire apparatus is unduly difficult, or where the size or configuration of the building or contents limits normal fire suppression efforts, the AHJ shall have the authority to require additional safeguards consisting of additional fire safety equipment, more than one type of fire safety equipment, or special systems suitable for the protection of the hazard involved.

A.13.1.12 Such safeguards or fire safety equipment can include, but should not be limited to, automatic fire alarm systems, automatic sprinkler or water spray systems, standpipe and hose, fixed or portable fire extinguishers, breathing apparatus, manual or automatic covers, smoke and heat vents, and carbon dioxide, foam, halogenated, dry chemical, or other special fire-extinguishing systems.

13.1.13 The AHJ shall have the authority to require locking fire department connection (FDC) plugs or caps on all water-based fire protection systems.

13.2 Standpipe Systems

13.2.1 General. The design and installation of standpipe systems shall be in accordance with Section 13.2 and NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

13.2.2 Where Required.

13.2.2.1 Where required by this *Code* or the referenced codes and standards listed in Chapter 2, standpipe systems shall be installed in accordance with 13.2.1.

13.2.2.2 New buildings shall be equipped with a Class I standpipe system installed in accordance with the provisions of Section 13.2 where any of the following conditions exist:

(1) More than three stories above grade where the building is protected by an approved automatic sprinkler system
(2) More than two stories above grade where the building is not protected by an approved automatic sprinkler system
(3)* More than 50 ft (15 m) above grade and containing intermediate stories or balconies

•
N **A.13.2.2.2(3)** Building height should be measured in accordance with the building code adopted in the jurisdiction.

(4) More than one story below grade
(5) More than 20 ft (6.1 m) below grade

13.2.2.3 High-rise buildings shall be protected throughout by a Class I standpipe system in accordance with 13.2.2. [***101:***11.8.3.2]

Standpipes in high-rise buildings can serve to increase life safety, as well as property protection, because of the lengthy evacuation times associated with tall buildings. In many cases, fire emergency plans advise occupants who are not in immediate danger of exposure to fire to remain within the building to allow responding fire service personnel better access to the standpipes within the exit stair enclosures (staged evacuation). Use of standpipes at such times supplements the operation of the required automatic sprinkler system. Exhibit 13.2 shows a typical combination sprinkler/standpipe system.

13.2.2.4 In new assembly occupancies, regular stages over 1000 ft^2 (93 m^2) in area and all legitimate stages shall be equipped with 1½ in. (38 mm) hose lines for first aid fire fighting at each side of the stage. [***101:***12.4.6.12.1]

13.2.2.4.1 In existing assembly occupancies, stages over 1000 ft^2 (93 m^2) in area shall be equipped with 1½ in. (38 mm) hose lines for first aid fire fighting at each side of the stage. [***101:***13.4.6.12.1]

Δ **13.2.2.4.2** Hose connections shall be in accordance with NFPA 13, unless Class II or Class III standpipes in accordance with NFPA 14 are used. [***101:***12.4.6.12.2; ***101:***13.4.6.12.2]

Regardless of whether a stage has automatic sprinkler protection, 1½ in. (38 mm) hose lines are required on each side of stages as specified in 13.2.2.4 through 13.2.2.4.2 to provide stagehands with first aid fire-fighting capability in the area of a theater where a fire is most likely to occur. See 3.3.274, 3.3.274.1, and 3.3.274.2 of NFPA *101*®, *Life Safety Code*®, for definitions of the terms *stage, legitimate stage,* and *regular stage.*

Exhibit 13.2

Typical combination sprinkler/standpipe system with a 2½ in. (64 mm) fire department valve.

Δ **13.2.2.5 New and Existing Detention and Correctional Facilities.** Standpipe and hose systems shall be provided in accordance with Section 9.10 of NFPA *101* as follows, unless otherwise permitted by 13.2.2.5.1:

(1) Class I standpipe systems shall be provided for any building three or more stories in height.
(2) Class III standpipe and hose systems shall be provided for all nonsprinklered buildings three or more stories in height.

[***101:***22.3.5.5; ***101:***23.3.5.5]

The requirements of 13.2.2.5 for standpipes intend that 2½ in. (64 mm) hose connections be available for fire department use in any detention and correctional occupancy more than two stories in height. In addition, if such buildings are nonsprinklered, 1½ in. (38 mm) connections and hose for staff and resident use are required.

Δ **13.2.2.5.1** The requirements of 13.2.2.5 shall not apply where otherwise permitted by the following:

(1) Formed hose, 1 in. (25 mm) in diameter, on hose reels shall be permitted to provide Class II service.
(2) Separate Class I and Class II systems shall be permitted in lieu of a Class III system.

[***101:***22.3.5.6; ***101:***23.3.5.6]

Item (1) in 13.2.2.5.1 permits the use of 1 in. (25 mm) formed rubber hose in place of the fabric-jacketed, rubber-lined hose normally required in standpipe systems. Rubber hose is normally stored on reels and is easier to use.

13.2.2.6* The AHJ shall be authorized to permit the removal of existing occupant-use hose lines where all of the following are met:

(1) This *Code* does not require their installation.
(2) The current building code does not require their installation.
(3) The AHJ determines that the occupant-use hose line will not be utilized by trained personnel or the fire department.

A.13.2.2.6 It is not the intent of 13.2.2.6 to permit the removal of portions of the existing standpipe system other than hose lines, and that such remaining system components be maintained and available for use by the fire department or other appropriate fire suppression personnel.

The provisions of 13.2.2.6, which was new to the 2015 edition of the *Code*, are intended to explicitly allow the removal of nonrequired, occupant-use standpipe hose from buildings. Prior to the 2015 edition, some AHJs might have been wary of permitting the removal of occupant-use hose, lacking any *Code* language stating its removal was permitted. Provided that the hose is not required by NFPA 1 or the applicable building code, and no trained on-site fire suppression personnel would be expected to utilize it, the hose can be removed. It is preferable for untrained building occupants to evacuate rather than attempt to extinguish a fire using hose lines.

13.2.3 Inspection, Testing, and Maintenance.

13.2.3.1 A standpipe system installed in accordance with this *Code* shall be properly maintained to provide at least the same level of performance and protection as designed.

13.2.3.2 The owner shall be responsible for maintaining the standpipe system and keeping it in good working condition.

Δ **13.2.3.3** A standpipe system installed in accordance with this *Code* shall be inspected, tested, and maintained in accordance with NFPA 25.

13.2.3.4 Existing Systems.

13.2.3.4.1 Where an existing standpipe system, including yard piping and fire department connection, is modified, the new piping shall be independently tested in accordance with 11.4.1 of NFPA 14. [**14:**11.4.7.1]

13.2.3.4.2 Modifications that cannot be isolated, such as new valves or the point of connection for new piping, shall not require testing in excess of system static pressure. [**14:**11.4.7.2]

Testing in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems,* is the only way to ensure piping integrity. The new section of piping might be isolated from the existing piping by test blanks or an isolation valve. However, if possible, it is always good practice to retest existing systems for weakness. The provision of 13.2.3.4.2 clarifies that, where modifications are not able to be isolated due to their configuration, they are subject only to testing at the normal system static pressure.

13.3 Automatic Sprinklers

13.3.1 General.

13.3.1.1* Automatic sprinklers shall be installed and maintained in full operating condition in the occupancies specified in this *Code* or in the codes or standards referenced in Chapter 2.

A.13.3.1.1 This *Code* contains requirements for automatic sprinkler protection that might not be required by other NFPA codes. These requirements are included in this *Code* from a property protection standpoint in an effort to reduce property damage due to fires as well as to reduce the costs of manual fire suppression in years to come.

Δ **13.3.1.2** Installations shall be in accordance with NFPA 13, NFPA 13R, or NFPA 13D as appropriate.

13.3.1.3 Existing systems shall be in accordance with 1.3.6.2 and 10.3.2.

13.3.1.4 Sprinkler piping serving not more than six sprinklers for any hazardous area shall be permitted to be connected directly to a domestic water supply system having a capacity sufficient to provide 0.15 gpm/ft^2 (6.1 mm/min) throughout the entire enclosed area. [***101:***9.7.1.2]

Δ **13.3.1.5** Sprinkler piping serving hazardous areas as described in 13.3.1.4 shall be provided with an indicating shutoff valve, supervised in accordance with 13.3.1.8 or NFPA 13 and installed in an accessible, visible location between the sprinklers and the connection to the domestic water supply. [***101:***9.7.1.3]

The general provisions of Section 8.7 of NFPA *101* for special hazard protection — in combination with the specific requirements for protection from hazards of the X.3.2 subsection of each occupancy chapter of NFPA *101* — make extensive use of sprinklering hazardous contents rooms in otherwise nonsprinklered buildings. Such sprinklers are permitted by 13.3.1.4 to be supplied by the domestic water supply and its associated distribution piping. The domestic water supply must provide a sufficient volume of water at the appropriate pressure to deliver a sprinkler discharge density of 0.15 gpm/ft^2 (6.1 mm/min) within the hazardous contents room. For a 100 ft^2 (9.3 m^2) room, the water supply would have to provide at least 15 gpm (57 L/min) at the pressure appropriate to such a discharge from a specific size and model of sprinkler. Additionally, the provisions of 13.3.1.4 can be used (in lieu of a devoted sprinkler system piping network and water supply) only if any given room requires six or fewer sprinklers for adequate protection, based on the spacing and location rules of the applicable installation standards referenced in 13.3.1.2.

Another hazardous contents room on the same floor or in some other part of the building can obtain its protection by repeating a similar maximum six-sprinkler installation in accordance with 13.3.1.4 and 13.3.1.5.

Δ **13.3.1.6*** In areas protected by automatic sprinklers, automatic heat-detection devices required by other sections of this *Code* shall not be required. [***101:***9.7.1.4]

A.13.3.1.6 Properly designed automatic sprinkler systems provide the dual function of both automatic alarms and automatic extinguishment. Dual function is not provided in those cases where early detection of incipient fire and early notification of occupants are needed to initiate actions in behalf of life safety earlier than can be expected from heat-sensitive fire detectors. [***101:***A.9.7.1.4]

Because the operation of an automatic sprinkler system is initiated by a heat-sensing element and works on the same principle as an automatic heat detection and alarm system, a sprinkler system is judged to be capable of serving the same purpose. Even though some sprinkler systems do not sound an alarm on activation, many do. Furthermore, although a particular sprinkler system might not sound an alarm, it does immediately initiate extinguishment, a feature that is at least as valuable, if not more so, than a system that sounds an alarm only.

Detection of smoke, on the other hand, can be accomplished at the incipient stages of a fire and can give rise to an earlier warning than that provided by heat detection, so smoke detection is considered in a somewhat different light. One school of thought is that a system that starts suppression of a fire immediately upon detection is better than one that simply detects the fire and sounds an alarm, even though the latter can be quicker to initiate an alarm signal. An alternative belief, however, is that an early alarm is more advantageous. The first strategy is concerned with the immediate suppression or containment of fire, since it might take considerable time for fire fighters to arrive. The second approach stresses immediate notification of occupants. The *Code* recognizes the value of both strategies and strives for a balanced approach to occupant protection by requiring, in some occupancies, both early warning and automatic suppression systems, depending on the characteristics of the occupants. The extent of protection provided should be commensurate with the ability of the occupants, as a group, to evacuate or relocate to a safe location within the building before the egress routes are compromised by the effects of a fire.

13.3.1.7 Automatic sprinkler systems installed to make use of an alternative permitted by this *Code* shall be considered required systems and shall meet the provisions of this *Code* that apply to required systems. [***101:***9.7.1.5]

The provisions of 13.3.1.7 specify that an automatic sprinkler system voluntarily installed as a *Code* alternative is considered a required system; therefore, it is subject to the same requirements (including maintenance) that apply to a sprinkler system specifically mandated by the *Code*. For example, if an occupancy that does not require a sprinkler system permits the use of the delayed-egress electrical locking system addressed by 14.5.3.1, and if the designer or building operator meets one of the unlocking provisions of 14.5.3.1 via the installation of an approved, supervised automatic sprinkler system, the sprinkler system is considered a required system. Therefore, the system must meet all requirements that apply to a similar system installed to comply with the *Code* in addition to those of the alternative system, such as delayed-egress door locking.

13.3.1.8 Supervision.

Automatic sprinkler system supervision is not required by 13.3.1.8. Rather, the requirements of 13.3.1.8 apply where a supervised automatic sprinkler system is mandated by another section of the *Code*. Most of the occupancy chapters of NFPA *101* that require an automatic sprinkler system for life safety purposes also require the system to be electrically supervised in accordance with 13.3.1.8.

13.3.1.8.1* Supervisory Signals.

Δ **A.13.3.1.8.1** *NFPA 72* provides details of standard practice in sprinkler supervision. Subject to the approval of the AHJ, sprinkler supervision is also permitted to be provided by direct connection to municipal fire departments or, in the case of very large establishments, to a private headquarters providing similar functions. *NFPA 72* covers such matters. System components and parameters that are required to be monitored should include, but should not be limited to, control valves, water tank levels and temperatures, tank pressure, and air pressure on dry-pipe valves. [***101:***A.9.7.2.1]

Where municipal fire alarm systems are involved, reference should also be made to NFPA 1221. [***101:***A.9.7.2.1]

13.3.1.8.1.1 Where supervised automatic sprinkler systems are required by another section of this *Code*, supervisory attachments shall be installed and monitored for integrity in accordance with *NFPA 72* and a distinctive supervisory signal shall be provided to indicate a condition that would impair the satisfactory operation of the sprinkler system. [***101:***9.7.2.1.1]

13.3.1.8.1.2 Supervisory signals shall sound and shall be displayed either at a location within the protected building that is constantly attended by qualified personnel or at an approved, remotely located receiving facility. [***101:***9.7.2.1.2]

One reason the automatic sprinkler system has attained a high level of satisfactory performance and response to fire conditions is that, through supervision, it can be kept in operative condition. Of course, keeping the system operative depends on routine maintenance and the owner's willingness to repair the system when there are indications of impairment. Features of the system, such as the following, can be automatically monitored:

1. Opening and closing of water control valves
2. Power supplies for required fire pumps
3. Water tank level

If an undesirable situation develops, a signal is annunciated in the protected building or relayed to a monitoring facility.

A supervisory system will also indicate or activate a waterflow alarm. In addition to being transmitted to an alarm-monitoring agency, the waterflow alarm can be transmitted directly to the fire department. The signals for electrical and mechanical problems need not burden the fire department unnecessarily, yet those signals indicating a fire can be received directly.

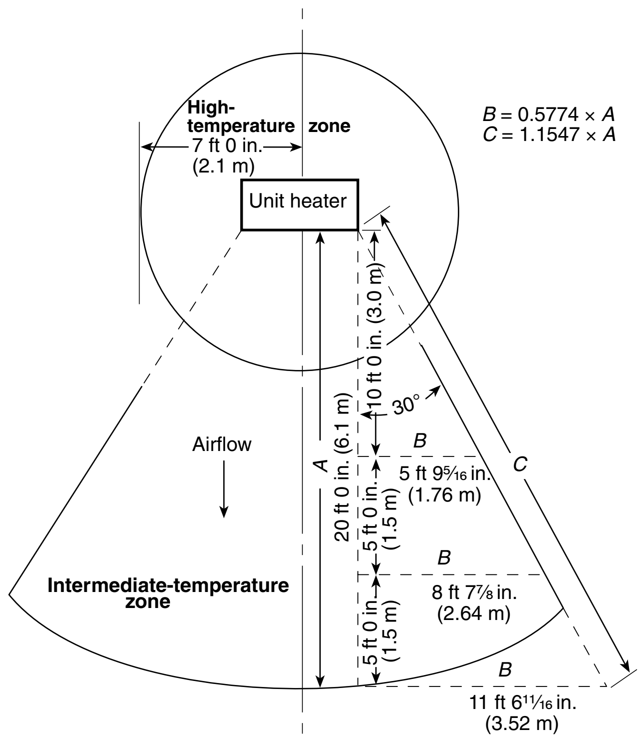
13.3.1.8.2 Alarm Signal Transmission.

13.3.1.8.2.1 Where supervision of automatic sprinkler systems is required by another section of this *Code*, waterflow alarms shall be transmitted to an approved, proprietary alarm-receiving facility, a remote station, a central station, or the fire department. [***101:***9.7.2.2.1]

13.3.1.8.2.2 The connection described in 13.3.1.8.2.1 shall be in accordance with 13.7.1.1. [***101:***9.7.2.2.2]

13.3.1.9 The following practices shall be observed to provide sprinklers of other than ordinary-temperature classification unless other temperatures are determined or unless high-temperature sprinklers are used throughout, and temperature selection shall be in accordance with Table 13.3.1.9(a), Table 13.3.1.9(b), and Figure 13.3.1.9:

(1) Sprinklers in the high-temperature zone shall be of the high-temperature classification, and sprinklers in the intermediate-temperature zone shall be of the intermediate-temperature classification.



Δ *FIGURE 13.3.1.9 High-Temperature and Intermediate-Temperature Zones at Unit Heaters. [**13:**Figure 8.3.2.5]*

(2) Sprinklers located within 12 in. (300 mm) to one side or 30 in. (750 mm) above an uncovered steam main, heating coil, or radiator shall be of the intermediate-temperature classification.

(3) Sprinklers within 7 ft (2.1 m) of a low-pressure blowoff valve that discharges free in a large room shall be of the high-temperature classification.

(4) Sprinklers under glass or plastic skylights exposed to the direct rays of the sun shall be of the intermediate-temperature classification.

(5) Sprinklers in an unventilated, concealed space, under an uninsulated roof, or in an unventilated attic shall be of the intermediate-temperature classification.

(6) Sprinklers in unventilated show windows having high-powered electric lights near the ceiling shall be of the intermediate-temperature classification.

(7) Sprinklers protecting commercial-type cooking equipment and ventilation systems shall be of the high- or extra high-temperature classification as determined by use of a temperature-measuring device. *(See 7.9.6 of NFPA 13.)*

(8) Sprinklers protecting residential areas installed near specific heat sources identified in Table 13.3.1.9(c) shall be installed in accordance with Table 13.3.1.9(c).

(9) Ordinary-temperature sprinklers located adjacent to a heating duct that discharges air that is less than 100°F (38°C) are not required to be separated in accordance with Table 13.3.1.9(a).

(10) Sprinklers in walk-in type coolers and freezers with automatic defrosting shall be of the intermediate-temperature classification or higher.

[**13:**8.3.2.5]

A.13.3.1.9 A diffuser in ceiling sheathing labeled by the manufacturer as "horizontal discharge" has directional vanes to move air further along the ceiling, and sprinklers located within the 2 ft 6 in. (750 mm) radius should have an intermediate-temperature rating. [**13:**A.8.3.2.5]

The requirements specified in 13.3.1.9 relate to the use of sprinklers covered in Table 6.2.5.1 of NFPA 13. The temperature rating criteria allow the sprinklers to operate in response to a fire rather than to high ambient temperatures.

13.3.2 Where Required.

13.3.2.1 Where required by this *Code* or the referenced codes and standards listed in Chapter 2, automatic sprinkler systems shall be installed in accordance with 13.3.1.

13.3.2.2 Basements exceeding 2500 ft^2 (232 m^2) in new buildings shall be protected throughout by an approved automatic sprinkler system.

Fires in basement areas pose a significant hazard to fire fighters. Basement areas are often used for storage and can contain large quantities of combustibles and confusing stock arrangements. Access to utilities often requires entry to buildings through the basement. Access for fire fighting is generally limited to one or two stairways, which can quickly become filled with heat and

Δ ***TABLE 13.3.1.9(a)*** *Temperature Ratings of Sprinklers Based on Distance from Heat Sources*

Type of Heat Condition	Ordinary-Temperature Rating	Intermediate-Temperature Rating	High-Temperature Rating
(1) Heating ducts			
(a) Above	More than 2 ft 6 in. (750 mm)	2 ft 6 in. or less (750 mm)	
(b) Side and below	More than 1 ft 0 in. (300 mm)	1 ft 0 in. or less (300 mm)	
(c) Diffuser	Any distance except as shown under Intermediate-Temperature Rating column	*Downward discharge:* Cylinder with 1 ft 0 in. (300 mm) radius from edge extending 1 ft 0 in. below and 2 ft 6 in. (750 mm) above *Horizontal discharge:* Semicylinder or cylinder with 2 ft 6 in. (750 mm) radius in direction of flow extending 1 ft 0 in. (300 mm) below and 2 ft 6 in. (750 mm) above	
(2) Unit heater			
(a) Horizontal discharge		*Discharge side:* 7 ft 0 in. (2.1 m) to 20 ft 0 in. (6.1 m) radius pie-shaped cylinder *(see Figure 13.3.1.8)* extending 7 ft 0 in. (2.1 m) above and 2 ft 0 in. (600 mm) below heater; also 7 ft 0 in. (2.1 m) radius cylinder more than 7 ft 0 in. (2.1 m) above unit heater	7 ft 0 in. (2.1 m) radius cylinder extending 7 ft 0 in. (2.1 m) above and 2 ft 0 in. (600 mm) below unit heater
(b) Vertical downward discharge *(for sprinklers below unit heater, see Figure 13.3.1.9)*		7 ft 0 in. (2.1 m) radius cylinder extending upward from an elevation 7 ft 0 in. (2.1 m) above unit heater	7 ft 0 in. (2.1 m) radius cylinder extending from the top of the unit heater to an elevation 7 ft 0 in. (2.1 m) above unit heater
(3) Steam mains (uncovered)			
(a) Above	More than 2 ft 6 in. (750 mm)	2 ft 6 in. or less (750 mm)	
(b) Side and below	More than 1 ft 0 in. (300 mm)	1 ft 0 in. or less (300 mm)	
(c) Blowoff valve	More than 7 ft 0 in. (2.1 m)		7 ft 0 in. or less (2.1 m)

[**13:** Table 8.3.2.5(a)]

smoke. Fire fighters must advance downward with hose lines, approaching the top of a fire, as opposed to advancing from beside or below the fire. Ventilation means are often restricted to the same stairway used by fire fighters to attack the fire. Horizontal ventilation is generally impossible.

A serious fire in a basement can jeopardize the structural integrity of the building, which can lead to floor collapse or more serious structural collapse. Installation of an approved automatic sprinkler system limits fire development and allows fire fighters the opportunity to quickly extinguish a fire and complete overhaul activities.

13.3.2.3 New buildings housing emergency fire, rescue, or ambulance services shall be protected throughout by approved supervised automatic sprinkler systems.

The requirement of 13.3.2.3 for new public safety buildings to be protected by supervised automatic sprinkler systems not only protects the emergency services personnel occupying the facility but also diminishes the probability of disrupting the provision of emergency services to the community as a result of a fire. This requirement is consistent with the public welfare goal and objective of the *Code* — see 4.1.5 and its associated commentary.

13.3.2.4 New buildings three or more stories in height above grade shall be protected throughout by an approved automatic sprinkler system in accordance with Section 13.3 unless otherwise permitted by 13.3.2.5.

13.3.2.5 Stand-alone open parking structures that are detached from other occupancies shall not be required to be protected by an automatic sprinkler system.

TABLE 13.3.1.9(b) Temperature Ratings of Sprinklers in Specified Locations

Location	Ordinary-Temperature Rating	Intermediate-Temperature Rating	High-Temperature Rating
Skylights		Glass or plastic	
Attics	Do not use	Ventilated or unventilated	
Peaked roof: metal or thin boards, concealed or not concealed, insulated or uninsulated	Ventilated	Unventilated	
Flat roof: metal, not concealed	Ventilated or unventilated	Note: For uninsulated roof, climate and insulated or uninsulated occupancy can necessitate intermediate sprinklers. Check on job.	
Flat roof: metal, concealed, insulated, or uninsulated	Ventilated	Unventilated	
Show windows	Ventilated	Unventilated	

Note: A check of job condition by means of thermometers might be necessary.

[**13:** Table 8.3.2.5(b)]

Δ *TABLE 13.3.1.9(c) Ratings of Sprinklers in Specified Residential Areas*

	Minimum Distance from Edge of Source to Ordinary-Temperature Sprinkler		Minimum Distance from Edge of Source to Intermediate-Temperature Sprinkler	
Heat Source	in.	mm	in.	mm
Side of open or recessed fireplace	36	915	12	300
Front of recessed fireplace	60	1525	36	915
Coal- or wood-burning stove	42	1070	12	305
Kitchen range	18	460	9	230
Wall oven	18	460	9	230
Hot air flues	18	460	9	230
Uninsulated heat ducts	18	460	9	230
Uninsulated hot water pipes	12	305	6	155
Side of ceiling- or wall-mounted hot air diffusers	24	610	12	305
Front of wall-mounted hot air diffusers	36	915	18	460
Hot water heater or furnace	6	155	3	75
Light fixture:				
0 W–250 W	6	155	3	75
250 W–499 W	12	305	6	155

[**13:** Table 8.3.2.5(c)]

The requirement of 13.3.2.4, which requires automatic sprinklers in all new buildings three or more stories in height above grade, other than open parking structures as specified by 13.3.2.5, was new to the 2012 edition of the *Code*. It recognizes the challenges posed to the fire service when fighting a fire in a multistory building. Where a fire occurs on an upper floor of a multistory building, the fire department must first locate the fire and then stretch hose lines up stairs or carry hose packs up stairs and connect to the building standpipe system. In either case, the time required to apply water to the fire is increased, allowing the fire to continue to develop. In many cases, the room of fire origin in multistory buildings will reach flashover prior to the application of water by the fire service. The onset of flashover significantly increases the production of heat, smoke, and other toxic products of combustion and can also adversely impact the building's structural integrity. With the installation of automatic sprinklers, the risk of flashover is all but eliminated, greatly enhancing the protection of building occupants, emergency responders, the building itself, and the building's contents.

The *Code* does not prescribe a method for determining a building's number of stories in height above grade. For such determination, the AHJ might defer to the building code adopted by the jurisdiction. Where no building code is adopted, the AHJ might refer to the criteria specified by other recognized codes, such as NFPA *101* or *NFPA 5000®*, *Building Construction and Safety Code®*.

13.3.2.6* Exterior Roofs, Canopies, Porte-Cocheres, Balconies, Decks, or Similar Projections. In buildings protected throughout by automatic sprinklers in accordance with NFPA 13, automatic sprinkler protection shall be provided for the exterior spaces in accordance with 13.3.2.6.

A.13.3.2.6 Small loading docks, covered platforms, ducts, or similar small unheated areas can be protected by dry pendent sprinklers extending through the wall from wet sprinkler piping in an adjacent heated area. Where protecting covered platforms, loading docks, and similar areas, a dry pendent sprinkler should extend down at a 45 degree angle. The width of the area to be protected should not exceed 7½ ft (2.3 m). Sprinklers should be spaced not over 12 ft (3.7 m) apart. Exterior projections include, but are not limited to, exterior roofs, canopies, porte-cocheres, balconies, decks, or similar projections. *(See Figure A.13.3.2.6.)* [**13:**A.8.15.7]

13.3.2.6.1 Unless the requirements of 13.3.2.6.2, 13.3.2.6.3, or 13.3.2.6.4 are met, sprinklers shall be installed under exterior projections exceeding 4 ft (1.2 m) in width. [**13:**8.15.7.1]

Exterior canopies exceeding 4 ft (1.2 m) in width that are constructed of combustible materials must be sprinklered unless they meet the requirements of 13.3.2.6.4 and do not have combustible goods stored or handled underneath them. Canopies less than 4 ft (1.2 m) in width do not need to be sprinklered, regardless of construction type, provided that no combustibles are stored beneath them.

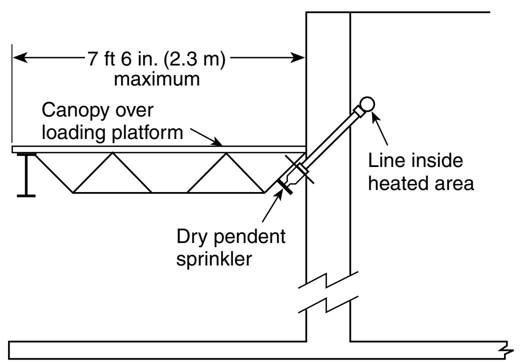


***FIGURE A.13.3.2.6** Dry Pendent Sprinklers for Protection of Covered Platforms, Loading Docks, and Similar Areas. [**13:** Figure A.8.15.7]*

Balconies under 4 ft (1.2 m) in width, such as those on many multistory apartment buildings, do not require sprinkler protection. Balconies more than 4 ft (1.2 m) in width are required to be sprinklered, unless the requirements of 13.3.2.6.1 are met.

13.3.2.6.2* Sprinklers shall be permitted to be omitted where the exterior canopies, roofs, porte-cocheres, balconies, decks, and similar projections are constructed with materials that are noncombustible, limited-combustible, or fire retardant–treated wood as defined in NFPA 703, or where the projections are constructed utilizing a noncombustible frame, limited-combustibles, or fire retardant-treated wood with an inherently flame-resistant fabric overlay as demonstrated by Test Method 2 in accordance with NFPA 701. [**13:**8.15.7.2]

Sprinklers can be omitted if the canopy construction assembly is composed entirely of noncombustible, limited-combustible, or fire-retardant materials and the area underneath is essentially restricted to pedestrian use. The reference to noncombustible and limited-combustible construction applies to the entire canopy assembly and not just to the exposed surface. Cases where the exterior roof or canopy is surfaced with noncombustible, limited-combustible, or fire-retardant-treated materials normally require sprinklers, but sprinklers may be omitted if the requirements of 13.3.2.6.2 are met.

The roof canopy typically found on strip shopping malls, where the area under the canopy is limited to pedestrians, is one example of this condition where pedestrian traffic is the primary use. Areas where automobiles stop briefly to pick up or drop off passengers are not considered storage areas. Areas located at drive-in bank windows or porte-cocheres at motels and hotels normally do not require sprinklers. However, the area under the exterior ceiling shown in Exhibit 13.3 would require sprinkler protection. The space is used primarily for parking vehicles, and the remainder of the building is sprinklered.

Exhibit 13.3

Parking area under exterior ceiling that is required to be sprinklered.

Figure A.13.3.2.6 shows one method of protecting areas under roofs or canopies up to 7 ft 6 in. (2.3 m) wide. Sprinklers are required under all such coverings where combustible goods are stored or handled.

A.13.3.2.6.2 Vehicles that are temporarily parked are not considered storage. Areas located at drive-in bank windows or porte-cocheres at hotels and motels normally do not require sprinklers where there is no occupancy above, where the area is entirely constructed of noncombustible or limited-combustible materials or fire retardant treated lumber, and where the area is not the only means of egress. However, areas under exterior ceilings where the building is sprinklered should be protected due to the occupancy above. [**13:**A.8.15.7.2]

13.3.2.6.3 Sprinklers shall be permitted to be omitted from below the exterior projections of combustible construction, provided the exposed finish material on the exterior projections are noncombustible, limited-combustible, or fire retardant–treated wood as defined in NFPA 703, and the exterior projections contain only sprinklered concealed spaces or any of the following unsprinklered combustible concealed spaces:

(1) Combustible concealed spaces filled entirely with noncombustible insulation
(2) Light or ordinary hazard occupancies where noncombustible or limited-combustible ceilings are directly attached to the bottom of solid wood joists so as to create enclosed joist spaces 160 ft^3 (4.5 m^3) or less in volume, including space below insulation that is laid directly on top or within the ceiling joists in an otherwise sprinklered attic *[see 11.2.3.1.4(4)(d) of NFPA 13]*
(3) Concealed spaces over isolated small exterior projections not exceeding 55 ft^2 (5.1 m^2) in area

[**13:**8.15.7.3]

Sprinklers are permitted to be omitted from a combustible roof, canopy, or porte-cochere where the exterior surfaces are of noncombustible, limited-combustible, or fire-retardant materials; where the roof, canopy, or porte-cochere contains only combustible concealed spaces that are completely filled with noncombustible insulation; where the concealed space is formed when the noncombustible surface is directly attached to joists so as to create spaces of 160 ft^3 (4.5 m^3) or less in volume; or where the area is less than 55 ft^2 (5.1 m^2). All these conditions do not require sprinklers per 8.15.1.2 of NFPA 13.

13.3.2.6.4 Sprinklers shall be permitted to be omitted from exterior exit corridors when the exterior walls of the corridor are at least 50 percent open and when the corridor is entirely of noncombustible construction. [**13:**8.15.7.4]

Exit corridors, such as those that might be found on the outside of a motel or similar structure, do not normally contain combustibles and do not require sprinklers, provided that the corridor is entirely constructed of noncombustible materials and the exterior walls are 50 percent open so that there is access for fire fighting if a fire occurs.

13.3.2.6.5* Sprinklers shall be installed under exterior projections greater than 2 ft (600 mm) wide over areas where combustibles are stored. [**13:**8.15.7.5]

A.13.3.2.6.5 Short-term transient storage, such as that for delivered packages, and the presence of planters, newspaper machines, and so forth, should not be considered for storage or handling of combustibles. The presence of combustible furniture on balconies for occupant use should not require sprinkler protection. [**13:**A.8.15.7.5]

Paragraph 13.3.2.6.5 requires sprinklers to be installed under exterior roofs, canopies, or porte-cocheres where combustibles are stored and handled, but it does not define the amount of combustibles that must be present. Paragraph A.13.3.2.6.5 clarifies that temporary "storage," such as newspaper vending machines and planters, is not sufficient to justify sprinklers. Another example of temporary storage that does not justify sprinklers is an automobile stopped at a bank's drive-up window or parked under a hotel's porte-cochere used for unloading luggage and checking in.

13.3.2.7 New Assembly Occupancies.

Δ **13.3.2.7.1** The following assembly occupancies shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.1.2:

(1) Dance halls
(2) Discotheques
(3) Nightclubs
(4) Assembly occupancies with festival seating

[***101:***12.3.5.1]

Δ **13.3.2.7.2** Any building containing one or more assembly occupancies where the aggregate occupant load of the assembly occupancies exceeds 300 shall be protected by an approved, supervised automatic sprinkler system in accordance with NFPA 13 as follows *(see also 12.1.6, 12.2.6, 12.3.2, and 12.3.6 of* NFPA *101):*

(1) Throughout the story containing the assembly occupancy
(2) Throughout all stories below the story containing the assembly occupancy
(3) In the case of an assembly occupancy located below the level of exit discharge, throughout all stories intervening between that story and the level of exit discharge, including the level of exit discharge

[***101:***12.3.5.2]

Δ **13.3.2.7.3** The requirements of 13.3.2.7.2 shall not apply to the following:

(1)* Assembly occupancies consisting of a single multipurpose room of less than 12,000 ft^2 (1115 m^2) that are not used for exhibition or display and are not part of a mixed occupancy

A.13.3.2.7.3(1) It is the intent to permit a single multipurpose room of less than 12,000 ft^2 (1115 m^2) to have certain small rooms as part of the single room. These rooms could be a kitchen, office, equipment room, and the like. It is also the intent that an addition could be made to an existing building without requiring that the existing building be sprinklered, where both the new and existing buildings have independent means of egress and a fire-rated separation is provided to isolate one building from the other. [*101:*A.12.3.5.3(1)]

A school gymnasium with egress independent of, and separated from, the school would be included in this exception, as would a function hall attached to a church with a similar egress arrangement. [*101:*A.12.3.5.3(1)]

(2) Gymnasiums, skating rinks, and swimming pools used exclusively for participant sports with no audience facilities for more than 300 persons

(3)* Locations in stadia and arenas as follows:
   (a) Over the floor areas used for contest, performance, or entertainment, provided that the roof construction is more than 50 ft (15 m) above the floor level, and use is restricted to low fire hazard uses
   (b) Over the seating areas, provided that use is restricted to low fire hazard uses
   (c) Over open-air concourses where an approved engineering analysis substantiates the ineffectiveness of the sprinkler protection due to building height and combustible loading

A.13.3.2.7.3(3) Examples of low fire hazard uses include spectator sporting events, concerts, and performances on platforms.

The following uses are not low fire hazard uses: concerts and performances on stages; tradeshows; exhibition and display of combustible items; displays of vehicles, boats, or similar items; or events using open flames or pyrotechnic effects. [*101:*A.12.3.5.3(3)]

•

(4) Locations in unenclosed stadia and arenas as follows:
   (a) Press boxes of less than 1000 ft^2 (93 m^2)
   (b) Storage facilities of less than 1000 ft^2 (93 m^2) if enclosed with not less than 1-hour fire resistance–rated construction
   (c) Enclosed areas underneath grandstands that comply with 25.3.4

[*101:*12.3.5.3]

13.3.2.7.4 Where another provision of Chapter 12 of NFPA *101* requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with NFPA 13. [*101:*12.3.5.4]

The provisions of 13.3.2.7 and 13.3.2.8 specify two primary locations where automatic sprinkler protection might be required in new and existing assembly occupancies. The others are 12/13.1.6 and 12/13.4.4 of NFPA *101*, which apply to minimum construction requirements and high-rise buildings, respectively. Each of these subsections is to be applied independently to determine whether automatic sprinkler protection is required. For example, if the building is not high-rise and 12/13.1.6 of NFPA *101* does not require sprinklers for a particular assembly occupancy on the basis of building construction type and location within the building, 13.3.2.7 might require automatic sprinklers for that assembly occupancy based on use or occupant load, or 13.3.2.8 might require automatic sprinklers based on use or floor area that is capable of being used for exhibition purposes. If one subparagraph requires sprinklers and the other does not, sprinklers must be provided.

The requirements of 13.3.2.7.1 for new nightclub-type assembly occupancies to be sprinklered and of 13.3.2.8.1 for existing nightclub-type assembly occupancies with more than a 100-person occupant load to be sprinklered were added to the *Code* in 2006. The provisions were developed in response to the February 2003 fire at The Station nightclub in West Warwick, Rhode Island, which claimed the lives of 100 patrons.

The provisions of 13.3.2.7.1 and 13.3.2.8.1 were revised for the 2012 edition of the *Code*. Previously, an entry for "bars with live entertainment" was included in the list of nightclub-type assembly occupancies requiring sprinklers. Judgment of what constitutes a bar with live entertainment is difficult. Would the presence of a folk singer with a guitar sitting on a stool raise the danger level to that of a nightclub as learned from the fire at The Station nightclub so as to justify sprinklering? Questions like that convinced the technical committee to delete "bars with live entertainment" from the list.

The requirement of 13.3.2.7.2 for automatic sprinkler protection for new assembly occupancies with an occupant load in excess of 300 persons was prompted by the occurrence of fires involving assembly occupancies, most notably the Beverly Hills Supper Club fire in 1977 in Kentucky and the MGM Grand Hotel fire in 1980 in Las Vegas.

Paragraph 13.3.2.7.2 was revised for the 2009 edition of the *Code* to clarify that a 300-person occupant load threshold is to be applied to the aggregate occupant load of all the assembly occupancies in the building. For example, if two assembly occupancies are in the building, and each has an occupant load of 160 persons, the 300-person threshold of 13.3.2.7.2 is exceeded so as to require sprinklers. The extent of the sprinkler system is addressed by 13.3.2.7.2(1), (2), and (3).

The exemptions from the sprinkler requirement of 13.3.2.7.2, as contained in 13.3.2.7.3, are important in that they limit the areas or buildings requiring sprinkler protection. Two of the exemptions in 13.3.2.7.3, related to stadia and arenas, were revised for the 2012 edition of the *Code,* but similar exemptions in 13.3.2.8.3 for existing situations were left unchanged. The provision of 13.3.2.7.3(3)(a) was revised to add criteria for minimum clearance between floor and roof and a restriction to low fire hazard uses. The provision of 13.3.2.7.3(3)(b) was revised to add a restriction that the seating area have low fire hazard uses.

The concepts used in footnote a of Table 12.1.6 and Table 13.1.6 of NFPA *101* are also used with regard to which areas must be sprinklered — see 13.3.2.7.2(1), (2), and (3). If a five-story building has an assembly occupancy on the first floor, the floors above the assembly occupancy are not required to be sprinklered by the assembly occupancy provisions; however, the applicable occupancy chapter might require sprinklering of those floors. If the assembly occupancy were on the fifth floor, then the fifth floor and all floors below it would be required to be sprinklered.

Paragraph 13.3.2.7.3(1) exempts sprinkler protection for multipurpose assembly occupancies that are contained in one room, have an area of less than 12,000 ft² (1115 m²), and are not used as an exhibition hall or for a display room. Exhibit and display halls have been shown to be fire and life safety problems because of their high fuel load and potential for rapid fire spread.

The text of A.13.3.2.7.3(1) clarifies that it is not the intent of 13.3.2.7.3(1) to prohibit the presence of normal ancillary spaces. However, a number of assembly rooms or a mixed occupancy would not be permitted to use this exemption.

Paragraph 13.3.2.7.3(2) exempts gymnasiums, skating rinks (including ice and roller rinks), and swimming pools where there is an audience or spectator gallery with an occupant load of 300 or fewer persons. If the skating rink or swimming pool can be floored over and used for other purposes, then the multipurpose room requirements contained in 13.3.2.7.3(1) might apply. If the spectator gallery has an occupant load greater than 300, then an automatic sprinkler system is required. In effect, 13.3.2.7.3(2) exempts the participants on the gym floor, on the skating rink, or in the swimming pool from being counted as part of the 300-person threshold at which the provisions of 13.3.2.7.2 apply.

Two major questions that arise with regard to 13.3.2.7 deal with multiple occupancies (especially assembly/educational) and multiple assembly occupancies (especially religious halls with multipurpose rooms).

With regard to multiple occupancies, 6.1.14.3 states that, if mixed occupancies provisions are to be used to protect a multiple occupancy, the most stringent requirements applicable to any of the involved occupancies must be provided for all occupancies. Therefore, new schools with assembly occupancies with an occupant load in excess of 300 need to be fully sprinklered, unless the multiple occupancy is treated as separated occupancies in accordance with 6.1.14.4, which would require independent exit access systems and substantial fire-rated separating construction. If separated occupancies can be established, only the assembly occupancy with an occupant load in excess of 300 would need to be sprinklered. Also, multipurpose assembly rooms in a multiple occupancy assembly and educational occupancies building utilizing the separated occupancies provisions of 6.1.14.4 could potentially use 13.3.2.7.3(1) for exemption from the sprinkler requirement. Paragraph 13.3.2.7.3(1) emphasizes that the assembly occupancy is essentially a single room and, thus, cannot be part of a multiple occupancy building protected as mixed occupancies in accordance with 6.1.14.3.

Paragraph 13.3.2.7.3(1) was originally intended for a typical fellowship hall, such as a VFW, an American Legion, or a Grange hall. Some ancillary rooms, such as kitchens, restrooms, storage rooms, or minor offices, will exist, and it is not the intent that these ancillary spaces disqualify a facility from using this exemption [see A.13.3.2.7.3(1)]; however, it is the intent that the facility consist essentially of only one major room.

The provisions of 13.3.2.8.2 — which apply to existing assembly occupancies used or capable of being used for exhibition or display purposes — are not as stringent as those for new assembly occupancies. This requirement would apply to many facilities over 15,000 ft² (1400 m²), unless fixed seating or similar permanent obstruction to exhibition use is provided.

13.3.2.7.5 Fire Protection. Every stage shall be protected by an approved, supervised automatic sprinkler system in compliance with Section 13.3. [***101:***12.4.6.10]

13.3.2.7.5.1 Protection shall be provided throughout the stage and in storerooms, workshops, permanent dressing rooms, and other accessory spaces contiguous to stages. [***101:***12.4.6.10.1]

13.3.2.7.5.2 Sprinklers shall not be required for stages 1000 ft² (93 m²) or less in area and 50 ft (15 m) or less in height where the following criteria are met:

(1) Curtains, scenery, or other combustible hangings are not retractable vertically.
(2) Combustible hangings are limited to borders, legs, a single main curtain, and a single backdrop.

[***101:***12.4.6.10.2]

13.3.2.7.5.3 Sprinklers shall not be required under stage areas less than 48 in. (1220 mm) in clear height that are used exclusively for chair or table storage and lined on the inside with ⅝ in. (16 mm) Type X gypsum wallboard or the approved equivalent. [***101:***12.4.6.10.3]

Stages pose a host of life safety protection challenges. Scenery might be shifted horizontally, vertically, or both ways. The use of thrust stages and arena stages introduces new challenges.

The classic stage of the past rose high above the proscenium opening to accommodate the rigid asbestos curtain. The high void was a natural place to house combustible scenery for a performance, along with the rigging necessary for handling scene changes. This vertical storage area represented both a high fuel load and a space difficult to reach in case of fire. Many new theaters use a flexible, noncombustible curtain that does not require much height to accommodate it. Scenery on these stages is moved horizontally, thus reducing the distance necessary for storage between the top of the proscenium opening and the stage ceiling. Most combustible scenery is now stored in areas adjacent to the stage. All rigging and lighting is condensed in less vertical space.

13.3.2.8 Existing Assembly Occupancies.

See the commentary following 13.3.2.7.4.

Δ **13.3.2.8.1** Where the occupant load exceeds 100, the following assembly occupancies shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13:

(1) Dance halls
(2) Discotheques

(3) Nightclubs
(4) Assembly occupancies with festival seating
[***101:***13.3.5.1]

13.3.2.8.2 Any assembly occupancy used or capable of being used for exhibition or display purposes shall be protected throughout by an approved automatic sprinkler system in accordance with Section 13.3 where the exhibition or display area exceeds 15,000 ft^2 (1400 m^2). [***101:***13.3.5.2]

Δ **13.3.2.8.3** The sprinklers specified by 13.3.2.8.2 shall not be required where otherwise permitted in the following locations:

(1) Locations in stadia and arenas as follows:
  (a) Over the floor areas used for contest, performance, or entertainment
  (b) Over the seating areas
  (c) Over open-air concourses where an approved engineering analysis substantiates the ineffectiveness of the sprinkler protection due to building height and combustible loading
(2) Locations in unenclosed stadia and arenas as follows:
  (a) Press boxes of less than 1000 ft^2 (93 m^2)
  (b) Storage facilities of less than 1000 ft^2 (93 m^2) if enclosed with not less than 1-hour fire resistance–rated construction
  (c) Enclosed areas underneath grandstands that comply with 25.3.4

[***101:***13.3.5.3]

13.3.2.8.4 Where another provision of this chapter and Chapter 13 of NFPA *101* requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with NFPA 13. [***101:***13.3.5.4]

13.3.2.8.5 Fire Protection. Every stage shall be protected by an approved automatic sprinkler system in compliance with Section 13.3. [***101:***13.4.6.10]

13.3.2.8.5.1 Protection shall be provided throughout the stage and in storerooms, workshops, permanent dressing rooms, and other accessory spaces contiguous to such stages. [***101:***13.4.6.10.1]

13.3.2.8.5.2 Sprinklers shall not be required for stages 1000 ft^2 (93 m^2) or less in area where the following criteria are met:

(1) Curtains, scenery, or other combustible hangings are not retractable vertically.
(2) Combustible hangings are limited to borders, legs, a single main curtain, and a single backdrop.

[***101:***13.4.6.10.2]

13.3.2.8.5.3 Sprinklers shall not be required under stage areas less than 48 in. (1220 mm) in clear height that are used exclusively for chair or table storage and lined on the inside with ⅝ in. (16 mm) Type X gypsum wallboard or the approved equivalent. [***101:***13.4.6.10.3]

13.3.2.9 New Educational Occupancies.

Δ **13.3.2.9.1** Educational occupancy buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***14.3.5.1]

• *N* **13.3.2.9.2** The requirement of 13.3.2.9.1 shall not apply to any of the following:

(1) Non-relocatable buildings having an area not exceeding 1000 ft^2 (93 m^2)
(2) Non-relocatable buildings containing a single classroom
(3) Relocatable buildings complying with all of the following:
  (a) Building area does not exceed 1000 ft^2 (93 m^2)
  (b) Building contains a single classroom
  (c) Building is located not less than 30 ft (9.1 m) from another building

[***101:***14.3.5.2]

13.3.2.9.3 Every portion of educational buildings below the level of exit discharge shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***14.3.5.3]

13.3.2.9.4 Buildings with unprotected openings in accordance with 8.6.6 of NFPA *101* shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***14.3.5.4]

13.3.2.9.5 Where another provision of Chapter 14 of NFPA *101* requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with NFPA 13. [***101:***14.3.5.5]

The provision of 13.3.2.9.1 was revised for the 2018 edition of NFPA *101* and requires new educational occupancy buildings to be fully sprinklered, unless they can apply an exemption per 13.3.2.9.2. The previous 12,000 ft^2 (1120 m^2) building size and the four stories in height threshold for requiring sprinklers have been deleted. Fully sprinklered schools provide active fire protection regardless of any scenario for which they are used. Public schools are often used as public shelters, before or after a tornado, hurricane, flood, wild fire, and so forth. Some states require new schools be built as public shelters. In many emergencies, whether natural or man-made disasters, a school becomes the center for several temporary occupancies and agencies that provide emergency services, such as cooking, nursing, surgery, psychiatric, along with housing, to area residents. All these emergency uses, if built separately from a school, require sprinklers.

The NFPA document *Workshop on School Safety, Codes and Security: Final Report* makes several suggestions to improve school security. Several areas of the report suggest improving fire protection, such as fire sprinklers, to facilitate egress options. One example is delayed evacuation when lockdown procedures are implemented. A procedure that holds students and staff in an area, preventing egress after fire alarm activation, is a concept contrary to NFPA *101*. Only by mandating an active fire protection system is this even remotely possible.

Schools are a significant investment by the community, the state, and the federal government. Losing schools through fire is irresponsible planning, and the cost to rebuild places a heavy burden to the school district and local taxpayers. According to the abstract for the 2016 NFPA report *Structure Fires in Educational Properties*, "In 2009–2013, U.S. fire departments responded to an estimated average of 5,100 structure fires in educational properties, annually. These fires caused an annual average of one civilian death, 79 civilian fire injuries and $88 million in direct property damage." Where sprinklers are installed, fire damage is 62 percent less than damage to buildings without sprinklers.

Mandating sprinklers is only part of the emergency planning and by no means solves all the security aspects of schools. However, from experience, it is one of the more easily obtainable of all goals and provides a safe environment from fire.

Paragraph 13.3.2.9.2 has been updated to recognize three specific exemptions from the sprinkler requirement. Nonrelocatable buildings containing a single classroom or having an area not exceeding 1000 ft^2 (93 m^2) as well as relocatable buildings meeting the provisions of 13.3.2.9.2(3)(a) through (c) are exempt from the sprinkler provisions. These exemptions recognize modular-type classrooms that can be used as overflow classroom space during renovations, for example, or permanent buildings that are small enough in area and use that the sprinkler requirement is not justified. Paragraphs 13.3.2.9.3, 13.3.2.9.4, and 13.3.2.9.5 remain unchanged because not all new buildings will be required to be sprinklered. The non-sprinkler options must be retained because Chapter 43, Building Rehabilitation, of NFPA *101* requires compliance with Chapter 14 (new educational occupancies), but not Chapter 15 (existing educational occupancies) of NFPA *101*, for added or replaced elements and systems. The user who is performing the renovation in a nonsprinklered existing school building must not be misled into using provisions that apply only to new construction. The provision of 13.3.2.9.3 and the provisions of 13.3.2.10.1 through 13.3.2.10.3 address the need for sprinklers based on whether there are levels or floors below the level of exit discharge. For new construction, 13.3.2.9.3 will normally require basements of schools to be sprinklered; for existing educational occupancies, the basement will need to be sprinklered if it is used for student occupancy.

13.3.2.10 Existing Educational Occupancies.

See the commentary following 13.3.2.9.5.

13.3.2.10.1 Where student occupancy exists below the level of exit discharge, every portion of such floor shall be protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***15.3.5.1]

13.3.2.10.2 Where student occupancy does not exist on floors below the level of exit discharge, such floors shall be separated from the rest of the building by 1-hour fire resistance–rated construction or shall be protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***15.3.5.2]

Δ **13.3.2.10.3** Automatic sprinkler protection shall not be required where student occupancy exists below the level of exit discharge, provided that both of the following criteria are met:

(1) The approval of the AHJ shall be required.
(2) Windows for rescue and ventilation shall be provided in accordance with 15.2.11.1 of NFPA *101*.

[***101:***15.3.5.3]

13.3.2.10.4 Buildings with unprotected openings in accordance with 8.6.6 of NFPA *101* shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***15.3.5.4]

13.3.2.10.5 Where another provision of Chapter 15 of NFPA *101* requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with NFPA 13. [***101:***15.3.5.5]

13.3.2.11 New Health Care Occupancies.

13.3.2.11.1* Buildings containing health care occupancies shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3, unless otherwise permitted by 13.3.2.11.3. [***101:***18.3.5.1]

A.13.3.2.11.1 In areas where the replenishment of water supplies is not immediately available from on-site sources, alternate provisions for the water-fill rate requirements of NFPA 13 and NFPA 22 that are acceptable to the AHJ should be provided. Appropriate means for the replenishment of these supplies from other sources, such as fire department tankers, public safety organizations, or other independent contractors should be incorporated into the overall fire safety plan of the facility. [***101:***A.18.3.5.1]

With automatic sprinkler protection required throughout new health care facilities and quick-response sprinklers required in smoke compartments containing patient sleeping rooms, a fire and its life-threatening byproducts can be reduced, thereby allowing the defend-in-place concept to continue. The difficulty in maintaining the proper integrity of life safety elements has been considered and it has been judged that the probability of a sprinkler system operating as designed is equal to or greater than other life safety features. [***101:***A.18.3.5.1]

13.3.2.11.2 The sprinkler system required by 13.3.2.11.1 shall be installed in accordance with NFPA 13. [***101:***18.3.5.4]

13.3.2.11.3 In Type I and Type II construction, alternative protection measures shall be permitted to be substituted for sprinkler protection, without causing a building to be classified as nonsprinklered, in specified areas where the AHJ has prohibited sprinklers. [***101:***18.3.5.5]

13.3.2.11.4* Listed quick-response or listed residential sprinklers shall be used throughout smoke compartments containing patient sleeping rooms. [***101:***18.3.5.6]

A.13.3.2.11.4 The requirements for use of quick-response sprinklers intend that quick-response sprinklers be the predominant type of sprinkler installed in the smoke compartment. It is recognized, however, that quick-response sprinklers might not be approved for installation in all areas such as those where NFPA 13 requires sprinklers of the intermediate- or high-temperature classification. It is not the intent of the 13.3.2.11.4 requirements to prohibit the use of standard sprinklers in limited areas of a smoke compartment where intermediate- or high-temperature sprinklers are required. [***101:***A.18.3.5.6]

Residential sprinklers are considered acceptable in patient sleeping rooms of all health care facilities, even though not specifically listed for this purpose in all cases. [***101:***A.18.3.5.6]

Where the installation of quick-response sprinklers is impracticable in patient sleeping room areas, appropriate equivalent protection features acceptable to the AHJ should be provided. It is recognized that the use of quick-response sprinklers might be limited in facilities housing certain types of patients or by the installation limitations of quick-response sprinklers. [***101:***A.18.3.5.6]

13.3.2.11.5* Sprinklers shall not be required in clothes closets of patient sleeping rooms in hospitals where the area of the closet does not exceed 6 ft^2 (0.55 m^2), provided that the distance from the sprinkler in the patient sleeping room to the back wall of the closet does not exceed the maximum distance permitted by NFPA 13. [***101:***18.3.5.10]

A.13.3.2.11.5 This exception is limited to hospitals, as nursing homes and many limited care facilities might have more combustibles within the closets. The limited amount of clothing found in the small clothes closets in hospital patient rooms is typically far less than the amount of combustibles in casework cabinets that do not require sprinkler protection, such as nurse servers. In many hospitals, especially new hospitals, it is difficult to make a distinction between clothes closets and cabinet work. The exception is far more restrictive than similar exceptions for hotels and apartment buildings. NFPA 13 already permits the omission of sprinklers in wardrobes *[see 8.1.1(7) of NFPA 13]*. It is not the intent of 13.3.2.11.5 to affect the wardrobe provisions of NFPA 13. It is the intent that the sprinkler protection in the room covers the closet as if there were no door on the closet. *(See 8.5.3.2.3 of NFPA 13.)* [***101:***A.18.3.5.10]

13.3.2.11.6* Sprinklers in areas where cubicle curtains are installed shall be in accordance with NFPA 13. [***101:***18.3.5.11]

A.13.3.2.11.6 For the proper operation of sprinkler systems, cubicle curtains and sprinkler locations need to be coordinated. Improperly designed systems might obstruct the sprinkler spray from reaching the fire or might shield the heat from the sprinkler. Many options are available to the designer including, but not limited to, hanging the cubicle curtains 18 in. (455 mm) below the sprinkler deflector; using a ½ in. (13 mm) diagonal mesh or a 70 percent open weave top panel that extends 18 in. (455 mm) below the sprinkler deflector; or designing the system to have a horizontal and minimum vertical distance that meets the requirements of NFPA 13. The test data that form the basis of the NFPA 13 requirements are from fire tests with sprinkler discharge that penetrated a single privacy curtain. [***101:***A.18.3.5.11]

Paragraph 13.3.2.11.1 requires automatic sprinkler protection throughout all new health care facilities; 13.3.2.11.4 requires the use of quick-response or residential sprinklers throughout all smoke compartments containing patient sleeping rooms.

Paragraph 13.3.2.12.1 requires automatic sprinkler protection throughout all existing nursing homes.

Paragraph 13.3.2.12.2 extracts the existing health care occupancies high-rise building sprinkler requirement in 19.4.2 of NFPA *101*. Without the extract, the user who consults 13.3.2.12 to identify the sprinkler requirements applicable to existing health care occupancies might miss the requirement that is located in the chapter subsection on high-rise buildings.

Where sprinkler protection is specified, complete building coverage in accordance with the provisions of NFPA 13 is required (see 13.3.2.11.2 and 13.3.2.12.6). The *Code* does not exempt any area of the building from sprinkler protection (see Section 13.3). However, where automatic sprinkler protection is omitted from certain spaces in Type I and Type II construction at the mandate of the AHJ, and the AHJ approves alternative protective measures, the building is still considered fully protected throughout in accordance with 13.3.2.11.3 and 13.3.2.12.7. Sprinklers are permitted to be omitted only from building areas of fire-rated, noncombustible construction, locations believed to have sufficient structural fire resistance to outlast most fires. Use of alternative protective measures should be carefully evaluated to ensure protection equivalent to that provided by automatic sprinklers. Where other automatic fire-extinguishing systems are used as an alternative to sprinklers for specific spaces, it is suggested that such spaces also be separated by fire resistance–rated construction from the remainder of the building that is protected by automatic sprinklers.

The word *supervised,* as used in 13.3.2.11.1 and 13.3.2.12.1, means that a distinct supervisory signal must be provided to a constantly attended location in the event of any malfunction or action that would impair sprinkler performance. Supervision must be provided, for example, for water supply and sprinkler control valves, fire pump power and running conditions, water tank levels and temperatures, pressure in pressure tanks, air pressure in dry-pipe systems, building temperature, and city water pressure. Supervision should include all sprinkler sectional control valves, in addition to main control valves. See also 13.3.1.8.

The intent of 13.3.2.12.8 is to permit the deletion of redundant features of fire protection within an individual smoke compartment that is sprinklered. Paragraph 13.3.2.12.8, for example, could be used to permit higher flame spread for interior wall/ceiling finish or nonrated corridor partitions within the sprinklered smoke compartment. In a limited care facility, the corridor smoke detection could be eliminated within the sprinklered smoke compartment as detailed in 13.7.2.8.5.1(2). However, certain general building protection features must be maintained, unless the building is fully sprinklered. For example, no relaxation in exit features (see Section 19.2 of NFPA *101*) or building construction requirements (see 19.1.6 of NFPA *101*) should be granted, unless the building is fully protected by automatic sprinklers.

Paragraph 13.3.2.12.9 provides sprinkler system criteria, which other sections of NFPA *101* can require by reference, that permit exemptions from requirements where automatic sprinkler protection is provided that utilizes quick-response sprinklers throughout smoke compartments having sleeping rooms. For example, 19.3.7.3(2) of NFPA *101* permits elimination of dampers in ducts penetrating smoke barriers where compartments on both sides of the barriers are sprinkler protected under certain conditions. This paragraph permits the elimination of dampers where compartments not used for patient sleeping are sprinklered, using either standard-response or quick-response sprinklers, or where compartments having patient sleeping rooms use quick-response or residential sprinklers.

The exemption provided by 13.3.2.12.9(6), for use of standard-response sprinklers in lieu of quick-response or residential sprinklers, has been used for purposes not intended by NFPA *101*. When the exemption was written for the 1991 edition of NFPA *101*, it addressed the case in which quick-response or residential sprinklers were installed throughout the smoke compartment, except in locations where the listing of the sprinkler prohibited its use. For example, the earliest quick-response sprinklers were not listed for use under sloped ceilings, in skylights, or in high ambient temperature areas. The exemption has been editorially revised over multiple editions of NFPA *101* so as to become unclear and subject to misapplication. The exemption has been misapplied to situations where the smoke compartment is sprinklered with standard-response sprinklers that were installed prior to the advent of quick-response or residential sprinklers. The exemption is not intended to grandfather such existing systems. Where another provision of Chapter 19 of NFPA *101* references 19.3.5.8 of NFPA *101* (13.3.2.12.9 of this *Code*), such reference is made because the presence of quick-response or residential sprinklers is needed to afford the intended level of life safety.

The provisions of 13.3.2.11.5 and 13.3.2.12.11 exempt sprinklers from small clothes closets where the sprinkler protecting the room is positioned so as to be able to discharge water to the back wall of the closet. The concept is explained in A.13.3.2.11.5 and A.13.3.2.12.11.

13.3.2.12 Existing Health Care Occupancies.

See the commentary following A.13.3.2.11.6.

13.3.2.12.1 Buildings containing nursing homes shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3 and Section 9.7 of NFPA *101*, unless otherwise permitted by 13.3.2.12.7. [***101:***19.3.5.1]

13.3.2.12.2 All high-rise buildings containing health care occupancies shall be protected throughout by an approved, supervised automatic sprinkler system installed in accordance with Section 13.3 within 12 years of the adoption of this *Code*, except as otherwise provided in 13.3.2.12.3 or 13.3.2.12.4. [***101:***19.4.2.1]

13.3.2.12.3 Where a jurisdiction adopts this edition of the *Code* and previously adopted the 2015 edition, the sprinklering required by 13.3.2.12.2 shall be installed within 9 years of the adoption of this *Code*. [***101:***19.4.2.2]

13.3.2.12.4 Where a jurisdiction adopts this edition of the *Code* and previously adopted the 2012 edition, the sprinklering required by 13.3.2.12.2 shall be installed within 6 years of the adoption of this *Code*. [***101:***19.4.2.3]

13.3.2.12.5 Where required by 19.1.6 of NFPA *101*, buildings containing hospitals or limited care facilities shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3 and Section 9.7 of NFPA *101*, unless otherwise permitted by 13.3.2.12.7. [***101:***19.3.5.3]

13.3.2.12.6* The sprinkler system required by 13.3.2.12.1 or 13.3.2.12.5 shall be installed in accordance with NFPA 13. [***101:***19.3.5.4]

A.13.3.2.12.6 It is not the intent to require existing standard sprinklers in existing sprinkler systems to be replaced with listed quick-response or listed residential sprinklers. It is the intent that new sprinkler systems installed in existing buildings comply with the requirements of Chapter 18 of NFPA *101*, including 18.3.5.6. [***101:***A.19.3.5.4]

13.3.2.12.7 In Type I and Type II construction, alternative protection measures shall be permitted to be substituted for sprinkler protection in specified areas where the AHJ has prohibited sprinklers, without causing a building to be classified as nonsprinklered. [***101:***19.3.5.5]

13.3.2.12.8* Where this *Code* permits exceptions for fully sprinklered buildings or smoke compartments, the sprinkler system shall meet all of the following criteria:

(1) It shall be in accordance with Section 13.3.
(2) It shall be installed in accordance with NFPA 13, unless it is an approved existing system.
(3) It shall be electrically connected to the fire alarm system.
(4) It shall be fully supervised.
(5) In Type I and Type II construction, where the AHJ has prohibited sprinklers, approved alternative protection measures shall be permitted to be substituted for sprinkler protection in specified areas without causing a building to be classified as nonsprinklered.

[***101:***19.3.5.7]

A.13.3.2.12.8 It is intended that any valve that controls automatic sprinklers in the building or portions of the building, including sectional and floor control valves, be electrically supervised. Valves that control isolated sprinkler heads, such as in laundry and trash chutes, are not required to be electrically supervised. Appropriate means should be provided to ensure that valves that are not electrically supervised remain open. [***101:***A.19.3.5.7]

Δ **13.3.2.12.9*** Where this *Code* permits exceptions for fully sprinklered buildings or smoke compartments and specifically references this paragraph, the sprinkler system shall meet all of the following criteria:

(1) It shall be installed throughout the building or smoke compartment in accordance with Section 13.3.
(2) It shall be installed in accordance with NFPA 13, unless it is an approved existing system.
(3) It shall be electrically connected to the fire alarm system.
(4) It shall be fully supervised.
(5) It shall be equipped with listed quick-response or listed residential sprinklers throughout all smoke compartments containing patient sleeping rooms.
(6) Standard-response sprinklers shall be permitted to be continued to be used in approved existing sprinkler systems where quick-response and residential sprinklers were not listed for use in such locations at the time of installation.
(7) Standard-response sprinklers shall be permitted for use in hazardous areas protected in accordance with 19.3.2.1 of NFPA *101*.

[***101:***19.3.5.8]

A.13.3.2.12.9 The provisions of 13.3.2.12.9(6) and (7) are not intended to supplant NFPA 13, which requires that residential sprinklers with more than a 10°F (5.6°C) difference in temperature rating not be mixed within a room. Currently there are no additional prohibitions in NFPA 13 on the mixing of sprinklers having different thermal response characteristics. Conversely, there are no design parameters to make practical the mixing of residential and other types of sprinklers. [***101:***A.19.3.5.8]

Residential sprinklers are considered acceptable in patient sleeping rooms of all health care facilities, even through not specifically listed for this purpose in all cases. [***101:***A.19.3.5.8]

13.3.2.12.10 Isolated hazardous areas shall be permitted to be protected in accordance with 13.3.1.4. For new installations in existing health care occupancies, where more than two sprinklers are installed in a single area, waterflow detection shall be provided to sound the building fire alarm or to notify, by a signal, any constantly attended location, such as PBX, security, or emergency room, at which the necessary corrective action shall be taken. [***101:***19.3.5.9]

Δ **13.3.2.12.11*** Sprinklers shall not be required in clothes closets of patient sleeping rooms in hospitals where the area of the closet does not exceed 6 ft^2 (0.55 m^2), provided that the distance from the sprinkler in the patient sleeping room to the back wall of the closet does not exceed the maximum distance permitted by NFPA 13. [***101:***19.3.5.10]

A.13.3.2.12.11 This exception is limited to hospitals, as nursing homes and many limited care facilities might have more combustibles within the closets. The limited amount of clothing found in the small clothes closets in hospital patient rooms is typically far less than the amount of combustibles in casework cabinets that do not require sprinkler protection, such as nurse servers. In many hospitals, especially new hospitals, it is difficult to make a distinction between clothes closets and cabinet work. The exception is far more restrictive than similar exceptions for hotels and apartment buildings. NFPA 13 already permits the omission of sprinklers in wardrobes *[see 8.1.1(7) of NFPA 13]*. It is not the intent of 13.3.2.12.11 to affect the wardrobe provisions of NFPA 13. It is the intent that the sprinkler protection in the room covers the closet as if there were no door on the closet. *(See 8.5.3.2.3 of NFPA 13.)* [***101:***A.19.3.5.10]

13.3.2.12.12* Newly introduced cubicle curtains in sprinklered areas shall be installed in accordance with NFPA 13. [***101:***19.3.5.11]

A.13.3.2.12.12 For the proper operation of sprinkler systems, cubicle curtains and sprinkler locations need to be coordinated. Improperly designed systems might obstruct the sprinkler spray from reaching the fire or might shield the heat from the sprinkler. Many options are available to the designer including, but not limited to, hanging the cubicle curtains 18 in. (455 mm) below the sprinkler deflector; using ½ in. (13 mm) diagonal mesh or a 70 percent open weave top panel that extends 18 in. (455 mm) below the sprinkler deflector; or designing the system to have a horizontal and minimum vertical distance that meets the requirements of NFPA 13. The test data that forms the basis of the NFPA 13 requirements is from fire tests with sprinkler discharge that penetrated a single privacy curtain. [***101:***A.19.3.5.11]

13.3.2.13 New Detention and Correctional Facilities.

13.3.2.13.1 All buildings classified as Use Condition II, Use Condition III, Use Condition IV, or Use Condition V shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.13.2. [***101:***22.3.5.2]

Δ **13.3.2.13.2** The automatic sprinkler system required by 13.3.2.13.1 shall meet all of the following criteria:

(1) It shall be in accordance with Section 13.3.
(2) It shall be installed in accordance with NFPA 13.
(3) It shall be electrically connected to the fire alarm system.
(4) It shall be fully supervised.

[***101:***22.3.5.3]

Paragraph 13.3.2.13.1 requires that new detention and correctional occupancies — other than Use Condition I — be protected throughout by approved, supervised automatic sprinkler systems. However, in establishing the sprinkler requirement, the Technical Committee on Detention and Correctional Occupancies realized that rehabilitation, modernizations, and renovations might take place in nonsprinklered existing buildings. Thus, 22.4.4 of NFPA *101* provides additional criteria needed for the proper protection of nonsprinklered existing building renovations.

Where automatic sprinklers are installed to comply with the *Code*, the system must be a complete, approved automatic sprinkler system installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*. The use of manually operated sprinklers is not recognized by the *Code*. Informal surveys of detention and correctional occupancy staff indicate no significant problems with the installation, maintenance, and use of automatic sprinkler systems in detention and correctional

Exhibit 13.4

Typical institutional sprinkler.

facilities. The system must also be supervised in accordance with the requirements of 13.3.1.8 to comply with the *Code*.

Exhibit 13.4 illustrates a typical institutional sprinkler. The sprinkler body and frame are designed to prevent residents from hanging items or themselves from the sprinkler.

13.3.2.14 Existing Detention and Correctional Facilities.

13.3.2.14.1* Where required by Table 23.1.6.1 of NFPA *101*, facilities shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.14.2. [***101:***23.3.5.2]

A.13.3.2.14.1 Where the openings in ceilings or partitions are ¼ in. (6.3 mm) or larger in the smallest dimension, where the thickness or depth of the material does not exceed the smallest dimension of the openings, and where such openings constitute not less than 70 percent of the area of the ceiling or partition material, the disruption of sprinkler spray patterns is permitted to be disregarded. [***101:***A.23.3.5.2]

Δ **13.3.2.14.2** Where this *Code* permits exceptions for fully sprinklered detention and correctional occupancies or sprinklered smoke compartments, the sprinkler system shall meet all of the following criteria:

(1) It shall be in accordance with Section 13.3.
(2) It shall be installed in accordance with NFPA 13.
(3) It shall be electrically connected to the fire alarm system.
(4) It shall be fully supervised.
[***101:***23.3.5.3]

Existing detention and correctional occupancies must be sprinklered where required based on the building's construction type in accordance with 23.1.6 of NFPA *101*, as indicated in 13.3.2.14.1. Also, where this *Code* permits a modification to a requirement based on the installation of a complete automatic sprinkler system, the sprinkler system must meet the requirements of 13.3.2.14.2, which include electrical supervision.

13.3.2.15 New Hotels and Dormitories.

13.3.2.15.1 All buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.15.2. [***101:***28.3.5.1]

13.3.2.15.2 Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be in accordance with Section 13.3, as modified by 13.3.2.15.3. In hotel or dormitory occupancies up to and including four stories in height, that are located in buildings not exceeding 60 ft (18.3 m) in height above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***28.3.5.3]

N **13.3.2.15.2.1** Where located in a building of Type III, Type IV, or Type V construction designed in accordance with 4.6.3(5) of NFPA *101*, and where the roof assembly is located more than 55 ft (17 m) above the lowest level of required fire department vehicle access, attics shall comply with 13.3.2.15.2.1.1, 13.3.2.15.1.2, and one of the following:

(1) Attics shall be provided with sprinkler protection.
(2) Attics shall be constructed with noncombustible materials.
(3) Attics shall be constructed with fire-retardant-treated wood.
(4) Attics shall be filled with noncombustible insulation.
[***101:***28.3.5.3.1]

N **13.3.2.15.2.1.1** The height of the roof assembly shall be determined by measuring the distance from the lowest level of required fire department vehicle access adjacent to the building to the eave of the highest pitched roof, the intersection of the highest roof to the exterior wall, or the top of the highest parapet, whichever yields the greatest distance. [***101:***28.3.5.3.1.1]

N **13.3.2.15.2.1.2** Required fire department vehicle access roads used in 28.3.5.3.1.1 shall include only those roads that are necessary for required fire department vehicle access in accordance with Section 18.2. [***101:***28.3.5.3.1.2]

13.3.2.15.3 The provisions for draft stops and closely spaced sprinklers in NFPA 13 shall not be required for openings complying with 8.6.9.1 of NFPA *101* where the opening is within the guest room or guest suite. [***101:***28.3.5.4]

13.3.2.15.4 Listed quick-response or listed residential sprinklers shall be used throughout guest rooms and guest room suites. [***101:***28.3.5.6]

Δ **13.3.2.15.5** Open parking structures that comply with NFPA 88A and are contiguous with hotels or dormitories shall be exempt from the sprinkler requirements of 13.3.2.15.1. [***101:***28.3.5.7]

New hotels and dormitories must be protected throughout by an approved, supervised automatic sprinkler system. The disproportionate percentage of deaths associated with residential occupancies and the conditions precipitating fatalities in hotel and dormitory settings (the need to wake sleeping occupants and to escape in unfamiliar surroundings) prompted the *Code* to require new hotels and dormitories to be provided with automatic sprinkler systems.

One objective of the *Code* is to protect occupants who are not intimate with the initial fire development from loss of life and to improve the survivability of those who are intimate with the fire development, as stated in 4.1.3.1.2.1. Based on that objective, new hotels and dormitories are required to use quick-response or residential sprinklers throughout guest rooms and guest suites per 13.3.2.15.4. The technology associated with quick-response and residential sprinklers helps to maintain tenability within the room of fire origin.

Per 13.3.2.16.1, an automatic sprinkler system is required in existing high-rise hotels and dormitories, unless every guest room or guest suite has exterior exit access. The presence of exterior exit access eliminates the need to traverse a corridor where conditions might not remain tenable.

The provisions of 13.3.2.15.2.1 through 13.3.2.15.2.1.2 are new to the 2018 edition of NFPA *1*. They are intended to provide attic protection to pedestal-type buildings (e.g., a four-story hotel situated atop a one-story, above-grade parking structure) that are protected by residential sprinkler systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, which permits the omission of sprinklers from attics under most conditions. Where the roof is located more than 55 ft (17 m) above the fire department access roadway as determined by 13.3.2.15.2.1.1 and 13.3.2.15.2.1.2, access to the roof for fire suppression operations via ladders can be hindered. The protection mandated by the four options in 13.3.2.15.2.1 (1) through (4) will help to mitigate the fire-fighting challenge posed by such high roofs.

13.3.2.16 Existing Hotels and Dormitories.

See the commentary following 13.3.2.15.5.

13.3.2.16.1 All high-rise buildings, other than those where each guest room or guest suite has exterior exit access in accordance with 7.5.3 of NFPA *101*, shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.16.2. [***101:***29.3.5.1]

13.3.2.16.2* Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be in accordance with Section 13.3, as modified by 13.3.2.16.3 and 13.3.2.16.4. In buildings four or fewer stories in height and not exceeding 60 ft (18.3 m) in height above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***29.3.5.3]

A.13.3.2.16.2 Although not required by NFPA *101*, the use of residential sprinklers or quick-response sprinklers is encouraged for new installations of sprinkler systems within dwelling units, apartments, and guest rooms. Caution should be exercised, as the system needs to be designed for the sprinkler being used. [***101:***A.29.3.5.3]

13.3.2.16.3 The provisions for draft stops and closely spaced sprinklers in NFPA 13 shall not be required for openings complying with 8.6.9.1 of NFPA *101* where the opening is within the guest room or guest suite. [***101:***29.3.5.4]

13.3.2.16.4 In guest rooms and in guest room suites, sprinkler installations shall not be required in closets not exceeding 24 ft² (2.2 m²) and in bathrooms not exceeding 55 ft² (5.1 m²). [***101:***29.3.5.5]

13.3.2.17 New Apartment Buildings.

13.3.2.17.1 All buildings shall be protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 13.3.2.17.2. [***101:***30.3.5.1]

Δ **13.3.2.17.2** Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be in accordance with Section 13.3, as modified by 13.3.2.17.3 and 13.3.2.17.5. In apartment buildings up to and including four stories in height, that are located in buildings not exceeding 60 ft (18.3 m) in height above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***30.3.5.2]

N **13.3.2.17.2.1** Where located in a building of Type III, Type IV, or Type V construction designed in accordance with 4.6.3(5) of NFPA *101*, and where the roof assembly is located more than 55 ft (17 m) above the lowest level of required fire department vehicle access, attics shall comply with 13.3.2.17.2.1.1, 13.3.2.17.2.1.2, and one of the following:

(1) Attics shall be provided with sprinkler protection.
(2) Attics shall be constructed with noncombustible materials.
(3) Attics shall be constructed with fire-retardant-treated wood.
(4) Attics shall be filled with noncombustible insulation.

[***101:***30.3.5.2.1]

N **13.3.2.17.2.1.1** The height of the roof assembly shall be determined by measuring the distance from the lowest level of required fire department vehicle access adjacent to the building to the eave of the highest pitched roof, the intersection of the highest roof to the exterior wall, or the top of the highest parapet, whichever yields the greatest distance. [***101:***30.3.5.2.1.1]

N **13.3.2.17.2.1.2** Required fire department vehicle access roads used in 13.3.2.17.2.1.1 shall include only those roads that are necessary for required fire department vehicle access in accordance with Section 18.2. [***101:***30.3.5.2.1.2]

13.3.2.17.3 In buildings sprinklered in accordance with NFPA 13, closets less than 12 ft² (1.1 m²) in area in individual dwelling units shall not be required to be sprinklered. Closets that contain equipment such as washers, dryers, furnaces, or water heaters shall be sprinklered, regardless of size. [***101:***30.3.5.3]

Paragraph 13.3.2.17.3 exempts small closets from being sprinklered because of the limited fuel load characteristic of apartment unit closets. The closets exempted are limited to those within a living unit; closets in common building areas are not exempted. Also, any closet that contains HVAC equipment or washers and dryers is not permitted to take advantage of the sprinkler exemption due to the inherent ignition sources and combustible fuel load.

Δ **13.3.2.17.4** In buildings sprinklered in accordance with NFPA 13 bathrooms not greater than 55 ft² (5.1 m²) in individual dwelling units shall not be required to be sprinklered. [***101:***30.3.5.4]

13.3.2.17.5 The draft stop and closely spaced sprinkler requirements of NFPA 13 shall not be required for convenience openings complying with 8.6.9.1 of NFPA *101* where the convenience opening is within the dwelling unit. [***101:***30.3.5.5]

13.3.2.17.6 Listed quick-response or listed residential sprinklers shall be used throughout all dwelling units. [***101:***30.3.5.6]

The *Code* permits NFPA 13R to be used, within its scope, in place of NFPA 13. However, the provision of 13.3.2.17.6, which requires the use of listed quick-response sprinklers or listed residential sprinklers within dwelling units of new apartment buildings, supersedes any sprinkler options permitted by NFPA 13R or NFPA 13.

Δ **13.3.2.17.7** Open parking structures complying with NFPA 88A that are contiguous with apartment buildings shall be exempt from the sprinkler requirements of 13.3.2.17.1. [***101:***30.3.5.7]

13.3.2.17.8 Buildings with unprotected openings in accordance with 8.6.6 of NFPA *101* shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.17.1. [***101:***30.3.5.8]

13.3.2.18 Existing Apartment Buildings.

13.3.2.18.1* Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be installed in accordance with Section 13.3, as modified by 13.3.2.18.2 and 13.3.2.18.4. In buildings four or fewer stories in height and not exceeding 60 ft (18.3 m) in height above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***31.3.5.2]

A.13.3.2.18.1 Although not required by NFPA *101*, the use of residential sprinklers or quick-response sprinklers is encouraged for new installations of sprinkler systems within dwelling units, apartments, and guest rooms. Caution should be exercised, because the system needs to be designed for the sprinkler being used. [***101:***A.31.3.5.2]

13.3.2.18.2 In individual dwelling units, sprinkler installation shall not be required in closets not exceeding 24 ft^2 (2.2 m^2) and in bathrooms not exceeding 55 ft^2 (5.1 m^2). Closets that contain equipment such as washers, dryers, furnaces, or water heaters shall be sprinklered, regardless of size. [***101:***31.3.5.3]

Δ **13.3.2.18.3*** In buildings sprinklered in accordance with NFPA 13 bathrooms not greater than 55 ft^2 (5.1 m^2) in individual dwelling units shall not be required to be sprinklered. [***101:***31.3.5.4]

Δ **A.13.3.2.18.3** The provision of 13.3.2.18.3 differs from NFPA 13 because fire data shows that in apartment fires where sprinklers were present, bathrooms were the area of origin in 1 percent of the total fires, and resulted in no civilian deaths, civilian injuries, or property loss. [***101:***A.31.3.5.4]

13.3.2.18.4 The draft stop and closely spaced sprinkler requirements of NFPA 13 shall not be required for convenience openings complying with 8.6.9.1 of NFPA *101* where the convenience opening is within the dwelling unit. [***101:***31.3.5.5]

13.3.2.18.5 Buildings using Option 3 in accordance with NFPA *101* shall be provided with automatic sprinkler protection installed in accordance with 13.3.2.18.5.1 through 13.3.2.18.5.4. [***101:***31.3.5.9]

13.3.2.18.5.1 Automatic sprinklers shall be installed in the corridor, along the corridor ceiling, utilizing the maximum spacing requirements of the standards referenced in 13.3.1.2. [***101:***31.3.5.9.1]

13.3.2.18.5.2 An automatic sprinkler shall be installed within every dwelling unit that has a door opening to the corridor, with such sprinkler positioned over the center of the door, unless the door to the dwelling unit has not less than a 20-minute fire protection rating and is self-closing. [***101:***31.3.5.9.2]

13.3.2.18.5.3 The workmanship and materials of the sprinkler installation specified in 13.3.2.18.5 shall meet the requirements of 13.3.1.2. [***101:***31.3.5.9.3]

13.3.2.18.5.4 Where Option 3 is being used to permit the use of 1¾ in. (44 mm) thick, solid-bonded wood-core doors in accordance with 31.2.2.1.3 of NFPA *101*, sprinklers shall be provided within the exit enclosures in accordance with NFPA 13. [***101:***31.3.5.9.4]

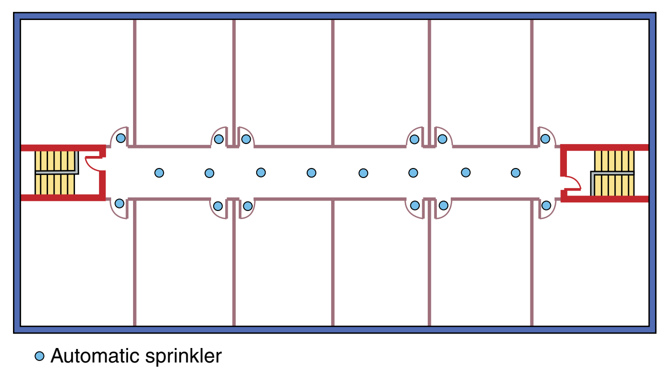
13.3.2.18.6 Buildings using Option 4 in accordance with NFPA *101* shall be protected throughout by an approved automatic sprinkler system in accordance with 13.3.2.18.1 and meeting the requirements of Section 13.3 for supervision for buildings seven or more stories in height. [***101:***31.3.5.10]

13.3.2.18.7* Where sprinklers are being used as an option to any requirement in this *Code*, the sprinklers shall be installed throughout the space in accordance with the requirements of that option. [***101:***31.3.5.11]

A.13.3.2.18.7 For example, if an Option 3 sprinkler system were being used to justify use of Class C wall finish in an exit enclosure, the sprinkler system would need to be extended into the exit enclosure, even if the rest of the requirements for Option 3 did not require the sprinklers in the exit enclosure. [***101:***A.31.3.5.11]

For existing apartment buildings, Option 3 and Option 4, as defined by 31.1.1.1 of NFPA *101*, require the installation of automatic sprinklers. Exhibit 13.5 illustrates the sprinkler location

Exhibit 13.5



Option 3 sprinkler protection for existing apartment buildings.

requirements for an Option 3 existing apartment building. A 20-minute fire protection–rated, self-closing corridor door is permitted by 13.3.2.18.5.2 to serve in lieu of the sprinklers positioned inside each apartment unit in the vicinity of the corridor door; however, the corridor sprinklers still must be provided.

13.3.2.19 Lodging or Rooming Houses.

13.3.2.19.1 All new lodging or rooming houses shall be protected throughout by an approved automatic sprinkler system in accordance with 13.3.2.19.2. [***101:***26.3.6.1]

If a new lodging or rooming house is part of a multiple occupancy and the occupancies are mixed, the entire mixed occupancy is required to be sprinklered. To waive this requirement, the occupancies would have to be arranged so that the lodging or rooming house is treated as a separate occupancy in accordance with 6.1.14.4. This arrangement would require the exit access for each occupancy to be separate. Doors that open directly to the outside from each of the occupancies usually achieve such independent exit access.

13.3.2.19.2 Where an automatic sprinkler system is required or is used as an alternative method of protection, either for total or partial building coverage, the system shall be in accordance with Section 13.3 and 13.3.2.19.2.1 through 13.3.2.19.2.6. [***101:***26.3.6.2]

13.3.2.19.2.1 Activation of the automatic sprinkler system shall actuate the fire alarm system in accordance with Section 13.7. [***101:***26.3.6.2.1]

13.3.2.19.2.2 In buildings four or fewer stories in height and not exceeding 60 ft (18.3 m) in height above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***26.3.6.2.2]

13.3.2.19.2.3* Systems in accordance with NFPA 13D shall be permitted where all of the following requirements are met:

(1) The lodging or rooming house shall not be part of a mixed occupancy.
(2) Entrance foyers shall be sprinklered.
(3) Lodging or rooming houses with sleeping accommodations for more than eight occupants shall be treated as two-family dwellings with regard to the water supply.

[***101:***26.3.6.2.3]

A.13.3.2.19.2.3 The decision to permit the use of the criteria from NFPA 13D in these occupancies is based on the following:

(1) The desire to obtain a level of fire suppression and control that is approximately equivalent to that delivered by residential facilities protected by such systems (see A.1.1 in NFPA 13D)
(2) The fact that potential fire exposure and challenge to the suppression system in a small lodging and rooming occupancy is of the same nature and no more severe than that found in residences

[***101:***A.26.3.6.2.3]

Because there is such a wide variety of buildings that might fall into the classification of lodging or rooming houses, it is necessary to provide references to all three of the standards for the installation of automatic sprinkler systems.

The use of NFPA 13R is appropriate for many lodging or rooming houses.

In certain lodging or rooming house occupancies, the use of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes,* is also appropriate. Some lodging or rooming houses are similar in physical configuration to a one- or two-family dwelling, whereas others are not. For example, an NFPA 13D system would be appropriate for a single-family dwelling that is used as a bed-and-breakfast (lodging or rooming house classification for purposes of applying this *Code*) but not for a fire station with a bunk room. The provision of 13.3.2.19.2.3(3) describes the provision of 6.5.2 of NFPA 13D, which specifies in multipurpose piping systems, where common water supply connections serve more than one dwelling unit, 5 gpm (19 L/min) must be added to the sprinkler system demand to determine the size of common piping and the size of the total water supply requirements where no provision is made to prevent flow into the domestic water system upon operation of a sprinkler.

13.3.2.19.2.4 In buildings sprinklered in accordance with NFPA 13, closets less than 12 ft^2 (1.1 m^2) in area in individual dwelling units shall not be required to be sprinklered. [***101:***26.3.6.2.4]

13.3.2.19.2.5 In buildings sprinklered in accordance with NFPA 13, closets that contain equipment such as washers, dryers, furnaces, or water heaters shall be sprinklered, regardless of size. [***101:***26.3.6.2.5]

13.3.2.19.2.6 In existing lodging or rooming houses, sprinkler installations shall not be required in closets not exceeding 24 ft^2 (2.2 m^2) and in bathrooms not exceeding 55 ft^2 (5.1 m^2). [***101:***26.3.6.2.6]

13.3.2.20 One- and Two-Family Dwellings.

13.3.2.20.1 All new one- and two-family dwellings shall be protected throughout by an approved automatic sprinkler system in accordance with 13.3.2.20.2. [***101:***24.3.5.1]

Δ **13.3.2.20.2** Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be in accordance with Section 13.3. [***101:***24.3.5.2]

In response to the unacceptable number of fire deaths occurring in one- and two-family dwellings on an annual basis (an average of 2570 civilian fire deaths per year in the United States for the period 2007–2011), the *Code*, starting with the 2006 edition, requires all new one- and two-family dwellings to be protected by automatic sprinkler systems. While the requirement for sprinkler systems in one- and two-family dwellings was new to the 2006 edition of the *Code*, the concept of residential sprinkler protection was not. As part of its decision to mandate sprinklers in new one- and two-family dwellings, the NFPA Technical Committee on Residential Occupancies evaluated economic and sprinkler success data from communities such as Scottsdale, Arizona, and Prince Georges County, Maryland, which have required sprinklers in new homes since 1986 and 1992, respectively. Data from the Scottsdale report have been updated to January 1, 2001, expanding its scope from 10 years to 15 years. Some of the highlights of the updated report (*Automatic Sprinklers: A 10 Year Study: A Detailed History of the Effects of the Automatic Sprinkler Code in Scottsdale, Arizona*) are as follows:

1. A total of 41,408 homes (more than 50 percent of the homes in Scottsdale) were protected by automatic sprinklers.
2. Since the sprinkler ordinance was implemented, 598 home fires occurred — 49 of which were in sprinklered homes.
   a. No fatalities occurred in the sprinklered homes.
   b. Thirteen people died in homes with no sprinklers.
3. There was less water damage in homes protected by sprinklers.
   a. Ninety-two percent of the fires in sprinklered homes were controlled by one or two sprinklers.
   b. Sprinkler systems discharged an average of 341 gal (1291 L) of water per fire.
   c. In nonsprinklered homes, fire fighter hose streams discharged an average of 2935 gal (11,110 L) of water per fire.
4. Fire damage was less in sprinklered homes.
   a. The average loss per fire in sprinklered homes was $2166 (1986–2001, 49 fires).
   b. The average loss per fire in nonsprinklered homes was $45,019 (1998–2001, 86 fires).
5. Technological advances have made residential sprinklers less costly and easier to install.
   a. On a national average, sprinkler systems add between 1 percent and 1.5 percent to the total cost of the construction of a home.
   b. In Scottsdale, the average installation cost was $0.80 per square foot ($8.61 per square meter) of floor area.

13.3.2.21 New Residential Board and Care Occupancies.

13.3.2.21.1 Large Facilities.

13.3.2.21.1.1 General. All buildings shall be protected throughout by an approved automatic sprinkler system installed in accordance with NFPA 13 and provided with quick-response or residential sprinklers throughout. [***101:***32.3.3.5.1]

13.3.2.21.1.2 Supervision. Automatic sprinkler systems shall be provided with electrical supervision in accordance with 13.3.1.8. [***101:***32.3.3.5.5]

13.3.2.21.2 Small Facilities.

13.3.2.21.2.1* All facilities, other than those meeting the requirement of 13.3.2.21.2.2, shall be protected throughout by an approved automatic sprinkler system, installed in accordance with 13.3.2.21.2.3, using quick-response or residential sprinklers. [***101:***32.2.3.5.1]

A.13.3.2.21.2.1 Where any provision requires the use of an automatic sprinkler system in accordance with 13.3.2.21.2, the provision of 13.3.2.21.2.2 is not permitted to be used. [***101:***A.32.2.3.5.1]

13.3.2.21.2.2* In conversions, sprinklers shall not be required in small board and care homes serving eight or fewer residents when all occupants have the ability as a group to move reliably to a point of safety within 3 minutes. [***101:***32.2.3.5.2]

A.13.3.2.21.2.2 Where a facility utilizing the provision of 13.3.2.21.2.2 contains residents who can no longer comply with the 3-minute evacuation response, 33.1.8 of NFPA *101* requires the facility to comply with the requirements for new construction, including automatic sprinkler protection. (See also A.33.1.8 of NFPA *101*.) [***101:***A.32.2.3.5.2]

Δ **13.3.2.21.2.3** Where an automatic sprinkler system is installed, for either total or partial building coverage, all of the following requirements shall be met:

(1) The system shall be in accordance with NFPA 13 and shall initiate the fire alarm system in accordance with 13.7.2.19.
(2) The adequacy of the water supply shall be documented to the AHJ.

[***101:***32.2.3.5.3]

13.3.2.21.2.3.1 In buildings four or fewer stories in height and not exceeding 60 ft (18.3 m) in height above grade plane, systems in accordance with NFPA 13R shall be permitted. All habitable areas, closets, roofed porches, roofed decks, and roofed balconies shall be sprinklered. [***101:***32.2.3.5.3.1]

Δ **13.3.2.21.2.3.2*** An automatic sprinkler system with a 30-minute water supply, and complying with all of the following requirements and with NFPA 13D, shall be permitted:

(1) All habitable areas, closets, roofed porches, roofed decks, and roofed balconies shall be sprinklered.
(2) Facilities with more than eight residents shall be treated as two-family dwellings with regard to water supply.

[***101:***32.2.3.5.3.2]

A.13.3.2.21.2.3.2 The decision to permit the use of the criteria from NFPA 13D in these occupancies is based on the following:

(1) The desire to obtain a level of fire suppression and control approximately equivalent to that delivered by residential facilities protected by such systems *(See A.1.1 in NFPA 13D.)*
(2) The fact that potential fire exposure and challenge to the suppression system in a small board and care facility are of the same nature and are no more severe than those found in residences

[***101:***A.32.2.3.5.3.2]

Chapter 13 permits the use of NFPA 13D and NFPA 13R outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. The requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy. [***101:***A.32.2.3.5.3.2]

NFPA 13D contains additional requirements for a piping system serving both sprinkler and domestic needs. [***101:***A.32.2.3.5.3.2]

13.3.2.21.2.4 Automatic sprinkler systems installed in accordance with NFPA 13 and NFPA 13R shall be provided with electrical supervision in accordance with 13.3.1.8. [***101:***32.2.3.5.4]

Δ **13.3.2.21.2.5** Automatic sprinkler systems installed in accordance with NFPA 13D shall be provided with valve supervision by one of the following methods:

(1) Single listed control valve that shuts off both domestic and sprinkler systems and separate shutoff for the domestic system only
(2) Electrical supervision in accordance with 13.3.1.8
(3) Valve closure that causes the sounding of an audible signal in the facility

[***101:***32.2.3.5.5]

Δ **13.3.2.21.2.6** Sprinkler piping serving not more than six sprinklers for any isolated hazardous area shall be permitted to be installed in accordance with 13.3.1.4 and shall meet all of the following requirements:

(1) In new installations, where more than two sprinklers are installed in a single area, waterflow detection shall be provided to initiate the fire alarm system required by 13.7.2.19.
(2) The duration of water supplies shall be as required by 13.3.2.21.2.3.2.

[***101:***32.2.3.5.6]

13.3.2.21.2.7 Attics shall be protected in accordance with 13.3.2.21.2.7.1 or 13.3.2.21.2.7.2. [***101:***32.2.3.5.7]

13.3.2.21.2.7.1 Where an automatic sprinkler system is required by 13.3.2.21.2, attics used for living purposes, storage, or fuel fired equipment shall be protected with automatic sprinklers that are part of the required, approved automatic sprinkler system in accordance with 13.3.1.2. [***101:***32.2.3.5.7.1]

Δ **13.3.2.21.2.7.2** Where an automatic sprinkler system is required by 13.3.2.21.2, attics not used for living purposes, storage, or fuel-fired equipment shall meet one of the following criteria:

(1) Attics shall be protected throughout by a heat detection system arranged to activate the building fire alarm system in accordance with Section 13.7.
(2) Attics shall be protected with automatic sprinklers that are part of the required, approved automatic sprinkler system in accordance with 13.3.1.2.
(3) Attics shall be of noncombustible or limited-combustible construction.
(4) Attics shall be constructed of fire-retardant-treated wood in accordance with NFPA 703.

[***101:***32.2.3.5.7.2]

13.3.2.22 Existing Residential Board and Care Facilities.

13.3.2.22.1 Large Facilities.

13.3.2.22.1.1* General. Where an automatic sprinkler system is installed, for either total or partial building coverage, the system shall be installed in accordance with Section 13.3, as modified by 13.3.2.22.1.1.1 through 13.3.2.22.1.1.3. [***101:***33.3.3.5.1]

A.13.3.2.22.1.1 It is intended that this requirement apply to existing small facilities that are converted to large facilities. [***101:***A.33.3.3.5.1]

Chapter 13 permits the use of NFPA 13D and NFPA 13R outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. In some circumstances, such as those for impractical evacuation capabilities, the requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy. [***101:***A.33.3.3.5.1]

13.3.2.22.1.1.1 In buildings four or fewer stories above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***33.3.3.5.1.1]

13.3.2.22.1.1.2 In facilities having prompt or slow evacuation capability, automatic sprinklers shall not be required in closets not exceeding 24 ft^2 (2.2 m^2) and in bathrooms not exceeding 55 ft^2 (5.1 m^2), provided that such spaces are finished with noncombustible or limited-combustible materials. [***101:***33.3.3.5.1.2]

13.3.2.22.1.1.3 Initiation of the fire alarm system shall not be required for existing installations in accordance with 13.3.2.22.1.6. [***101:***33.3.3.5.1.3]

13.3.2.22.1.2 Impractical Evacuation Capability. All facilities having impractical evacuation capability shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13. [***101:***33.3.3.5.2]

13.3.2.22.1.3 High-Rise Buildings. All high-rise buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.22.1. Such systems shall initiate the fire alarm system in accordance with 13.7.1.4. [***101:***33.3.3.5.3]

13.3.2.22.1.4 Attics shall be protected in accordance with 13.3.2.22.1.4.1 or 13.3.2.22.1.4.2. [***101:***33.3.3.5.4]

13.3.2.22.1.4.1 Where an automatic sprinkler system is installed, attics used for living purposes, storage, or fuel-fired equipment shall be protected with automatic sprinklers that are part of the required, approved automatic sprinkler system in accordance with 13.3.1.2. [***101:***33.3.3.5.4.1]

Δ **13.3.2.22.1.4.2** Where an automatic sprinkler system is installed, attics not used for living purposes, storage, or fuel-fired equipment shall meet one of the following criteria:

(1) Attics shall be protected throughout by a heat detection system arranged to activate the building fire alarm system in accordance with Section 13.7.

(2) Attics shall be protected with automatic sprinklers that are part of the required, approved automatic sprinkler system in accordance with 13.3.1.2.
(3) Attics shall be of noncombustible or limited-combustible construction.
(4) Attics shall be constructed of fire-retardant-treated wood in accordance with NFPA 703.

[***101:***33.3.3.5.4.2]

13.3.2.22.1.5 Supervision. Automatic sprinkler systems shall be supervised in accordance with Section 13.3; waterflow alarms shall not be required to be transmitted off-site. [***101:***33.3.3.5.5]

13.3.2.22.1.6 Domestic Water Supply Option. Sprinkler piping serving not more than six sprinklers for any isolated hazardous area in accordance with 13.3.1.4 shall be permitted; in new installations where more than two sprinklers are installed in a single area, waterflow detection shall be provided to initiate the fire alarm system required by 13.7.2.22. [***101:***33.3.3.5.6]

13.3.2.22.2 Small Facilities.

Δ **13.3.2.22.2.1** Where an automatic sprinkler system is installed, for either total or partial building coverage, all of the following requirements shall be met:

(1) The system shall be in accordance with Section 13.3 and shall initiate the fire alarm system in accordance with 13.7.2.21, as modified by 13.3.2.22.2.1.1 through 13.3.2.22.2.1.6.
(2) The adequacy of the water supply shall be documented to the AHJ.

[***101:***33.2.3.5.3]

Δ **13.3.2.22.2.1.1*** In prompt evacuation capability facilities, all of the following shall apply:

(1) An automatic sprinkler system in accordance with NFPA 13D shall be permitted.
(2) Automatic sprinklers shall not be required in closets not exceeding 24 ft² (2.2 m²) and in bathrooms not exceeding 55 ft² (5.1 m²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier.

[***101:***33.2.3.5.3.1]

A.13.3.2.22.2.1.1 The decision to permit the use of the criteria from NFPA 13D in these occupancies is based on the following:

(1) The desire to obtain a level of fire suppression and control approximately equivalent to that delivered by residential facilities protected by such systems. *(See A.1.1 in NFPA 13D.)*
(2) The fact that potential fire exposure and challenge to the suppression system in a small board and care facility are of the same nature and are no more severe than those found in residences.

[***101:***A.32.2.3.5.3.1]

Chapter 13 permits the use of NFPA 13D and NFPA 13R outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. In some circumstances, such as those for impractical evacuation capabilities, the requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

[***101:***A.33.2.3.5.3.1]

Δ **13.3.2.22.2.1.2** In slow and impractical evacuation capability facilities, all of the following shall apply:

(1) An automatic sprinkler system in accordance with NFPA 13D, with a 30-minute water supply, shall be permitted.
(2) All habitable areas and closets shall be sprinklered.
(3) Automatic sprinklers shall not be required in bathrooms not exceeding 55 ft² (5.1 m²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier.

[***101:***33.2.3.5.3.2]

13.3.2.22.2.1.3 In prompt and slow evacuation capability facilities, where an automatic sprinkler system is in accordance with NFPA 13, sprinklers shall not be required in closets not exceeding 24 ft² (2.2 m²) and in bathrooms not exceeding 55 ft² (5.1 m²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier. [***101:***33.2.3.5.3.3]

13.3.2.22.2.1.4 In prompt and slow evacuation capability facilities in buildings four or fewer stories above grade plane, systems in accordance with NFPA 13R shall be permitted. [***101:***33.2.3.5.3.4]

13.3.2.22.2.1.5 In impractical evacuation capability facilities in buildings four or fewer stories above grade plane, systems in accordance with NFPA 13R shall be permitted. All habitable areas and closets shall be sprinklered. Automatic sprinklers shall not be required in bathrooms not exceeding 55 ft² (5.1 m²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier. [***101:***33.2.3.5.3.5]

13.3.2.22.2.1.6 Initiation of the fire alarm system shall not be required for existing installations in accordance with 13.3.2.22.3. [***101:***33.2.3.5.3.6]

13.3.2.22.2.2 All impractical evacuation capability facilities shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.22.2.1. [***101:***33.2.3.5.3.7]

Δ **13.3.2.22.3** Sprinkler piping serving not more than six sprinklers for any isolated hazardous area shall be permitted to be installed in accordance with 13.3.1.4 and shall meet all of the following requirements:

(1) In new installations, where more than two sprinklers are installed in a single area, waterflow detection shall be provided to initiate the fire alarm system required by 13.7.2.21.
(2) The duration of water supplies shall be as required for the sprinkler systems addressed in 13.3.2.22.2.1.

[***101:***33.2.3.5.6]

13.3.2.22.4 Attics shall be protected in accordance with 13.3.2.22.4.1 or 13.3.2.22.4.2. [***101:***33.2.3.5.7]

13.3.2.22.4.1 Where an automatic sprinkler system is installed, attics used for living purposes, storage, or fuel-fired equipment shall be protected with automatic sprinklers that are part of the required, approved automatic sprinkler system in accordance with 13.3.1.2. [***101:***33.2.3.5.7.1]

Δ **13.3.2.22.4.2** Where an automatic sprinkler system is installed, attics not used for living purposes, storage, or fuel-fired equipment shall meet one of the following criteria:

(1) Attics shall be protected throughout by a heat detection system arranged to activate the building fire alarm system in accordance with Section 13.7.
(2) Attics shall be protected with automatic sprinklers that are part of the required, approved automatic sprinkler system in accordance with 13.3.1.2.
(3) Attics shall be of noncombustible or limited-combustible construction.
(4) Attics shall be constructed of fire-retardant-treated wood in accordance with NFPA 703.
(5) Attics shall be protected by heat alarms arranged to provide occupant notification in accordance with 33.2.3.4.2.

[***101:***33.2.3.5.7.2]

13.3.2.23 New Mercantile Occupancies.

Δ **13.3.2.23.1** Mercantile occupancies shall be protected by an approved automatic sprinkler system in accordance with NFPA 13 in any of the following specified locations:

(1) Throughout all mercantile occupancies three or more stories in height
(2) Throughout all mercantile occupancies exceeding 12,000 ft^2 (1115 m^2) in gross area
(3) Throughout stories below the level of exit discharge where such stories have an area exceeding 2500 ft^2 (232 m^2) and are used for the sale, storage, or handling of combustible goods and merchandise
(4) Throughout multiple occupancies protected as mixed occupancies in accordance with 6.1.14 where the conditions of 13.3.2.23.1(1), (2), or (3) apply to the mercantile occupancy

[***101:***36.3.5.1]

13.3.2.23.2 Automatic sprinkler systems in Class A mercantile occupancies shall be supervised in accordance with 13.3.1.8. [***101:***36.3.5.2]

All basement areas larger than 2500 ft^2 (232 m^2) and used for the sales, storage, or handling of combustible merchandise must be sprinklered per 13.3.2.23.1 and 13.3.2.24.1 to avoid the potential threat to occupants of the floors above. Studies have shown that there is a higher rate of fire incidence in basements than in other areas of stores. Because smoke and heat rise, a fire in a basement can quickly render exits and exit discharges located on the street floor unusable. This danger is especially acute in mercantile occupancies, where allowances for various vertical openings in accordance with the provisions of 36/37.3.1 of NFPA *101* are more lenient than those for many other occupancies.

13.3.2.23.3 Extinguishing Requirements. Bulk merchandising retail buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3 and the applicable provisions of the following:

(1) This *Code*
(2) NFPA 13, *Standard for the Installation of Sprinkler Systems*
(3) NFPA 30, *Flammable and Combustible Liquids Code*
(4) NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*

[***101:***36.4.5.5]

Bulk merchandising retail buildings provide life safety challenges that differ from those of typical mercantile occupancies. Fires in bulk merchandising retail buildings demonstrate the need for specific requirements to help ensure the adequate life safety of building occupants. The provisions of 36/37.4.5 of NFPA *101* apply to new bulk merchandising retail buildings exceeding 12,000 ft^2 (1115 m^2) and existing facilities exceeding 15,000 ft^2 (1400 m^2).

The term *bulk merchandising retail building* (see definition in 3.3.192.4) refers to occupancies with storage height in excess of 12 ft (3660 mm), which differentiates such a building from typical mercantile occupancies. If the storage and display of combustible materials exceeds 12 ft (3660 mm) in height, the requirements of 36/37.4.5 of NFPA *101* are to be applied.

13.3.2.23.4 Mall Buildings.

13.3.2.23.4.1 Automatic Extinguishing Systems.

13.3.2.23.4.1.1 The mall structure and all anchor buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13 and 13.3.2.23.4.1.2. [***101:***36.4.4.13.1]

13.3.2.23.4.1.2 The system shall be installed in such a manner that any portion of the system serving tenant spaces can be taken out of service without affecting the operation of the portion of the system serving the mall concourse. [***101:***36.4.4.13.2]

The design practice described in 13.3.2.23.4.1.2 permits the installation, addition, or modification of automatic sprinkler protection within the individual tenant spaces without affecting the level of protection in other areas of the building, particularly in the mall. It is recognized that renovation projects are frequently conducted in mall buildings where tenant leases and other business considerations cause modifications to the design and arrangement of tenant spaces. When construction to modify these spaces occurs, the sprinkler systems are frequently taken out of service. The maintenance of sprinkler protection is of prime importance in the overall level of protection required for buildings of this nature, particularly where certain spaces, specifically the mall (pedestrian way), are used as a portion of a means of egress. The effect of this provision is to minimize the area and duration of interruption to sprinkler protection for the mall building.

13.3.2.23.4.2 Hose Connections.

13.3.2.23.4.2.1 There shall be a hose outlet connected to a system sized to deliver 250 gal/min (946 L/min) at the most hydraulically remote outlet. [**5000:**27.4.4.8.2.1]

13.3.2.23.4.2.2 The outlet shall be supplied from the mall concourse zone sprinkler system and shall be hydraulically calculated. [**5000:**27.4.4.8.2.2]

13.3.2.23.4.2.3 Hose outlets shall be provided at each of the following locations:

(1) Within the mall concourse at the entrance to each exit passage or corridor
(2) At each floor level landing within enclosed stairways opening directly onto the mall concourse
(3) At exterior public entrances to the mall concourse

[***5000:***27.4.4.8.2.3]

13.3.2.24 Existing Mercantile Occupancies.

See the commentary related to 13.3.2.23 and its subparagraphs.

Δ **13.3.2.24.1** Mercantile occupancies, other than one-story buildings that meet the requirements of a street floor, as defined in 3.3.192.19, shall be protected by an approved automatic sprinkler system in accordance with NFPA 13 in any of the following specified locations:

(1) Throughout all mercantile occupancies with a story over 15,000 ft^2 (1400 m^2) in area
(2) Throughout all mercantile occupancies exceeding 30,000 ft^2 (2800 m^2) in gross area
(3) Throughout stories below the level of exit discharge where such stories have an area exceeding 2500 ft^2 (232 m^2) and are used for the sale, storage, or handling of combustible goods and merchandise
(4) Throughout multiple occupancies protected as mixed occupancies in accordance with 6.1.14 where the conditions of 13.3.2.24.1(1), (2), or (3) apply to the mercantile occupancy

[***101:***37.3.5.1]

13.3.2.24.2 Bulk merchandising retail buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3 and the applicable provisions of the following:

(1) This *Code*
(2) NFPA 13, *Standard for the Installation of Sprinkler Systems*
(3) NFPA 30, *Flammable and Combustible Liquids Code*
(4) NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*

[***101:***37.4.5.5]

13.3.2.25 Underground and Limited Access Structures. Underground and limited access structures, and all areas and floor levels traversed in traveling to the exit discharge, shall be protected by an approved, supervised automatic sprinkler system in accordance with Section 13.3, unless such structures meet one of the following criteria:

(1) They have an occupant load of 50 or fewer persons in new underground or limited access portions of the structure.
(2) They have an occupant load of 100 or fewer persons in existing underground or limited access portions of the structure.
(3) The structure is a one-story underground or limited access structure that is permitted to have a single exit, per Chapters 12 through 43 of NFPA *101*, with a common path of travel not greater than 50 ft (15 m).

[***101:***11.7.3.4]

Limited access and underground structures pose enhanced risks to life safety, because the buildings cannot be easily vented of products of combustion. In an area from which there is no direct access to the outside and where there are no windows to allow outside fire department rescue operations and ventilation, fire or smoke might cause occupants to panic. Therefore, additional corrective measures, such as complete automatic sprinkler protection and automatic smoke-venting systems (as required by NFPA *101*), must be provided where necessary to ensure an adequate level of life safety.

13.3.2.26 High-Rise Buildings.

13.3.2.26.1 New high-rise buildings shall be protected throughout by an approved automatic sprinkler system in accordance with Section 13.3.

Fires in high-rise buildings present unusual challenges to fire fighters. Fire-fighting equipment, including hose, tools, self-contained breathing apparatus, and spare air cylinders, often must be carried up many flights of stairs to the fire floor. The same stairways used by fire fighters to move equipment to the fire floor might also be used simultaneously by evacuating occupants.

Serious high-rise fires also usually require large numbers of fire fighters to search for and assist people evacuating the building. In other cases, fire fighters are required to assure occupants that they are safe in areas of the building not directly affected by the fire.

High-rise buildings are often subject to unusual air movement conditions, which can push fire from the compartment of origin into corridors. This situation makes it more difficult for occupants of the story of fire origin to evacuate and increases the danger to fire fighters trying to get onto the fire floor to rescue occupants or attack the fire. Ventilation of high-rise buildings is difficult, because breaking windows on upper stories can send broken glass onto fire fighters and others below. For these and other reasons, automatic sprinklers are required to contain and keep fires small, allowing fire fighters to effect extinguishment quickly.

13.3.2.26.2* Existing high-rise buildings shall be protected throughout by an approved automatic sprinkler system in accordance with this chapter and 13.3.2.26.2.1 through 13.3.2.26.2.3.

A.13.3.2.26.2 The enabling legislation adopting this *Code* should specify a specific date for compliance with 13.3.2.26.2. Building owners and managers should be notified of this requirement within 180 days of code adoption. The following items should be considered by the AHJ as guidance in evaluating compliance plans:

(1) Shortage of qualified contractors to install sprinkler systems
(2) Impact on owners and tenants as a result of existing conditions contained in lease agreements
(3) Environmental constraints resulting from contaminated material being removed from limited areas of the building during installation of sprinklers and attendant activity
(4) Available time to install sprinklers in the occupied spaces
(5) Financial constraints of owners being able to fund the cost of installing automatic sprinklers with associated costs
(6) Ability of the owner to coordinate general building remodeling with the actual sprinkler retrofit process

13.3.2.26.2.1 Each building owner shall, within 180 days of receiving notice, file an intent to comply with this regulation with the AHJ for approval.

13.3.2.26.2.2 The AHJ shall review and respond to the intent-to-comply submittal within 60 days of receipt.

13.3.2.26.2.3* The entire building shall be required to be protected by an approved automatic sprinkler system within 12 years of adoption of this *Code*.

A.13.3.2.26.2.3 Examples of retrofit schedules can include the following:

(1) Plan submitted and approved within 1 year; 33 percent of square footage completed within 4 years; 66 percent of square footage completed within 8 years; 100 percent of square footage completed within 12 years.
(2) Plans submitted and approved with 1 year; all common areas completed within 4 years; 50 percent of remaining area completed within 8 years; 100 percent of remaining area completed within 12 years.
(3) An alternative schedule can be approved by the AHJ that does not have any intermediary stages but has to be 100 percent complete within 8 years.

When notifying building owners of the need to comply with the requirement for automatic sprinkler systems in existing high-rise buildings, the AHJ should specify the information to be included in the owner's intent-to-comply notification. Existing buildings might contain asbestos, which necessitates the use of specific mitigation measures during the sprinkler system installation process. The intent-to-comply notification should contain a schedule to allow sufficient time for completion, as well as time for possible delays due to unforeseen circumstances. The building owner must also ensure that the schedule complies with the 12-year requirement of 13.3.2.26.2.3.

13.3.2.27* New Storage Occupancies.

A.13.3.2.27 For the purpose of the requirements in 13.3.2.27.1 through 13.3.2.27.3, combustibles include all combustible materials in storage as well as noncombustible materials that are enclosed, encapsulated, or packaged in combustible materials.

13.3.2.27.1 High-Piled Storage. An automatic sprinkler system shall be installed throughout all occupancies containing areas greater than 2500 ft^2 (232 m^2) for the high-piled storage of combustibles.

13.3.2.27.2* General Storage. An automatic sprinkler system shall be installed throughout all occupancies containing areas greater than 12,000 ft^2 (1115 m^2) for the storage of combustibles.

A.13.3.2.27.2 Portions of structures that are subdivided by fire walls can be considered to be separate buildings for the purpose of applying this *Code*. Fire walls by their definition have sufficient structural stability to maintain the integrity of the wall in the event of the collapse of the building construction on either side of the wall.

13.3.2.27.3 An automatic sprinkler system shall be installed throughout all occupancies containing storage commodities classified as Group A Plastics in excess of 5 ft (1.5 m) in height over an area exceeding 2500 ft^2 (232 m^2) in area.

13.3.2.27.4 Mini-Storage Building. An automatic sprinkler system shall be installed throughout all mini-storage buildings greater than 2500 ft^2 (232 m^2) and where any of the individual storage units are separated by less than a 1-hour fire resistance–rated barrier. [**5000:**30.3.5.3]

13.3.2.27.5 Bulk Storage of Tires. Buildings and structures where the volume for the storage of tires exceeds 20,000 ft^3 (566 m^3) shall be equipped throughout with an approved automatic fire sprinkler system. [**5000:**30.3.5.2]

13.3.2.28 Woodworking Operations. An approved automatic fire sprinkler system shall be installed in buildings containing woodworking operations exceeding 2500 ft^2 (232 m^2) that use equipment, machinery, or appliances; that generate finely divided combustible waste; or that use finely divided combustible materials. [**5000:**29.3.5.1.2]

13.3.2.29 New and Existing Day Care. Buildings with unprotected openings in accordance with 8.6.6 of NFPA *101* shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***16.3.5.3; ***101:***17.3.5.3]

13.3.2.30 New Industrial Occupancies. New industrial occupancies, other than low-hazard industrial occupancies, shall be protected by an approved automatic sprinkler system in accordance with NFPA 13 in any of the following locations:

(1) Throughout all industrial occupancies three or more stories in height
(2) Throughout all industrial occupancies exceeding 12,000 ft^2 (1115 m^2) in fire area
(3) Where the total area of all floors, including mezzanines, exceeds 24,000 ft^2 (2230 m^2)

[**5000:**29.3.5.1.1]

13.3.3 Inspection, Testing, and Maintenance.

13.3.3.1 A sprinkler system installed in accordance with this *Code* shall be properly maintained to provide at least the same level of performance and protection as designed. The owner shall be responsible for maintaining the system and keeping it in good working condition.

13.3.3.2 A sprinkler system installed in accordance with this *Code* shall be inspected, tested, and maintained in accordance with NFPA 25.

13.3.3.3 Ceiling Tiles and Ceiling Assemblies. Where automatic sprinklers are installed, ceilings necessary for the proper actuation of the fire protection device in accordance with NFPA 13 shall be maintained.

13.3.3.4 General Requirements.

13.3.3.4.1 Responsibility of the Property Owner or Designated Representative.

13.3.3.4.1.1* Responsibility for Inspection, Testing, Maintenance, and Impairment. The property owner or designated representative shall be responsible for properly maintaining a water-based fire protection system. [**25:**4.1.1]

In many jurisdictions, NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, is adopted through a model code or state law. However, due to a lack of manpower, AHJs often cannot actively enforce the standard in those jurisdictions. Even if the AHJ is not actively seeking the inspection, testing, and maintenance (ITM) inspection report, the owner still must follow the ITM program outlined by NFPA 25.

A.13.3.3.4.1.1 Any portion or all of the inspection, testing, and maintenance can be permitted to be contracted with an inspection, testing, and maintenance service. When an inspection, testing, and maintenance service company agrees to perform inspections and tests at a specific frequency required by this standard, the inspection, testing, and maintenance service company should perform all inspections and tests that are required more frequently than the specified frequency. For example, the ITM service provider agrees to perform required inspections and tests on an annual basis. Those inspections and tests required on a daily, weekly, quarterly, and semi-annual frequency should also be performed during the annual inspections and tests. [**25:**A.4.1.1]

13.3.3.4.1.1.1* Inspection, testing, maintenance, and impairment procedures shall be implemented in accordance those established in this document and in accordance with the manufacturer's instructions. [**25:**4.1.1.1]

As stated in Chapter 1 of NFPA 25, the requirements found in NFPA 25 are minimum requirements. Along with those minimum requirements, as indicated in this 13.3.3.4.1.1.1, ITM requirements found in manufacturers' instructions must be followed as well.

A.13.3.3.4.1.1.1 In order to ensure compliance, the owner should verify that windows, skylights, doors, ventilators, other openings and closures, concealed spaces, unused attics, stair towers, roof houses, and low spaces under buildings do not expose water-filled piping to freezing. This should occur prior to the onset of cold weather and periodically thereafter. [**25:**A.4.1.1.1]

13.3.3.4.1.1.2 Inspection, testing, and maintenance shall be performed by qualified personnel. [**25:**4.1.1.2]

The term *qualified* is defined in 3.3.34 of NFPA 25 and should not be confused with *licensed*. Qualification is the minimum level of training and expertise that NFPA 25 requires, whereas licensing is a governmental function. Regardless of whether the jurisdiction requires a license to perform ITM work, the person doing the work must be qualified. There are many levels of qualification as defined by NFPA 25. For example, building maintenance personnel might be qualified to inspect valves to ensure they remain in the correct position but might not be qualified to perform an internal inspection of some valves as required by Chapter 13 of this *Code*.

Although all ITM functions require at least some training, many of the individual tasks can be performed with minimal training and experience. Looking at a gauge to determine that it is still indicating normal pressure, for example, might be something that a trained building maintenance person can do.

As indicated earlier in this section, NFPA 25 assigns all ITM responsibilities to the owner. The owner can contract some or all of these functions out to a qualified contractor. Nothing in the standard is meant to prevent the owner from performing the tasks as long as the owner is qualified to do so. One important fact to keep in mind, however, is that the determination of qualification ultimately rests with the AHJ. The owner should verify any jurisdictional requirements before embarking on an in-house ITM program of any sort.

N **13.3.3.4.1.1.2.1*** The owner shall coordinate with the entity conducting the inspection, testing, and maintenance activities to minimize any water damage caused by the discharge of water. [**25:**4.1.1.2.1]

13.3.3.4.1.1.3* Where the property owner or designated representative is not the occupant, the property owner or designated representative shall be permitted to delegate the authority for inspecting, testing, maintenance, and the managing of impairments of the fire protection system to a designated representative. [**25:**4.1.1.3]

N **A.13.3.3.4.1.1.3** Water-based systems rely on the adequacy and ongoing maintenance of drainage systems such as roof drains storm drains and floor drains, during flowing water as part of testing systems. These systems are often used for other purposes than fire system testing and are not part of the fire protection system. They are often designed and maintained as part of building plumbing systems. [**25:**A.4.1.1.2.1]

Anytime water is released, consideration must be given to where that water might ultimately end up. This is not only a responsibility of the person performing the ITM, as required by 13.2.4 of NFPA 25, but must also involve the owner or designated representative. The owner or designated representative, such as maintenance personnel, is often more familiar with the condition of the plumbing system or the drainage characteristics of the surrounding area.

NOTE: The annex material was inadvertently misnumbered. Annex material A.13.3.3.4.1.1.3 should be associated with 13.3.3.4.1.1.2.1, and A.13.3.3.4.1.1.4 should be associated with 13.3.3.4.1.1.3. The text in 13.3.3.4.1.1.2.1 is new to the 2017 edition of NFPA 25.

13.3.3.4.1.1.4 Where a designated representative has received the authority for inspecting, testing, maintenance, and the managing of impairments, the designated representative shall comply with the requirements identified for the property owner or designated representative throughout this *Code*. [**25:**4.1.1.4]

A.13.3.3.4.1.1.4 Examples of designated representatives can include the occupant, management firm, or managing individual through specific provisions in the lease, written use agreement, or management contract. [**25:**A.4.1.1.3]

See the Note in the preceding commentary regarding Annex A material.

13.3.3.4.1.2* Freeze Protection. The property owner or designated representative shall ensure that water-filled piping is maintained at a minimum temperature of 40°F (4.0°C) unless an approved anti-freeze solution is utilized. [**25:**4.1.2]

Sprinkler system freeze-ups are a matter of simple physics. When untreated water reaches a temperature of 32°F (0°C), it begins to freeze. This is not a "failure" of the sprinkler system, but a matter of not preventing the system from being exposed to freezing temperatures. Section 1.1 of NFPA 25 states that the scope of that standard is to establish the ITM of water-based fire protection systems. Verifying the condition of the heating system in the building or identifying holes in walls that can let in cold weather is not part of the requirements of NFPA 25.

When a sprinkler system does freeze, it often requires expensive repairs to the system and to the building if water is discharged through broken pipe, fittings, or sprinklers. In addition, the sprinkler system is impaired, which creates a heightened risk of loss from a fire event. For those reasons, NFPA 25 establishes the requirement for maintaining building temperature and places the responsibility for this important task on the owner. Note that 13.3.3.4.1.2 specifically refers to an "approved" antifreeze solution.

The requirements for antifreeze systems have changed drastically since the 2011 edition of NFPA 25 was published. As outlined in Chapter 5 of NFPA 25, an acceptable antifreeze solution would be a solution with 30 percent propylene glycol or less or a solution with 38 percent glycerine or less. These solutions have been deemed acceptable for existing systems based on test data that have shown that solutions with this concentration of antifreeze do not increase the heat release rate of a fire when the solution is discharged.

Another design approach that might be acceptable would be an antifreeze solution that has been approved by the AHJ as described in a deterministic risk assessment. Refer to 5.3.3.4.1 of NFPA 25 for more information on deterministic risk assessments for antifreeze systems.

Δ **A.13.3.3.4.1.2** In areas that have the potential for freezing temperatures below the level that can be adequately protected by an allowable antifreeze solution, supplemental heat can be provided when temperatures fall below the level of the antifreeze solution. Other means of freeze protection for water-filled piping, including heated valve enclosures, heat tracing, insulation, or other methods are allowed by the applicable installation standard. Installation standards require heat tracing protecting fire protection piping against freezing to be supervised. [**25:**A.4.1.2]

13.3.3.4.1.2.1 All areas of the building containing water-filled piping that does not have another means of freeze protection shall be maintained at a minimum temperature of 40°F (4.0°C). [**25:**4.1.2.1]

13.3.3.4.1.2.2 Aboveground water-filled pipes that pass through open areas, cold rooms, passageways, or other areas exposed to temperatures below 40°F (4.0°C), protected against freezing by insulating coverings, frostproof casings, listed heat tracing systems, or other reliable means shall be maintained at temperatures between 40°F (4.0°C) and 120°F (48.9°C). [**25:**4.1.2.2]

13.3.3.4.1.2.3 Where other approved means of freeze protection for water-filled piping as described in 13.3.3.4.1.2.2 are utilized they shall be inspected, tested, and maintained in accordance with NFPA 25. [**25:**4.1.2.3]

This paragraph clarifies that when means other than running water-filled piping through heated areas are utilized, those means become an important part of the reliability of the fire protection system and must be maintained accordingly.

13.3.3.4.1.3* Accessibility. The property owner or designated representative shall provide ready accessibility to components of water-based fire protection systems that require inspection, testing, and maintenance. [**25:**4.1.3]

A.13.3.3.4.1.3 The components are not required to be open or exposed. Doors, removable panels, or valve pits can be permitted to satisfy the need for accessibility. Such equipment should not be obstructed by features such as walls, ducts, columns, direct burial, or stock storage. [**25:**A.4.1.3]

The requirement in 13.3.3.4.1.3 for accessibility is intended to address the all-too-common practice of placing objects such as file cabinets or stock in front of sprinkler risers and other control equipment. This requirement is not limited to the interior of the building. Exterior components of the system must be kept accessible as well. Exhibit 13.6 shows a fire department connection (FDC) that has been obstructed by shrubbery. Exterior components such as post indicator valves and FDCs might also be blocked by dumpsters and outdoor storage, as shown in Exhibit 13.7, and even snow piles as a result of plowing and shoveling, as shown in Exhibit 13.8.

Exhibit 13.8

FDC obstructed by snow. (Courtesy of Byron Blake and SimplexGrinnell)

13.3.3.4.1.4 Notification of System Shutdown or Testing. The property owner or designated representative shall notify the AHJ, the fire department, if required, and the alarm-receiving facility before testing or shutting down a system or its supply. [**25:**4.1.4]

Paragraph 13.3.3.4.1.4 establishes the requirement for notification when systems are removed from service. Testing a system without proper notification might — and often does — result in a false alarm. False alarms must be avoided, since they remove emergency services personnel from service at a time when their might be needed for an actual emergency. In many jurisdictions, repeated false alarms can result in a fine or other penalty for property owners. When flowing an inspector's test connection, it may be obvious that an alarm is intended to sound upon waterflow and that the supervisory service must be notified as prescribed by 13.3.3.4.1.4. Perhaps not so obvious is the fact that other tests, such as a fire pump test, hydrant test, or main drain test, can also lead to the tripping of a waterflow switch, which will sound an alarm and, potentially, send a signal to the fire department. At the conclusion of such tests, the alarm-receiving facility should be notified that any alarms received from that point on are not test generated and should be responded to appropriately.

13.3.3.4.1.4.1 The notification of system shutdown or test shall include the purpose for the shutdown, the system or component involved, the estimated time of shutdown or test, and the expected duration of the shutdown or test. [**25:**4.1.4.1]

13.3.3.4.1.4.2 The AHJ, the fire department, and the alarm-receiving facility shall be notified when the system, supply, or component is returned to service or when the test is complete. [**25:**4.1.4.2]

The requirement in 13.3.3.4.1.4.2 assists the AHJ or alarm company in establishing a follow-up program to ensure that systems are properly returned to service.

13.3.3.4.1.5* Corrections and Repairs.

A.13.3.3.4.1.5 Recalled products should be replaced or remedied. Remedies include entrance into a program for scheduled replacement. Such replacement or remedial product should be installed in accordance with the manufacturer's instructions and the appropriate NFPA installation standards. A recalled product is a product subject to a statute or administrative regulation specifically requiring the manufacturer, importer, distributor, wholesaler, or retailer of a product, or any combination of such entities, to recall the product, or a product voluntarily recalled by a combination of such entities. [**25:**A.4.1.5]

Needed corrections and repairs should be classified as an impairment, critical deficiency, or noncritical deficiency according to the effect on the fire protection system and the nature of the hazard protected. [**25:**A.4.1.5]

Impairments are the highest priority problem found during inspection, testing, and maintenance and should be corrected as soon as possible. The fire protection system cannot provide an adequate response to a fire, and implementation of impairment procedures outlined in 13.3.3.6 is required until the impairment is corrected. [**25:**A.4.1.5]

Critical deficiencies need to be corrected in a timely fashion. The fire protection system is still capable of performing, but its performance can be impacted and the implementation of impairment procedures might not be needed. However, special consideration must be given to the hazard in the determination of the classification. A deficiency that is critical for one hazard might be an impairment in another. [**25:**A.4.1.5]

Noncritical deficiencies do not affect the performance of the fire protection system but should be corrected in a reasonable time period so that the system can be properly inspected, tested, and maintained. [**25:**A.4.1.5]

Assembly occupancies, health care facilities, prisons, high- rise buildings, other occupancies where the life safety exposure is significant, or facilities that cannot be evacuated in a timely manner require special consideration. As an example, a nonfunctioning waterflow alarm might be considered a critical deficiency in a storage warehouse but an impairment in a hospital. [**25:**A.4.1.5]

High hazard occupancies where early response to a fire is critical also require special consideration. A small number of painted sprinklers could be considered an impairment for a system protecting a high hazard occupancy but might be considered a critical deficiency in a metal working shop. [**25:**A.4.1.5]

Classifications of needed corrections and repairs are shown in Table A.3.3.7 of NFPA 25. [**25:**A.4.1.5]

One of the most common misapplications of NFPA 25 comes from not understanding the document scope completely. NFPA 25 is intended to confirm the functionality of the system components that are installed, not to ensure that the designer has designed the system correctly and observed the rules of the design and installation standard.

This misapplication of scope can often lead to arguments among owners, inspectors, and AHJs when certain conditions exist in a building. In some cases, the owner has the expectation that the hired inspector is not only looking for "wear and tear" items associated with the water-based systems but also giving the system a clean bill of health from a design perspective as well. The level of effort to produce this clean bill of health is significantly more than what the standard intends and requires an inspector to deliver.

Simply put, if a condition that is found in the field does not comply with the design standard, but the components observed are in good working condition, it would not be considered a deficiency or impairment per NFPA 25.

Δ **13.3.3.4.1.5.1*** The property owner or designated representative shall correct or repair deficiencies or impairments. [**25:**4.1.5.1]

A.13.3.3.4.1.5.1 System deficiencies not explained by normal wear and tear, such as hydraulic shock, can often be indicators of system problems and should be investigated and evaluated by a qualified person or engineer. Failure to address these issues could lead to catastrophic failure. Examples of deficiencies that can be caused by issues beyond normal wear and tear are as follows:

(1) Pressure gauge deficiencies as follows:
  (a) Gauge not returning to zero
  (b) Gauge off scale
  (c) Gauge with bent needle
(2) Support devices deficiencies as follows:
  (a) Bent hangers and/or rods
  (b) Hangers pulled out/off structure
  (c) Indication of pipe or hanger movement such as the following:
    i. Hanger scrape marks on pipe, exposed pipe surface where pipe and hangers are painted
    ii. Firestop material damaged at pipe penetration of fire-rated assembly
(3) Unexplained system damage as follows:
  (a) Unexplained system damage beyond normal wear and tear
  (b) Bent or broken shafts on valves
  (c) Bent or broken valve clappers
  (d) Unexplained leakage at branch lines, cross main, or feed main piping
  (e) Unexplained leakage at closed nipples
  (f) Loose bolts on flanges and couplings
(4) Fire pump deficiencies as follows:
  (a) Fire pump driver out of alignment
  (b) Vibration of fire pump and/or driver
  (c) Unusual sprinkler system piping noises (sharp report, loud bang)

[**25:**A.4.1.5.1]

It should be noted that many jurisdictions regulate who can perform corrections and repairs, along with regulating specific licensing or certification requirements. In the case of corrections that do not involve the fire protection contractor, special attention should be paid to how these corrections are documented.

13.3.3.4.1.5.2 Corrections and repairs shall be performed by qualified maintenance personnel or a qualified contractor. [**25:**4.1.5.2]

13.3.3.4.1.6* Changes in Occupancy, Use, Process, or Materials. The property owner or designated representative shall not make changes in the occupancy, the use or process, or the materials used or stored in the building without evaluation of the fire protection system(s) for its capability to protect the new occupancy, use, or materials. [**25:**4.1.6]

A.13.3.3.4.1.6 The inspections and tests specified in this *Code* do not address the adequacy of design criteria or the capability of the fire protection system to protect the building or its contents. It is assumed that the original system design and installation were appropriate for the occupancy and use of the building and were approved by all applicable AHJs. If no changes to the water supply or to the building or its use have transpired since it was originally occupied, no evaluation is required. If changes are contemplated, it is the owner's responsibility to arrange for the evaluation of the fire protection system(s). Where the inspections and tests specified in the *Code* have been contracted to a qualified inspection provider or contractor, it is not the role of the inspector or contractor to determine if any changes have been made or the subsequent evaluation of the fire protection system. The evaluation of any building changes should be conducted before any proposed change is incorporated and should utilize the appropriate installation standard and input from applicable AHJs. [**25:**A.4.1.6]

Fire protection systems should not be removed from service when the building is not in use; however, where a system that has been out of service for a prolonged period (such as in the case of idle or vacant properties) is returned to service, it is recommended that a responsible and experienced contractor be retained to perform all inspections and tests. [**25:**A.4.1.6]

Note that in the fire protection and life safety field, there are different uses of the term *occupancy*. NFPA 13 bases its design/density criteria for sprinkler systems on occupancy classifications based on the quantity and/or combustibility of contents expected within that space. NFPA *101*, on the other hand, bases the application of that code on occupancy classification defined by the purpose for which a building, structure, or part thereof is intended to be used. Either one of these occupancy types can change while the other remains the same, or a change can result in both types falling under different definitions.

Changes to the occupancy that affect the definition from an NFPA *101* perspective are much more likely to call for building permits and require evaluation of the fire protection systems. Changes to the use of individual spaces or contents within an area are less likely to draw such a stringent review but can change the occupancy classification from an NFPA 13 perspective and drastically limit the effectiveness of a system. Regardless of which occupancy classification is affected, 13.3.3.4.1.6 requires an evaluation of the fire protection system for its capability to protect the new occupancy.

13.3.3.4.1.6.1 The evaluation required by 13.3.3.4.1.6 shall not be considered part of the normal inspection, testing, and maintenance required by this *Code*. [**25:**4.1.6.1]

It is a common misconception that NFPA 25 does not address changes. As outlined in Chapter 1 of NFPA 25, the scope of NFPA 25 does not require the inspector to evaluate the design and layout of the systems covered in that standard. The standard presupposes that the system, as designed and installed, complies with the applicable standards at the time of construction and at the points where changes were made to the building that would necessitate system modifications. However, the requirements in 13.3.3.4.1.6 address this concept by identifying that is it the owner's responsibility to understand the impact of changes in occupancy, use, process, or material and to take certain steps before those changes are made. In the event that changes are made to the building and this evaluation does not take place, any noncompliant conditions created by the changes are not the responsibility of the inspector to identify.

In some cases, a condition that does not comply with the design standard is relatively easy to identify. It can be identified from the floor level without the need of a lift, ladder, tape measure, or any other equipment. Exhibit 13.9 shows a sprinkler that is several feet below the ceiling. In this instance, a drop ceiling was removed and the sprinkler was not relocated to within 12 in. (305 mm) of the ceiling as required by NFPA 13. A similar case would be a sprinkler located too close to a hot air diffuser, as shown in Exhibit 13.10. Although the sprinkler shown is too close to the hot air diffuser according to the spacing rules of NFPA 13, this is not a deficiency according to NFPA 25 and should not be called out in an NFPA 25 inspection report.

That is not to say that inspectors cannot inform building owners that there might be an issue with a system as it relates to a design standard such as NFPA 13. The problem with providing a client with more information, though, is that it can open the inspector to liability. If an inspector is identifying some, but not all, design deficiencies on an NFPA 25 inspection report, the line can become blurred as to the depth of the review and the

Exhibit 13.11

Retrofitted cross-corridor door that affects sprinkler spacing.

inspector's contractual obligation to the owner. Many owners believe that NFPA 25 requires the inspector to conduct a hazard evaluation, so when an inspector includes a few design deficiencies with legitimate NFPA 25 deficiencies, it can further muddy the waters.

Many inspectors feel that they have a moral and ethical obligation, as members of the fire protection and life safety community, to inform their clients of all potential concerns. One way to comply with the requirements of NFPA 25 while still satisfying that moral obligation is to keep two deficiency reports: one dealing with NFPA 25 issues and another that could be called the "good Samaritan" list. The NFPA 25 report would catalog wear-and-tear issues while clearly identifying the scope of NFPA 25. The "good Samaritan" report would list all other items that are beyond the scope of NFPA 25, along with a disclaimer stating that these items are not considered part of an NFPA 25 inspection program. This way, the scope of NFPA 25 is acknowledged, as are any and all problems observed during the inspection.

The requirement in 13.3.3.4.1.6.1 states that the inspections and tests found in NFPA 25 do not include an evaluation of the capability of the system to adequately protect the property or its contents. The owner or designated representative is responsible for an evaluation of the adequacy (i.e., design criteria) of the fire protection systems when changes are proposed to the building or its use. However, most owners do not understand the significance of this requirement, nor do they know how to have the evaluation conducted. In addition, many users of NFPA 25 assume that the inspections and tests specified in that standard include an evaluation of the adequacy of the system to protect the hazard presented by the building, its use, and the contents. That assumption is incorrect. For example, an evaluation of the system design criteria would include an examination of the area of coverage and spacing of the sprinklers, and those tasks are not part of the annual inspection required in NFPA 25.

To further clarify this point, Exhibit 13.11 shows a retrofitted cross-corridor door. Prior to the retrofit, the spacing of the sprinklers in the corridor was according to the requirements of NFPA 13. However, after the retrofit, the sprinkler in the foreground must be evaluated against different criteria for spacing from a wall. In this case, the sprinkler is too far from the wall. This evaluation is required by 13.3.3.4.1.6.2, but the criteria for the evaluation are not within the scope of the inspections required by NFPA 25. The criteria for the evaluation of a sprinkler system are found in installation requirements specified by NFPA 13. This example of how the scopes of the two standards are interrelated is clarified further in 13.3.3.4.1.7.

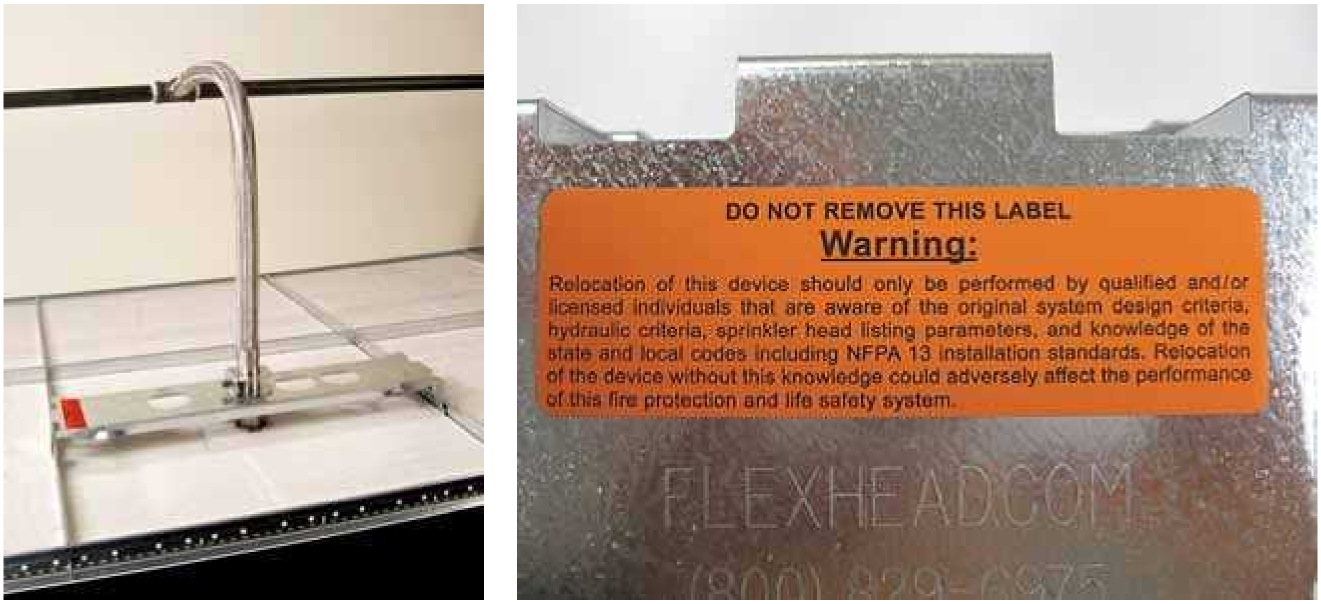
As stated in Chapter 1 of NFPA 25, the purpose of the inspections and tests required by that standard is to maintain the operational status of the system(s). Most inspectors are not trained to evaluate the design criteria of a system, and they should not attempt to do so. It is important that contractors or inspection providers are clear in explaining to the owner the scope of the work that they have been contracted to do. An owner might want to have the system evaluated for its adequacy — and it is certainly appropriate for contractors or inspection providers to conduct such evaluations if they are qualified to do so — but this evaluation is separate from the inspection and testing activities specified by NFPA 25.

Δ **13.3.3.4.1.6.2*** The evaluation shall consider factors that include, but are not limited to, the following:

(1) Occupancy changes such as converting office or production space into warehousing
(2) Process or material changes such as metal stamping to molded plastics
(3) Building revisions such as relocated walls, added mezzanines, and ceilings added below sprinklers
(4) Removal of heating systems in spaces with piping subject to freezing
(5) Changes to the storage method, arrangement, height, or commodities
(6) Changes in water supplies

[***25:***4.1.6.2]

Exhibit 13.12



Flexible sprinkler hose fitting (left) and warning label (right). (Courtesy of FlexHead Industries)

Occupancy changes usually involve a building permit and the subsequent review process by the AHJ. Yet, the more subtle changes listed in 13.3.3.4.1.6.2, items (3) and (4), might not always be reported. Moving walls and adding mezzanines and ceilings can severely affect the spray pattern of sprinklers. Sprinkler protection in unheated spaces frequently causes damage to systems and water damage to buildings and their contents. Monitoring of building alterations and performing inspections can help avoid costly damage to buildings and contents.

In recent years, a growing number of installations have included sprinklers attached to flexible sprinkler hose fittings. As a result, the relocation of sprinklers attached to flexible hose fittings and who should perform that work is an area of concern.

Flexible sprinkler hose fittings are recognized in NFPA 13. However, due to growing concern regarding the ability to move sprinklers without proper evaluation, NFPA 13 contains the following language in Chapter 9:

> **9.2.1.3.3.4*** Where flexible sprinkler hose fittings are used to connect sprinklers to branch lines in suspended ceilings, a label limiting relocation of the sprinkler shall be provided on the anchoring component.

The annex material for this requirement in NFPA 13 provides the following suggested language for the label:

> **CAUTION:** DO NOT REMOVE THIS LABEL.
>
> Relocation of this device should only be performed by qualified and/or licensed individuals that are aware of the original system design criteria, hydraulic criteria, sprinkler head listing parameters, and knowledge of the state and local codes including NFPA 13 installation standards. Relocation of the device without this knowledge could adversely affect the performance of this fire protection and life safety system.

Where flexible sprinkler hose fittings allow sprinklers to be adjusted and relocated, adjustments and relocations made by unqualified individuals could violate requirements, such as those for maximum or minimum sprinkler spacing or obstruction avoidance. For this reason, the committee has added a requirement for a label warning against relocation. To further discourage relocation, the length of flexible drops should be kept to the minimum required for adequate installation and proper performance.

Exhibit 13.12 shows a flexible sprinkler hose fitting along with its mounting and a warning label.

N **A.13.3.3.4.1.6.2** Fire protection systems are designed and installed based on a specific set of circumstances and building uses. For example, the volume of water needed for a sprinkler system to control a fire in the built environment is based upon the intended use of the facility known at the time the sprinkler system was designed and installed. Revisions to properties used for storage represent one of the most common scenarios that impact the ability of systems to provide adequate protection. Some of the most common changes include raising the storage height, changing the storage method arrangement such as adding racks, installing solid shelves in rack structures or decreasing the aisle widths between racks. Changes in product packaging with the use of foam inserts, bubble wrap, or other plastics or encapsulated storage can significantly increase the fire hazard. Changing from wood pallets to plastic pallets, converting to the use of plastic bin boxes, or revising or adding material handling systems such as conveyors could severely impact the effectiveness of the fire protection systems. [**25:**A.4.1.6.2]

13.3.3.4.1.7* Addressing Changes in Hazards.

A.13.3.3.4.1.7 See Annex E of NFPA 25 for an example of a hazard evaluation form. A hazard evaluation is not part of a system inspection. [**25:**A.4.1.7]

In addition to Annex E of NFPA 25, another tool for evaluating an existing system is NFPA 3, *Standard for Commissioning of Fire Protection and Life Safety Systems*. NFPA 3 provides requirements on the retro-commissioning of individual systems or integrated systems. The purpose of NFPA 3 is to provide a structure and reporting mechanism for the design and operation of a system. Properly documenting a system and its design at the same time as design decisions are being made and put on paper, which is what commissioning is intended to do, makes future assessments and evaluations easier and more cost effective to conduct.

13.3.3.4.1.7.1 Where changes in the occupancy, hazard, water supply, storage commodity, storage arrangement, building modification, or other condition that affects the installation criteria of the system are identified, the property owner or designated representative shall promptly take steps to evaluate the adequacy of the installed system in order to protect the building or hazard in question. [**25:**4.1.7.1]

13.3.3.4.1.7.2 Where the evaluation reveals that the installed system is inadequate to protect the building or hazard in question, the property owner or designated representative shall make the required corrections. [**25:**4.1.7.2]

13.3.3.4.1.7.3 Corrections shall be approved. [**25:**4.1.7.3]

The requirement in 13.3.3.4.1.7.3 clarifies the role of the AHJ in the evaluation of the adequacy of the system(s) when changes in the hazard are identified. The owner is not required to include the AHJ in evaluation of the buildings and its systems, but where a system is determined to be inadequate, the corrections must be acceptable to the AHJ. Annex E of NFPA 3 includes sample commissioning documentation. It is critical that whoever conducts the evaluation is qualified to do so.

13.3.3.4.1.8 Valve Location. The location of shutoff valves shall be identified at the system riser or other approved locations. [**25:**4.1.8]

13.3.3.4.1.9 Information Sign.

13.3.3.4.1.9.1 A permanently marked metal or rigid plastic information sign shall be placed at the system control riser supplying an antifreeze loop, dry system, preaction system, or auxiliary system control valve. [**25:**4.1.9.1]

13.3.3.4.1.9.2 Each sign shall be secured with a corrosion-resistant wire, chain, or other approved means and shall indicate at least the following information:

(1) Location of the design area or areas
(2) Discharge densities over the design area or areas
(3) Required flow and residual pressure demand at the base of riser
(4) Occupancy classification or commodity classification and maximum permitted storage height and configuration
(5) Hose stream allowance included in addition to the sprinkler demand
(6) The name of the installing contractor or person providing the information

[**25:**4.1.9.2]

The sign required by 13.3.3.4.1.9 is needed to provide vital information that might not otherwise be readily known to anyone maintaining a system. The sign is particularly useful in addressing freeze threats by identifying any locations with heat tape and acknowledging that auxiliary and low-point drains are installed on the system along with their number and location. If this information is not known, the system can be damaged due to freezing of water in the trapped sections of pipe. It is important to recognize that 13.3.3.4.1.9.2 is a retroactive requirement. For example, system information signs were not required by NFPA 13 prior to the 2007 edition, so many systems might not have them. This information is critical to the assessment of a building when certain ITM tasks are being performed, as evidenced by NFPA 13 requiring it in the last three editions of the standard. If this sign is not present, contractors and inspection providers should alert the owner to the need for the sign and the importance of the information. The required information could come from building records, which include the as-built sprinkler system drawing(s), the Contractor's Material and Test Certificate, or other documents. If these are not available, the owner might need to ask the contractor or other qualified entity or individual to survey the system and provide the information needed for the sign.

N **13.3.3.4.1.10 Antifreeze Information Sign.** An antifreeze information sign shall be placed on the antifreeze system main valve, which indicates the manufacture type and brand of the antifreeze solution, the concentration by volume of the antifreeze solution used, and the volume of the antifreeze solution used in the system. [**25:**4.1.10]

13.3.3.4.1.11 Impairments.

13.3.3.4.1.11.1 Where an impairment to a water-based fire protection system occurs or is identified during inspection, testing, or maintenance activities, the procedures outlined in Chapter 15 of NFPA 25 shall be followed, including the attachment of a tag to the impaired system. [**25:**4.1.11.1]

This paragraph clarifies that the requirements in Chapter 15 of NFPA 25 are to be implemented by the owner in the event that the system is impaired. Chapter 15 of NFPA 25 outlines the specific steps that must be taken. It is notable that although 3.3.21.1 and 3.3.21.2 of NFPA 25 define *emergency* and *preplanned impairment* separately, the actions that the owner must undertake are the same once the impairment occurs.

Exhibit 13.13 shows an impaired system that has been identified with an impairment tag by the AHJ. NFPA 25 does not mandate a certain style or color for the impairment tag; however, many

Exhibit 13.13

Example of an impaired system tag. (Courtesy of Byron Blake and SimplexGrinnell)

states have their own tagging system that should be consulted. Where a system impairment occurs in a location that is remote from the system control valve, the inspector will often provide a tag both at the system riser and at the impaired component. For instance, if a system has to be shut down due to a failed coupling in a section of feed main piping outside the sprinkler control room, it makes sense to tag both the coupling and the closed control valve. The tag on the control valve should note where the impairment is, leading the AHJ, owner, or inspector to the other tag.

13.3.3.4.1.11.2 Where a water-based fire protection system is returned to service following an impairment, the system shall be verified to be working properly by means of an appropriate inspection or test as described in the table, "Summary of Component Replacement [Action] Requirements" in the applicable chapters of NFPA 25. [**25:**4.1.11.2]

Component replacement and testing tables are included in NFPA 25 for each system type to assist the user in determining the type and extent of actions that are needed following a repair or adjustment. See the appropriate systems chapter in NFPA 25 for the pertinent component replacement and testing table. There are times when these actions are in accordance with the requirements of the appropriate installation standard. For example, the tests needed when an air maintenance device in a dry pipe sprinkler system is replaced would be performed in accordance with NFPA 13.

13.3.3.4.2 Manufacturer's Corrective Action. Manufacturers shall be permitted to make modifications to their own listed product in the field with listed devices that restore the original performance as intended by the listing, where acceptable to the AHJ. [**25:**4.2]

13.3.3.4.3 Records.

13.3.3.4.3.1* Records shall be made for all inspections, tests, and maintenance of the system and its components and shall be made available to the AHJ upon request. [**25:**4.3.1]

Although many local and some state jurisdictions require it, NFPA 25 does not mandate the transmittal of records to the AHJ. Some jurisdictions require that all ITM records be immediately sent to the AHJ upon completion of the inspection, test, or maintenance. Other jurisdictions require only that certain records, such as those indicating impairments, be forwarded. Still other jurisdictions only want the records to be maintained on site for review by fire inspectors or others, such as insurance companies. It is important that all stakeholders in the process are aware of any requirements to forward records to anyone other than the owner.

A.13.3.3.4.3.1 Inspection reports used for system inspections should contain an "Owner's Section" as shown in Figure A.13.3.3.4.3.1 that the property owner or designated representative should complete. Typical records include, but are not limited to, valve inspections; flow, drain, and pump tests; and trip tests of dry pipe, deluge, and preaction valves. [**25:**A.4.3.1]

Acceptance test records should be retained for the life of the system or its special components. Subsequent test records should be retained for a period of 1 year after the next test. The comparison determines deterioration of system performance or condition and the need for further testing or maintenance. [**25:**A.4.3.1]

13.3.3.4.3.1.1* Records shall be permitted to be stored and accessed electronically. [**25:**4.3.1.1]

A.13.3.3.4.3.1.1 Computer programs that file inspection and test results should provide a means of comparing current and past results and should indicate the need for corrective maintenance or further testing. [**25:**A.4.3.1.1]

The ITM records referred to in 13.3.3.4.3 provide written documentation of compliance with NFPA 25. These records also offer a service history of the installed systems by indicating their performance during testing and/or maintenance. The advances in electronic database software allow for complete and highly detailed histories of system maintenance. Many AHJs allow owners to use their own central database or that of a service provider to electronically file and maintain records, rather than to store traditional paper records on site. In some jurisdictions, the AHJ has contracted with a third-party records maintenance provider. These programs typically involve the ITM provider submitting the reports required by this chapter directly to the third party in addition to providing them to the owner. There may be a cost involved with these programs, so it is important that the owner and the ITM service provider both be familiar with the local requirements.

Δ **13.3.3.4.3.2** Records shall indicate the following:

(1) The procedure/activity performed (e.g., inspection, test, or maintenance)
(2) The organization that performed the activity
(3) The required frequency of the activity
(4) The results and date of the activity
(5) The name and contact information of the qualified contractor or owner, including lead person for activity

[**25:**4.3.2]

Owner's Section

A. Is the building occupied?	❏ Yes	❏ No
B. Has the occupancy and hazard of contents remained the same since the last inspection?	❏ Yes	❏ No
C. Are all fire protection systems in service?	❏ Yes	❏ No
D. Has the system remained in service without modification since the last inspection?	❏ Yes	❏ No
E. Was the system free of actuation of devices or alarms since the last inspection?	❏ Yes	❏ No

Explain any "no" answers:

Owner or Designated Representative (print)   Signature and Date

 NFPA 25

Δ *FIGURE A.13.3.3.4.3.1 Owner's Section on Inspection Report. [**25:**Figure A.4.3.1]*

Any form, whether produced commercially or developed independently, can be used to document ITM activities, provided it details the activity sufficiently to verify compliance with NFPA 25. Many people assume that NFPA 25 requires a specific series of forms that need to be filled out; however, a review of the standard, will show that it is completely devoid of forms. This absence of forms in the standard is not intended to lessen the importance of recording ITM data, but rather it allows the owners and inspectors the flexibility to use their own project management programs, software, and ITM forms to track their ITM work. NFPA has developed a series of electronic forms specific to the ITM requirements throughout NFPA 25. These completely customizable forms are available at www.nfpa.org. Exhibit 13.14 shows an example of a form that can be used for recording system information or documenting an ITM task that has been completed.

One of the main concerns of property owners and facility managers who own or manage multiple properties is the many different ITM forms they receive. The same holds true for AHJs. For that reason, in the 2017 edition of NFPA 25, annex guidance was expanded regarding recommended minimum information for ITM reports. Although not required, the annex provides a framework for consistency for those who choose to follow it. For more information, see Section B.4 in Annex B of NFPA 25.

13.3.3.4.3.3* Records shall be maintained by the property owner. [**25:**4.3.3]

A.13.3.3.4.3.3 See Section B.2 of NFPA 25 for information regarding sample forms. [**25:**A.4.3.3]

13.3.3.4.3.4 As-built system installation drawings, hydraulic calculations, original acceptance test records, and device manufacturer's data sheets shall be retained for the life of the system. [**25:**4.3.4]

13.3.3.4.3.5 Subsequent records shall be retained for a period of 1 year after the next inspection, test, or maintenance of that type required by the *Code*. [**25:**4.3.5]

13.3.3.5 Sprinkler Systems.

13.3.3.5.1 Maintenance — Sprinklers.

13.3.3.5.1.1 Where a sprinkler has been removed for any reason, it shall not be reinstalled. [**25:**5.4.1.1]

Δ **13.3.3.5.1.2*** Replacement sprinklers shall have the proper characteristics for the application intended, which include the following:

(1) Style
(2) Orifice size and K-factor
(3) Temperature rating
(4) Coating, if any
(5) Deflector type (e.g., upright, pendent, sidewall)
(6) Design requirements

[**25:**5.4.1.2]

Exhibit 13.14

FIRE SPRINKLER SYSTEM HAZARD EVALUATION

Changes in building occupancy, use, or process, or material used or stored, create the need for evaluation of the installed fire protection systems. This form is intended to identify and evaluate such changes and should be completed only by an individual property qualified in the area of system design.

Owner: ____________ Owner's address: ____________

Property being evaluated: ____________

Property address: ____________

Date of work: ____________

(All responses refer to the current hazard evaluation performed on this date.)

Section 1. Identification of Sprinklered Occupancy and Storage Hazards
(Use additional pages as needed.)

Area of Property (List nonsprinklered areas separately in Section 3.)	Type of System and Sprinklers	Design Capability of System	Hazard Protected (Uses or storage arrangements, including commodity)	Improvements Needed to Address Hazard
1.				
2.				
3.				
4.				
5.				

 (p. 1 of 4)

FIRE SPRINKLER SYSTEM HAZARD EVALUATION (Continued)

Section 2. Evaluation of Protection

For each area of the property evaluated in Section 1, please answer the following questions with a "yes," "no," "N/A," or "?" and explain all "no" and "?" responses below by row and column identification:

Answer the following for each identified property area:	1	2	3	4	5
a. Are all sprinklers the correct type for their application?					
b. Are the obstructions to sprinklers in all areas within acceptable limits for the specific types of sprinklers used?					
c. Are hazards associated with all occupancy areas consistent with hazards typical for that occupancy hazard classification?					
d. Are stockpiles of combustibles located within occupancy areas limited to appropriate heights?					
e. Are miscellaneous and dedicated storage areas properly identified and managed?					
f. Are all dedicated storage areas protected in accordance with the proper storage configuration and commodity classification?					
g. Is the storage or use of flammable liquids, combustible liquids, or aerosol products in any area properly addressed?					
h. Is all idle pallet storage properly protected?					
i. Is there any presence of nitrate film, pyroxylin plastic, compressed or liquefied gas cylinders, liquid or solid oxidizers, or organic peroxide formulations except where specifically addressed by appropriate protection measures?					
j. Are all sprinklers spaced appropriately for the hazard and the type of sprinkler?					
k. Do the available sources of heat and cooling appear adequate for the type of system and temperature rating of sprinklers?					

Explanation of "no" and "?" answers:

Examples:
b2 — no — Obstructions to ESFR sprinklers exceed currently accepted standards.
e3 — ? — ***Owner must provide information on type of plastic involved in product before evaluation can be finalized.***

 (p. 2 of 4)

FIRE SPRINKLER SYSTEM HAZARD EVALUATION (Continued)

Area of Property for Which Protection Is Not Provided	Basis of Lack of Protection (if known)	Basis for Omission Under Current Codes/Standards
1.		
2.		
3.		
4.		
5.		

Section 4. Water Supply Evaluation

If this hazard evaluation is the result of a reduction in the residual pressure during routine inspections, explain the results of the investigation made to determine the reasons for this change:

Explain the basis of continued acceptability of the water supply or proposed improvements:

 (p. 3 of 4)

FIRE SPRINKLER SYSTEM HAZARD EVALUATION (Continued)

Section 5. Hazard Evaluator's Information and Certification

Evaluator: ____________

Company: ____________

Company address: ____________

I state that the information on this form is correct at the time and place of my review of my evaluation.

Is this hazard evaluation completed? (Note: All "?" must be resolved.) Yes ❑ No ❑

Explain if answer is not "yes":

Have deficiencies in protection been identified that should be improved or corrected? Yes ❑ No ❑

Summarize improvements of corrections needed:

Signature of Evaluator: ____________ Date: ______

License or Certification Number (if applicable): ____________

 (p. 4 of 4)

Sample fire sprinkler hazard evaluation form.

There are many types of sprinklers, a number of which have similar appearances but different performance characteristics. Paragraph 13.3.3.5.1.2 identifies sprinkler characteristics that must be matched to the application.

Care must be taken to ensure that replacement sprinklers have the same characteristics as those they are replacing so that the design performance of the system is maintained. This is especially important for special sprinklers, as noted in 13.3.3.5.1.4. When the same make and model of a special sprinkler is no longer manufactured, persons with appropriate expertise and knowledge should be consulted for selection of a replacement sprinkler.

While replacement sprinklers must have the same characteristics, nothing in NFPA 25 or NFPA 13 requires that the replacement sprinkler be the same make and model. Sprinkler manufacturers may update or discontinue a particular model, but sprinklers with the same operating characteristics are almost always available.

The replacement sprinkler is not required to have the exact temperature rating of the sprinkler being replaced, but it should be of the temperature range appropriate for the environment installed, based on Table 6.2.5.1 of NFPA 13.

A.13.3.3.5.1.2 To help in the replacement of like sprinklers, unique sprinkler identification numbers (SINs) are provided on all sprinklers manufactured after January 1, 2001. The SIN accounts for differences in orifice size, deflector characteristics, pressure rating, and thermal sensitivity. [**25:**A.5.4.1.2]

13.3.3.5.1.2.1* Spray sprinklers shall be permitted to replace old-style sprinklers. [**25:**5.4.1.2.1]

A.13.3.3.5.1.2.1 Old-style sprinklers are permitted to replace existing old-style sprinklers. Old-style sprinklers should not be used to replace standard sprinklers without a complete engineering review of the system. The old-style sprinkler is the type manufactured before 1953. It discharges approximately 40 percent of the water upward to the ceiling, and it can be installed in either the upright or pendent position. [**25:**A.5.4.1.2.1]

N **13.3.3.5.1.2.2*** Where replacing residential sprinklers manufactured prior to 2003 that are no longer available from the manufacturer and are installed using a design density less than 0.05 gpm/ft^2 (204 mm/min), a residential sprinkler with an equivalent K-factor (± 5 percent) shall be permitted to be used provided the currently listed coverage area for the replacement sprinkler is not exceeded. [**25:**5.4.1.2.2]

N **A.13.3.3.5.1.2.2** It is recognized that the flow and pressure available to the replacement sprinkler might be less than its current flow and pressure requirement. [**25:**A.5.4.1.2.2]

The text of 13.3.3.5.1.2.2 is new to the 2018 edition of NFPA 1 and was added to correlate with NFPA 13 and NFPA 13R. Minimum design density requirements were added to the 2002 edition of NFPA 13. Since that change, many sprinkler manufacturers stopped making residential sprinklers listed for densities less than 0.05 gpm/ft^2 (204 mm/min). This paragraph gives owners NFPA 25–compliant options for replacing sprinklers installed prior to this change when sprinklers matching the exact characteristics are not available.

Δ **13.3.3.5.1.2.3** Replacement sprinklers for piers and wharves shall comply with NFPA 307. [**25:**5.4.1.2.3]

13.3.3.5.1.3 Only new, listed sprinklers shall be used to replace existing sprinklers. [**25:**5.4.1.3]

Δ **13.3.3.5.1.4*** Special and quick-response sprinklers as defined by NFPA 13 shall be replaced with sprinklers of the same orifice, size, temperature range and thermal response characteristics, and K-factor. [**25:**5.4.1.4]

A.13.3.3.5.1.4 It is imperative that any replacement sprinkler have the same characteristics as the sprinkler being replaced. If the same temperature range, response characteristics, spacing requirements, flow rates, and K-factors cannot be obtained, a sprinkler with similar characteristics should be used, and the system should be evaluated to verify the sprinkler is appropriate for the intended use. With regard to response characteristics, matching identical Response Time Index (RTI) and conductivity factors is not necessary unless special design considerations are given for those specific values. [**25:**A.5.4.1.4]

Prior to the 2008 edition of NFPA 25, the standard required that sprinklers be replaced by a sprinkler of the exact make and model, in addition to having the same performance characteristics. This is impractical, so NFPA 25 now simply requires that sprinklers be replaced with types having equal performance characteristics, such as orifice size, K-factor, temperature rating, and thermal response.

13.3.3.5.1.5* Stock of Spare Sprinklers. A supply of at least six spare sprinklers shall be maintained on the premises so that any sprinklers that have operated or been damaged in any way can be promptly replaced. [**25:**5.4.1.5]

A.13.3.3.5.1.5 A minimum of two sprinklers of each type and temperature rating installed should be provided. [**25:**A.5.4.1.5]

Following an incident in which a sprinkler has operated, either due to a fire or mechanical damage, it is important to minimize system impairments. Thus, 13.3.3.5.1.5 specifies that a supply of spare sprinklers must be available so that sprinklers can be replaced quickly following a small fire or accidental discharge. Note that the supply must be "on the premises" but need not be in each building of a complex or specifically at the sprinkler system riser. For example, a supply of spare sprinklers for a complex can be stored in a central location, provided that the supply is accessible and does not substantially delay the replacement of sprinklers following an incident.

13.3.3.5.1.5.1 The sprinklers shall correspond to the types and temperature ratings of the sprinklers in the property. [**25:**5.4.1.5.1]

13.3.3.5.1.5.2 The sprinklers shall be kept in a cabinet located where the temperature in which they are subjected will at no time exceed 100°F (38°C). [**25:**5.4.1.5.2]

13.3.3.5.1.5.3 Where dry sprinklers of different lengths are installed, spare dry sprinklers shall not be required, provided that a means of returning the system to service is furnished. [**25:**5.4.1.5.3]

Dry sprinklers are manufactured to specific lengths. Due to the pitching of pipe or various ceiling heights, the dry sprinklers on a system are often of varying lengths, so it is impractical to have spare sprinklers for each specific length. However, if all the dry sprinklers on a system are the same length, spare dry sprinklers should be kept in the sprinkler cabinet. For example, freezer boxes with dry sprinklers supplied by a wet system can all be the same length, and it is practical and reasonable to provide the spare dry sprinklers.

Δ **13.3.3.5.1.5.4** The stock of spare sprinklers shall include all types and ratings installed and shall be as follows:

(1) For protected facilities having under 300 sprinklers — no fewer than 6 sprinklers
(2) For protected facilities having 300 to 1000 sprinklers — no fewer than 12 sprinklers
(3) For protected facilities having over 1000 sprinklers — no fewer than 24 sprinklers

[**25:**5.4.1.5.4]

13.3.3.5.1.5.5* One sprinkler wrench as specified by the sprinkler manufacturer shall be provided in the cabinet for each type of sprinkler installed to be used for the removal and installation of sprinklers in the system. [**25:**5.4.1.5.5]

A.13.3.3.5.1.5.5 One sprinkler wrench design can be appropriate for many types of sprinklers, and multiple wrenches of the same design should not be required. [**25:**A.5.4.1.5.5]

Special wrenches as prescribed by the manufacturer must be kept in the sprinkler cabinet so that sprinklers can be properly replaced following an incident or in the event that inspection or testing indicates damage. There should be an appropriate wrench provided for each sprinkler type installed in the system.

13.3.3.5.1.5.6 A list of the sprinklers installed in the property shall be posted in the sprinkler cabinet. [**25:**5.4.1.5.6]

13.3.3.5.1.5.6.1* The list shall include the following:

(1) Sprinkler Identification Number (SIN) if equipped; or the manufacturer, model, orifice, deflector type, thermal sensitivity, and pressure rating
(2) General description

Sprinklers Contained in this Cabinet

Sprinkler Identification, SIN	General Description	Temperature Rating, °F	Sprinkler Quantity Maintained
TY9128	Extended Coverage, K-25, upright	155	6
VK425	Concealed pendent residential	145	6
Issued: 10/3/05	Revised:		

Δ ***FIGURE A.13.3.3.5.1.5.6.1*** *Sample List. [25:Figure A.5.4.1.5.6.1]*

(3) Quantity of each type to be contained in the cabinet
(4) Issue or revision date of the list

[**25:**5.4.1.5.6.1]

A.13.3.3.5.1.5.6.1 The minimum information in the list contained in the spare sprinkler cabinet should be marked with the following:

(1) General description of the sprinkler, including upright, pendent, residential, ESFR, and so forth
(2) Quantity of sprinklers that is to be maintained in the spare sprinkler cabinet. An example of the list is shown in Figure A.13.3.3.5.1.5.6.1.

[**25:**A.5.4.1.5.6.1]

13.3.3.5.1.6* Sprinklers shall not be altered in any respect or have any type of ornamentation, paint, or coatings applied after shipment from the place of manufacture. [**25:**5.4.1.6]

A.13.3.3.5.1.6 Corrosion-resistant or specially coated sprinklers should be installed in locations where chemicals, moisture, or other corrosive vapors exist. [**25:**A.5.4.1.6]

13.3.3.5.1.7 Sprinklers and automatic spray nozzles used for protecting commercial-type cooking equipment and ventilating systems shall be replaced annually. [**25:**5.4.1.7]

13.3.3.5.1.7.1 Where automatic bulb-type sprinklers or spray nozzles are used and annual examination shows no buildup of grease or other material on the sprinklers or spray nozzles, such sprinklers and spray nozzles shall not be required to be replaced. [**25:**5.4.1.7.1]

13.3.3.5.1.8 Protective Coverings.

13.3.3.5.1.8.1* Sprinklers protecting spray areas and mixing rooms in resin application areas installed with protective coverings shall continue to be protected against overspray residue so that they will operate in the event of fire. [**25:**5.4.1.8.1]

A.13.3.3.5.1.8.1 Typical sandwich bags purchased in a grocery store are generally plastic, not cellophane. Plastic bags have a tendency to shrink and adhere to the sprinkler prior to sprinkler activation, creating the potential for disruption of sprinkler spray patterns. Bags placed over sprinklers need to be true cellophane or paper. [**25:**A.5.4.1.8.1]

13.3.3.5.1.8.2 Sprinklers installed as described in 13.3.3.5.1.8.1 shall be protected using cellophane bags having a thickness of 0.003 in. (0.076 mm) or less or thin paper bags. [**25:**5.4.1.8.2]

Testing has shown that lightweight cellophane or paper bags will not adversely affect the operation of a sprinkler. However, sprinklers protected by lightweight cellophane or paper bags might require more frequent inspection than the annual inspection outlined in 5.2.1.1 of NFPA 25, to prevent excessive buildup on the bags. Depending on the use of the spray coating area, the inspection and subsequent replacement of the bags might need to be done daily. The use of plastic bags is not permitted due to concerns for the potential of a plastic bag to shrink prior to sprinkler activation and disrupt the discharge pattern. Exhibit 13.15 illustrates a sprinkler protected from overspray by a cellophane bag.

Exhibit 13.15

Sprinkler protected from overspray with a cellophane bag.

13.3.3.5.1.8.3 Coverings shall be replaced periodically so that heavy deposits of residue do not accumulate. [**25:**5.4.1.8.3]

13.3.3.5.2* Dry Pipe Systems. Dry pipe systems shall be kept dry at all times. [**25:**5.4.2]

A.13.3.3.5.2 Conversion of dry pipe systems to wet pipe systems on a seasonal basis causes corrosion and accumulation of foreign matter in the pipe system and loss of alarm service. [**25:**A.5.4.2]

Moisture is one of the main causes of corrosion in sprinkler piping. Alternating from a dry system to a wet system allows moisture to enter the system and can accelerate corrosion rates. In addition, the waterflow alarm on most dry systems will need to be removed from service if the system is left wet. To minimize corrosion and prevent freezing of sprinkler piping, it is required that these systems always remain dry, and it is recommended that they be reset and drained following operation to minimize moisture inside the system. Exhibit 13.16 shows rust and scale removed from a dry pipe system.

Exhibit 13.16

Rust and scale removed from dry pipe system.

13.3.3.5.2.1 During nonfreezing weather, a dry pipe system shall be permitted to be left wet if the only other option is to remove the system from service while waiting for parts or during repair activities. [**25:**5.4.2.1]

13.3.3.5.2.2 Refrigerated spaces or other areas within the building interior where temperatures are maintained at or below 40°F (4.4°C) shall not be permitted to be left wet. [**25:**5.4.2.2]

13.3.3.5.2.3 Air driers shall be maintained in accordance with the manufacturer's instructions. [**25:**5.4.2.3]

13.3.3.5.2.4 Compressors used in conjunction with dry pipe sprinkler systems shall be maintained in accordance with the manufacturer's instructions. [**25:**5.4.2.4]

13.3.3.6 Impairments.

The most common impairments involve closed water-control valves, but other examples can include conditions such as a nonfunctioning fire pump, painted sprinklers, heavily corroded sprinklers, or a broken hose valve.

The requirements in 13.3.3.6 deal primarily with preplanned impairments — those impairments in which the system or a portion thereof is out of service due to work, such as modifications to the water supply or sprinkler system piping, that has been planned in advance. But in reality, an effective impairment program is one that is established and understood well in advance of any impairment and can be implemented in the event of an emergency impairment as well. Note that the appointment of an impairment coordinator (see 13.3.3.6.2) does not necessarily coincide with the actual impairment. In fact, 13.3.3.4.1.11.1 directs the user to Chapter 15 of NFPA 25 whenever an impairment occurs or is identified.

Rarely is a facility more exposed to a potentially catastrophic fire loss than when a fire protection system or portion of a system is out of service. Many devastating fires could have been mitigated had a proper impairment program been in place and adhered to. Whether an impairment is preplanned or occurs in an emergency situation seems to have little bearing on its tendency to lead to catastrophe. A major factor in numerous large-loss fires included the failure to do the following:

- Recognize the risks created by the impairment
- Establish a fire watch and provide backup fire protection
- Control ignition sources and/or shut down hazardous processes
- Expedite repairs
- Ensure that the fire protection system is properly placed back into service

13.3.3.6.1 General.

13.3.3.6.1.1 Minimum Requirements.

13.3.3.6.1.1.1 Subsection 13.3.3.6 shall provide the minimum requirements for a water-based fire protection system impairment program. [**25:**15.1.1.1]

13.3.3.6.1.1.2 Measures shall be taken during the impairment to ensure that increased risks are minimized and the duration of the impairment is limited. [**25:**15.1.1.2]

13.3.3.6.2 Impairment Coordinator.

13.3.3.6.2.1 The property owner or designated representative shall assign an impairment coordinator to comply with the requirements of 13.3.3.6. [**25:**15.2.1]

Prior to removing a system from service, the impairment coordinator should ensure that the necessary tools, equipment, and replacement parts are on hand to minimize the duration of the impairment. This typically involves coordination with the contractor or service provider who is scheduled to perform the work that necessitates shutdown of the system. As stated earlier, the building and its occupants are at higher risk when fire protection systems are impaired. Thus, the role of the impairment coordinator in performing this important function should not be understated.

13.3.3.6.2.2 In the absence of a specific designee, the property owner or designated representative shall be considered the impairment coordinator. [**25:**15.2.2]

13.3.3.6.2.3 Where the lease, written use agreement, or management contract specifically grants the authority for inspection, testing, and maintenance of the fire protection system(s) to the tenant, management firm, or managing individual, the tenant, management firm, or managing individual shall assign a person as impairment coordinator. [**25:**15.2.3]

13.3.3.6.3 Tag Impairment System.

Many jurisdictions have requirements to identify the system's operational status. These often include tags that are placed at the system riser or other specified locations to indicate that ITM has been performed and whether any deficiencies or impairments were found. System status tagging programs often use color-coded tags for this purpose. For more information on color-coded system status tagging programs, see Annex G of NFPA 25. Those programs, and the tags they utilize, are not typically part of the requirements of Chapter 15 of NFPA 25. For example, a system that is found to have impairments during inspection or testing may be tagged as such by the qualified person conducting the ITM, but that simply triggers the implementation of the requirements found in Chapter 15 of NFPA 25. The impairment coordinator would then place the impairment tags as required by 13.3.3.6.3.

13.3.3.6.3.1* A tag shall be used to indicate that a system, or part thereof, has been removed from service. [**25:**15.3.1]

A.13.3.3.6.3.1 A clearly visible tag alerts building occupants and the fire department that all or part of the water-based fire protection system is out of service. The tag should be weather resistant, plainly visible, and of sufficient size [typically 4 in. × 6 in. (100 mm × 150 mm)]. The tag should identify which system is impaired, the date and time impairment began, and the person responsible. Figure A.13.3.3.6.3.1 illustrates a typical impairment tag. [**25:**A.15.3.1]

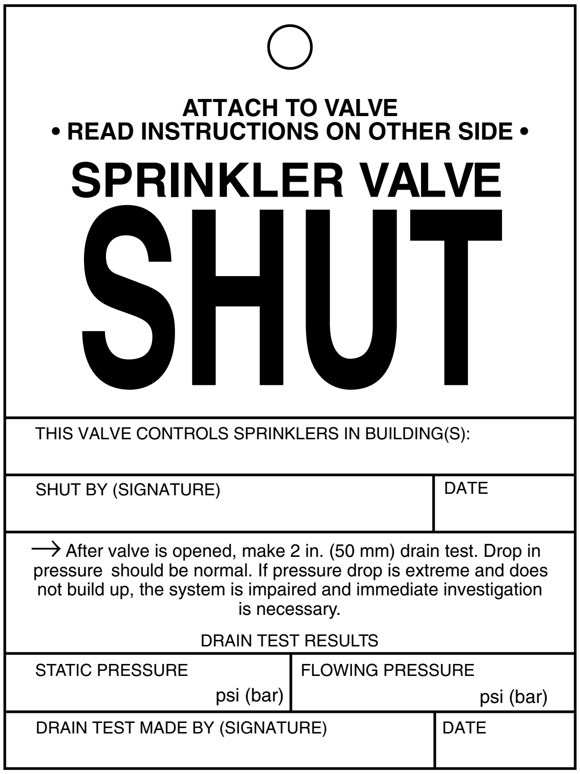

FIGURE A.13.3.3.6.3.1 *Sample Impairment Tag. [**25:**Figure A.15.3.1]*

13.3.3.6.3.2* The tag shall be posted at each fire department connection and the system control valve, and other locations required by the AHJ indicating which system, or part thereof, has been removed from service. [**25:**15.3.2]

A.13.3.3.6.3.2 An impairment tag should be placed on the fire department connection to alert responding fire fighters of an abnormal condition. An impairment tag that is located on the system riser only could go unnoticed for an extended period if fire fighters encounter difficulty in gaining access to the building or sprinkler control room. [**25:**A.15.3.2]

13.3.3.6.4 Impaired Equipment.

13.3.3.6.4.1 The impaired equipment shall be considered to be the water-based fire protection system, or part thereof, that is removed from service. [**25:**15.4.1]

Δ **13.3.3.6.4.2** The impaired equipment shall include, but shall not be limited to, the following:

(1) Sprinkler systems
(2) Standpipe systems
(3) Fire hose systems
(4) Underground fire service mains
(5) Fire pumps
(6) Water storage tanks
(7) Water spray fixed systems
(8) Foam-water sprinkler systems
(9) Water mist systems
(10) Fire service control valves
(11) Water supply

[**25:**15.4.2]

13.3.3.6.5* Preplanned Impairment Programs.

A.13.3.3.6.5 The need for temporary fire protection, termination of all hazardous operations, and frequency of inspections in the areas involved should be determined. All work possible should be done in advance to minimize the length of the impairment. Where possible, temporary feedlines should be used to maintain portions of systems while work is completed. [**25:**A.15.5]

Water-based fire protection systems should not be removed from service when the building is not in use. Where a system that has been out of service for a prolonged period, such as in the case of idle or vacant properties, is returned to service, qualified personnel should be retained to inspect and test the systems. [**25:**A.15.5]

13.3.3.6.5.1 All preplanned impairments shall be authorized by the impairment coordinator. [**25:**15.5.1]

Δ **13.3.3.6.5.2** Before authorization is given, the impairment coordinator shall be responsible for verifying that the following procedures have been implemented:

(1) The extent and expected duration of the impairment have been determined.
(2) The areas or buildings involved have been inspected and the increased risks determined.
(3) Recommendations to mitigate any increased risks have been submitted to management or the property owner or designated representative.
(4) Where a fire protection system is out of service for more than 10 hours in a 24-hour period, the impairment coordinator shall arrange for one of the following:
    (a) Evacuation of the building or portion of the building affected by the system out of service
    (b)* An approved fire watch

Fire watch personnel should be trained to understand the hazards at the job site and the nature of hot work where hot work operations are used. They should ensure that safe conditions are maintained during all hot work operations and should have the authority to stop work if unsafe conditions develop. Fire-extinguishing equipment should be readily available, and fire watch personnel should be trained in its use. The fire watch personnel should be familiar with the facilities and procedures for sounding an alarm in the event of a fire.

Fire watch personnel should be trained in proper incipient fire response procedures, such as notifying the fire department and persons in the fire area before attempting to extinguish a fire. They should attempt to extinguish a fire only if it is obviously within the capacity of the equipment available. It is important to note that many AHJs have specific requirements that fire watch personnel must meet. Fire watch personnel may be allowed to perform additional tasks, but those tasks should not distract them from their watch responsibilities. For additional guidance on fire watch operations, see NFPA 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work*.

For torch-applied roofing operations, a fire watch must be posted for the duration of the work and for 60 minutes thereafter.

A.13.3.3.6.5.2(4)(b) A fire watch should consist of trained personnel who continuously patrol the affected area. Ready access to fire extinguishers and the ability to promptly notify the fire department are important items to consider. During the patrol of the area, the person should not only be looking for fire, but making sure that the other fire protection features of the building such as egress routes and alarm systems are available and functioning properly. [**25:**A.15.5.2(4)(b)]

    (c)* Establishment of a temporary water supply

A.13.3.3.6.5.2(4)(c) Temporary water supplies are possible from a number of sources, including use of a large-diameter hose from a fire hydrant to a fire department connection, use of a portable tank and a portable pump, or use of a standby fire department pumper and/or tanker. [**25:**A.15.5.2(4)(c)]

Temporary water supplies can be established through the use of existing systems or portions of systems that are not involved in the maintenance or repair activity. Exhibit 13.17 shows one type of temporary water supply in the form of portable bladder tanks. Exhibit 13.18 shows another type of temporary water supply in which a hard-piped connection was made to the fire department connection (FDC) in order to bypass work on the main water supply. The temporary water supply for fire protection

Exhibit 13.17

Portable storage tanks as an alternative source of water. (Courtesy of National Park Service)

Exhibit 13.18

Temporary water supply connection to FDC.

should be available as soon as existing fire protection systems are shut down for maintenance or repair.

In situations involving automatic sprinklers, the system should be returned to service as soon as possible. The operation of sprinkler control valves should be limited to properly authorized personnel only. Where the sprinkler protection is regularly turned off and on to facilitate connection of newly repaired segments, the sprinkler control valves should be checked at the end of each work shift and the impairment program followed to verify that protection is in service. If at all possible, sprinkler systems should be isolated from standpipes in order to keep the standpipe system in service and readily available for manual fire fighting.

(d)* Establishment and implementation of an approved program to eliminate potential ignition sources and limit the amount of fuel available to the fire

An approved fire prevention program, as referred to in 13.3.3.6.5.2(4)(d), should include the following:

1. Good housekeeping
2. On-site security
3. Immediate activation of new or repaired fire protection systems as construction and repairs allow
4. Preservation of existing fire protection systems during building construction or renovation
5. Development of a prefire plan with the local fire department
6. Accurate and rapid communication process
7. Consideration of any special hazards resulting from construction operations
8. Protection of existing structures and equipment from exposure fires resulting from construction, alteration, and demolition operations

Temporary fire extinguishers should be provided in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*. At least one approved fire extinguisher should be provided in plain sight on each floor at each usable stairway, and access to permanent, temporary, or portable fire equipment should be maintained at all times.

A.13.3.3.6.5.2(4)(d) Depending on the use and occupancy of the building, it could be enough in some circumstances to stop certain processes in the building or to cut off the flow of fuel to some machines. It is also helpful to implement “No Smoking” and “No Hot Work” (cutting, grinding, or welding) policies while the system is out of service because these activities are responsible for many fire ignitions. [**25:**A.15.5.2(4)(d)]

Although shop welding of pipe is preferred, welding of pipe and pipe supports is permitted by NFPA 13, provided that welding operations are conducted in accordance with NFPA 51B. In some areas, a permit issued by the local AHJ might be required.

(5) The fire department has been notified.

Although many fire departments might not require a permit for maintenance activities, notification to the department that a system or a portion of a system is out of service is still required. This notification of an impaired system serves two purposes:

1. It assists fire department pre-incident planning should an emergency response to the affected property be necessary.
2. It allows the fire department to monitor progress in repairs and avoid a system impairment that is longer than necessary.

(6) The insurance carrier, the alarm company, property owner or designated representative, and other AHJs have been notified.

Notifying the insurance carrier, the alarm company, the property owner or designated representative, and other AHJs is important for the following reasons:

1. In addition to ensuring that the alarm company does not inadvertently initiate a fire department response to an

alarm signal, alarm companies often require an estimated time period for the impairment and will respond if the system is not placed in service at the end of the specified time period.

2. Insurance companies might have requirements or recommendations for temporary protection during impairments and provide assistance in monitoring the impairment. Many insurance companies have specific tag impairment systems that must be used during impairments.
3. Water or health departments might have special requirements when systems are shut off and brought back on line, such as testing of backflow prevention devices.

(7) The supervisors in the areas to be affected have been notified.
(8) A tag impairment system has been implemented. *(See 13.3.3.6.3.)*

Prior to any scheduled inspection or testing that could impair the system, the contractor or service company should consult with the property owner or impairment coordinator. The following issues should be discussed and agreed upon by all parties prior to the start of any work:

1. Requirements for advance notification to the building occupants
2. Coordination of any business interruption
3. Procedures for the evacuation or for the restoration of protection
4. Additional related issues

(9) All necessary tools and materials have been assembled on the impairment site.

[**25:**15.5.2]

13.3.3.6.6* Emergency Impairments.

A.13.3.3.6.6 Emergency impairments include, but are not limited to, system leakage, interruption of water supply, frozen or ruptured piping, equipment failure, or other impairments found during inspection, testing, or maintenance activities. [**25:**A.15.6]

13.3.3.6.6.1 Emergency impairments shall include, but are not limited to, interruption of water supply, frozen or ruptured piping, and equipment failure, and includes impairments found during inspection, testing, or maintenance activities.
[**25:**15.6.1]

An emergency impairment is a condition in which the water-based fire protection system or a portion thereof is out of service due to an unexpected occurrence. Such an impairment might occur as the result of a successful system operation during a fire.

Following a fire, sprinklers that have operated must be replaced and the system must be returned to service. The replacement of sprinklers illustrates the importance of the sprinkler cabinet inspections required by 13.3.3.5.1, since the impairment time can be substantially reduced if replacement sprinklers are on site.

Exhibit 13.19

Emergency impairment notice. (Courtesy of Liberty Mutual Commercial Markets)

13.3.3.6.6.2* The coordinator shall implement the steps outlined in 13.3.3.6.5. [**25:**15.6.2]

The impairment coordinator can use an emergency impairment notice, such as the one shown in Exhibit 13.19, to coordinate emergency repairs of a fire protection system.

A.13.3.3.6.6.2 When one or more impairments are discovered during inspection, testing, and maintenance activities the owner or owner's authorized representative should be notified in writing. See Figure A.13.3.3.6.6.2 for an example of written notification. [**25:**A.15.6.2]

The impairment coordinator can use an emergency impairment notice (see Exhibit 13.19) to coordinate the emergency repairs of a fire protection system.

Δ **13.3.3.6.7* Restoring Systems to Service.** When all impaired equipment is restored to normal working order, the impairment coordinator shall verify that the following procedures have been implemented:

(1) Any necessary inspections and tests have been conducted to verify that affected systems are operational. The appropriate chapter of NFPA 25 shall be consulted for guidance on the type of inspection and test required.

The most common tests required following a system repair include the hydrostatic pressure test to verify that the piping system will not leak and the main drain test to verify that all water supply control valves have been returned to their full open

IMPAIRMENT NOTICE

DURING A RECENT INSPECTION OF YOUR FIRE PROTECTION SYSTEM(S), AN ***EMERGENCY IMPAIRMENT*** WAS DISCOVERED AND INDICATED ON THE INSPECTION REPORT. AS DEFINED BY NFPA 25, AN ***EMERGENCY IMPAIRMENT*** IS "A CONDITION WHERE A WATER-BASED FIRE PROTECTION SYSTEM OR PORTION THEREOF IS OUT OF ORDER DUE TO AN UNEXPECTED OCCURRENCE, SUCH AS A RUPTURED PIPE, OPERATED SPRINKLER, OR AN INTERRUPTION OF WATER SUPPLY TO THE SYSTEM." NFPA 25 FURTHER STATES, "EMERGENCY IMPAIRMENTS INCLUDE BUT ARE NOT LIMITED TO SYSTEM LEAKAGE, INTERRUPTION OF WATER SUPPLY, FROZEN OR RUPTURED PIPING, AND EQUIPMENT FAILURE."

WE RECOMMEND THAT IMMEDIATE STEPS BE TAKEN, AS DESCRIBED IN THE ATTACHED COPY OF CHAPTER 15 OF NFPA 25, TO CORRECT THE FOLLOWING IMPAIRMENT(S) TO YOUR FIRE PROTECTION SYSTEM(S):

[ ] CONTROL VALVE SHUT. SYSTEM OUT OF SERVICE.
[ ] LOW WATER PRESSURE DURING FLOW TEST. POSSIBLE OBSTRUCTION IN WATER SUPPLY OR PARTIALLY SHUT VALVE.
[ ] PIPE(S) FROZEN.
[ ] PIPE(S) LEAKING.
[ ] PIPE(S) ARE OBSTRUCTED.
[ ] SYSTEM PIPING OR PORTIONS OF SYSTEM PIPING ARE DISCONNECTED.
[ ] FIRE DEPT. CONNECTION MISSING OR DAMAGED OR OBSTRUCTED.
[ ] DRY PIPE VALVE CANNOT BE RESET.
[ ] DRY PIPE SYSTEM QUICK OPENING DEVICE IS OUT OF SERVICE.
[ ] SPRINKLERS ARE PAINTED, CORRODED, DAMAGED, OR LOADED.
[ ] FIRE PUMP IS OUT OF SERVICE.
[ ] DETECTION/ACTUATION SYSTEM IS OUT OF SERVICE.
[ ] OTHER: ______________________________

FIGURE A.13.3.3.6.6.2 Sample Impairment Notice.

positions. Other tests, such as a running test for fire pumps and flow or alarm tests to check the functioning of replaced components, are required when components are repaired or replaced. The specific actions required for placing a system or a system component in service following repair, replacement, or other corrective actions can be found in the appropriate chapter in NFPA 25.

(2) Supervisors have been advised that protection is restored.
(3) The fire department has been advised that protection is restored.
(4) The property owner or designated representative, insurance carrier, alarm company, and other AHJs have been advised that protection is restored.

All parties involved in the original impairment notification should be advised when protection is restored. See the commentary following 13.3.3.6.5.2(5) for further information.

(5) The impairment tag has been removed.
[**25:**15.7]

Impairment tags are required to be removed and should be accounted for. Counting these tags can be a means of verifying that all system control valves have been returned to their proper operating position and the system is fully operational.

A.13.3.3.6.7 Occasionally, fire protection systems in idle or vacant buildings are shut off and drained. When the equipment is eventually restored to service after a long period of not being maintained, it is recommended that a qualified person perform the work. The following is an example of a procedure:

(1) All piping should be traced from the extremities of the system to the main connections with a careful check for blank gaskets in flanges, closed valves, corroded or damaged sprinklers, nozzles or piping, insecure or missing hangers and insufficient support. Proper repairs or adjustments should be made and needed extensions or alterations for the equipment should be completed.
(2) An air test at low pressure (40 psi) should be conducted prior to allowing water to fill the system. When the piping has been proven tight by passing the air test, water can be introduced slowly into the system with proper precautions against damage by escape of water from previously undiscovered defects. When the system has been filled under normal service pressure, drain valve tests should be made to detect any closed valve that possible could have been overlooked. All available pipes should be flushed and an obstruction investigation completed to make sure that the system is clear of debris.
(3) Where the system was known to have been damaged by freezing or where other extensive damage may have occurred, a full hydrostatic test can be performed in accordance with NFPA 13 to determine whether the system integrity has been maintained.
(4) Dry-pipe valves, quick opening devices, alarm valves and all alarm connections should be examined, put in proper condition and tested.
(5) Fire pumps, pressure and gravity tanks, reservoirs and other water supply equipment should receive proper attention before being placed in service. Each supply should be tested separately; and then together if they are designed to work together.
(6) All control valves should be operated from the closed to fully open position and should be left sealed, locked or equipped with a tamper switch.

[**25:**A.15.7]

13.4 Fire Pumps

13.4.1 General.

Δ **13.4.1.1** Where provided, fire pumps shall be installed in accordance with NFPA 20 and Section 13.4.

13.4.1.2 Permits. Permits, where required, shall comply with Section 1.12.

13.4.1.3 Retroactivity. The provisions of this section reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this section at the time the section was issued. [**20:**1.4]

The retroactivity statement in 13.4.1.3 appears in most NFPA codes and standards. The purpose of the statement here is to reinforce the premise that any fire pump installed in accordance with the applicable edition of NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*, is considered to be compliant with that standard for the lifetime of the fire pump, as long as the associated hazards remain unchanged and the pump is properly inspected, tested, and maintained. Therefore, an existing installation is not required to be reviewed for compliance with every new edition of NFPA 20.

Omission of the retroactivity statement would require the never-ending task of updating and revising a fire pump installation every time a new edition of NFPA 20 is published. Although newer editions contain information that may provide a greater level of safety or a more effective means of accomplishing a certain objective than that prescribed by older editions, the provisions of older editions should not necessarily be interpreted as unsafe. In those instances where a severe deficiency is discovered, 13.4.1.3 allows latitude for any AHJ to require an upgrade.

13.4.1.3.1 Unless otherwise specified, the provisions of this section shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the section. Where specified, the provisions of this section shall be retroactive. [**20:**1.4.1]

13.4.1.3.2 In those cases where the AHJ determines that the existing situation presents an unacceptable degree of risk, the AHJ shall be permitted to apply retroactively any portion of this section deemed appropriate. [**20:**1.4.2]

13.4.1.3.3 The retroactive requirements of this section shall be permitted to be modified if their application clearly would be impractical in the judgment of the AHJ, and only where it is clearly evident that a reasonable degree of safety is provided. [**20:**1.4.3]

13.4.1.4* Approval Required.

A.13.4.1.4 Because of the unique nature of fire pump units, the approval should be obtained prior to the assembly of any specific component. [**20:**A.4.2]

Fire pumps are typically long-lead items. Making changes to the fire pump after the pump is ordered can lead to project delay and additional costs.

13.4.1.4.1 Stationary pumps shall be selected based on the conditions under which they are to be installed and used. [**20:**4.2.1]

The fire protection system designer should verify the fire pump suction and discharge pressures over the operating range of the fire pump. The fire pump should provide sufficient discharge pressure to supply the fire protection system demands, but the discharge pressure should not subject the fire protection system components to pressures in excess of their listed pressure rating.

Fire pumps should be located in a suitable environment. See 13.4.2 for further guidance.

13.4.1.4.2 The pump manufacturer or its authorized representative shall be given complete information concerning the liquid and power supply characteristics. [**20:**4.2.2]

Pump capacities are based on the calculated system demand. Pressure boost or output of the pump is determined by the difference between the pressures available from the attached water supply and the pressure required by the fire protection system. The characteristics of that water supply — whether positive pressure or static — must be determined in order to select the correct type of pump and its performance characteristics.

The available power supply for electric pumps must be suitable for the fire pump controller. The power supply must be analyzed for reliability, capacity, and suitability. This information must be made available to the pump manufacturer or manufacturer's representative for analysis.

While fire pumps are traditionally associated with water, they are also used for pumping foam concentrate, foam water, water with other water additives, seawater, and possibly other liquids. The characteristics of the liquid are part of the critical information needed by the pump manufacturer.

Using salt water in a fire protection system requires special considerations to minimize corrosion issues. Dissimilar materials should be avoided.

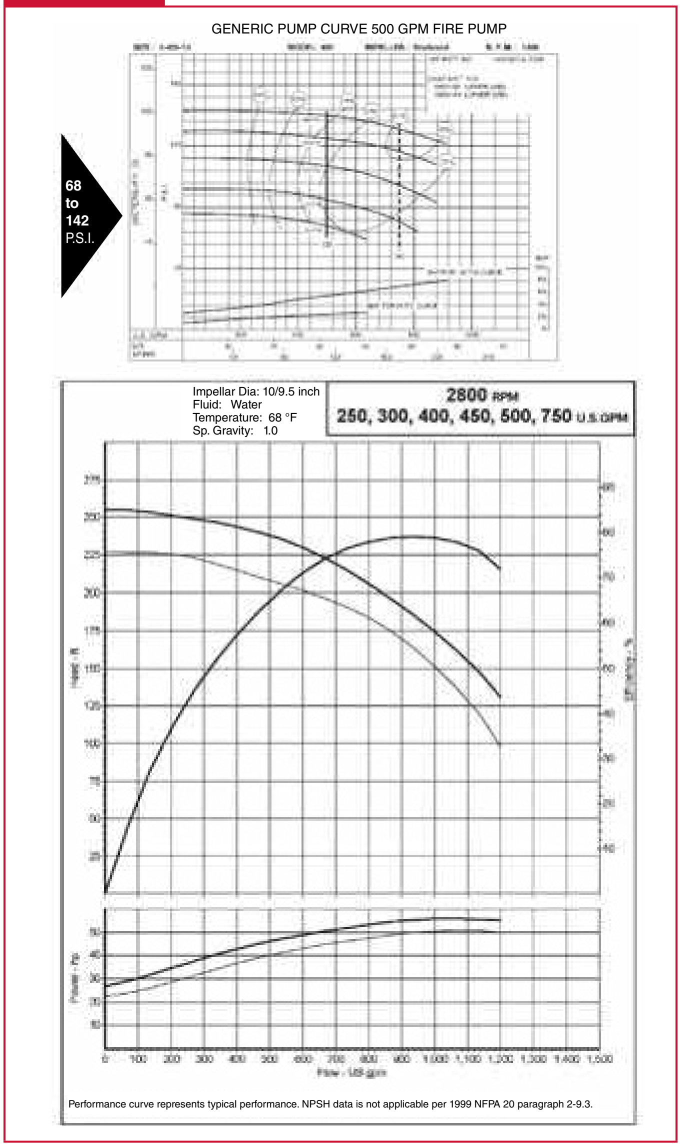
13.4.1.4.3 A complete plan and detailed data describing pump, driver, controller, power supply, fittings, suction and discharge connections, and liquid supply conditions shall be prepared for approval. [**20:**4.2.3]

Generic pump curves can be obtained from the pump manufacturer to determine the churn pressure and the pressure available at the required flow rate. See Exhibit 13.20. The certified pump curve is not available until the pump is manufactured, but it should be close to the generic curve. If system hydraulic calculations have been performed using a generic pump curve, they should be reconfirmed upon receipt of the certified pump curve to ensure that system demands will be met.

Ordinarily, upon purchase of a fire pump, the manufacturer or supplier provides the buyer with product data for the pump, the driver, the controller, and all accessories. This data package should include the pump's rated capacity and speed in addition to other performance characteristics. The data package should be submitted to the registered design professional (RDP) and the AHJ for approval before shipment of the pump and its accessories. The reviewing authority should be contacted prior to submittal to determine the number of plans, calculations, or product data needed for review. The submitter should include an additional number of copies of the package to be returned documenting the approval or comments from the AHJ.

In addition to the data package, a complete plan of the proposed installation, drawn to scale, should be submitted, indicating, at a minimum, the information outlined in Exhibit 13.21.

Exhibit 13.20



Sample generic fire pump curves. (Courtesy of Aon Fire Protection Engineering)

Δ **13.4.1.4.3.1** Plans shall be drawn to an indicated scale, on sheets of uniform size, and shall indicate, as a minimum, the items from the following list that pertain to the design of the system:

(1) Name(s) of owner and occupant
(2) Location, including street address
(3) Point of compass
(4) Name and address of installing contractor
(5) Pump make and model number
(6) Pump rating _______ gpm @ _____ psi ______ rpm
(7) Suction main size, length, location, type and class/schedule of material, and point of connection to water supply, as well as depth to top of pipe below grade
(8) Water storage tank, if applicable
(9) Size and type of valves, regulators, meters, and valve pits, if applicable
(10) Water supply information including the following flow test information, if applicable:
  (a) Location and elevation of static and residual test gauge with relation to the elevation reference point
  (b) Flow location
  (c) Static pressure, psi (bar)
  (d) Residual pressure, psi (bar)
  (e) Flow, gpm (L/min)
  (f) Date
  (g) Time
  (h) Name of person who conducted the test or supplied the information
  (i) Other sources of water supply, with pressure or elevation
(11) Pump driver details including manufacturer and horsepower
(12) Voltage for electric motor-driven pumps
(13) Fuel system details for diesel-driven pumps
(14) Controller manufacturer, type, and rating
(15) Suction and discharge pipe, fitting, and valve types
(16) Test connection piping and valves
(17) Flow meter details, if applicable
(18) Pressure maintenance pump and controller arrangement, including sensing line details, if applicable

[**20:**4.2.3.1]

13.4.1.4.4 Each pump, driver, controlling equipment, power supply and arrangement, and liquid supply shall be approved by the AHJ for the specific field conditions encountered. [**20:**4.2.4]

13.4.1.5 Pump Operation.

13.4.1.5.1 In the event of fire pump operation, qualified personnel shall respond to the fire pump location to determine that the fire pump is operating in a satisfactory manner. [**20:**4.3.1]

A qualified person is one who is familiar with the purpose and function of the fire pump and related equipment. This person does not need to be qualified to work on the pump but should be trained in the operation of the pump.

The regularly scheduled nonflow test required by NFPA 25 is an excellent training opportunity that can be used to demonstrate the proper operation of pumping equipment. One of the reasons for placing a fire pump in a protected enclosure, as required in 13.4.2, is to provide protection for both the pump operator and the pumping equipment. Consideration should be given to locating the fire pump room at grade level, with direct access to the exterior of the building, to afford quick and easy egress for the pump operator and access to the pumping equipment for fire department personnel.

13.4.1.5.2 System Designer.

13.4.1.5.2.1 The system designer shall be identified on the system design documents. [**20:**4.3.2.1]

13.4.1.5.2.2 Acceptable minimum evidence of qualifications or certification shall be provided when requested by the AHJ. [**20:**4.3.2.2]

Exhibit 13.21

PUMP INSTALLATION PLAN CHECKLIST

General
- ❑ Name of owner or occupant
- ❑ Location including street address
- ❑ Point of compass
- ❑ Name and address of designer and installing contractor
- ❑ Listed pump, make, model number, driver type, and rated capacity
- ❑ Type of system supplied by pump
- ❑ Design standard used including edition

Water Supply Characteristics
- ❑ Flow test data not more than 5 years old
- ❑ Underground main of adequate size
- ❑ Water storage tank of adequate capacity with automatic refill connection

Suction Piping
- ❑ Proper size
- ❑ Galvanized or painted on the inside for corrosion protection
- ❑ Isolation valve (OS&Y) in the proper location
- ❑ Backflow prevention or other device in proper location
- ❑ Elbows in the proper orientation or more than 10 pipe diameters away from suction flange of pump
- ❑ Eccentric reducer (if needed) installed correctly
- ❑ Pump bypass
- ❑ Suction and discharge pressure gauges
- ❑ Circulation relief valve

Discharge Piping
- ❑ Proper size
- ❑ Check valve
- ❑ Discharge isolation valve

Fire Pump Controller
- ❑ Listed for type of pump served
- ❑ If electric, type and arrangement of power supply

Water Flow Test Devices
- ❑ Test header or flowmeter
- ❑ Proper number of 2½ in. hose valves on test header
- ❑ Test header piping of proper size
- ❑ Proper size of flowmeter (if provided)

Jockey Pump
- ❑ Jockey pump bypasses fire pump
- ❑ Separate and dedicated sensing line for jockey pump
- ❑ Sensing lines ½ in. diameter and of brass, copper, or stainless steel piping
- ❑ No shutoff valves in sensing lines

Isolation Valves
- ❑ All isolation valves supervised in the open position
- ❑ Test header and flowmeter valves supervised in the closed position

Diesel Fire Pump
- ❑ Relief valve (if provided) with no isolation valves
- ❑ Two storage batteries provided with charger
- ❑ Cooling system from heat exchanger or cooling water supply from pump discharge
- ❑ Diesel tank located above ground
- ❑ Diesel tank of sufficient capacity 1 gallon per horsepower (gal/hp) plus 10 percent

Notes:
1. For all types of pumping equipment, a complete bill of material should be provided. This list should include the make, model, and part numbers of all components.
2. For all electrically operated pumps, provide an electrical schematic drawing that depicts which components are proposed for the power supply from the utility connection to the pump motor controller.
3. Ratings of all equipment and components and settings of breakers, fuses, switches, and transformers should be indicated. Size and length of all circuit conductors should also be noted.

Checklist for plan of proposed installation.

Δ **13.4.1.5.2.3** Qualified personnel shall include, but not be limited to, one or more of the following:

(1) Personnel who are factory trained and certified for fire pump system design of the specific type and brand of system being designed
(2) Personnel who are certified by a nationally recognized fire protection certification organization acceptable to the AHJ
(3) Personnel who are registered, licensed, or certified by a state or local authority

[**20:**4.3.2.3]

13.4.1.5.2.4 Additional evidence of qualification or certification shall be permitted to be required by the AHJ. [**20:**4.3.2.4]

13.4.1.5.3 System Installer.

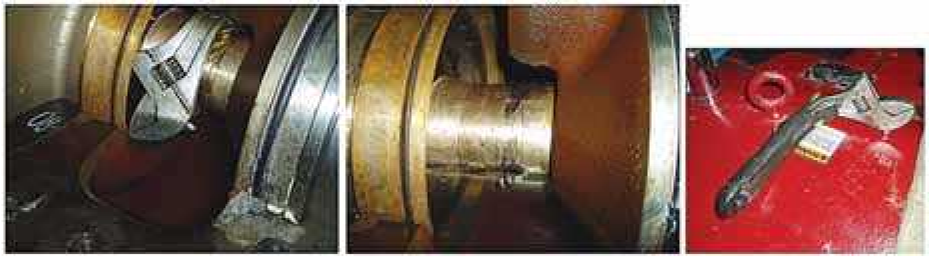
13.4.1.5.3.1 Installation personnel shall be qualified or shall be supervised by persons who are qualified in the installation, inspection, and testing of fire protection systems [**20:**4.3.3.1].

13.4.1.5.3.2 Minimum evidence of qualifications or certification shall be provided when requested by the AHJ. [**20:**4.3.3.2]

Δ **13.4.1.5.3.3** Qualified personnel shall include, but not be limited to, one or more of the following:

(1) Personnel who are factory trained and certified for fire pump system installation of the specific type and brand of system being designed

Exhibit 13.22



Fire pump damage from careless installation and maintenance procedures. (Courtesy of Aon Fire Protection Engineering)

(2) Personnel who are certified by a nationally recognized fire protection certification organization acceptable to the AHJ
(3) Personnel who are registered, licensed, or certified by a state or local authority

[**20:**4.3.3.3]

13.4.1.5.3.4 Additional evidence of qualification or certification shall be permitted to be required by the AHJ. [**20:**4.3.3.4]

13.4.1.5.4 Service Personnel Qualifications and Experience.

13.4.1.5.4.1 Service personnel shall be qualified and experienced in the inspection, testing, and maintenance of fire protection systems. [**20:**4.3.4.1]

Δ **13.4.1.5.4.2** Qualified personnel shall include, but not be limited to, one or more of the following:

(1) Personnel who are factory trained and certified for fire pump system servicing of the specific type and brand of system being designed
(2) Personnel who are certified by a nationally recognized fire protection certification organization acceptable to the AHJ
(3) Personnel who are registered, licensed, or certified by a state or local authority
(4) Personnel who are employed and qualified by an organization listed by a nationally recognized testing laboratory for the servicing of fire protection systems

[**20:**4.3.4.2]

13.4.1.5.4.3 Additional evidence of qualification or certification shall be permitted to be required by the AHJ. [**20:**4.3.4.3]

13.4.2* Equipment Protection.

Subsection 13.4.2 provides requirements and guidance on the proper placement of a fire pump and related equipment. It is also intended to provide a relatively safe environment for the equipment operator. In accordance with 13.4.1.5, a qualified fire pump operator will report to the fire pump room to confirm that the equipment is operating properly in the event of operation of the pump. By locating the fire pump room near an exterior wall and enclosing the equipment in a fire-rated room, the operator is provided with a means of egress, and both the operator and the equipment are protected from fire exposure.

Although not specifically addressed in this subsection, damage to fire pump systems can occur from careless installation and maintenance procedures. Exhibit 13.22 shows the effect of one such incident.

Multiple fire pumps can be located in one fire pump room. Although not required by this *Code*, separate rooms might be required by the insuring authority where redundant pumps are not required by this *Code* but are installed because of risk management considerations.

The intent of this subsection, by requiring fire separation, is to locate a fire pump and its related equipment in a dedicated fire pump room. For installations with multiple pumps, a single fire pump room is needed. Fire pumps must not be located in mechanical equipment spaces, which would expose the equipment and the operator to damage and potential injury.

A.13.4.2 Special consideration needs to be given to fire pump installations installed belowgrade. Light, heat, drainage, ventilation, and potential flooding are several of the variables that need to be addressed. Some locations or installations might not require a pump house. Where a pump room or pump house is required, it should be of ample size and located to permit short and properly arranged piping. The suction piping should receive first consideration. The pump house should preferably be a detached building of noncombustible construction. A one-story pump room with a combustible roof, either detached or well protected from an adjoining one-story building, is acceptable if sprinklered. Where a detached building is not feasible, the pump room should be located and constructed to protect the pump unit and controls from falling floors or machinery, and from fire that could drive away the pump operator or damage the pump unit or controls. Access to the pump room should be provided from outside the building. Where the use of brick or reinforced concrete is not feasible, metal lath and plaster is recommended for the construction of the pump room. The pump room or pump house should not be used for storage purposes. Vertical shaft turbine–type pumps might necessitate a removable panel in the pump house roof to permit the pump to be removed for inspection or repair. Proper clearances to equipment should be provided as recommended by the manufacturer's drawings. [**20:**A.4.13]

13.4.2.1* General Requirements. The fire pump, driver, controller, water supply, and power supply shall be protected against possible interruption of service through damage caused by explosion, fire, flood, earthquake, rodents, insects, windstorm, freezing, vandalism, and other adverse conditions. [**20:**4.13.1]

A.13.4.2.1 A fire pump that is inoperative for any reason at any time constitutes an impairment to the fire protection system. It should be returned to service without delay. [**20:**A.4.12.1]

Rain and intense heat from the sun are adverse conditions to equipment not installed in a completely protective enclosure. At a minimum, equipment installed outdoors should be shielded by a roof or deck. [**20:**A.4.12.1]

13.4.2.1.1* Indoor Fire Pump Units.

A.13.4.2.1.1 Most fire departments have procedures requiring operation of a fire pump unit during an incident. Building designers should locate the fire pump room to be easily accessible during an incident. [**20:**A.4.12.1.1]

13.4.2.1.1.1 Except as permitted in 13.4.2.1.1.3, fire pump units serving high-rise buildings shall be protected from surrounding occupancies by a minimum of 2-hour fire-rated construction or physically separated from the protected building by a minimum of 50 ft (15.3 m). [**20:**4.13.1.1.1]

A minimum of 50 ft (15.3 m) of separation or a 2-hour fire-rated enclosure will protect the building's fire pump and personnel from an exposure fire.

13.4.2.1.1.2* Except as permitted in 13.4.2.1.1.3, indoor fire pump rooms in non-high-rise buildings or in separate fire pump buildings shall be physically separated or protected by fire-rated construction in accordance with Table 13.4.2.1.1.2. [**20:**4.13.1.1.2]

A.13.4.2.1.1.2 The purpose for the "Not Sprinklered" column in Table 13.4.2.1.1.2 is to provide guidance for unsprinklered buildings. This does not permit sprinklers to be omitted from pump rooms in fully sprinklered buildings. [**20:**A.4.12.1.1.2]

For the purposes of Table 13.4.2.1.1.2, a building with a fire protection system(s) supplied from the fire pump is considered to be a building exposing the pump room/house. There may also be other buildings or hazards that expose the pump room/house.

TABLE 13.4.2.1.1.2 *Equipment Protection*

Pump Room/House	Building(s) Exposing Pump Room/House	Required Separation
Not sprinklered Not sprinklered Fully sprinklered	Not sprinklered Fully sprinklered Not sprinklered	2 hour fire-rated or 50 ft (15.3 m)
Fully sprinklered	Fully sprinklered	1 hour fire-rated or 50 ft (15.3 m)

[**20:** Table 4.13.1.1.2]

The purpose of Table 13.4.2.1.1.2 is to prevent a fire in the protected building from impairing the fire pump that provides protection to the protected building. A fire pump located a minimum of 50 ft (15.3 m) from a protected building is adequately protected from a fire in that building. A fire in the fire pump enclosure could still impair the fire pump; however, a fire in the fire pump enclosure is unlikely to occur simultaneously with a fire in the protected building.

N **13.4.2.1.1.3** Fire pump units supplying a local application fire protection system(s) shall be physically separated from the hazard being protected in a manner that will prevent a fire associated with the hazard from directly exposing the pumping unit. [**20:**4.12.1.1.3]

13.4.2.1.1.4 The location of and access to the fire pump room shall be preplanned with the fire department. [**20:**4.13.1.1.3]

13.4.2.1.1.5* Except as permitted in 13.4.2.1.1.6, rooms containing fire pumps shall be free from storage, equipment, and penetrations not essential to the operation of the pump and related components. [**20:**4.13.1.1.4]

It is the intent of this *Code* to prohibit the use of a fire pump room for the purposes of storage. It is not the intent of this *Code* to prohibit the installation of other types of equipment such as domestic water distribution equipment, as indicated in 13.4.2.1.1.6. No materials or equipment that add to the combustibility of the space should be placed in the fire pump room. This provision is intended to provide protection to equipment as well as operating personnel.

A.13.4.2.1.1.5 Equipment that increases the fire hazard (such as boilers) and is not related to fire protection systems should not be in a fire pump room. [**20:**A.4.12.1.1.4]

13.4.2.1.1.6 Equipment related to domestic water distribution shall be permitted to be located within the same room as the fire pump equipment. [**20:**4.13.1.1.5]

Δ **13.4.2.1.1.7** The pump room or pump house shall be sized to fit all of the components necessary for the operation of the fire pump and to accommodate the following:

(1) Clearance between components for installation and maintenance
(2) Clearance between a component and the wall for installation and maintenance
(3) Clearance between energized electrical equipment and other equipment in accordance with *NFPA 70*
(4) Orientation of the pump to the suction piping to allow compliance with 4.15.6.3 of NFPA 20

[**20:**4.13.1.1.6]

13.4.2.1.2 Outdoor Fire Pump Units.

Exhibit 13.23 shows an outdoor fire pump unit.

13.4.2.1.2.1 Fire pump units that are outdoors shall be located at least 50 ft (15.3 m) away from any buildings and other fire exposures exposing the building. [**20:**4.13.1.2.1]

Exhibit 13.23

Outdoor fire pump installation. (Courtesy of Aon Fire Protection Engineering)

13.4.2.1.2.2 Outdoor installations shall be required to be provided with protection against possible interruption, in accordance with 13.4.2.1. [**20:**4.13.1.2.2]

13.4.2.2 Equipment Access.

13.4.2.2.1 The location of and access to the fire pump room(s) shall be pre-planned with the fire department. [**20:**4.13.2.1]

A properly operating fire pump is essential to fire department fire-fighting operations. Coordinating the location and access with the fire department is necessary to allow monitoring by the fire department.

13.4.2.2.1.1 Except as provided in 13.4.2.2.1.1.1 fire pump rooms not directly accessible from the outside shall be accessible through an enclosed passageway from an enclosed stairway or exterior exit. [**20:**4.13.2.1.1]

N **13.4.2.2.1.1.1** Fire pump units supplying only local application fire protection systems shall be accessible by a path that is not subject to exposure from a fire in any hazard protected by the fire pump. [**20:**4.13.2.1.1.1]

13.4.2.2.1.2 The enclosed passageway shall have a fire-resistance rating not less than the fire-resistance rating of the fire pump room. [**20:**4.13.2.1.2]

A properly operating fire pump is essential to fire department operations. Fire pump rooms should be accessible under fire conditions to allow the fire department to monitor the fire pump to provide early warning and modifications to the fire-fighting operations should a fire pump not operate satisfactorily. Where a fire pump room cannot be located on grade with direct access from outside the building, a protected space with a fire rating in accordance with Table 13.4.2.1.1.2 must be provided. The space must be accessible through an enclosed passageway from an exterior exit or from an enclosed stairway.

13.4.2.3 Heat.

13.4.2.3.1 An approved or listed source of heat shall be provided for maintaining the temperature of a pump room or pump house, where required, above 40°F (4°C). [**20:**4.13.3.1]

Although maintaining the water temperature above 32°F (0°C) will prevent freezing, maintaining a minimum temperature of 40°F (4°C) provides a safety factor to account for isolated temperature variations and the accuracy of the temperature control equipment.

13.4.2.3.2 The requirements of 13.4.4.5 shall be followed for higher temperature requirements for internal combustion engines. [**20:**4.13.3.2]

Temperatures above 40°F (4°C) may be necessary to ensure starting of diesel engines.

13.4.2.4 Normal Lighting. Artificial light shall be provided in a pump room or pump house. [**20:**4.13.4]

13.4.2.5 Emergency Lighting.

Δ **13.4.2.5.1** Emergency lighting shall be provided in accordance with NFPA *101*.

13.4.2.5.2 Emergency lights shall not be connected to an engine-starting battery. [**20:**4.13.5.2]

13.4.2.6 Ventilation. Provision shall be made for ventilation of a pump room or pump house. [**20:**4.13.6]

For an engine drive pump, the ventilation must be adequate to provide combustion air. See 11.3.2 of NFPA 20.

13.4.2.7* Drainage.

A.13.4.2.7 Pump rooms and pump houses should be dry and free of condensate. To accomplish a dry environment, heat might be necessary. [**20:**A.4.12.7]

13.4.2.7.1 Floors shall be pitched for adequate drainage of escaping water away from critical equipment such as the pump, driver, controller, and so forth. [**20:**4.13.7.1]

13.4.2.7.2 The pump room or pump house shall be provided with a floor drain that will discharge to a frost-free location. [**20:**4.13.7.2]

Where a reduced pressure zone (RPZ) backflow prevention device is installed in a fire pump room, the discharge from the middle chamber should be piped outside, or the floor drain should be sized to accommodate the full discharge from the RPZ. An RPZ is shown in Exhibit 13.24

Δ **13.4.2.8 Guards.** Couplings and flexible connecting shafts shall be installed with a coupling guard in accordance with Section 7 of ANSI B11.19, *Performance Requirements for Safeguarding*. [**20:**4.13.8]

Exhibit 13.24

RPZ backflow prevention device. (Courtesy of Aon Fire Protection Engineering)

13.4.3* Valve Supervision.

A.13.4.3 Isolation valves and control valves are considered to be identical when used in conjunction with a backflow prevention assembly. [**20:**A.4.16]

Δ **13.4.3.1 Supervised Open.** Where provided, the suction valve, discharge valve, bypass valves, and isolation valves on the backflow prevention device or assembly shall be supervised open by one of the following methods:

(1) Central station, proprietary, or remote station signaling service
(2) Local signaling service that will cause the sounding of an audible signal at a constantly attended point
(3) Locking valves open
(4) Sealing of valves and approved weekly recorded inspection where valves are located within fenced enclosures under the control of the owner

[**20:**4.17.1]

The four methods of supervision represented in 13.4.3.1 help to ensure that a common mode of sprinkler system failure is reduced to a minimum. Approximately one-third of system failures are attributable to closed or partially closed sprinkler system control valves. The methods listed are in descending order of preference.

Central station, proprietary, or remote station supervision methods are preferred over the other methods listed. Supervisory signals received at such alarm facilities are usually forwarded to maintenance staff responsible for the protected property. This method also allows for much more efficient notification of the responding fire department (the signal is not considered a fire alarm signal and, therefore, does not require an immediate response). Early notification that a control valve has been closed for any reason might alter the fire department's response and fire-fighting tactics. However, central station, proprietary, or remote station supervision methods are not mandated by NFPA 20.

All bypass valves are required to be supervised open. Where a bypass is installed, water is expected to flow through the bypass into the fire protection system automatically — that is, without human intervention — in the event that the fire pump does not start. When the control valves are open, water can flow through the bypass automatically. A check valve, therefore, needs to be installed in the bypass line so that, when the pump is running, water does not circulate through the bypass back to the pump.

13.4.3.2 Supervised Closed. Control valves located in the pipeline to the hose valve header shall be supervised closed by one of the methods allowed in 13.4.3.1. [**20:**4.17.2]

For test headers that are installed outside or where freezing is a danger, an isolation valve as required by 4.21.3.3.1 of NFPA 20 must be installed. This valve is normally closed and is opened only for testing purposes. The valve is required to be supervised in the closed position to prevent accidental freezing of the test header. The hose header is required to have an automatic drain valve (typically a ball drip valve) where it is subject to freezing conditions.

13.4.4* Diesel Engine Driver System Operation.

A.13.4.4 Internal combustion engines necessarily embody moving parts of such design and in such number that the engines cannot give reliable service unless given diligent care. The manufacturer's instruction book covering care and operation should be readily available, and pump operators should be familiar with its contents. All of its provisions should be observed in detail. [**20:**A.11.6]

13.4.4.1 Weekly Run.

13.4.4.1.1 Engines shall be designed and installed so that they can be started no less than once a week and run for no less than 30 minutes to attain normal running temperature. [**20:**11.6.1.1]

Running the engine for a minimum of 30 minutes provides sufficient time for the engine to reach its full operating temperature and for condensation to evaporate from the crankcase. Any irregularities in the engine operation should be investigated and repaired immediately. Running the engine for this length of time also gives the operator sufficient time to check out the pump operations, the cooling loop operation, the battery chargers, and all other pump room components requiring an inspection. Subsection 8.1.2 and Table 8.1.1.2 of NFPA 25 describe the schedules and the specific requirements for periodically required maintenance items. Additionally, 8.6.1 of NFPA 25 provides the necessary testing required after repairs or upgrades are completed on any pump room component.

13.4.4.1.2 Engines shall run smoothly at rated speed, except for engines addressed in 13.4.4.1.3. [**20:**11.6.1.2]

13.4.4.1.3 Engines equipped with variable speed pressure limiting control shall be permitted to run at reduced speeds provided factory-set pressure is maintained and they run smoothly. [**20:**11.6.1.3]

13.4.4.2* Engine Maintenance. Engines shall be designed and installed so that they can be kept clean, dry, and well lubricated to ensure adequate performance. [**20:**11.6.2]

A.13.4.4.2 See NFPA 25, for proper maintenance of engine(s), batteries, fuel supply, and environmental conditions. [**20:**A.11.6.2]

13.4.4.3 Battery Maintenance.

13.4.4.3.1 Storage batteries shall be designed and installed so that they can be kept charged at all times. [**20:**11.6.3.1]

13.4.4.3.2 Storage batteries shall be designed and installed so that they can be tested frequently to determine the condition of the battery cells and the amount of charge in the battery. [**20:**11.6.3.2]

Lead-acid batteries last between 24 months and 30 months of service. When replacements of batteries are required, it is best to replace both units where two batteries are required to make a starting set. This is particularly true in a system requiring two batteries to make a set (24 V dc). See NFPA 25 for the recommended replacement schedule.

13.4.4.3.3 Only distilled water shall be used in battery cells. [**20:**11.6.3.3]

13.4.4.3.4 Battery plates shall be kept submerged at all times. [**20:**11.6.3.4]

If the battery requires an excessive amount of replacement water, the battery should be checked to make sure it is not overcharging. Also, the battery plates need to be covered with water to help eliminate the possibility of battery explosions. Exposed plates can create an arc or a spark, which can ignite the hydrogen gases present during the starting and charging cycles.

13.4.4.3.5 The automatic feature of a battery charger shall not be a substitute for proper maintenance of battery and charger. [**20:**11.6.3.5]

13.4.4.3.6 The battery and charger shall be designed and installed so that periodic inspection of both battery and charger is physically possible. [**20:**11.6.3.6]

13.4.4.3.6.1 This inspection shall determine that the charger is operating correctly, the water level in the battery is correct, and the battery is holding its proper charge. [**20:**11.6.3.6.1]

13.4.4.4* Fuel Supply Maintenance.

Δ **A.13.4.4.4** Active systems that are permanently added to fuel tanks for removing water and particulates from the fuel can be acceptable, provided the following apply:

(1) All connections are made directly to the tank and are not interconnected with the engine or its fuel supply and return piping in any way.
(2) There are no valves or other devices added to the engine or its fuel supply and return piping in any way.

13.4.4.4.1 The fuel storage tanks shall be designed and installed so that they can be kept as full and maintained as practical at all times but never below 66 percent (two-thirds) of tank capacity. [**20:**11.6.4.1]

13.4.4.4.2 The tanks shall be designed and installed so that they can always be filled by means that will ensure removal of all water and foreign material. [**20:**11.6.4.2]

13.4.4.5* Temperature Maintenance.

A.13.4.4.5 Proper engine temperature, in accordance with 11.2.8.2 of NFPA 20 and 13.4.4.5.1, maintained through the use of a supplemental heater has many benefits, as follows:

(1) Quick starting (a fire pump engine might have to carry a full load as soon as it is started)
(2) Reduced engine wear
(3) Reduced drain on batteries
(4) Reduced oil dilution
(5) Reduced carbon deposits, so that the engine is far more likely to start every time

[**20:**A.11.6.5]

13.4.4.5.1 The temperature of the pump room, pump house, or area where engines are installed shall be designed so that the temperature is maintained at the minimum recommended by the engine manufacturer and is never less than the minimum recommended by the engine manufacturer. [**20:**11.6.5.1]

Fuel tanks installed outdoors generate a greater volume of water from condensation than do tanks installed inside the fire pump room.

If possible, diesel fuel tanks should be located inside the pump room, where they will be subjected to fewer temperature variances. If a diesel fuel tank is placed outside, fuel maintenance intervals should be increased because the fuel tank is likely to have additional condensate buildup inside the tank. Tank drain valves should be added to the end of the tank opposite the fuel line that feeds the fuel pump to allow for removal of sediment and water. The valves should be closed at all times except annually, when 5 gal (20 L) of diesel fuel should be removed from the bottom of the tank. This will minimize the amount of debris that could enter the fuel pump.

13.4.4.6 Emergency Starting and Stopping.

13.4.4.6.1 The sequence for emergency manual operation, arranged in a step-by-step manner, shall be posted on the fire pump engine. [**20:**11.6.6.1]

13.4.4.6.2 It shall be the engine manufacturer's responsibility to list any specific instructions pertaining to the operation of this equipment during the emergency operation. [**20:**11.6.6.2]

The manufacturer's instructions and the sequence of steps for emergency manual operation must be clearly posted, typically on the engine near the instrument panel, since it is possible that a person not strictly qualified in accordance with 13.4.1.5 will be the responder in an emergency.

13.4.5 Components.

13.4.5.1 Indicators on Controller.

13.4.5.1.1 All visible indicators shall be plainly visible. [**20:**12.4.1.1]

13.4.5.1.2* Visible indication shall be provided to indicate that the controller is in the automatic position. If the visible indicator is a pilot lamp, it shall be accessible for replacement. [**20:**12.4.1.2]

Visible indication is necessary whether the controller is located in a dark room, in a brightly lit pump house, or outdoors. This requirement applies to alarm, trouble, and status indicators, as well as digital displays.

Legacy, or traditional, controllers commonly used incandescent lamp–type or pilot light–type indicators. Some modern controllers make use of LED-type indicators and/or digital displays in one form or another. Most now make use of touch-sensitive display screens. All controllers make use of multiple menu screens for accessing additional data and for entering parametric data such as enabling or disabling options, setting timer values, start and stop pressure settings, alarm set-points, and so on.

A.13.4.5.1.2 It is recommended that the pilot lamp for signal service have operating voltage less than the rated voltage of the lamp to ensure long operating life. When necessary, a suitable resistor should be used to reduce the voltage for operating the lamp. [**20:**A.12.4.1.2]

This recommendation was important for legacy controllers, which made use of filament-type pilot lights. Other controllers use 14 V and 28 V rated lamps for 12 V dc and 24 V dc rated systems, respectively. This is one reason why replacement lamps should be what the controller manufacturer recommends.

The life of filament (incandescent) lamps is inversely proportional to the 12th power of the voltage. Hence, operating a 14 V lamp at 13.2 V dc (typical battery charger float voltage) is a 9.1 percent reduction in voltage, which results in approximately a 314 percent increase in lamp life.

Δ **13.4.5.1.3** Separate visible indicators and a common audible fire pump alarm capable of being heard while the engine is running and operable in all positions of the main switch except the off position shall be provided to immediately indicate the following conditions:

The audible device must be capable of being heard. Traditionally, controllers used alarm bells or horns that could usually be heard over the noise of a running engine. The exception was 3000 rpm engines, which are not as prevalent as they once were. It is important to note that solid-state devices, such as piezoelectric beepers, are sometimes used and are sometimes not audible over the sound of a running engine.

(1) Critically low oil pressure in the lubrication system.

The oil pressure referred to is lube oil pressure, not fuel oil pressure. In most, if not all, cases the testing is accomplished by switching the controller to the manual mode or one of the two manual modes (MAN1 or MAN2), not by cranking the engine. The low oil pressure switch should be closed in manual mode, and the controller visible indicator should be lit. However, the audible device and remote failure contacts should remain in their "normal" (non-alarm) state. Typically, there is a delay time of a few seconds after the controller receives the cranking terminating (engine running) signal from the engine speed switch prior to actuating the audible device and alarm contacts. This delay is intended to prevent false alarms. See also 12.7.2.7.4 and 12.7.2.7.5 of NFPA 20.

(2) High engine temperature.

Similar to the low lube oil pressure alarm, the controller will not shut down the engine due to a high water alarm condition if it is running under a true demand, such as pressure loss, remote start, and so forth. The controller will shut down the engine if it is running under test. Note that some engines add an oil pressure switch in series with the high temperature switch to avoid false alarms after a high horsepower demand running. See also 12.7.2.7.4 and 12.7.2.7.5 of NFPA 20 for further requirements and information.

(3) Failure of engine to start automatically.

This condition occurs if the engine fails to start after six cranking attempts or if the engine (speed switch) fails to notify the controller that the engine is running. See 12.7.4 of NFPA 20 for more information. The controller treats this condition as a shutdown requirement, even though the engine might not be running. The reason for this shutdown is to kill the water and fuel solenoids to avoid further battery drain and also to avoid cooling water drain, which can be significant over an extended period, such as a 3-day weekend.

(4) Shutdown from overspeed.

Typically, the engine overspeed switch is set to trip at approximately 20 percent of the engine's rated running speed.

Although the general philosophy is that the fire pump and the engine are sacrificial if an overspeed condition is detected by the engine speed switch and transmitted to the controller, the controller will immediately shut down the engine. The reason is that a true engine overspeed condition is considered an imminent destruction condition. It is also a personnel safety consideration, since engines sometimes throw parts in the process of overspeed destruction. By shutting down the engine, there may also be a possibility of manual intervention to correct or temporarily remedy the situation.

(5) High cooling water temperature
[**20:**12.4.1.3]

This condition was added in the 2016 edition of NFPA 20 to correlate with the requirements of 13.4.5.1.4(11). By way of background, some field cases were found where the temperature of the "cooling" water for the diesel engine was too high to enable adequate cooling of the diesel engine when fully loaded. This is another signal that requires a switch closure on the diesel engine to notify the fire pump controller of the alarm condition. See 13.4.5.1.4(11) for more information on this alarm.

13.4.5.1.3.1 The controller shall provide means for testing the low oil pressure alarms and circuit in conjunction with the engine circuit testing method. [**20**:12.4.1.3.1]

The usual method for checking this alarm signal is to set the controller control switch to the manual position (or MAN1 or MAN2 on controllers with two manual switch positions) but not crank or start the engine. In this condition, the engine pressure switch should be closed (no oil pressure) and, consequently, the controller's low oil pressure alarm signal should be active.

13.4.5.1.3.2 Instructions shall be provided on how to test the operation of the signals in 13.4.5.1.3. [**20:**12.4.1.3.2]

Paragraph 13.4.5.1.3.2 mandates that instructions be provided for testing the alarm circuits specified in 13.4.5.1.3 because the test method for a specific engine controller was not always evident, which resulted in inadequate or no testing of alarm circuits.

Δ **13.4.5.1.4** Separate visible indicators and a common audible signal capable of being heard while the engine is running and operable in all positions of the main switch except the off position shall be provided to immediately indicate the following conditions:

(1)* Battery failure or missing battery. Each controller shall be provided with a separate visible indicator for each battery. The battery failure signal shall initiate at no lower than two-thirds of battery nominal voltage rating (8.0 V dc on a 12 V dc system). Sensing shall be delayed to prevent nuisance signals.

The battery failure signal initiates when the engine cranking voltage is too low to effectively crank (turn over) the engine. In addition to initiating the signal, the controller must also switch to the other battery set. This provision quantifies the initiation of the battery failure signal by setting a voltage limit at which initiation must commence.

As batteries age, their actual capacity (amp-hours) increases somewhat, then declines over the life of the battery. Once a battery's actual capacity returns to its initial capacity, the capacity curve will indicate that the capacity is declining rapidly and will soon be inadequate. Battery replacement is advised at this time. Note that this could also be an indication of a failed battery charger function on the newer battery or an actual failure of the newer battery.

A.13.4.5.1.4(1) The controller can set the signal trip point above the two-thirds level. But, higher than ¾ of nominal is not recommended to avoid false signals during normal battery aging. [**20:**A.12.4.1.4(1)]

Cranking voltage under normal conditions (nominal batteries fully charged and nominal engine cranking current) typically will be 80 percent of nominal, or around 9.5 volts on a 12 V dc nominal system or around 19 volts on a 24 V dc system. Cranking voltage of 75 percent of nominal is still acceptable; however, it indicates that the system needs attention. This is because cranking voltages this low indicate either excessive starter motor draw, inadequately charged batteries, or batteries that are approaching end of life. End of life means that the battery capacity has dropped, or is dropping, below nominal rated capacity (ampere hour or A-H capacity or, alternatively, the battery's reserve capacity rating).

(2) Battery charger failure. Each controller shall be provided with a separate visible indicator for battery charger failure and shall not require the audible signal for battery charger failure.

The controller is required to actuate a signal if the battery charger either fails to maintain the charge in the battery or fails to recharge the battery as required. Some controllers trip the charger failure alarm *before* the batteries lose their charge. This is done by setting the alarm trip voltage around halfway between the nominal charger float voltage and the battery's full charge open circuit voltage. For typical SAE 8D truck-type starting batteries, the trip voltage would be around 12.75 (halfway between 13.2 and 12.5 V dc) for a 12 V dc nominal system. Equipment with lower trip set-points will result in either a partially discharged or a fully discharged battery before tripping the charger failure alarm. See Sections 12.5 and 12.6 of NFPA 20 for more requirements.

(3) Low air or hydraulic pressure. Where air or hydraulic starting is provided *(see 11.2.7 and 11.2.7.4 of NFPA 20)*, each pressure tank shall provide to the controller separate visible indicators to indicate low pressure.

A low air or low hydraulic pressure condition is analogous to the battery failure alarm and its need for a signal. Note that while not commonly used, a controller for either hydraulically or pneumatically started engines will usually make use of two batteries for controller power, although these batteries may be fairly small. In any event, the controller usually will still be provided with the battery failure and charger failure alarms, since both the battery and the charger remain critical to the operation of the fire pump.

(4) System overpressure, for engines equipped with variable speed pressure limiting controls, to actuate at 115 percent of set pressure.

Pressure limiting diesel drivers use feedback from the pump discharge pressure to modulate the speed governor setting. The system overpressure signal is used to indicate a problem or manual intervention resulting in pressure higher than the desired set-point value. This signal also indicates that the main pressure relief valve might be open and flowing large quantities of water or that it might not be working at all. See Section 4.19 of NFPA 20 for more information on relief valves.

(5) ECM selector switch in alternate ECM position (only for engines with ECM controls).

Note that this position should also indicate when the alternate electronic control module (ECM) is selected automatically by the engine.

(6) Common alarm for fuel injection malfunction (only for engines with ECM).

This signal from the engine occurs when the ECM detects an internal failure.

(7) Low fuel level. Signal at two-thirds tank capacity.

The low fuel alarm alerts those responsible for maintaining the fire pump in good operating condition. NFPA 20 requires that a diesel fuel tank be capable of containing enough fuel for 8 hours of pump run time. The standard also allows the fuel tank level to drop as low as two-thirds capacity, which equates to 6 hours run time. It is important that the fuel level not drop below the two-thirds level because it is not uncommon for fire pumps to run for long durations during a fire event. Exhibit 13.25 shows a low fuel level switch.

(8) Low air pressure (air-starting engine controllers only). The air supply container shall be provided with a separate visible indicator to indicate low air pressure.
(9) Low engine temperature.

The low engine temperature alarm picks up the low engine temperature sensor. This signal indicates that there is a loss of ac (mains) power to the engine heater or a malfunction of the heater, that the heater is unplugged or disconnected, or that the heater has a kinked or plugged hose(s).

(10) Supervisory signal for interstitial space liquid intrusion.
(11) High cooling water temperature.
(12) Fuel maintenance needed if automatic fuel maintenance system is provided.
[**20:**12.4.1.4]

Traditionally, diesel fuels of the type used for diesel fire pump engines had a certain amount of sulfur content. This was beneficial to the engines since it not only added a certain amount of upper cylinder lubrication but also acted as a biocide — that is, it retarded or prevented the growth of biologicals, namely bacteria (algae) and fungi. Modern fuels are of the low-sulfur type. As a result, biological growth poses a problem, especially with fuel tanks that store the fuel for extended periods of time. Note that biological growth is not usually a problem for vehicles because their fuel is used at a faster rate and hence is a deterrent to biological growth.

Growth of biologicals can clog fuel filters and create other problems for fire pump engines. As a result, it is now common for fire pump fuel tanks to be equipped with some sort of maintenance program or device to prevent or retard such growth. This maintenance could be periodic service from a fuel supplier or other vendor or be an automatic fuel treatment system such as is common with boiler feed water. The automatic systems themselves might require periodic maintenance. If an automatic device is used, the controller must provide a signal (e.g., contact closure) when the system needs attention or maintenance.

Exhibit 13.25

Low fuel level switch. (Courtesy of Master Control Systems, Inc.)

13.4.5.1.5 A separate signal silencing switch or valve, other than the controller main switch, shall be provided for the conditions reflected in 13.4.5.1.3 and 13.4.5.1.4. [**20:**12.4.1.5]

Field experience has demonstrated situations in which audible alarms were disabled, resulting in no audible alarm for a new alarm condition and situations in which the fire pump failed to respond when needed. Paragraphs 13.4.5.1.5.1, 13.4.5.1.5.2, and 13.4.5.1.5.3 specify the conditions under which any of the audible alarms in 13.4.5.1.3 or signals in 13.4.5.1.4 may be silenced.

Audible alarm and signal silencing requirements address situations in which conditions that are alarmed cannot be corrected immediately (such as low engine temperature or fuel injection malfunction alarms). In such situations, it could take 24 hours or longer to correct the condition. Under such circumstances, it is not necessary to acknowledge the alarm until the condition is corrected. In addition, the alarm is unavailable for additional alarm conditions during that period. The words "or valve" address controllers that operate pneumatically or use fluidic logic rather than traditional electrical circuitry.

13.4.5.1.5.1 The switch or valve shall allow the audible device to be silenced for up to 4 hours and then re-sound repeatedly for the conditions in 13.4.5.1.3, [**20:**12.4.1.5.1.]

The trouble conditions specified in 13.4.5.1.3 could exist for extended periods. Silencing these alarms is needed in the case of attended pump rooms. Silencing is also needed to avoid unnecessary battery drain during power outages and to avoid the controller being taken out of service to quiet the alarm.

13.4.5.1.5.2 The switch or valve shall allow the audible device to be silenced for up to 24 hours and then re-sound repeatedly for the conditions in 13.4.5.1.4. [**20:**12.4.1.5.2]

The trouble conditions specified in 13.4.5.1.4 could exist for extended periods. Silencing these alarms is needed in the case of attended pump rooms. Silencing is also needed to avoid unnecessary battery drain during power outages and to avoid the controller being taken out of service to quiet the alarm.

13.4.5.1.5.3 The audible device shall re-sound until the condition is corrected or the main switch is placed in the off position. [**20:**12.4.1.5.3]

13.4.5.1.6* The controller shall automatically return to the nonsilenced state when the alarm(s) have cleared (returned to normal). [**20:**12.4.1.6]

A.13.4.5.1.6 This automatic reset function can be accomplished by the use of a silence switch of the automatic reset type or of the self-supervising type. [**20:**A.12.4.1.6]

13.4.5.1.6.1 This switch shall be clearly marked as to its function. [**20:**12.4.1.6.1]

13.4.5.2 Signal Devices Remote from Controller.

13.4.5.2.1 Where the pump room is not constantly attended, audible or visible signals powered by a source other than the engine starting batteries and not exceeding 125 V shall be provided at a point of constant attendance. [**20:**12.4.2.1]

Paragraph 13.4.5.2.1 requires the fire pump controller to be constantly monitored or supervised. This is not a requirement of the controller, although the controller is required to provide the contacts necessary to fulfill this requirement.

A boiler room where operating personnel are required 24 hours a day is one type of a constantly attended location. Because most new installations are not able to satisfy the provisions for a constantly attended location, a remote alarm panel often is installed at a place of constant attendance, such as a guard house or a 24-hour phone switchboard. Although these units are termed *alarm sets* or *alarm panels*, they are usually not built or sold as alarm equipment in accordance with *NFPA 72®, National Fire Alarm and Signaling Code.*

As an alternative, the AHJ may require an off-site fire alarm monitoring station or alarm service. Note that a fire alarm monitoring station is often preferred. These signals are not considered a fire alarm as defined in *NFPA 72*. They would instead be considered supervisory or trouble signals. The monitoring station would normally notify the plant personnel, rather than the fire department, when these signals occur. A notable exception can be the engine running signal. This signal is often used to meet the required weekly line test function of *NFPA 72*, since this signal will — or should — occur during the weekly ½-hour engine test run. When an engine running signal occurs during any time other than during the expected weekly test run, the alarm company may signal the fire department of a potential fire.

The 125 V maximum requirement is to avoid imposing higher voltages on the controller remote alarm contacts of 13.4.5.3. This voltage is often the maximum voltage rating of these contacts.

13.4.5.2.2 Remote Indication. Controllers shall be equipped to operate circuits for remote indication of the conditions covered in 13.4.5.1.3, 13.4.5.1.4, and 13.4.5.2.3. [**20:**12.4.2.2]

The controller is required to have at least three sets of contacts for engine running, switch-off, and engine (or controller) failure. Many controllers have more than these three sets as a standard, and all controllers are available with additional or individual alarm contacts for the various conditions supervised by the controller.

Δ **13.4.5.2.3** The remote panel shall indicate the following:

(1) The engine is running (separate signal).

It is good practice for the weekly test run to be attended to monitor the starting and running conditions of the engine and the controller. It is imperative that appropriate personnel be immediately dispatched to the pump room at any other time the engine is running to determine the cause and to monitor the engine and controller operation, because it is highly likely that the engine and the controller are supplying, or attempting to supply, water for fire fighting. Note that with building alarm systems, the fire pump running signal may be programmed either as a fire alarm signal or as a trouble signal. In the case of the latter, it is up to the remote monitoring facility to determine whether to call the fire department to the building. This sometimes includes calling the building in question.

(2) The controller main switch has been turned to the off or manual position (separate signal).

If the controller control or selector switch is not in the auto (automatic) mode position, the controller, the engine, and thus the fire pump are out of service. For a sole source pump installation, which is a common situation, that means the protected premises (building, plant, etc.) has no fire protection. This condition may require a fire watch or even that a fire pump truck to be connected to the building until fire protection is restored.

(3)* There is trouble on the controller or engine (separate or common signals). *(See 13.4.5.1.4 and 13.4.5.1.5.)*

[**20:**12.4.2.3]

Δ **A.13.4.5.2.3(3)** The following signals should be monitored remotely from the controller:

(1) A common signal can be used for the following trouble indications: the items in 13.4.5.1.4(1) through 13.4.5.1.4(7) and loss of output of battery charger on the load side of the dc overcurrent protective device.
(2) The arrangement specified in A.13.4.5.2.3(3) is permitted only where approved by the AHJ in accordance with Section 1.5 of NFPA 20 and allows, upon loss of the ac power supply, the batteries to maintain their charge, activates ventilation in case conditions require cooling the engine, and/or maintains engine temperature in case conditions require heating the engine. *(See also A.4.6.4 and A.11.4.1.3.1 of NFPA 20.)*

[**20:**A.12.4.2.3(3)]

It is suggested that, when the engine is allowed by the AHJ to be run to charge the batteries or keep the pump room temperature above freezing, it should not be run any longer than necessary. The AHJ may require the controller to be set up for automatic stop operation after a minimum running period, typically 30 minutes.

In some cases, the AHJ requires power failure pump starting where hot processes are involved, such as with furnaces and molten salt baths. The purpose is to bring the fire water supply on-line because plantwide power loss will result in the loss of cooling fans, blowers, and/or pumps, which presents an increased likelihood of a fire.

13.4.5.3 Controller Contacts for Remote Indication. Controllers shall be equipped with open or closed contacts to operate circuits for the conditions covered in 13.4.5.2. [**20:**12.4.3]

These contacts are part of the fire pump controller. Modern controllers employ contacts rated for 1.0 amp or less at 125 V ac or 28 V dc. See also the commentary to 13.4.5.2.1 of this *Code* and 12.4.4 of NFPA 20.

13.4.6 Field Acceptance Tests.

The field acceptance test evaluates the pump performance over a range of conditions to assess the performance of the installation and to ensure that the pump will perform as needed during an actual fire. The acceptance should be completely documented to serve as a baseline for subsequent performance testing required by NFPA 25.

13.4.6.1* The pump manufacturer, the engine manufacturer (when supplied), the controller manufacturer, and the transfer switch manufacturer (when supplied) or their factory-authorized representatives shall be present for the field acceptance test. *(See Section 4.4 of NFPA 20.)* [**20:**14.2.1]

NFPA 20 requires a single entity to have the responsibility for ensuring a properly completed, tested, and accepted fire pump installation. To that end, 13.4.6.1 requires that all key component manufacturers or their representatives be present at the field acceptance test. The presence of the manufacturer's representatives allows any problems with the quality of the installation, the equipment, and the performance of the completed fire pump installation to be effectively identified and corrected to the satisfaction of the owner, the design entity, the AHJ, the installing contractor, and any other involved parties.

A.13.4.6.1 In addition, representatives of the installing contractor, insurance company, and owner should be present. [**20:**A.14.2.1]

13.4.6.2 The date, time, and location of the field acceptance test shall be coordinated with the AHJ. [**20:**14.2.2]

The requirement of 13.4.6.1 can be met by the presence of a single factory-authorized representative.

In many cases, the local fire/building official ultimately has legal jurisdictional responsibility and may be needed to approve an installation or even issue a valid Certificate of Occupancy. As such, adequate notice needs to be given to arrange the testing. See Exhibit 13.26 for a sample Certificate of Occupancy.

Exhibit 13.26

CERTIFICATE OF OCCUPANCY

Building Permit Number ______ **Date** ______

The undersigned hereby applies for a permit of occupancy in accordance with 780 CMR 120, sixth edition:

1. Location of building ______ *Street Address* ______ *Unit Number*
2. Applicant ______
3. Owner ______
   Address ______
4. Occupant ______
5. Use group ______ Occupancy ______
6. Construction type ______ Occupant load ______
7. Special stipulations or conditions ______

Plumbing/gas ______ Fire ______

Electrical ______ Water and sewer ______

Health ______ Public works ______

I hereby certify that the work specified by the above named building permit has been completed and is ready for occupancy.

Building Inspector ______

Inspection Director ______

Date ______

Sample Certificate of Occupancy.

While the AHJ can represent a number of different individuals, such as various code enforcement officers, it is best to have all involved parties, such as the owner, tenant, or insurance companies, notified and present rather than to have to repeat the acceptance test multiple times. Sometimes, the owner or owner's representative can assist in notifying other interested parties. The owner may also be needed to provide access to other important areas, such as electrical rooms.

13.4.6.3 Pump Room Electrical Wiring. All electric wiring to the fire pump motor(s), including control (multiple pumps) interwiring, normal power supply, alternate power supply where provided, and jockey pump, shall be completed and checked by the electrical contractor prior to the initial startup and acceptance test. [**20:**14.2.3]

It is important to verify that all wiring and connections are completed and tested prior to acceptance testing and the pump rotation direction verified so that any problems associated with incorrect or incomplete connections, unacceptable quality, incompatibilities due to mismatched components, or any other performance problems can be readily identified and corrected. Acceptance should not be granted on the assumption that an incomplete installation will be completed correctly at some future time.

Most instances of driver failures during the acceptance testing of electric motor–driven fire pumps are usually traced back to noncompliant wiring methods, materials, or practices. By checking the entire installation prior to the acceptance test, unnecessary and time-consuming troubleshooting efforts can be avoided.

13.4.6.4* Certified Pump Curve.

The manufacturer's certified pump test characteristic curve provides a graphical representation of the pump's performance under controlled conditions, prior to any damage that might occur in transit and prior to the completion of the installation. The curve provides a benchmark to which installed pumps can be compared (see Section 4.5 of NFPA 20).

A.13.4.6.4 If a complete fire pump submittal package is available, it should provide for comparison of the equipment specified. Such a package should include an approved copy of the fire pump room general arrangement drawings, including the electrical layout, the layout of the pump and water source, the layout of the pump room drainage details, the pump foundation layout, and the mechanical layout for heat and ventilation. [**20:**A.14.2.4]

Δ **13.4.6.4.1** A copy of the manufacturer's certified pump test curve shall be available for comparison of the results of the field acceptance test. [**20:**14.2.4.1]

13.4.6.4.1.1 For water mist positive displacement pumping units, a copy of the manufacturer's certified shop test data for both variable speed and non-variable speed operation shall be available for comparison of the results of the field acceptance test. [**20:**14.2.4.1.1]

The manufacturer must provide separate certified pump curves for water mist positive displacement pumping units with the variable speed features both active and deactivated. The manufacturer also provides certified pump curves for each individual pump, with the variable speed features both active and deactivated. The individual curves are intended to assist in the evaluation of underperforming units and do not need to be verified during the acceptance test.

13.4.6.4.2 At all flow conditions, including those required to be tested in 14.2.6.2 of NFPA 20, the fire pump as installed shall equal the performance as indicated on the manufacturer's certified shop test curve within the accuracy limits of the test equipment. [**20:**14.2.4.2]

Exhibit 13.27 shows fire pump test data obtained from a fire pump acceptance test, and Exhibit 13.28 shows the plots of the test data with respect to the manufacturer's certified test curve.

13.4.6.4.2.1 For water mist positive displacement pumping units with variable speed features, the pump unit as installed shall equal the performance as indicated on the fire pump unit manufacturer's certified shop test data, with variable speed features deactivated within the accuracy limits of the test equipment. [**20:**14.2.4.2.1]

Testing a water mist positive displacement pumping unit with variable speed features deactivated provides verification of the pumping unit performance. The pumps do not need to be tested individually unless it is necessary to investigate an underperforming unit. The unit test results are compared to the pump unit manufacturer's certified shop test data with variable speed features deactivated.

13.4.6.4.2.2 For water mist positive displacement pumping units, the pump unit as installed shall equal the performance as indicated on the fire pump unit manufacturer's certified shop test data, with variable speed features activated within the accuracy limits of the test equipment. [**20:**14.2.4.2.2]

Testing water mist positive displacement pumping units with variable speed features active allows verification of the operation of the unit under simulated fire flow demand. The pumps do not need to be tested individually unless it is necessary to investigate an underperforming unit. The unit test results for variable speed operation are compared to the pump unit manufacturer's certified shop test data with variable speed features active. The unit test results with variable speed deactivated are compared to the pump unit manufacturer's certified shop test data with variable speed features deactivated.

13.4.6.5 System Demand. The actual unadjusted fire pump discharge flows and pressures installed shall meet or exceed the fire protection system's demand. [**20:**14.2.5]

It is possible for a fire pump to perform satisfactorily but still not deliver the system demand. This situation can occur if the residual pressures in the water supply have decreased or if the pump is operating below rated speed. It is important to apply speed adjustment as necessary to verify the fire pump performance. It is equally important to verify that the actual discharge pressure from the fire pump will meet the system demand.

13.4.7* Record Drawings, Test Reports, Manuals, Special Tools, and Spare Parts.

A.13.4.7 It is the intent to retain the record drawing, equipment manual, and completed test report for the life of the fire pump system. [**20:**A.14.3]

13.4.7.1 One set of record drawings shall be provided to the building owner. [**20:**14.3.1]

13.4.7.2 One copy of the completed test report shall be provided to the building owner. [**20:**14.3.2]

13.4.7.3* One set of instruction manuals for all major components of the fire pump system shall be supplied by the manufacturer of each major component. [**20:**14.3.3]

A.13.4.7.3 Consideration should be given to stocking spare parts for critical items not readily available. [**20:**A.14.3.3]

Δ **13.4.7.4** The manual shall contain the following:

(1) A detailed explanation of the operation of the component
(2) Instructions for routine maintenance
(3) Detailed instructions concerning repairs
(4) Parts list and parts identification

(6)* List of recommended spare parts and lubricants

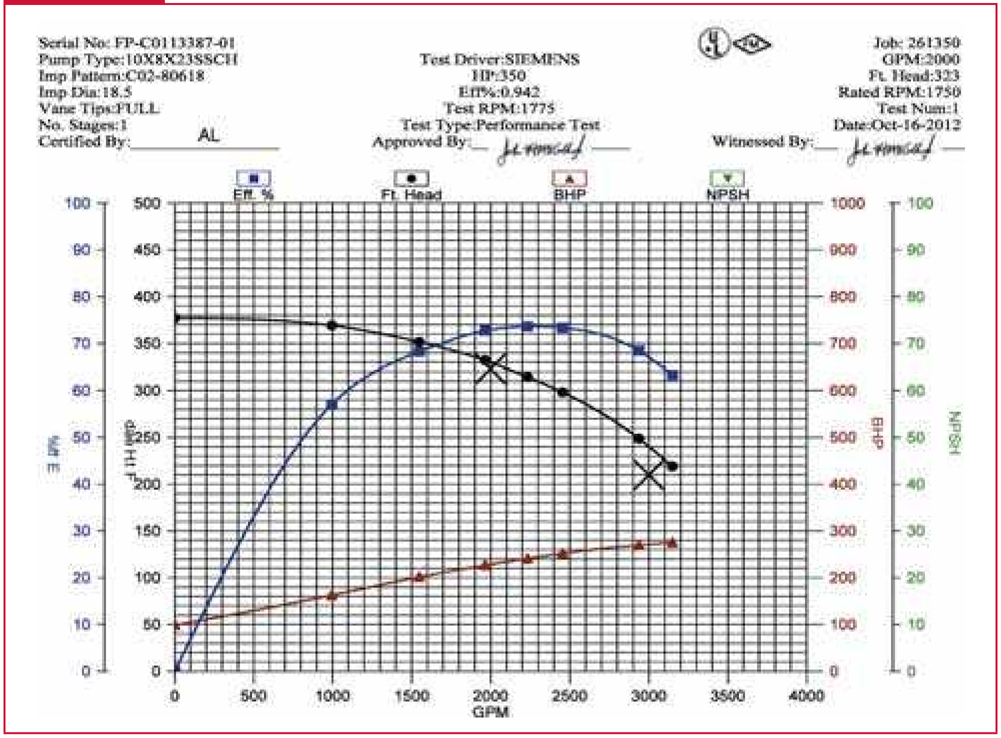
[**20:**14.3.4]

Ordinarily, the operation and maintenance manual is submitted by the installing contractor for review and approval by the building owner or his or her representative, usually the project engineer. Multiple copies of the manual need to be maintained on file for future reference. The manual should be made available at the time of the acceptance test for review of systems and components. Prior to final acceptance, the manual should be used for training operating personnel.

A.13.4.7.4(6) Recommended spare parts and lubricants should be stored on-site to minimize system impairment. [**20:**A.14.3.4(6)]

13.4.7.5 Any special tools and testing devices required for routine maintenance shall be available for inspection by the AHJ at the time of the field acceptance test. [**20:**14.3.5]

Exhibit 13.28



Manufacturer certified test curve. (Courtesy of Aon Fire Protection Engineering)

Δ **13.4.8 Periodic Inspection, Testing, and Maintenance.** Fire pumps shall be inspected, tested, and maintained in accordance with NFPA 25. [**20:**14.4]

Following are a few requirements and recommendations based on the ITM requirements from NFPA 25 as they relate to NFPA 20.

1. **Test frequencies.** Nonflow testing, which consists of starting the pump and running it at full speed at the regular intervals as required by NFPA 25, helps to ensure that the pump installation is always ready for service. The 2014 edition of NFPA 25 requires weekly nonflow testing for the following fire pumps:

   - Diesel engine–driven fire pumps
   - Electric motor fire pumps with limited service controllers
   - Electric motor fire pumps supplied from a tank
   - Electric motor fire pumps in a high-rise building

   Monthly nonflow testing is required for electric motor–driven fire pumps not identified above. In editions of NFPA 25 prior to the 2014 edition, weekly testing was required for electric motor–driven fire pumps.
2. **Five-percent degradation investigation.** NFPA 25 requires an investigation whenever the net pump pressure is less than 95 percent of the original pump curve at 100 percent of rated flow. A more pronounced reduction in capacity could be due to one or more causes, as shown in Annex B of NFPA 20. A plugged impeller, worn wear rings, and obstructed suction are among the most common causes. In some cases, the reading of the suction gauge indicates whether the trouble is due to an obstruction in the water supply or in the suction pipe. In other cases, the difference between the reading of the suction gauge and that of the discharge gauge is the indicator of a plugged impeller or overly worn wear rings.
3. **Flowmeter testing.** When testing a pump by discharging through a listed meter back to the pump suction, a hydraulic imbalance within the pump is possible. Additionally, this test method is not able to check the suction supply and piping upstream of the connection to the pump suction. If possible, the flowmeter should not be piped to the pump suction. Piping the flow back to the water storage tank (with an air gap) or to the pump house exterior results in accurate measurements.
4. **Diesel fire pumps.** At least once a year, diesel engine–driven pumps should be checked for overheating by running them with the pump discharging at 150 percent or more of its rated capacity. Once the engine temperature has stabilized, the engine should be run for at least an additional 15 minutes. If the engine overheats, a blockage of the cooling system is probably the cause, such as an inadequate cooling waterflow caused by an obstruction in the cooling water system, a plugged strainer, or a partly closed valve.

In addition to the requirements of NFPA 25 for engine-driven pumps, the engine should be kept clean and dry. The fuel tank should be kept at a level at least capable of running the engine for 6 hours at peak load. The crankcase oil should be checked to verify that it is at the proper level, that it has not become fouled, and that it has not lost its viscosity. Additionally, the strainers in the cooling water system should be cleaned, and the specific gravity of the battery electrolyte should be checked monthly.

5. **Records.** Even though NFPA 25 specifies the records that should be kept, it is also beneficial to maintain a specific record of the temperature and tightness of the glands, the readings of the suction and discharge gauges, and the condition of the suction supply.

13.4.9 Component Replacement.

13.4.9.1 Positive Displacement Pumps.

13.4.9.1.1 Whenever a critical path component in a positive displacement fire pump is replaced, as defined in 14.5.2.5 of NFPA 20, a field test of the pump shall be performed. [**20:**14.5.1.1]

13.4.9.1.2 If components that do not affect performance are replaced, such as shafts, then only a functional test shall be required to ensure proper installation and reassembly. [**20:**14.5.1.2]

13.4.9.1.3 If components that affect performance are replaced, such as rotors, plungers, and so forth, then a retest shall be conducted by the pump manufacturer or designated representative or qualified persons acceptable to the AHJ. [**20:**14.5.1.3]

13.4.9.1.3.1 For water mist positive displacement pumping units, the retest shall include the pump unit as a whole. [**20:**14.5.1.3.1]

13.4.9.1.4 Field Retest Results.

13.4.9.1.4.1 The field retest results shall be compared to the original pump performance as indicated by the fire pump manufacturer's original factory-certified test curve, whenever it is available. [**20:**14.5.1.4.1]

13.4.9.1.4.2 The field retest results shall meet or exceed the performance characteristics as indicated on the pump nameplate, and the results shall be within the accuracy limits of field testing as stated elsewhere in NFPA 20. [**20:**14.5.1.4.2]

13.5 Water Supply

Δ **13.5.1** Private fire service mains shall be installed in accordance with NFPA 13 and NFPA 24.

Δ **13.5.2** Where no adequate and reliable water supply exists for fire-fighting purposes, the requirements of NFPA 1142 shall apply.

NFPA 1142, *Standard on Water Supplies for Suburban and Rural Fire Fighting*, identifies minimum requirements for water supplies for fire-fighting purposes in areas in which adequate and reliable water supply systems for fire-fighting purposes do not exist. The water typically must be transported from a river, lake, canal, bay, stream, pond, well, cistern, or other similar source that is available as a suction supply for fire department use.

In some areas, water supply systems have been installed for domestic water purposes only. These systems can be equipped with hydrants that might not be standard fire hydrants, with available volume, pressure, and duration of flow being inadequate for fire-fighting purposes. Where such conditions exist, the requirements of NFPA 1142 should be applied.

Δ **13.5.3*** The installation of devices to protect the public water supply from contamination shall comply with the provisions of NFPA 13, NFPA 13D, NFPA 13R, NFPA 24, and the plumbing code.

A.13.5.3 The installation of backflow prevention devices on services supplying water to existing fire protection systems can result in excessive pressure losses. Therefore, installation of backflow prevention devices to protect public health has to be accomplished with due regard for the implications on fire protection. The provisions of AWWA M14, *Backflow Prevention and Cross-Connection Control: Recommended Practices*, should be used as a guide for determining the appropriate protection for public health. Hydraulic calculations and water supply analysis should be conducted prior to installation to determine the impact on fire protection.

Δ **13.5.3.1** Backflow prevention devices shall be inspected, tested, and maintained in accordance with the requirements of NFPA 25.

13.5.4 Inspection, Testing, and Maintenance.

13.5.4.1 A private fire service main installed in accordance with this *Code* shall be properly maintained to provide at least the same level of performance and protection as designed. The owner shall be responsible for maintaining the system and keeping it in good working condition.

13.5.4.2 A private fire service main installed in accordance with this *Code* shall be inspected, tested, and maintained in accordance with NFPA 25.

13.6 Portable Fire Extinguishers

13.6.1 General Requirements.

13.6.1.1 Scope. The selection, installation, inspection, maintenance, recharging, and testing of portable fire extinguishers shall be in accordance with NFPA 10 and Section 13.6.

13.6.1.1.1 The requirements given herein are minimum. [**10:**1.1.1]

13.6.1.1.2 The requirements shall not apply to permanently installed systems for fire extinguishment, even where portions of such systems are portable (such as hose and nozzles attached to a fixed supply of extinguishing agent). [**10:**1.1.2]

13.6.1.2* Where Required. Fire extinguishers shall be provided where required by this *Code* as specified in Table 13.6.1.2 and the referenced codes and standards listed in Chapter 2.

Portable fire extinguishers are required by this *Code* to be installed in the occupancies specified by Table 13.6.1.2. It is noted that this

TABLE 13.6.1.2 Portable Fire Extinguishers Required

Occupancy Use	Where Required
Ambulatory health care occupancies	Yes
Apartment occupancies[a]	Yes
Assembly occupancies[b]	Yes
Business occupancies	Yes
Day-care occupancies	Yes
Detention and correctional occupancies[c,d]	Yes
Educational occupancies	Yes
Health care occupancies	Yes
Hotel and dormitory occupancies	Yes
Industrial occupancies	Yes
Lodging and rooming house occupancies	Yes
Mercantile occupancies	Yes
Occupancies in special structures	Yes
One- and two-family dwelling occupancies	No
Residential board and care occupancies	Yes
Storage occupancies[e]	Yes

[a]Portable fire extinguishers shall be permitted to be located at exterior locations or interior locations so that all portions of the buildings are within 75 ft (22.8 m) of travel distance to an extinguishing unit.

[b]Portable fire extinguishers are not required in seating or outdoor performance areas.

[c]Access to portable fire extinguishers shall be permitted to be locked.

[d]Portable fire extinguishers shall be permitted to be located at staff locations only.

[e]In storage areas where forklift, powered industrial truck, or cart operators are the primary occupants, fixed extinguishers, as specified in NFPA 10, need not be provided when:

(1) Use of vehicle-mounted extinguishers is approved by the AHJ.

(2) Each vehicle is equipped with a 10 lb, 40-A:80-B:C extinguisher affixed to the vehicle using a mounting bracket approved by the extinguisher manufacturer or the AHJ for vehicular use.

(3) Not less than two spare extinguishers of equal or greater rating are available onsite to replace a discharged extinguisher.

(4) Vehicle operators are trained in the proper operation and use of the extinguisher.

(5) Inspections of vehicle-mounted extinguishers are performed daily.

Code requires portable fire extinguishers in buildings of every occupancy classification other than one- and two-family dwellings, whereas NFPA *101* requires portable fire extinguishers in far fewer occupancies. The different requirements of NFPA 1 and NFPA *101* are sometimes, incorrectly, perceived as a conflict — there is none. The scope of this *Code* includes occupant safety, emergency responder safety, and property protection; the scope of NFPA *101* is limited to occupant life safety. The broader scope of NFPA 1 warrants different protection requirements — in this case, more stringent requirements than those of NFPA *101* for the installation of portable fire extinguishers. By meeting the more stringent requirements for portable fire extinguishers of NFPA 1, the requirements of NFPA *101* are also met. A conflict would exist only if one code required portable fire extinguishers and another code prohibited them. Exhibit 13.29 depicts examples of portable fire extinguishers.

Exhibit 13.29

Portable fire extinguishers.

A.13.6.1.2 Employees expected or anticipated to use fire extinguishers should be instructed on the hazards of fighting fire, how to properly operate the fire extinguishers available, and what procedures to follow in alerting others to the fire emergency.

The intended application of footnote e in Table 13.6.1.2 is for warehouse areas that are generally unoccupied except by operators on forklifts or similar vehicles or occasional workers or maintenance personnel. The footnote is not intended to apply to office or process areas. Office and process areas have to be provided with fixed extinguishers in accordance with NFPA 10 and applicable provisions in this *Code*.

13.6.1.3 Listing and Labeling.

Δ **13.6.1.3.1*** Portable fire extinguishers used to comply with Section 13.6 shall be listed and labeled and shall meet or exceed all the requirements of ANSI/UL 711, CAN/ULC-S508, *Standard for Rating and Fire Testing of Fire Extinguishers*, and one of the following applicable performance standards:

(1) Carbon dioxide types: ANSI/UL 154, CAN/ULC-S503, *Standard for Carbon-Dioxide Fire Extinguishers*
(2) Dry chemical types: ANSI/UL 299, CAN/ULC-S504, *Standard for Dry Chemical Fire Extinguishers*
(3) Water types: ANSI/UL 626, CAN/ULC-S507, *Standard for Water Fire Extinguishers*
(4) Halon types: CAN/ULC-S512, *Standard for Halogenated Agent Hand and Wheeled Fire Extinguishers*
(5) Film-forming foam types: ANSI/UL 8, CAN/ULC-S554, *Water Based Agent Fire Extinguishers*
(6) Halocarbon types: ANSI/UL 2129, CAN/ULC-S566, *Standard for Halocarbon Clean Agent Fire Extinguishers*

[**10:**4.1.1]

A.13.6.1.3.1 Listed and labeled halon portable fire extinguishers currently comply with Section 13.6 and have demonstrated compliance with the requirements of UL-1093, *Standard for Halogenated Agent Fire Extinguishers*, which also includes fire testing and rating criteria. As a result of the Montreal Protocol on Substances that Deplete the Ozone Layer, UL has withdrawn UL-1093. This does not imply that extinguishers that are listed and labeled to the requirements of UL-1093 are unsafe for use as fire extinguishers, nor does it mean that UL or the EPA is requiring that halon extinguishers be removed from service. It does mean that UL will not accept new designs of halon extinguishers for testing or UL listing. It also means that no changes or updates are allowed to models that are currently listed and that had previously demonstrated compliance with UL 1093. [**10:**A.4.1.1]

Extinguisher manufacturers are allowed to manufacture their current design of UL -listed halon extinguishers with the UL listing mark until October 2025. Halon extinguishers currently in use will continue to be listed beyond the 2025 date and should be permitted to be used to comply with the requirements of NFPA 10 and this *Code* when installed, inspected, and maintained in accordance with NFPA 10 and this *Code*. [**10:**A.4.1.1]

13.6.1.3.2* Each fire extinguisher shall be marked with the following:

(1) Identification of the listing and labeling organization
(2) Product category indicating the type of extinguisher
(3) Extinguisher classification as indicated in Section 5.3 of NFPA 10
(4) Performance and fire test standards that the extinguisher meets or exceeds

[**10:**4.1.2]

A.13.6.1.3.2 AHJs should determine the acceptability and credibility of the organization listing or labeling fire extinguishers. Authorities should determine if the organization tests to all the requirements of NFPA 10. Factors such as the structure of the organization, its principal fields of endeavor, its reputation and established expertise, its involvement in the standards-writing process, and the extent of its follow-up service programs should all be assessed before recognition is given. [**10:**A.4.1.2]

The listing and labeling organization identification marking might be in the form of a symbol of the organization. The product category marking should identify the extinguisher, for example, “Carbon Dioxide Fire Extinguisher,” “Dry Chemical Fire Extinguisher,” or “Clean Agent Fire Extinguisher.” Extinguisher ratings should indicate the classification of fire type, such as A, B, or C, and the associated fire size. An example of an extinguisher rating is 1-A: 5-B:C, which designates a Class A fire (wood) rating with an associated fire size of 1, as described in ANSI/UL711, CAN/ULC-S508, *Standard for Rating and Testing of Fire Extinguishers*; a Class B fire (flammable liquid) rating with an associated fire size of 5, as described in ANSI/UL711, CAN/ULC-S508; and a Class C compatible rating as described in ANSI/UL711, CAN/ULC-S508. [**10:**A.4.1.2]

A fire extinguisher label includes the identification of the listing and labeling organization, and the fire test and performance standards it meets or exceeds. The label also includes which classifications (A:B:C:D:K) and rating (size of fire) the extinguisher meets, the agent weight, the suitable use temperature range, and the operating instructions. Also included on the label are maintenance and field inspection instructions, the correct charged pressure, the extinguisher gross weight, and any necessary cautions and warnings. The labels on some extinguishers manufactured before 1986 were not required to provide all the information described.

13.6.1.3.2.1 Fire extinguishers manufactured prior to January 1, 1986, shall not be required to comply with 13.6.1.3.2. [**10:**4.1.2.1]

13.6.1.3.2.2 Halon extinguishers listed and labeled to UL 1093, *Standard for Halogenated Agent Fire Extinguishers*, shall be permitted to be used to comply with the requirements of Section 13.6 when installed, inspected and maintained in accordance with Section 13.6. [**10:**4.1.2.2]

13.6.1.3.3* An organization listing fire extinguishers used to comply with the requirements of Section 13.6 shall utilize a third-party certification program for portable fire extinguishers that meets or exceeds UL 1803, *Standard for Factory Follow-Up on Third Party Certified Portable Fire Extinguishers*. [**10:**4.1.3]

A.13.6.1.3.3 AHJs should determine the thoroughness of the factory follow-up quality assurance program exercised by third-party certification organizations listing and labeling portable fire extinguishers. The specified factory follow-up standard provides a minimum basis for that determination. Application of the factory follow-up standard provides a reasonable assurance that portable fire extinguishers sold to the public continue to have the same structural reliability and performance as the fire extinguishers the manufacturer originally submitted to the listing and labeling organization for evaluation. [**10:**A.4.1.3]

13.6.1.3.3.1 Fire extinguishers manufactured prior to January 1, 1989, shall not be required to comply with 13.6.1.3.3. [**10:**4.1.3.1]

13.6.1.3.3.2 Certification organizations accredited by the Standards Council of Canada shall not be required to comply with 13.6.1.3.3. [**10:**4.1.3.2]

13.6.1.3.3.3 Listed and labeled Class D extinguishing agents intended to be manually applied to combustible metal fires shall comply with the fire test requirements specified in ANSI/UL 711, CAN/ULC-S508, *Standard for Rating and Fire Testing of Fire Extinguishers*. [**10:**4.1.3.3]

13.6.1.3.4 Electrical Conductivity. Extinguishers listed for the Class C rating shall not contain an agent that is a conductor of electricity. [**10:**4.1.4]

13.6.1.3.4.1 In addition to successfully meeting the requirements of ANSI/UL 711, CAN/ULC-S508, *Standard for Rating and Fire Testing of Fire Extinguishers*, water-based agents that are listed for the Class C rating shall be tested in accordance with ASTM D5391, *Standard Test for Electrical Conductivity and Resistivity of a Flowing High Purity Water Sample*. [**10:**4.1.4.1]

13.6.1.3.4.2 Fire extinguishers containing water-based agents that have a conductivity higher than 1.00 µS/cm at 77°F (25°C) shall be considered a conductor of electricity and therefore shall not be rated Class C. [**10:**4.1.4.2]

13.6.1.3.4.3 Paragraphs 13.6.1.3.4.1 and 13.6.1.3.4.2 shall apply only to water-based extinguishers manufactured after August 15, 2002. [**10:**4.1.4.3]

Δ **13.6.1.4* Identification of Contents.** A fire extinguisher shall have a label, tag, or stencil attached to it providing the following information:

(1) The content's product name as it appears on the manufacturer's Material Safety Data Sheet (MSDS)
(2) Listing of the hazardous material identification in accordance with *Hazardous Materials Identification System (HMIS), Implementation Manual* [in Canada, *Globally Harmonized System of Classification and Labeling of Chemicals (GHS)*] developed by the National Paint and Coatings Association
(3) List of any hazardous materials that are in excess of 1.0 percent of the contents
(4) List of each chemical in excess of 5.0 percent of the contents
(5) Information as to what is hazardous about the agent in accordance with the MSDS
(6) Manufacturer's or service agency's name, mailing address, and phone number

[**10:**4.2]

Δ **A.13.6.1.4** Federal OSHA regulations require that manufacturers communicate information as to the type of chemicals in a product that can be hazardous and the level of hazard. This information is contained in the MSDS created for each chemical or mixture of chemicals and is summarized on labels or tags attached to the product. Additionally, state and local authorities have enacted similar acts and regulations requiring identification of chemicals and hazardous ingredients in products. MSDSs for fire extinguisher agents are available on request from fire equipment dealers or distributors or the fire equipment manufacturer. [**10:**A.4.2]

The identification of contents information enables determination of the type of chemicals contained in the fire extinguisher and helps to resolve complications arising from an unusual use of the agent. The *Hazardous Materials Identification System (HMIS)*, developed by the American Coatings Association uses a three-place format with numerical indexes from 0 to 4. The first place is for "toxic properties," the second place is for "flammability," and the third place is for "reactivity" with other chemicals. Most fire extinguishers have a 0 numerical index in the second and third places because they are nonflammable and relatively inert. [**10:**A.4.2]

Information on the HMIS can be obtained from Label Master, Inc., in Chicago, IL, or from the American Coatings Association in Washington, DC. Extinguisher contents information can be integrated into the standard fire extinguisher label in some form, or it can be on a separate label or tag. The following example is a typical chemical contents identification marking:

CONTENTS: ABC DRY CHEMICAL/HMIS 1-0-0 MUSCOVITE MICA, MONOAMMONIUM PHOSPHATE AMMONIUM SULFATE/NUISANCE DUST IRRITANT/CONTENTS UNDER PRESSURE [Manufacturer's Name, Mailing Address, Phone Number]
[**10:**A.4.2]

13.6.1.5* Instruction Manual.

A.13.6.1.5 The manual can be specific to the fire extinguisher involved, or it can cover many types. [**10:**A.4.3]

The fire extinguisher instruction manual should cover the required inspection, maintenance, and recharging frequencies and requirements as specified by Chapter 7 of NFPA 10.

13.6.1.5.1 The owner or the owner's agent shall be provided with a fire extinguisher instruction manual that details condensed instructions and cautions necessary to the installation, operation, inspection, and maintenance of the fire extinguisher(s). [**10:**4.3.1]

13.6.1.5.2 The manual shall refer to NFPA 10 as a source of detailed instruction. [**10:**4.3.2]

Δ **13.6.1.6 Obsolete Fire Extinguishers.** The following types of fire extinguishers are considered obsolete and shall be removed from service:

(1) Soda acid
(2) Chemical foam (excluding film-forming agents)
(3) Carbon tetrachloride, methyl bromide, and chlorobromomethane (CBM)
(4) Cartridge-operated water
(5) Cartridge-operated loaded stream
(6) Copper or brass shell (excluding pump tanks) joined by soft solder or rivets
(7) Carbon dioxide extinguishers with metal horns
(8) Solid charge–type AFFF extinguishers (paper cartridge)
(9) Pressurized water fire extinguishers manufactured prior to 1971
(10) Any extinguisher that needs to be inverted to operate
(11) Any extinguisher manufactured prior to 1955
(12) Any extinguishers with 4B, 6B, 8B, 12B, and 16B fire ratings
(13) Stored-pressure water extinguishers with fiberglass shells (pre-1976)

[**10:**4.4]

Δ **13.6.1.6.1*** Dry chemical stored-pressure extinguishers with an indicated manufacturing date of 1984 or prior shall be removed from service. [**10:**4.4.1]

Δ **A.13.6.1.6.1** The requirement in 13.6.1.6.1 brings the standard into line with the 1984 changes to ANSI/UL 299, CAN/ULC-S504, *Standard for Dry Chemical Fire Extinguishers*, and to ANSI/UL 711, *Rating and Fire Testing of Fire Extinguishers*.

(1) *Hose*. The 1984 edition of UL 299 requires extinguishers rated 2A or higher or 20-B or higher to be equipped with a discharge hose. Before this change, almost all 5 lb (2.3 kg) extinguishers and many 10 lb (4.5 kg) extinguishers were equipped with a fixed nozzle on the outlet of the extinguisher valve and without hoses. These extinguishers, rated 2-A to 4-A and 10-B to 60-B are used to comply with the installation requirements now

contained in Chapter 6 of NFPA 10. To properly use one of these extinguishers, the user must keep it in the upright position, apply the dry chemical to the base of the fire, and sweep the discharge back and forth. The requirement for the addition of a hose to these extinguishers came out of the novice fire tests sponsored by Underwriters Laboratories (UL) and the Fire Equipment Manufacturers Association. The film footage of these tests shows that those who had never used a fire extinguisher before often used both hands to operate these extinguishers, turning the extinguisher cylinder in a horizontal position while squeezing the handle and lever to open the valve. Sometimes they even inverted the extinguisher. The result of such actions is a partial discharge of the extinguisher contents or possibly only the expellant gas and, therefore, no extinguishment of the fire can be achieved. The addition of a hose also makes it much easier to direct the discharge at the base of the flames and to sweep the discharge from side to side. The requirement to add a hose makes it more likely that the extinguisher will be used in an upright position. In fact, it is almost impossible to do otherwise, since one hand opens the valve and the other hand, which holds the hose, directs the discharge stream to the fire. It is important to note that field modification of an extinguisher is generally not allowed since the modification might not have been evaluated to comply with the test requirements in the applicable UL extinguisher standards, and the extinguisher might not operate as intended. Thus, a fixed nozzle cannot simply be removed from an extinguisher and replaced with a hose and nozzle.

(2) *Minimum Discharge Time.* This requirement, found in the 1984 edition of UL 711, requires a minimum 13-second discharge duration for an extinguisher rated 2-A or higher. The 13-second minimum requirement was the result of recommendations from the novice fire tests mentioned in A.13.6.1.6.1(1). Before 1984, almost all 2-A-rated dry chemical extinguishers had discharge durations of only 8 seconds to 10 seconds. The novice fire tests clearly showed that longer discharge duration resulted in an increased likelihood of extinguishment. The revision to UL 711 mandated a 50 percent to 60 percent increase in the minimum discharge duration for a 2-A-rated dry chemical extinguisher. Modification of extinguishers with a nozzle/hose that gives different or longer discharge duration is not allowed. Such modification would not have been evaluated to comply with the test requirements in the applicable UL extinguisher standards, and the extinguisher might not operate as intended.

(3) *Pull Pins.* A revision to the extinguisher standards, including UL 299, required a maximum 30 lb (133 N) of force to remove a safety pin or pull pin from an extinguisher. This again came from the novice testing, in which some individuals could not physically remove the pin and actuate the extinguisher. The UL extinguisher standards also included a design requirement so that the pin is visible from the front of the extinguisher unless noted by the operating instructions.

(4) *Operating Instructions/Marking.* The extinguisher standards, including the 1984 revision of UL 299, mandated the use of pictographic operating instructions and code symbols on all but Class D extinguishers and wheeled extinguishers. These requirements also came out of the novice fire tests, which showed many individuals taking too long to read and understand the written operating instructions. The novice tests actually developed the pictographic operating instructions and tested them on novice operators for effectiveness. The details of the number of instructions per pictogram came from the test program. The novice fire tests were also the impetus for making the use code symbols for the various classes of fires more understandable. The new pictographic use code symbols were also mandated in 1984 as well as a uniform method of applying A, B, and C symbols to extinguishers with ABC or BC only ratings. The result was a uniform, consistent set of easily understood symbols that made the extinguisher more user friendly.

(5) *Service Manuals.* The extinguisher standards, including UL 299, for the first time mandated that extinguisher manufacturers have a service manual for their products. In addition, the 1984 edition of UL 299 required a reference to the service/maintenance manual on the extinguisher nameplate. Prior to 1984, service manuals were not required.[**10:**A.4.4.1]

13.6.1.6.1.1 Paragraph 13.6.1.6.1 shall not apply to wheeled-type dry chemical stored-pressure fire extinguishers. [**10:**4.4.1.1]

13.6.1.6.2* Any fire extinguisher that can no longer be serviced in accordance with the manufacturer's maintenance manual is considered obsolete and shall be removed from service. [**10:**4.4.2]

A.13.6.1.6.2 Fire extinguishers manufactured by companies that are no longer in business can remain in use if they meet the requirements of NFPA 10 and this *Code*, and are maintained in accordance with the manufacturer's service manual. When these extinguishers require recharging or maintenance and the required extinguishing agent or necessary repair parts are not available, the extinguishers should be removed from service. [**10:**A.4.4.2]

Extinguishers that can still be serviced in accordance with the manufacturer's service manual are not obsolete, even if the manufacturer is no longer in business. However, to maintain an extinguisher in accordance with the manufacturer's manual, the service company must use the replacement parts specified in the manual. This usually becomes difficult when the original manufacturer no longer exists; therefore, such extinguishers often are removed from service anyway. However, it is still important to understand that the standard does not require their removal as long as they can be maintained.

13.6.2 Selection of Portable Fire Extinguishers.

13.6.2.1 General Requirements. The selection of fire extinguishers for a given situation shall be determined by the applicable requirements of Sections 5.2 through 5.6 of NFPA 10 and the following factors:

(1) Type of fire most likely to occur
(2) Size of fire most likely to occur
(3) Hazards in the area where the fire is most likely to occur
(4) Energized electrical equipment in the vicinity of the fire
(5) Ambient temperature conditions
(6) Other factors *(see Section H.2 of NFPA 10)*

[**10:**5.1]

13.6.2.1.1 Portable fire extinguishers shall be installed as a first line of defense to cope with fires of limited size, except as required by 5.5.5 of NFPA 10. [**10:**5.1.1]

13.6.2.1.2 The selection of extinguishers shall be independent of whether the building is equipped with automatic sprinklers, standpipe and hose, or other fixed protection equipment. [**10:**5.1.2]

13.6.2.2 Classification of Fires. See 3.3.110.

13.6.2.3 Extinguisher Classification System.

For an explanation of the extinguisher classification per ANSI/UL 711, see G.1.1 of NFPA 10.

13.6.2.3.1 The classification of fire extinguishers shall consist of a letter that indicates the class of fire on which a fire extinguisher has been found to be effective. [**10:**5.3.1]

13.6.2.3.1.1 Fire extinguishers classified for use on Class A or Class B hazards shall be required to have a rating number preceding the classification letter that indicates the relative extinguishing effectiveness. [**10:**5.3.1.1]

13.6.2.3.1.2 Fire extinguishers classified for use on Class C, Class D, or Class K hazards shall not be required to have a number preceding the classification letter. [**10:**5.3.1.2]

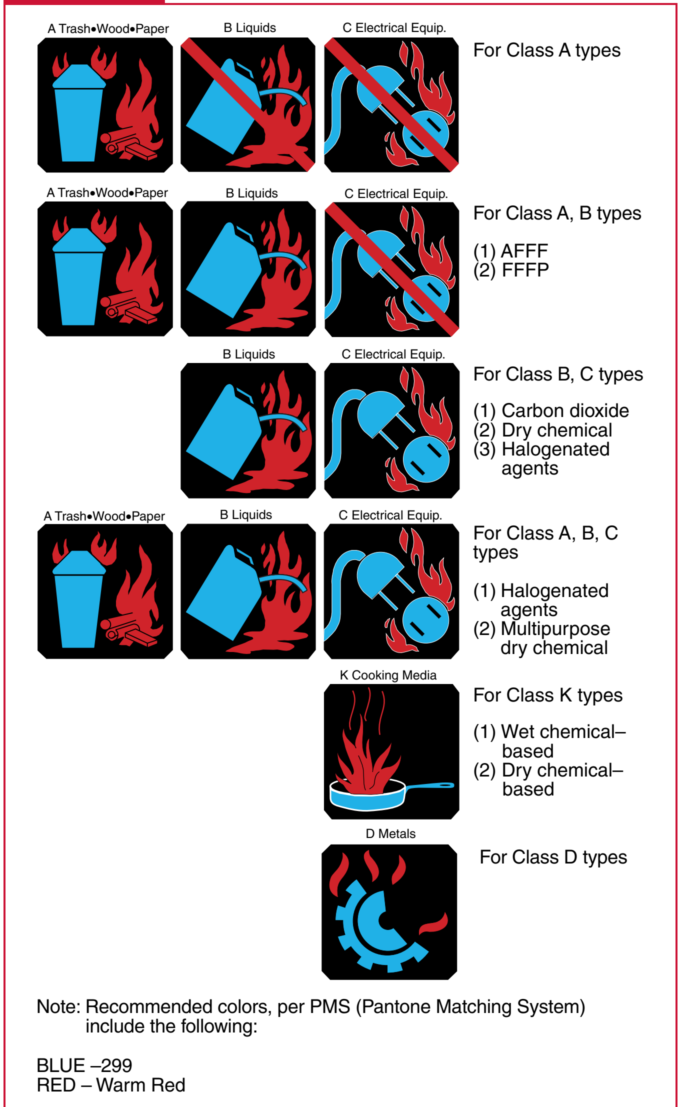
A typical fire extinguisher rated 4-A:20-B:C indicates the unit should extinguish approximately twice as much Class A fire as a 2-A–rated fire extinguisher. It should extinguish approximately four times as much fire as a 5-B–rated fire extinguisher, and the C classification indicates it is suitable to use on energized electrical equipment. The classes of fire are shown by pictographic code symbols. (See Exhibit 13.30 and Exhibit 13.31.) If a fire extinguisher is not large enough to obtain a rating for a minimum class test fire, the pictographic symbol is not shown on the label.

A 10-B:C–rated dry chemical extinguisher with an agent weight of 2.5 lb (1.13 kg), for example, is safe to use on a Class A fire but does not include a Class A pictographic use code symbol on the label. If an extinguisher is unsafe for use on a class of fire, the pictographic use code symbol includes a red diagonal line that passes through the symbol that signals the user that the extinguisher is not for use on that type of fire. For example, water units show the red line passing through the Class B flammable liquids and Class C energized electrical equipment symbols.

13.6.2.3.2 Fire extinguishers shall be selected for the class(es) of hazards to be protected in accordance with 13.6.2.3.2.1 through 13.6.2.3.2.5. *(For specific hazards, see Section 5.5 of NFPA 10.)* [**10:**5.3.2]

13.6.2.3.2.1* Fire extinguishers for the protection of Class A hazards shall be selected from types that are specifically listed and labeled for use on Class A fires. *(For halon agent–type extinguishers, see 13.6.2.3.2.6.)* [**10:**5.3.2.1]

Exhibit 13.30



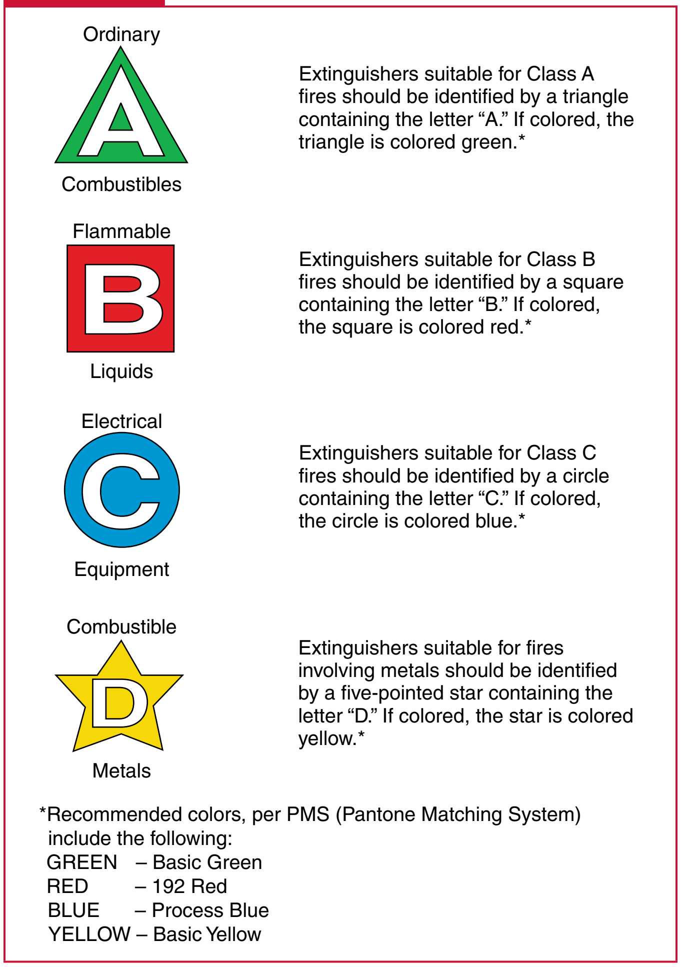
Recommended marking system for fire extinguishers.

A.13.6.2.3.2.1 Examples of extinguishers for protecting Class A hazards are as follows:

(1) Water type
(2) Halogenated agent type *(For halogenated agent–type fire extinguishers, see 13.6.2.3.2.6.)*
(3) Multipurpose dry chemical type
(4) Wet chemical type
[**10:**A.5.3.2.1]

13.6.2.3.2.2* Fire extinguishers for the protection of Class B hazards shall be selected from types that are specifically listed and labeled for use on Class B fires. *(For halon agent–type extinguishers, see 13.6.2.3.2.6.)* [**10:**5.3.2.2]

Exhibit 13.31



Letter-shaped symbol markings for fire extinguishers.

A.13.6.2.3.2.2 Examples of extinguishers for protecting Class B hazards are as follows:

(1) Aqueous film-forming foam (AFFF)
(2) Film-forming fluoroprotein foam (FFFP)
(3) Carbon dioxide
(4) Dry chemical type
(5) Halogenated agent type *(For halogenated agent–type fire extinguishers, see 13.6.2.3.2.6.)*

[**10:**A.5.3.2.2]

13.6.2.3.2.3* Fire extinguishers for the protection of Class C hazards shall be selected from types that are specifically listed and labeled for use on Class C hazards. *(For halon agent–type fire extinguishers, see 13.6.2.3.2.6.)* [**10:**5.3.2.3]

A.13.6.2.3.2.3 The use of dry chemical fire extinguishers on wet energized electrical equipment (such as rain-soaked utility poles, high-voltage switch gear, and transformers) could aggravate electrical leakage problems. The dry chemical in combination with moisture provides an electrical path that can reduce the effectiveness of insulation protection. The removal of all traces of dry chemical from such equipment after extinguishment is recommended. [**10:**A.5.3.2.3]

Pound for pound, dry chemical agent is far more effective on fires than carbon dioxide agent, particularly outdoors in windy conditions. For many applications, such as fires in electric motors, enclosed electrical panels, and other electrical equipment that is semiconfined or housed in cabinets, properly sized carbon dioxide agent extinguishers are effective and clean. The carbon dioxide evaporates after use, leaving no residue.

13.6.2.3.2.4* Fire extinguishers and extinguishing agents for the protection of Class D hazards shall be of the types specifically listed and labeled for use on the specific combustible metal hazard. [**10:**5.3.2.4]

Δ **A.13.6.2.3.2.4** The following information pertains to Class D hazards:

(1) Chemical reaction between burning metals and many extinguishing agents (including water) can range from explosive to inconsequential, depending in part on the type, form, and quantity of metal involved. In general, the hazards from a metal fire are significantly increased when such extinguishing agents are applied. The advantages and limitations of a wide variety of commercially available metal fire extinguishing agents are discussed in NFPA 484 and in Section 6, Chapter 9, of the NFPA *Fire Protection Handbook*. The MSDS of the Class D hazard being protected or the extinguisher manufacturer should be consulted.
(2) The agents and fire extinguishers discussed in this section are of specialized types, and their use often involves special techniques peculiar to a particular combustible metal. A given agent will not necessarily control or extinguish all metal fires. Some agents are valuable in working with several metals; others are useful in combating only one type of metal fire. The AHJs should be consulted in each case to determine the desired protection for the particular hazard involved.
(3) Certain combustible metals require special extinguishing agents or techniques. See NFPA 484 for additional information. If there is doubt, NFPA 484 or the NFPA *Fire Protection Guide to Hazardous Materials* should be consulted. (NFPA 49 and NFPA 325 have been officially withdrawn from the *National Fire Codes*, but the information is contained in the NFPA *Fire Protection Guide to Hazardous Materials.*)
(4) Reference should be made to the manufacturer's recommendations for use and special techniques for extinguishing fires in various combustible metals.
(5) Fire of high intensity can occur in certain metals. Ignition is generally the result of frictional heating, exposure to moisture, or exposure from a fire in other combustible materials. The greatest hazard exists when these metals are in the molten state or in finely divided forms of dust, turnings, or shavings. [**10:**A.5.3.2.4]

The properties of a wide variety of combustible metals and the agents available for extinguishing fires in these metals are discussed in NFPA 484 and the NFPA *Fire Protection Handbook*. [**10:**A.5.3.2.4]

A given agent does not necessarily control or extinguish all metal fires. Some agents work well for the extinguishment of several types of metal fires; others are useful in combating only one type of metal fire. The properties of a wide variety of combustible metals and the agents available for extinguishing fires involving those metals are discussed in the *NFPA Fire Protection Handbook®*. The AHJ should be consulted to determine the required protection for the particular hazard involved.

13.6.2.3.2.5 Fire extinguishers for the protection of Class K hazards shall be selected from types that are specifically listed and labeled for use on Class K fires. [**10:**5.3.2.5]

Prior to the early 1990s, fire extinguishers for cooking media (vegetable or animal oils and fats) traditionally followed Table 13.6.3.3.1.1 for extra (high) hazard, requiring a minimum 40-B–rated sodium bicarbonate or potassium bicarbonate dry chemical extinguisher. The evolution of high-efficiency cooking appliances and the transition of the cooking medium from animal fats to vegetable oils (which have a higher auto-ignition temperature) have created a more severe fire hazard. Testing has shown that wet chemical extinguishers have several times the fire-extinguishing capability of a minimum 40-B–rated sodium bicarbonate or potassium bicarbonate dry chemical extinguisher; this finding prompted the creation of a new classification and a new listing test protocol in 1994.

For fires within cooking appliances protected by a fixed automatic fire extinguishing system, the system should be actuated before a portable fire extinguisher is used, since the fixed fire extinguishing system will automatically shut off the fuel source to the cooking appliance. In such an instance, the portable fire extinguisher provides supplemental protection.

See NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*, and Chapter 50 of this *Code* for further information.

13.6.2.3.2.6* Use of halon agent fire extinguishers shall be limited to applications where a clean agent is necessary to extinguish fire efficiently without damaging the equipment or area being protected, or where the use of alternative agents has the potential to cause a hazard to personnel in the area. [**10:**5.3.2.6]

A.13.6.2.3.2.6 Halon agent is highly effective for extinguishing fire and evaporates after use, leaving no residue. Halon agent is, however, included in the Montreal Protocol list of controlled substances developed under the United Nations Environment Program. Where agents other than halon can satisfactorily protect the hazard, they should be used instead of halon. Halon use should be limited to extinguishment of unwanted fire; it should not be used for routine training of personnel. [**10:**A.5.3.2.6]

13.6.2.3.2.6.1* Placement of portable fire extinguishers containing halogenated agents shall conform to minimum confined space volume requirement warnings contained on the fire extinguisher nameplates. [**10:**5.3.2.6.1]

A.13.6.2.3.2.6.1 ANSI/UL 2129, CAN/ULC-S566, *Standard for Halocarbon Clean Agent Fire Extinguishers*, and CAN/ULC-S512, *Standard for Halogenated Agent Hand and Wheeled Fire Extinguishers*, require halocarbon and halogenated agent nameplates to provide safety guidelines for avoiding overexposure to agent vapors when the agents are discharged into confined spaces. The UL minimum volume requirement for confined spaces is based on exposure to the agent in the absence of a fire and does not include considerations of fire or agent decomposition products. [**10:**A.5.3.2.6.1]

Δ **13.6.2.3.2.7*** Wheeled fire extinguishers shall be considered for hazard protection in areas in which a fire risk assessment has shown the following:

(1) High hazard areas are present
(2) Limited available personnel are present, thereby requiring an extinguisher that has the following features:
    (a) High agent flow rate
    (b) Increased agent stream range
    (c) Increased agent capacity

[**10:**5.3.2.7]

A.13.6.2.3.2.7 Wheeled fire extinguishers are available in capacities of 33 gal (125 L) for foam units and range from 30 lb to 350 lb (13.6 kg to 158.8 kg) for other types of extinguishers. These fire extinguishers are capable of delivering higher agent flow rates and greater agent stream range than normal portable-type fire extinguishers. Wheeled fire extinguishers are capable of furnishing increased fire-extinguishing effectiveness for high hazard areas and have added importance where a limited number of people are available. [**10:**A.5.3.2.7]

13.6.2.4 Classification of Hazards.

13.6.2.4.1 Classifying Occupancy Hazard. Rooms or areas shall be classified as being light hazard, ordinary hazard, or extra hazard. [**10:**5.4.1]

13.6.2.4.1.1* Light Hazard. Light hazard occupancies shall be classified as locations where the quantity and combustibility of Class A combustibles and Class B flammables are low and fires with relatively low rates of heat release are expected. These occupancies consist of fire hazards having normally expected quantities of Class A combustible furnishings, and/or the total quantity of Class B flammables typically expected to be present is less than 1 gal (3.8 L) in any room or area. [**10:**5.4.1.1]

A.13.6.2.4.1.1 Light hazard occupancies can include some buildings or rooms occupied as offices, classrooms, churches, assembly halls, guest room areas of hotels or motels, and so forth. This classification anticipates that the majority of content items are either noncombustible or so arranged that a fire is not likely to spread rapidly. Small amounts of Class B flammables used for duplicating machines, art departments, and so forth, are included, provided that they are kept in closed containers and safely stored. [**10:**A.5.4.1.1]

13.6.2.4.1.2* Ordinary Hazard. Ordinary hazard occupancies shall be classified as locations where the quantity and combustibility of Class A combustible materials and Class B flammables are moderate and fires with moderate rates of heat release are expected.

These occupancies consist of fire hazards that only occasionally contain Class A combustible materials beyond normal anticipated furnishings, and/or the total quantity of Class B flammables typically expected to be present is from 1 gal to 5 gal (3.8 L to 18.9 L) in any room or area. [**10:**5.4.1.2]

A.13.6.2.4.1.2 Ordinary hazard occupancies could consist of dining areas, mercantile shops and allied storage, light manufacturing, research operations, auto showrooms, parking garages, workshop or support service areas of light hazard occupancies, and warehouses containing Class I or Class II commodities as defined by NFPA 13. [**10:**A.5.4.1.2]

A Class I commodity is defined by NFPA 13 as a noncombustible product that meets one of the following criteria:

(1) It is placed directly on wooden pallets.
(2) It is placed in single-layer corrugated cartons, with or without single-thickness cardboard dividers, with or without pallets.
(3) It is shrink-wrapped or paper-wrapped as a unit load, with or without pallets.

[**10:**A.5.4.1.2]

A Class II commodity is defined by NFPA 13 as a noncombustible product that is in slatted wooden crates, solid wood boxes, multiple-layered corrugated cartons, or equivalent combustible packaging material, with or without pallets. [**10:**A.5.4.1.2]

13.6.2.4.1.3* Extra Hazard. Extra hazard occupancies shall be classified as locations where the quantity and combustibility of Class A combustible material are high or where high amounts of Class B flammables are present and rapidly developing fires with high rates of heat release are expected. These occupancies consist of fire hazards involved with the storage, packaging, handling, or manufacture of Class A combustibles, and/or the total quantity of Class B flammables expected to be present is more than 5 gal (18.9 L) in any room or area. [**10:**5.4.1.3]

A.13.6.2.4.1.3 Extra hazard occupancies could consist of woodworking; vehicle repair; aircraft and boat servicing; cooking areas; individual product display showrooms; product convention center displays; and storage and manufacturing processes such as painting, dipping, and coating, including flammable liquid handling. Also included is warehousing or in-process storage of other than Class I and Class II commodities. [**10:**A.5.4.1.3]

13.6.2.4.1.4 Limited areas of greater or lesser hazard shall be protected as required. [**10:**5.4.1.4]

13.6.2.4.2* Selection by Occupancy. Fire extinguishers shall be provided for the protection of both the building structure and the occupancy hazards contained therein regardless of the presence of any fixed fire suppression systems. [**10:**5.4.2]

A.13.6.2.4.2 All buildings have Class A fire hazards. In any occupancy, there could be a predominant hazard as well as special hazard areas requiring extinguishers with ratings to match those hazards. For example, a hospital will generally have need for Class A fire extinguishers covering patient rooms, corridors, offices, and so forth, but will need Class B fire extinguishers in laboratories and where flammable anesthetics are stored or handled, Class C fire extinguishers in electrical switch gear or generator rooms, and Class K extinguishers in kitchens. [**10:**A.5.4.2]

13.6.2.4.2.1 Required building protection shall be provided by fire extinguishers for Class A fires. [**10:**5.4.2.1]

Most buildings include Class A fire hazards. In any occupancy, there might be a predominant hazard and special hazard areas that require supplemental protection. For example, a hospital generally requires Class A fire extinguishers to cover patient rooms, corridors, offices, and so forth. However, a hospital also requires Class B fire extinguishers in laboratories and areas where flammable anesthetics are stored or handled, Class C fire extinguishers in electrical switch gear or generator rooms, and Class K fire extinguishers in kitchens.

13.6.2.4.2.2* Occupancy hazard protection shall be provided by fire extinguishers for such Class A, B, C, D, or K fire potentials as might be present. [**10:**5.4.2.2]

A.13.6.2.4.2.2 If fire extinguishers intended for different classes of fires are grouped, their intended use should be marked conspicuously to aid in the choice of the proper fire extinguisher at the time of a fire. In an emergency, the tendency is to reach for the closest fire extinguisher. If this fire extinguisher is of the wrong type, users could endanger themselves and the property they are endeavoring to protect. Wherever possible, it is preferable to have only those fire extinguishers available that can be safely used on any type of fire in the immediate vicinity. [**10:**A.5.4.2.2]

13.6.2.4.2.3 Fire extinguishers provided for building protection shall be permitted to also be considered for the protection of occupancies having a Class A fire potential. [**10:**5.4.2.3]

Where a code or standard requires portable extinguishers to be installed for general building protection, extinguishers rated for Class A fires are used, since the purpose of the extinguisher is to provide a first line of defense against a structure fire. Where the building contents are also a Class A fire risk, this paragraph permits the same extinguishers to be used for both purposes. Without this requirement, 13.6.2.4.2 might be interpreted to require a full complement of extinguishers for the building structure protection and additional extinguishers for the occupancy hazards.

13.6.2.4.2.4 Buildings having an occupancy hazard subject to Class B or Class C fires, or both, shall have a standard complement of Class A fire extinguishers for building protection, plus additional Class B or Class C fire extinguishers, or both. [**10:**5.4.2.4]

13.6.2.4.2.5 Where fire extinguishers have more than one letter classification (such as 2-A:20-B:C), they shall be permitted to satisfy the requirements of each letter class. [**10:**5.4.2.5]

13.6.2.5 Selection for Specific Hazards.

13.6.2.5.1 Class B Fires.

13.6.2.5.1.1* Extinguishers for Pressurized Flammable Liquids and Pressurized Gas Fires.

A.13.6.2.5.1.1 Pressurized flammable liquids and pressurized gas fires are considered to be a special hazard. Class B fire extinguishers containing agents other than dry chemical are relatively ineffective on this type of hazard due to stream and agent characteristics. The system used to rate the effectiveness of fire extinguishers on Class B fires (flammable liquids in depth) is not applicable to these types of hazards. It has been determined that special nozzle design and rates of agent application are required to cope with such hazards. [**10:**A.5.5.1.1]

13.6.2.5.1.1.1* Extinguishers for Pressurized Flammable Liquids and Pressurized Gas Fires. Large-capacity dry chemical extinguishers of 10 lb (4.54 kg) or greater and a discharge rate of 1 lb/sec (0.45 kg/sec) or more shall be used to protect these hazards. [**10:**5.5.1.1]

A.13.6.2.5.1.1.1 A three-dimensional Class B fire involves Class B materials in motion, such as pouring, running, or dripping flammable liquids, and generally includes vertical as well as one or more, horizontal surfaces. Fires of this nature are considered to be a special hazard. The system used to rate fire extinguishers on Class B fires (flammable liquids in depth) is not directly applicable to this type of hazard. The installation of fixed systems should be considered where applicable. [**10:**A.5.5.2]

• **13.6.2.5.2 Three-Dimensional Fires.** Large capacity dry chemical extinguishers of 10 lb (4.54 kg) or greater and having a discharge rate of 1 lb/sec (0.45 kg/sec) or more shall be used to protect these hazards. [**10:**5.5.2]

Δ **13.6.2.5.3 Obstacle Fires.** Selection of a fire extinguisher for this type of hazard shall be based on one of the following:

(1) Extinguisher containing a vapor-suppressing foam agent
(2)* Multiple extinguishers containing non-vapor-suppressing Class B agents intended for simultaneous application

A.13.6.2.5.3(2) Where multiple extinguishers are utilized, simultaneous discharge from multiple locations to eliminate any blind spots created by an obstacle should be employed. [**10:**A.5.5.3(2)]

(3) Larger capacity extinguishers of 10 lb (4.54 kg) or greater and a minimum discharge rate of 1 lb/sec (0.45 kg/sec)

[**10:**5.5.3]

13.6.2.5.4 Water-Soluble Flammable Liquid Fires (Polar Solvents). Aqueous film-forming foam (AFFF) and film-forming fluoroprotein foam (FFFP) types of fire extinguishers shall not be used for the protection of water-soluble flammable liquids, such as alcohols, acetone, esters, ketones, and so forth, unless specifically referenced on the fire extinguisher nameplate. [**10:**5.5.4]

13.6.2.5.5* Class K Cooking Media Fires. Fire extinguishers provided for the protection of cooking appliances that use combustible cooking media (vegetable or animal oils and fats) shall be listed and labeled for Class K fires. [**10:**5.5.5]

A.13.6.2.5.5 Fire extinguishers for cooking media (vegetable or animal oils and fats) traditionally followed Table 6.3.1.1 of NFPA 10 for extra hazard, requiring a minimum 40-B -rated sodium bicarbonate or potassium bicarbonate dry chemical extinguisher. The evolution of high-efficiency cooking appliances and the change to hotter-burning vegetable shortening has created a more severe fire hazard. Testing has shown that wet chemical extinguishers have several times the cooking fire–extinguishing capability of a minimum 40-B rated sodium bicarbonate or potassium bicarbonate dry chemical extinguisher, which has prompted the creation of a new classification and a new listing test protocol. The test protocol is found in ANSI/UL 711, CAN/ULC-S508. [**10:**A.5.5.5]

See NFPA 96 for further information. Persons in cooking areas need specific training on the use of extinguishers as an essential step for personal safety. Class K fire extinguishers equipped with extended wand–type discharge devices should not be used in a manner that results in subsurface injection of wet chemical extinguishing agents into hot cooking media. Subsurface injection causes a thermodynamic reaction comparable to an explosion. Class K fire extinguishers are no longer manufactured with extended wand–type discharge devices. [**10:**A.5.5.5]

13.6.2.5.5.1 Class K fire extinguishers manufactured after January 1, 2002, shall not be equipped with extended wand–type discharge devices. [**10:**5.5.5.1]

As described in D.4.7 of NFPA 10, Class K wet chemical extinguishers have replaced dry chemical extinguishers in commercial kitchens.

Wet chemical agents are salt-based agents, such as potassium carbonate, dissolved in water. When discharged onto a burning fryer, the salt combines with the oil to create a foamy soap-like layer, which is capable of maintaining a vapor barrier over the surface of the oil. Simultaneously, the large quantity of water absorbs heat from the oil, cooling it significantly. For those reasons, wet chemical agents quickly became the standard agent for fixed commercial kitchen systems once ANSI/UL 300, *Standard for Fire Testing of Fire Extinguishing Systems for Protection of Restaurant Cooking Areas*, was adopted.

With this change, manufacturers also began to offer wet chemical portable extinguishers to avoid compatibility issues between agents and to ensure the effectiveness of the portable extinguisher when used on a deep-fat fryer. Some of the initial designs included an extended wand-type discharge device, which were intended to allow the user to discharge into the fryer from a safe distance. However, there was concern that people would submerge the wand and inject the water-based agent below the oil surface. The high temperature of the oil could cause the water to vaporize at an explosive rate and cause burning oil to splash out of the fryer. For that reason, NFPA 10 specifically forbids manufacture of Class K extinguishers with wands. Because the listing for Class K extinguishers was developed after this prohibition was added to NFPA 10, listed Class K extinguishers should not have a wand.

13.6.2.5.5.2 Fire extinguishers installed specifically for the protection of cooking appliances that use combustible cooking media (animal or vegetable oils and fats) without a Class K rating shall be removed from service. [**10:**5.5.5.2]

13.6.2.5.5.3* Where a hazard is protected by an automatic fire protection system, a placard shall be conspicuously placed near the extinguisher that states that the fire protection system shall be actuated prior to using the fire extinguisher. [**10:**5.5.5.3]

A.13.6.2.5.5.3 Figure A.13.6.2.5.5.3(a) and Figure A.13.6.2.5.5.3(b) show the recommended wording for the Class K placard. Recommended size is 7⅝ in. × 11 in. (194 mm × 279 mm). [**10:**A.5.5.5.3]

13.6.2.5.6* Electronic Equipment Fires. Fire extinguishers for the protection of delicate electronic equipment shall be selected

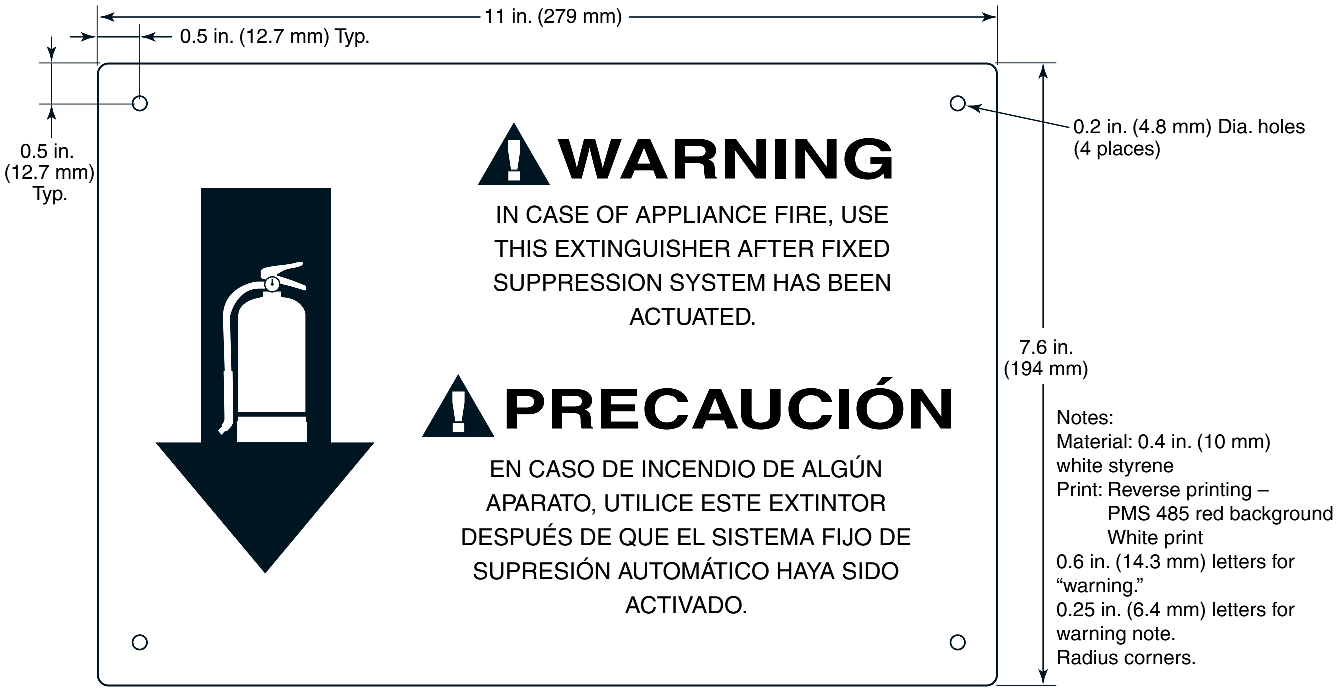


***FIGURE A.13.6.2.5.5.3(a)** Typical Class K Placard in English and Spanish. [**10:**Figure A.5.5.5.3(a)]*

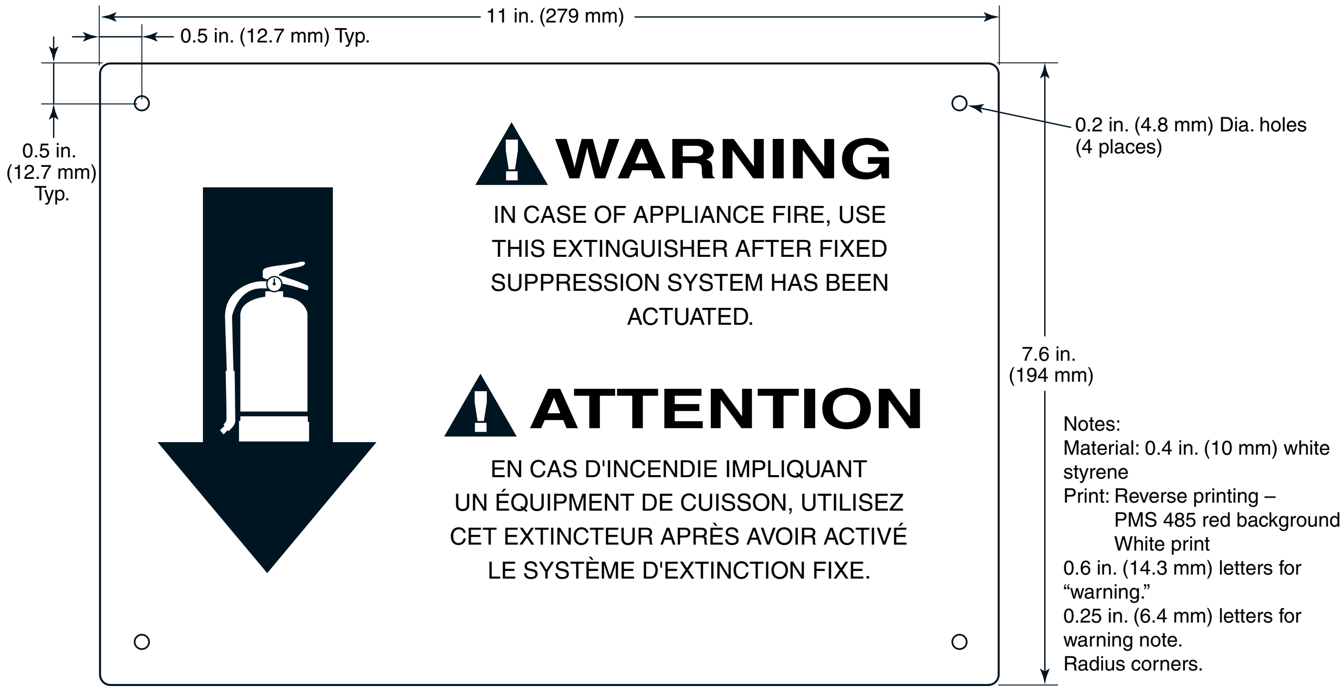

***FIGURE A.13.6.2.5.5.3(b)** Typical Class K Placard in English and French. [**10:**Figure A.5.5.5.3(b)]* from types specifically listed and labeled for Class C hazards. *(See 13.6.2.3.2.3.)* [**10:**5.5.6]

Δ **A.13.6.2.5.6** Where occupancies are required to have extinguishers installed, this section is applicable to areas where the electronic equipment is located. Delicate electronic equipment includes, but is not limited to, telecommunications, computers, servers, robotics, and reproduction equipment. [**10:**A.5.5.6]

It is up to the equipment owner to determine whether electronic equipment is considered "delicate." In modern terminology, it is more common to refer to such equipment as "mission critical." With the advent of comparatively cheap replacement parts, multiple-site processing, and distributed data storage, very few computer and server rooms would be considered to be delicate, despite the antiquated language in A.13.6.2.5.6. However, one-of-a-kind machines or other irreplaceable systems should be considered "delicate" and thus should not be protected with or located within areas containing portable extinguishers that use corrosive or damaging agents.

13.6.2.5.6.1* Dry chemical fire extinguishers shall not be installed for the protection of delicate electronic equipment. [**10:**5.5.6.1]

A.13.6.2.5.6.1 Dry chemical residue will probably not be able to be completely and immediately removed, and, in addition, multipurpose dry chemical exposed to temperatures in excess of 250°F (121°C) or relative humidity in excess of 50 percent can cause corrosion. [**10:**A.5.5.6.1]

13.6.2.5.7 Areas Containing Oxidizers.

13.6.2.5.7.1 Only water or foam extinguishers shall be installed in areas where pool chemicals containing chlorine or bromine are stored. [**10:**5.5.7.1]

13.6.2.5.7.2 Multipurpose dry chemical fire extinguishers shall not be installed in areas where pool chemicals containing chlorine or bromine are stored. [**10:**5.5.7.2]

N **13.6.2.5.7.3** Fire extinguishers intended for use on oxidizer fires where oxidizers are stored or used shall be selected and installed based on the specific recommendations contained within the material's safety data sheet (SDS) for the oxidizer, surrounding conditions, and NFPA 400. [**10:**5.5.7.3]

13.6.2.5.8 Class D Combustible Metal Fires. Fire extinguishers or containers of Class D extinguishing agents provided for the protection of Class D fires shall be listed and labeled for Class D fires. [**10:**5.5.8]

13.6.2.5.8.1* Class D fire extinguishers and agents shall be compatible with the specific metal for which protection is provided. [**10:**5.5.8.1]

A.13.6.2.5.8.1 Other nonlisted agents can be used if acceptable to the AHJ. Other nonlisted agents include specially dried sand, dolomite, soda ash, lithium chloride, talc, foundry flux, and zirconium silicate or other agents shown to be effective. Consult NFPA 484 for use and limitations of these agents and other nonlisted alternatives. [**10:**A.5.5.8.1]

13.6.2.6 Selection for Specific Locations.

Δ **13.6.2.6.1*** Where portable fire extinguishers are required to be installed, the following documents shall be reviewed for the occupancies outlined in their respective scopes:

(1) This *Code*
(2) NFPA 2, *Hydrogen Technologies Code*
(3) NFPA 22, *Standard for Water Tanks for Private Fire Protection*
(4) NFPA 30, *Flammable and Combustible Liquids Code*
(5) NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*
(6) NFPA 33, *Standard for Spray Application Using Flammable or Combustible Materials*
(7) NFPA 40, *Standard for the Storage and Handling of Cellulose Nitrate Film*
(8) NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*
(9) NFPA 51, *Standard for the Design and Installation of Oxygen–Fuel Gas Systems for Welding, Cutting, and Allied Processes*
(10) NFPA 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work*
(11) NFPA 52, *Vehicular Natural Gas Fuel Systems Code*
(12) NFPA 58, *Liquefied Petroleum Gas Code*
(13) NFPA 59, *Utility LP-Gas Plant Code*
(14) NFPA 59A, *Standard for the Production, Storage, and Handling of Liquefied Natural Gas (LNG)*
(15) NFPA 72, *National Fire Alarm and Signaling Code*
(16) NFPA 75, *Standard for the Fire Protection of Information Technology Equipment*
(17) NFPA 76, *Standard for the Fire Protection of Telecommunications Facilities*
(18) NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*
(19) NFPA 99, *Health Care Facilities Code*
(20) NFPA 99B, *Standard for Hypobaric Facilities*
(21) NFPA *101*, *Life Safety Code*
(22) NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*
(23) NFPA 115, *Standard for Laser Fire Protection*
(24) NFPA 120, *Standard for Fire Prevention and Control in Coal Mines*
(25) NFPA 122, *Standard for Fire Prevention and Control in Metal/Nonmetal Mining and Metal Mineral Processing Facilities*
(26) NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems*
(27) NFPA 140, *Standard on Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations*
(28) NFPA 150, *Standard on Fire and Life Safety in Animal Housing Facilities*
(29) NFPA 160, *Standard for the Use of Flame Effects Before an Audience*
(30) NFPA 232, *Standard for the Protection of Records*
(31) NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*

(32) NFPA 301, *Code for Safety to Life from Fire on Merchant Vessels*
(33) NFPA 302, *Fire Protection Standard for Pleasure and Commercial Motor Craft*
(34) NFPA 303, *Fire Protection Standard for Marinas and Boatyards*
(35) NFPA 307, *Standard for the Construction and Fire Protection of Marine Terminals, Piers, and Wharves*
(36) NFPA 326, *Standard for the Safeguarding of Tanks and Containers for Entry, Cleaning, or Repair*
(37) NFPA 385, *Standard for Tank Vehicles for Flammable and Combustible Liquids*
(38) NFPA 400, *Hazardous Materials Code*
(39) NFPA 403, *Standard for Aircraft Rescue and Fire-Fighting Services at Airports*
(40) NFPA 407, *Standard for Aircraft Fuel Servicing*
(41) NFPA 408, *Standard for Aircraft Hand Portable Fire Extinguishers*
(42) NFPA 409, *Standard on Aircraft Hangars*
(43) NFPA 410, *Standard on Aircraft Maintenance*
(44) NFPA 418, *Standard for Heliports*
(45) NFPA 423, *Standard for Construction and Protection of Aircraft Engine Test Facilities*
(46) NFPA 484, *Standard for Combustible Metals*
(47) NFPA 495, *Explosive Materials Code*
(48) NFPA 498, *Standard for Safe Havens and Interchange Lots for Vehicles Transporting Explosives*
(49) NFPA 501A, *Standard for Fire Safety Criteria for Manufactured Home Installations, Sites, and Communities*
(50) NFPA 502, *Standard for Road Tunnels, Bridges, and Other Limited Access Highways*
(51) NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations*
(52) NFPA 655, *Standard for Prevention of Sulfur Fires and Explosions*
(53) NFPA 731, *Standard for the Installation of Electronic Premises Security Systems*
(54) NFPA 801, *Standard for Fire Protection for Facilities Handling Radioactive Materials*
(55) NFPA 804, *Standard for Fire Protection for Advanced Light Water Reactor Electric Generating Plants*
(56) NFPA 805, *Performance-Based Standard for Fire Protection for Light Water Reactor Electric Generating Plants*
(57) NFPA 820, *Standard for Fire Protection in Wastewater Treatment and Collection Facilities*
(58) NFPA 909, *Code for the Protection of Cultural Resource Properties — Museums, Libraries, and Places of Worship*
(59) NFPA 914, *Code for Fire Protection of Historic Structures*
(60) NFPA 1123, *Code for Fireworks Display*
(61) NFPA 1125, *Code for the Manufacture of Model Rocket and High Power Rocket Motors*
(62) NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*
(63) NFPA 1141, *Standard for Fire Protection Infrastructure for Land Development in Wildland, Rural, and Suburban Areas*
(64) NFPA 1192, *Standard on Recreational Vehicles*
(65) NFPA 1194, *Standard for Recreational Vehicle Parks and Campgrounds*
(66) NFPA 1221, *Standard for the Installation, Maintenance, and Use of Emergency Services Communications Systems*
(67) NFPA 1901, *Standard for Automotive Fire Apparatus*
(68) NFPA 1906, *Standard for Wildland Fire Apparatus*
(69) NFPA 1925, *Standard on Marine Fire-Fighting Vessels*
(70) *NFPA 5000, Building Construction and Safety Code*

[**10:**5.6.1]

A.13.6.2.6.1 Where portable fire extinguishers are required to be installed, the following documents should be reviewed for the occupancies outlined in their respective scopes:

(1) NFPA 77, *Recommended Practice on Static Electricity*
(2) NFPA 402, *Guide for Aircraft Rescue and Fire-Fighting Operations*
(3) NFPA 610, *Guide for Emergency and Safety Operations at Motorsports Venues*
(4) NFPA 850, *Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations*
(5) NFPA 921, *Guide for Fire and Explosion Investigations*
(6) NFPA 1452, *Guide for Training Fire Service Personnel to Conduct Community Risk Reduction*

[**10:**A.5.6.1]

Many building codes, fire codes, and specific occupancy standards simply refer to NFPA 10 to provide all the requirements for the selection, installation, and maintenance of extinguishers. However, there are also many standards that include more stringent requirements based on the nature of the occupancy. It is important to be aware of such exceptions. The list in 13.6.2.6.1 provides some guidance on other standards that should be consulted in specific situations. The list, however, is not exhaustive. Whether it appears on this list or not, the appropriate standard, if one exists, should always be consulted to ensure that adequate protection is provided.

13.6.2.6.2 In no case shall the requirements of the documents in 13.6.2.6.1 be less than those specified in Section 13.6 and Chapter 2. [**10:**5.6.2]

13.6.3 Installation of Portable Fire Extinguishers.

13.6.3.1 General.

13.6.3.1.1* Number of Extinguishers. The minimum number of fire extinguishers needed to protect a property shall be determined as outlined in 13.6.3. [**10:**6.1.1]

A.13.6.3.1.1 The following items affect distribution of portable fire extinguishers:

(1) Area and arrangement of the building occupancy conditions
(2) Severity of the hazard
(3) Anticipated classes of fire
(4) Other protective systems or devices
(5) Distances to be traveled to reach fire extinguishers

[**10:**A.6.1.1]

In addition, the following factors should be considered:

(1) Anticipated rate of fire spread
(2) Intensity and rate of heat development
(3) Smoke contributed by the burning materials

[**10:**A.6.1.1]

Wheeled fire extinguishers have additional agent and range and should be considered for areas where the additional protection is needed. Portable fire extinguishers offer the occupant a means to assist in evacuation of a building or occupancy. They are useful to knock down the fire if it occurs along the evacuation route. If possible, the individual property should be surveyed for actual protection requirements. [**10:**A.6.1.1]

13.6.3.1.1.1 The installation of extinguishers shall be independent of whether the building is equipped with automatic sprinklers, standpipe and hose, or other fixed protection equipment. [**10:**6.1.1.1]

13.6.3.1.1.2 Additional extinguishers shall be permitted to be installed to provide more protection as necessary. [**10:**6.1.1.2]

As with all NFPA standards, the requirements of NFPA 10 are designed to provide the minimum level of protection. It is always acceptable to provide protection that is above and beyond the requirements of NFPA 10, including the installation of additional or higher-rated extinguishers, when deemed appropriate.

13.6.3.1.1.3 Fire extinguishers having ratings less than those specified in Table 13.6.3.2.1.1 and Table 13.6.3.3.1.1 shall be permitted to be installed, provided they are not used in fulfilling the minimum protective requirements of this subsection, except as modified in 13.6.3.2.1.4, 13.6.3.2.1.5, and 13.6.3.3.1.1.1. [**10:**6.1.1.3]

13.6.3.1.2 Extinguisher Readiness. Portable fire extinguishers shall be maintained in a fully charged and operable condition and shall be kept in their designated places at all times when they are not being used. [**10:**6.1.2]

13.6.3.1.3 Placement.

13.6.3.1.3.1 Fire extinguishers shall be conspicuously located where they are readily accessible and immediately available in the event of fire. [**10:**6.1.3.1]

13.6.3.1.3.2 Fire extinguishers shall be located along normal paths of travel, including exits from areas. [**10:**6.1.3.2]

Locating portable fire extinguishers along normal paths of travel helps to ensure that occupants are able to easily find an obviously placed extinguisher and that they will not put themselves in danger while retrieving the extinguisher.

13.6.3.1.3.3 Visual Obstructions.

13.6.3.1.3.3.1 Fire extinguishers shall be installed in locations where they are visible except as permitted by 13.6.3.1.3.3.2. [**10:**6.1.3.3.1]

Δ **13.6.3.1.3.3.2*** In rooms and in locations where visual obstructions cannot be completely avoided, signs or other means shall be provided to indicate the extinguisher location. [**10:**6.1.3.3.2]

NFPA 10 does not specify a means of identifying the locations of extinguishers to occupants, nor does it provide design specifications, such as color, font size, and so forth, for signs or other identifiers. It is within the purview of the AHJ to determine whether the extinguisher locations are conspicuous and/or identifiable.

Δ **A.13.6.3.1.3.3.2** The primary means for identifying locations of fire extinguishers should be by the installation of the fire extinguisher signs that are specifically designed for that purpose. Examples of other means of identifying the fire extinguisher locations include arrows, lights, or coding of the wall or column. [**10:**A.6.1.3.3.2]

N **13.6.3.1.3.3.3** Signs or other means used to indicate fire extinguisher location shall be located in close proximity to the extinguisher. [**10:**6.1.3.3.3]

N **13.6.3.1.3.3.4** Signs or other means used to indicate fire extinguisher location shall be visible from the normal path of travel. [**10:**6.1.3.3.4]

Δ **13.6.3.1.3.4*** Portable fire extinguishers other than wheeled extinguishers shall be installed using any of the following means:

(1) Securely on a hanger intended for the extinguisher
(2) In a bracket incorporating releasing straps or bands supplied by the extinguisher manufacturer
(3) In a listed bracket incorporating releasing straps or bands approved for such purpose
(4) In approved cabinets or wall recesses

[**10:**6.1.3.4]

Δ **A.13.6.3.1.3.4** In situations where it is necessary that fire extinguishers be provided temporarily, a good practice is to provide portable stands on uprights with feet, on which the fire extinguishers can be installed. Portable stands should be designed to comply with the mounting heights for extinguishers. [**10:**A.6.1.3.4]

13.6.3.1.3.5 Wheeled fire extinguishers shall be located in designated locations. [**10:**6.1.3.5]

13.6.3.1.3.6 Fire extinguishers installed in vehicles or under other conditions where they are subject to dislodgement shall be installed in approved strap-type brackets specifically designed for this application. [**10:**6.1.3.6]

Fire extinguishers that are installed in narrow corridors with two-way traffic are subject to people bumping into and dislodging them. Extinguishers are also sometimes mounted in areas where children might reach up and dislodge them. Extinguishers accidentally dislodged from their brackets can fall and cause injury. In such situations, extinguishers should be secured in strap brackets or mounted in properly marked recesses or cabinets to protect them from accidental dislodgment.

13.6.3.1.3.7 Fire extinguishers installed under conditions or in locations where they are subject to physical damage (e.g., from impact, vibration, the environment) shall be protected against such damage. [**10:**6.1.3.7]

If an extinguisher is located where it could be susceptible to damage, consult with the extinguisher manufacturer to determine whether special mounting brackets or protective coverings are available

13.6.3.1.3.8 Installation Height.

13.6.3.1.3.8.1 Fire extinguishers having a gross weight not exceeding 40 lb (18.14 kg) shall be installed so that the top of the fire extinguisher is not more than 5 ft (1.53 m) above the floor. [**10:**6.1.3.8.1]

13.6.3.1.3.8.2 Fire extinguishers having a gross weight greater than 40 lb (18.14 kg) (except wheeled types) shall be installed so that the top of the fire extinguisher is not more than 3½ ft (1.07 m) above the floor. [**10:**6.1.3.8.2]

13.6.3.1.3.8.3 In no case shall the clearance between the bottom of the hand portable fire extinguisher and the floor be less than 4 in. (102 mm). [**10:**6.1.3.8.3]

13.6.3.1.3.9 Label Visibility.

13.6.3.1.3.9.1 Fire extinguishers shall be installed so that the fire extinguisher's operating instructions face outward. [**10:**6.1.3.9.1]

Operating instructions that face outward are immediately visible at all times. They should not be covered by inspection tags, mounting straps, or other materials. This remains true even where the extinguisher is installed inside a cabinet, as shown in Exhibit 13.32

13.6.3.1.3.9.2 Hazardous materials identification systems (HMIS) labels, 6-year maintenance labels, hydrostatic test labels, or other labels shall not be located or placed on the front of the extinguisher. [**10:**6.1.3.9.2]

Exhibit 13.32

Inspection and maintenance tags on a cabinet-mounted extinguisher.

13.6.3.1.3.9.3 The restrictions of 13.6.3.1.3.9.2 shall not apply to the original manufacturer's labels, labels that specifically relate to the extinguisher's operation or fire classification, or inventory control labels specific to that extinguisher. [**10:**6.1.3.9.3]

In an emergency situation, information other than an extinguisher's operating instructions can confuse or distract the user, causing a delay in putting the extinguisher into operation. The pictographic operating instructions cover a minimum 120-degree arc of the extinguisher label on the front of the extinguisher.

Extensive live fire testing with novice operators proved that pictographic instructions and the elimination of unnecessary information from the front of the extinguisher significantly improved fire extinguishment. Inspection tags, hydrostatic test labels, service agency identification labels, and any other markings that are not necessary for understanding how to properly operate the extinguisher should be kept out of the 120-degree arc operating instruction area on the front of the extinguisher.

13.6.3.1.3.10 Cabinets.

13.6.3.1.3.10.1 Cabinets housing fire extinguishers shall not be locked, except where fire extinguishers are subject to malicious use and cabinets include a means of emergency access. [**10:**6.1.3.10.1]

13.6.3.1.3.10.2 The location of fire extinguishers as described in 13.6.3.1.3.3.2 shall be marked conspicuously. [**10:**6.1.3.10.2]

13.6.3.1.3.10.3 Fire extinguishers mounted in cabinets or wall recesses shall be placed so that the fire extinguisher's operating instructions face outward. [**10:**6.1.3.10.3]

13.6.3.1.3.10.4* Where fire extinguishers are installed in closed cabinets that are exposed to elevated temperatures, the cabinets shall be provided with screened openings and drains. [**10:**6.1.3.10.4]

A.13.6.3.1.3.10.4 Vented fire extinguisher cabinets should utilize tinted glass and should be constructed to prevent the entrance of insects and the accumulation of water. Vented fire extinguisher cabinets constructed in this manner lower the maximum internal temperature by 10°F to 15°F (5.6°C to 8.3°C). [**10:**A.6.1.3.10.4]

Extinguishers installed in unventilated outside cabinets in areas exposed to direct sunlight can be subject to significant heat buildup (greenhouse effect) and can be too hot to handle [approximately 140°F (60°C)]. Louvered cabinets, which allow air to circulate into and out of the cabinet, should be used. Screened openings should be provided to prevent insects from nesting in the cabinet. Drains should be provided to prevent the accumulation of water and, in winter, the formation of ice. Cabinets suitable for installation in outdoor locations are readily available and should be used.

13.6.3.1.3.10.5 Cabinets or wall recesses for fire extinguishers shall be installed such that the extinguisher mounting heights specified in 13.6.3.1.3.8.1 and 13.6.3.1.3.8.2 are met. [**10:**6.1.3.10.5]

N 13.6.3.1.3.10.6* For fire resistance–rated walls, only surface-mounted cabinets or listed fire-rated cabinets shall be installed. [**10:**6.1.3.10.6]

N A.13.6.3.1.3.10.6 Certain fire resistance–rated cabinets are intended for installation into fire resistance–rated walls. Cabinets that are not fire resistance–rated make the entire fire resistance–rated wall noncompliant, so only surface-mounted cabinets or fire resistance–rated cabinets are appropriate for installation in fire resistance–rated walls. [**10:**A.6.1.3.10.6]

13.6.3.1.3.11* Fire extinguishers shall not be exposed to temperatures outside of the listed temperature range shown on the fire extinguisher label. [**10:**6.1.3.11]

A.13.6.3.1.3.11 The following precautions should be noted where fire extinguishers are located in areas that have temperatures outside the range of 40°F to 120°F (4°C to 49°C):

(1) AFFF and FFFP fire extinguishers cannot be protected against temperatures below 40°F (4°C) by adding an antifreeze charge, because it tends to destroy the effectiveness of the extinguishing agent.
(2) Plain water fire extinguishers should not be protected against temperatures below 40°F (4°C) with ethylene glycol antifreeze. Calcium chloride solutions should not be used in stainless steel fire extinguishers.
(3) Fire extinguishers installed in machinery compartments, diesel locomotives, automotive equipment, marine engine compartments, and hot processing facilities can easily be subjected to temperatures above 120°F (49°C). Selection of fire extinguishers for hazard areas with temperatures above the listed limits should be made on the basis of recommendations by manufacturers of this equipment.

[**10:**A.6.1.3.11]

13.6.3.1.4 Antifreeze.

13.6.3.1.4.1 Fire extinguishers containing only plain water shall be protected to temperatures as low as −40°F (−40°C) by the addition of an antifreeze that is stipulated on the fire extinguisher nameplate. [**10:**6.1.4.1]

13.6.3.1.4.2 Calcium chloride solutions shall not be used in stainless steel fire extinguishers. [**10:**6.1.4.2]

13.6.3.1.5 Electronic Monitoring and Alarm System.

13.6.3.1.5.1 The connection to the electronic monitoring device shall be continuously supervised for integrity. [**10:**6.1.5.1]

13.6.3.1.5.2 The power source for the electronic monitoring device shall be supervised for continuity of power. [**10:**6.1.5.2]

13.6.3.2 Installations for Class A Hazards.

13.6.3.2.1 Fire Extinguisher Size and Placement for Class A Hazards.

13.6.3.2.1.1 Minimal sizes of fire extinguishers for the listed grades of hazards shall be provided on the basis of Table 13.6.3.2.1.1, except as modified by 13.6.3.2.1.4 and 13.6.3.2.1.5. [**10:**6.2.1.1]

Δ ***TABLE 13.6.3.2.1.1*** *Fire Extinguisher Size and Placement for Class A Hazards*

Criteria	Light Hazard Occupancy	Ordinary Hazard Occupancy	Extra Hazard Occupancy
Minimum rated single extinguisher	2-A	2-A	4-A
Maximum floor area per unit of A	3000 ft^2	1500 ft^2	1000 ft^2
Maximum floor area per extinguisher	11,250 ft^2	11,250 ft^2	11,250 ft^2
Maximum travel distance to extinguisher	75 ft	75 ft	75 ft

For SI units, 1 ft = 0.305 m; 1 ft^2 = 0.0929 m^2.
Note: For maximum floor area explanations, see E.3.3 of NFPA 10. [**10:** Table 6.2.1.1]

13.6.3.2.1.2 The minimum number of extinguishers for Class A hazards shall be sufficient to meet the requirements of 13.6.3.2.1.2.1 through 13.6.3.2.1.2.3. [**10:**6.2.1.2]

13.6.3.2.1.2.1 The minimum number of fire extinguishers for Class A hazards for each floor of a building shall be determined by dividing the total floor area by the maximum area to be protected per extinguisher as determined by Table 13.6.3.2.1.1. *(See Annex E of NFPA 10.)* [**10:**6.2.1.2.1]

13.6.3.2.1.2.2 Fire extinguishers shall be located so that the maximum travel distances shall not exceed 75 ft(22.9 m), except as modified by 13.6.3.2.1.4. [**10:**6.2.1.2.2]

The requirement of 13.6.3.2.1.2.2 is intended to limit the time required to reach the extinguisher and then reach the fire and begin extinguishment. Locating extinguishers to meet the travel distance requirements must take into account the presence of obstacles in the area.

It is ineffective to distribute extinguishers in an empty warehouse and then fill it with pallets of stock. The true travel distance from the extinguisher to a potential fire location could significantly increase where pallets are in place. Extinguisher placement with respect to travel distance should be practical with respect to the intent, which is to limit the time required to put the extinguisher into operation. Annex E of NFPA 10 offers a comprehensive discussion on determining the effective distribution of portable fire extinguishers.

13.6.3.2.1.2.3 Where the quantity of extinguishers required to satisfy 13.6.3.2.1.2.2 exceeds the number calculated in 13.6.3.2.1.2.1, additional extinguishers shall be installed. [**10:**6.2.1.2.3]

13.6.3.2.1.3 Smaller fire extinguishers that are rated on Class B and Class C fires but do not have a minimum 1-A rating shall not be used to meet the requirements of 13.6.3.2.1. [**10:**6.2.1.3]

13.6.3.2.1.4 Fire extinguishers of lesser rating shall be permitted to be installed but shall not be considered as fulfilling any part of the requirements of Table 13.6.3.2.1.1, except as permitted in 13.6.3.2.1.4(A) and 13.6.3.2.1.4(B). [**10:**6.2.1.3.1]

13.6.3.2.1.4.1 Up to two water-type extinguishers, each with 1-A rating, shall be permitted to be used to fulfill the requirements of one 2-A rated extinguisher. [**10:**6.2.1.3.1.1]

13.6.3.2.1.4.2 Two 2½ gal (9.46 L) water-type extinguishers shall be permitted to be used to fulfill the requirements of one 4-A rated extinguisher. [**10:**6.2.1.3.1.2]

13.6.3.2.1.5 Up to one-half of the complement of fire extinguishers specified in Table 13.6.3.2.1.1 shall be permitted to be replaced by uniformly spaced 1½ in. (38 mm) hose stations for use by the occupants of the building. [**10:**6.2.1.4]

Δ **13.6.3.2.1.5.1** Where hose stations are so provided, they shall conform to NFPA 14. [**10:**6.2.1.4.1]

13.6.3.2.1.5.2 The location of hose stations and the placement of fire extinguishers shall be such that the hose stations do not replace more than every other fire extinguisher. [**10:**6.2.1.4.2]

13.6.3.2.1.6 Where the area of the floor of a building is less than that specified in Table 13.6.3.2.1.1, at least one fire extinguisher of the minimum size required shall be provided. [**10:**6.2.1.5]

13.6.3.2.1.7 The protection requirements shall be permitted to be fulfilled with fire extinguishers of higher rating, provided the travel distance to such larger fire extinguishers does not exceed 75 ft (22.9 m) and the maximum floor area per unit of A is not exceeded. [**10:**6.2.1.6]

13.6.3.3 Installations for Class B Hazards.

13.6.3.3.1 Spill Fires.

Δ **13.6.3.3.1.1** Minimum ratings of fire extinguishers for the listed grades of hazard shall be provided in accordance with Table 13.6.3.3.1.1 [**10:**6.3.1.1].

13.6.3.3.1.1.1 Two or more fire extinguishers of lower rating shall not be used to fulfill the protection requirements of Table 13.6.3.3.1.1 except as permitted by 13.6.3.3.1.1.2 and 13.6.3.3.1.1.3. [**10:**6.3.1.1.1]

13.6.3.3.1.1.2 Up to three AFFF or FFFP fire extinguishers of at least 2½ gal (9.46 L) capacity shall be permitted to be used to fulfill extra hazard requirements. [**10:**6.3.1.1.2]

13.6.3.3.1.1.3 Two AFFF or FFFP fire extinguishers of at least 1.6 gal (6 L) capacity shall be permitted to be used to fulfill ordinary hazard requirements. [**10:**6.3.1.1.3]

13.6.3.3.1.2 Fire extinguishers of lesser rating, designed for small specific hazards within the general hazard area, shall be permitted to be installed but shall not be considered as fulfilling any part of the requirements of Table 13.6.3.3.1.1, unless permitted by 13.6.3.3.1.1.1 or 13.6.3.3.1.1.2. [**10:**6.3.1.2]

13.6.3.3.1.3 Fire extinguishers shall be located so that the maximum travel distances do not exceed those specified in Table 13.6.3.3.1.1. [**10:**6.3.1.3]

Δ ***TABLE 13.6.3.3.1.1*** *Fire Extinguisher Size and Placement for Class B Hazards*

Type of Hazard	Basic Minimum Extinguisher Rating	Maximum Travel Distance to Extinguishers: ft	m
Light	5-B	30	9.14
	10-B	50	15.25
Ordinary	10-B	30	9.14
	20-B	50	15.25
Extra	40-B	30	9.14
	80-B	50	15.25

Note: The specified ratings do not imply that fires of the magnitudes indicated by these ratings will occur, but rather they are provided to give the operators more time and agent to handle difficult spill fires that have the potential to occur.

[**10:** Table 6.3.1.1]

13.6.3.3.1.4 The protection requirements shall be permitted to be fulfilled with fire extinguishers of higher ratings, provided the travel distance to such larger fire extinguishers does not exceed 50 ft (15.25 m). [**10:**6.3.1.4]

13.6.3.3.2 Flammable Liquids of Appreciable Depth.

13.6.3.3.2.1 Portable fire extinguishers shall not be installed as the sole protection for flammable liquid hazards of appreciable depth where the surface area exceeds 10 ft^2 (0.93 m^2.) [**10:**6.3.2.1]

13.6.3.3.2.2* Where personnel who are trained in extinguishing fires in the protected hazards are located on the premises and capable of responding immediately, the maximum surface area shall not exceed 20 ft^2 (1.86 m^2). [**10:**6.3.2.2]

A.13.6.3.3.2.2 Where such personnel are not available, the hazard should be protected by fixed systems. [**10:**A.6.3.2.2]

13.6.3.3.2.3 For flammable liquid hazards of appreciable depth, a Class B fire extinguisher shall be provided on the basis of at least 2 numerical units of Class B extinguishing potential per 1 ft^2 (0.09 m^2) of flammable liquid surface of the largest hazard area. [**10:**6.3.2.3]

13.6.3.3.2.4 AFFF- or FFFP-type fire extinguishers shall be permitted to be provided on the basis of 1-B of protection per 1 ft^2 (0.09 m^2) of hazard. *(For fires involving water-soluble flammable liquids, see 5.5.3 of NFPA 10.)* [**10:**6.3.2.4]

13.6.3.3.2.5 Two or more fire extinguishers of lower ratings, other than AFFF- or FFFP-type fire extinguishers, shall not be used in lieu of the fire extinguisher required for the largest hazard area. [**10:**6.3.2.5]

13.6.3.3.2.6 Up to three AFFF- or FFFP-type fire extinguishers shall be permitted to fulfill the requirements, provided the sum of the Class B ratings meets or exceeds the value required for the largest hazard area. [**10:**6.3.2.6]

13.6.3.3.2.7 Travel distances for portable fire extinguishers shall not exceed 50 ft (15.25 m). *(See Annex E of NFPA 10.)* [**10:**6.3.2.7]

13.6.3.3.2.7.1 Scattered or widely separated hazards shall be individually protected. [**10:**6.3.2.7.1]

13.6.3.3.2.7.2 A fire extinguisher in the proximity of a hazard shall be located to be accessible in the presence of a fire without undue danger to the operator. [**10:**6.3.2.7.2]

Fires in flammable liquids of appreciable depth can grow quickly, radiate significant heat, and be difficult to approach. Fire extinguishers should be located so that, in the case of a fully involved fire, an extinguisher is available without hazard to the operator and so that, if the fire spreads, the operator has a means of escape. Keeping this goal in mind, the fire extinguisher selected to protect the hazard should be the most obvious and convenient to use. For example, a 5 lb (2.27 kg) halogenated agent extinguisher used to protect a shop floor computer terminal should not be hung next to a 2.5 gal (9.46 L) film-forming fluoroprotein foam (FFFP) unit placed to protect a flammable liquid degreaser tank. In the event of a tank fire, the incorrect extinguisher might accidentally be selected.

13.6.3.3.3 Obstacle, Gravity/Three-Dimensional, and Pressure Fire Hazards.

13.6.3.3.3.1 Where hand portable fire extinguishers are installed or positioned for obstacle, gravity/three-dimensional, or pressure fire hazards, the actual travel distance to hazard shall not exceed 30 ft (9 m) unless otherwise specified *(See 5.6.1 of NFPA 10.)* [**10:**6.3.3.1]

13.6.3.3.3.2 Where wheeled fire extinguishers of 125 lb (56.7 kg) agent capacity or larger are installed or positioned for obstacle, gravity/three-dimensional, or pressure fire hazards, the actual travel distance to hazard shall not exceed 100 ft (30.5 m) unless otherwise specified. *(See 5.6.1 of NFPA 10.)* [**10:**6.3.3.2]

The provisions of 13.6.3.3.3 address the travel distances to extinguishers for obstacle, gravity/three-dimensional, and pressure fire hazards, which are described as follows:

1. Obstacle fires: fuel situations completely surrounding a sizable object
2. Gravity/three-dimensional fires: pouring, running, or dripping fuel situations
3. Pressure fires: forced, pumped, or sprayed fuel situations

13.6.3.4* Installations for Class C Hazards.

A.13.6.3.4 Electrical equipment should be de-energized as soon as possible to prevent reignition. [**10:**A.6.4]

13.6.3.4.1 Fire extinguishers with Class C ratings shall be required where energized electrical equipment can be encountered. [**10:**6.4.1]

13.6.3.4.2 The requirement in 13.6.3.4.1 shall include situations where fire either directly involves or surrounds electrical equipment. [**10:**6.4.2]

13.6.3.4.3 Because fire is a Class A or Class B hazard, the fire extinguishers shall be sized and located on the basis of the anticipated Class A or Class B hazard. [**10:**6.4.3]

13.6.3.5 Installations for Class D Hazards.

13.6.3.5.1* Fire extinguishers or extinguishing agents with Class D ratings shall be provided for fires involving combustible metals. [**10:**6.5.1]

A.13.6.3.5.1 Where Class D fire hazards exist, it is common practice to place bulk quantities of extinguishing agent near the potential Class D hazard. Depending on the type of metal present, the Class D agent selected for the protection of the hazard might not be a listed fire-extinguishing agent. In the case of the production of lithium metal, the agent of choice is lithium chloride, which is feed stock to the electrolytic cell where the lithium metal is manufactured. The use of lithium chloride on a lithium fire will not poison the electrolytic cell so the cell would not have to be drained and relined with fire brick. There are several Class D agents that have been shown to be effective on specific Class D fires. Additional information on Class D agents is provided in NFPA 484. [**10:**A.6.5.1]

The operation of Class D fire extinguishers is much different from that of dry chemical extinguishers rated for Class A, B, or C. The extinguishing agent from a Class D extinguisher should be applied to avoid spreading the combustible metal material and/or suspending the metal product in the air, which can result in an explosion, by slowly applying the agent. The application of a Class D agent on burning metals is intended to control the fire and assist in the formation of oxide crust that limits combustion. This is accomplished by first encircling the combustible metal material with the agent and then covering the burning metal in a smothering action. It is important to note that metal fires involving large quantities of metal beyond the incipient stage are nearly impossible to control or extinguish with a Class D agent. In most cases, the metal will continue to burn in a controlled fashion after application of the agent until it is completely oxidized. Disturbing the oxide crust can result in reignition and open burning if complete extinguishment, oxidation of the metal, or exclusion of oxygen has not occurred. Fires involving alkali earth metal and transitional metals will begin to form an oxide crust as they burn, which will limit open burning without the application of an extinguishing agent. Application of water or other extinguishing agents can result in an adverse reaction, including the potential for an explosion. Burning metals can also draw moisture from concrete or asphalt, which also maintains the potential for explosion. Large amounts of combustible metal materials involved in a fire can remain hot for some time and vigorously reignite if disturbed prior to complete extinguishment of the combustible metal materials. *(See A.13.6.2.3.2.4.)* [**10:**A.6.5.1]

Work areas that generate combustible metals in powder, flakes, shavings, chips, or similarly sized products must have Class D fire extinguishers available. The extinguisher should be specifically listed for the particular metal hazard or hazards involved. Listed hand portable fire extinguishers and wheeled-type fire extinguishers are available for metal fires involving magnesium, sodium, potassium, sodium potassium alloys, uranium, powdered aluminum, and lithium. The Class D agents accomplish fire extinguishment by coating and caking over the burning metal, absorbing heat and excluding oxygen.

13.6.3.5.2 Fire extinguishers or extinguishing agents (media) shall be located not more than 75 ft (22.9 m) of travel distance from the Class D hazard. *(See Section E.6 of NFPA 10.)* [**10:**6.5.2]

13.6.3.5.3* Portable fire extinguishers or extinguishing agents (media) for Class D hazards shall be provided in those work areas where combustible metal powders, flakes, shavings, chips, or similarly sized products are generated. [**10:**6.5.3]

A.13.6.3.5.3 See NFPA 484 for additional information. [**10:**A.6.5.3]

13.6.3.5.4* Size determination shall be on the basis of the specific combustible metal, its physical particle size, area to be covered, and recommendations by the fire extinguisher manufacturer based on data from control tests. [**10:**6.5.4]

A.13.6.3.5.4 See NFPA 484 for additional information. [**10:**A.6.5.4]

13.6.3.6 Installations for Class K Hazards.

13.6.3.6.1 Class K fire extinguishers shall be provided for hazards where there is a potential for fires involving combustible cooking media (vegetable or animal oils and fats). [**10:**6.6.1]

13.6.3.6.2 Maximum travel distance shall not exceed 30 ft (9.1 m) from the hazard to the extinguishers. [**10:**6.6.2]

13.6.3.6.3 All solid fuel cooking appliances (whether or not under a hood) with fire boxes of 5 ft^3 (0.14 m^3) volume or less shall have at least a listed 2-A rated water-type fire extinguisher or a 1.6 gal (6 L) wet chemical fire extinguisher that is listed for Class K fires. [**10:**6.6.3]

13.6.4 Inspection, Maintenance, and Recharging.

13.6.4.1* General.

A.13.6.4.1 Subsection 13.6.4 is concerned with the rules governing inspection, maintenance, and recharging of fire extinguishers. These factors are of prime importance in ensuring operation at the time of a fire. The procedure for inspection and maintenance of fire extinguishers varies considerably. Minimal knowledge is necessary to perform a monthly "quick check" or inspection in order to follow the inspection procedure as outlined in 13.6.4.2. [**10:**A.7.1]

13.6.4.1.1 Responsibility. The owner or designated agent or occupant of a property in which fire extinguishers are located shall be responsible for inspection, maintenance, and recharging. *(See 13.6.4.1.2.)* [**10:**7.1.1]

13.6.4.1.2 Personnel.

13.6.4.1.2.1* Persons performing maintenance and recharging of extinguishers shall be certified. [**10:**7.1.2.1]

It is up to the AHJ to adopt and enforce the certification requirements for persons performing maintenance on portable fire extinguishers. The AHJ is also responsible for identifying which certification programs are accepted.

A.13.6.4.1.2.1 Persons performing maintenance and recharging of extinguishers should meet one of the following criteria:

(1) Factory training and certification for the specific type and brand of portable fire extinguisher being serviced
(2) Certification by an organization acceptable to the AHJ
(3) Registration, licensure, or certification by a state or a local AHJ

[**10:**A.7.1.2.1]

Certification confirms that a person has fulfilled specific requirements as a fire extinguisher service technician and has earned the certification. For the purpose of Section 13.6, certification is the process of an organization issuing a document confirming that an applicant has passed a test based on the chapters and annexes of NFPA 10. The organization administering the test issues an official document that is relied upon as proof of passing the test. Ultimately, the document issued by the organization administering the test must be acceptable to the AHJ. Some AHJs do not rely on outside organizations and establish their own local licensing programs that include a test. [**10:**A.7.1.2.1]

13.6.4.1.2.1.1 Persons training to become certified shall be permitted to perform maintenance and recharging of extinguishers under the direct supervision and in the immediate presence of a certified person. [**10:**7.1.2.1.1]

13.6.4.1.2.1.2 Certification requires that a person pass a test administered by an organization acceptable to the AHJ. [**10:**7.1.2.1.2]

13.6.4.1.2.1.3 The test shall, at a minimum, be based upon knowledge of the chapters and annexes of NFPA 10. [**10:**7.1.2.1.3]

13.6.4.1.2.1.4 The testing process shall permit persons to use NFPA 10 during the test. [**10:**7.1.2.1.4]

13.6.4.1.2.1.5 Persons passing the test required in 13.6.4.1.2.1.2 shall be issued a document or a certificate. [**10:**7.1.2.1.5]

13.6.4.1.2.1.6 The document or certificate shall be made available when requested by the AHJ. [**10:**7.1.2.1.6]

13.6.4.1.2.2* Persons performing maintenance and recharging of extinguishers shall be trained and shall have available the appropriate manufacturer's servicing manual(s), the correct tools, recharge materials, lubricants, and manufacturer's replacement parts or parts specifically listed for use in the fire extinguisher. [**10:**7.1.2.2]

A.13.6.4.1.2.2 Industrial facilities that establish their own maintenance and recharge facilities and that provide training to personnel who perform these functions are considered to be in compliance with this requirement. Examples include power generation, petrochemical, and telecommunications facilities. A letter from the facility management can be used as the certification document. [**10:**A.7.1.2.1.2]

13.6.4.1.2.3* Persons performing inspections shall not be required to be certified. [**10:**7.1.2.3]

A.13.6.4.1.2.3 This requirement is not intended to prevent service technicians from performing the inspections. [**10:**A.7.1.2.3]

13.6.4.1.3 Replacement While Servicing. Fire extinguishers removed from service for maintenance or recharging shall be replaced by a fire extinguisher suitable for the type of hazard being protected and shall be of at least equal rating. [**10:**7.1.3]

The type of agent used in the replacement extinguisher should be compatible with the type of hazard being protected. A dry chemical type is not acceptable in a computer facility, because the extinguishing agent could cause damage to the equipment intended to be protected. An A:B:C type might not be suitable for use in a kitchen cooking unit, because it is unable to saponify flaming grease and permanently extinguish the fire.

Replacement extinguishers with ratings equal to, or larger in size than, the replaced extinguisher or extinguishers that have additional class ratings are acceptable. For example, a 40-B:C–rated sodium bicarbonate extinguisher used to protect against a flammable liquid fire could be replaced by a 2-A:40-B:C ammonium phosphate unit. Both are equally effective on a Class B fire hazard.

13.6.4.1.4 Tags or Labels.

13.6.4.1.4.1 Tags or labels intended for recording inspections, maintenance, or recharging shall be affixed so as not to obstruct the fire extinguisher use, fire extinguisher classification, or manufacturer's labels. [**10:**7.1.4.1]

13.6.4.1.4.2 Labels indicating fire extinguisher use or classification or both shall be permitted to be placed on the front of the fire extinguisher. [**10:**7.1.4.2]

13.6.4.2 Inspection.

13.6.4.2.1 Inspection Frequency.

13.6.4.2.1.1* Fire extinguishers shall be manually inspected when initially placed in service. [**10:**7.2.1.1]

A.13.6.4.2.1.1 Frequency of fire extinguisher inspections should be based on the need of the area in which fire extinguishers are located. The required monthly inspection is a minimum. [**10:**A.7.2.1.1]

13.6.4.2.1.2* Fire extinguishers and Class D extinguishing agents shall be inspected either manually or by means of an electronic monitoring device/system at intervals not exceeding 31 days. [**10:**7.2.1.2]

A.13.6.4.2.1.2 Inspections should be performed on extinguishers 12 times per year, at regular intervals not exceeding 31 days. [**10:**A.7.2.1.2]

13.6.4.2.1.2.1 Fire extinguishers and Class D extinguishing agents shall be inspected at least once per calendar month. [**10:**7.2.1.2.1]

13.6.4.2.1.3* Fire extinguishers and Class D extinguishing agents shall be manually inspected daily or weekly when conditions exist that indicate the need for more frequent inspections. [**10:**7.2.1.3]

A.13.6.4.2.1.3 Inspections should be more frequent if any of the following conditions exist:

(1) High frequency of fires in the past
(2) Severe hazards
(3) Susceptibility to tampering, vandalism, or malicious mischief
(4) Possibility of, or history of, theft of fire extinguishers
(5) Locations that make fire extinguishers susceptible to mechanical injury
(6) Possibility of visible or physical obstructions
(7) Exposure to abnormal temperatures or corrosive atmospheres
(8) Characteristics of fire extinguishers, such as susceptibility to leakage

[**10:**A.7.2.1.3]

More frequent inspections could be enhanced through electronic monitoring of the fire extinguisher. [**10:**A.7.2.1.3]

13.6.4.2.1.4 Extinguishers that are electronically monitored for location only, such as those monitored by means of a switch to indicate when the extinguisher is removed from its bracket or cabinet, shall be manually inspected in accordance with 13.6.4.2.2. [**10:**7.2.1.4]

Δ **13.6.4.2.2 Inspection Procedures.** Periodic inspection or electronic monitoring of fire extinguishers shall include a check of at least the following items:

(1) Location in designated place
(2) Visibility of the extinguisher or means of indicating the extinguisher location
(3) Access to the extinguisher
(4) Pressure gauge reading or indicator in the operable range or position
(5) Fullness determined by weighing or hefting
(6) Condition of tires, wheels, carriage, hose, and nozzle for wheeled extinguishers

A record of the inspection should be noted on the extinguisher service tag. Many fire equipment dealers and distributors use bar code identification on the extinguishers they inspect, service, and test. The bar code readout provides a convenient, accurate, up-to-date record of the inspections, maintenance, recharging, and hydrotesting performed on each extinguisher, which can be maintained in their files. If an inspection reveals a problem, full maintenance should be performed.

(7) Indicator for nonrechargeable extinguishers using push-to-test pressure indicators

[**10:**7.2.2]

N **13.6.4.2.2.1** The owner or the owner's agent shall determine the method of extinguisher inspection such as manual inspection, electronic monitoring, or any combination of the two. [**10:**7.2.2.1]

N **13.6.4.2.2.2** Any method(s) of inspection other than manual inspection shall require the approval of the authority having jurisdiction. [**10:**7.2.2.2]

Paragraphs 13.6.4.2.2.1 and 13.6.4.2.2.2 are new to the *Code*. The type of inspection service provided should be at the discretion of the building owner or designated agent. The owner or agent should also be the party that determines one method or another or a combination of methods. Any alternative method to visual inspection should be reviewed and approved by the AHJ.

Δ **13.6.4.2.2.3*** In addition to 13.6.4.2.2, fire extinguishers shall be visually inspected in accordance with 13.6.4.2.2.4 if they are located where any of the following conditions exists:

(1) High frequency of fires in the past
(2) Severe hazards
(3) Locations that make fire extinguishers susceptible to mechanical injury or physical damage
(4) Exposure to abnormal temperatures or corrosive atmospheres

[**10:**7.2.2.3]

A.13.6.4.2.2.3 Fire extinguishers in vehicles should be inspected at the beginning of a shift or whenever the vehicle is used. The inspection should ensure that the extinguisher is charged and ready for use. Extinguishers in compartments or trunks can become damaged or otherwise compromised because of weather exposure, other items in the compartment that are not secured, or other factors. [**10:**A.7.2.2.3]

13.6.4.2.2.4 Where required by 13.6.4.2.2.3, the following inspection procedures shall be in addition to those addressed in 13.6.4.2.2:

(1) Verify that operating instructions on nameplates are legible and face outward
(2) Check for broken or missing safety seals and tamper indicators
(3) Examine for obvious physical damage, corrosion, leakage, or clogged nozzle

[**10:**7.2.2.4]

13.6.4.2.2.5 Inspection Procedure for Containers of Class D Extinguishing Agent. Periodic inspection of containers of Class D extinguishing agent used to protect Class D hazards shall include verification of at least the following:

(1) Located in designated place
(2) Visibility of the container or means of indicating the container location
(3) Access to the container
(4) Lid is sealed
(5) Fullness by hefting or weighing
(6) No obvious physical damage to container

[**10:**7.2.2.5]

13.6.4.2.3 Corrective Action. When an inspection of any fire extinguisher reveals a deficiency in any of the conditions in 13.6.4.2.2 or 13.6.4.2.2.4, immediate corrective action shall be taken. [**10:**7.2.3]

13.6.4.2.3.1 Rechargeable Fire Extinguishers. When an inspection of any rechargeable fire extinguisher reveals a deficiency in any of the conditions in 13.6.4.2.2(3), 13.6.4.2.2(4), 13.6.4.2.2(5),or 13.6.4.2.2(1) through 13.6.4.2.2(3), the extinguisher shall be subjected to applicable maintenance procedures. [**10:**7.2.3.1]

13.6.4.2.3.2 Nonrechargeable Dry Chemical Fire Extinguisher. When an inspection of any nonrechargeable dry chemical fire extinguisher reveals a deficiency in any of the conditions listed in 13.6.4.2.2(3), 13.6.4.2.2(4),13.6.4.2.2(6), or 13.6.4.2.2.4(1) through 13.6.4.2.2.4(3), the extinguisher shall be removed from further use, discharged, and destroyed at the direction of the owner or returned to the manufacturer. [**10:**7.2.3.2]

13.6.4.2.3.3 Nonrechargeable Halon Agent Fire Extinguisher. When an inspection of any nonrechargeable fire extinguisher containing a halon agent reveals a deficiency in any of the conditions listed in 13.6.4.2.2(3), 13.6.4.2.2(4), 13.6.4.2.2(6), or 13.6.4.2.2.4(1) through 13.6.4.2.2.4(3), the extinguisher shall be removed from service, shall not be discharged, and shall be returned to the manufacturer, a fire equipment dealer, or a distributor to permit recovery of the halon. [**10:**7.2.3.3]

13.6.4.2.4 Inspection Record Keeping.

13.6.4.2.4.1 Manual Inspection Records.

13.6.4.2.4.1.1 Where manual inspections are conducted, records for manual inspections shall be kept on a tag or label attached to the fire extinguisher, on an inspection checklist maintained on file, or by an electronic method. [**10:**7.2.4.1.1]

13.6.4.2.4.1.2 Where manual inspections are conducted, the month and year the manual inspection was performed and the initials of the person performing the inspection shall be recorded. [**10:**7.2.4.1.2]

13.6.4.2.4.1.3 Personnel making manual inspections shall keep records of all fire extinguishers inspected, including those found to require corrective action. [**10:**7.2.4.1.3]

13.6.4.2.4.1.4 Records for manual inspection shall be kept to demonstrate that at least the last 12 monthly inspections have been performed. [**10:**7.2.4.1.4]

13.6.4.2.4.2 Electronic Inspection Records.

13.6.4.2.4.2.1 Where electronically monitored systems are employed for inspections, records shall be kept for fire extinguishers found to require corrective action. [**10:**7.2.4.2.1]

13.6.4.2.4.2.2 Records for electronic monitoring shall be kept to demonstrate that at least the last 12 monthly inspections have been performed. [**10:**7.2.4.2.2]

13.6.4.2.4.2.3 For electronically monitored fire extinguishers, where the extinguisher causes a signal at a control unit when a deficiency in any of the conditions listed in 13.6.4.2.2 occurs, record keeping shall be provided in the form of an electronic event log at the control panel. [**10:**7.2.4.2.3]

13.6.4.3 Extinguisher Maintenance.

Fire extinguisher maintenance includes a thorough examination of the mechanical parts, the extinguishing agent, and the expelling means. Different types of extinguishers require different maintenance schedules. For example, rechargeable water-type extinguishers are disassembled for complete maintenance and recharge annually. Stored-pressure extinguishers, which require a 12-year hydrostatic test, are not disassembled for annual maintenance. They are disassembled and undergo full maintenance every 6 years, and complete external/internal maintenance is performed every 12 years. Careful examination during full (disassembly) maintenance reveals whether the cylinder should be subjected to hydrostatic testing.

13.6.4.3.1* Maintenance Procedures. Where required by another section of this *Code* or NFPA 10, maintenance procedures shall include the procedures detailed in the manufacturer's service manual and a thorough examination of the basic elements of the fire extinguisher, including the following:

(1) Mechanical parts of all fire extinguishers
(2) Extinguishing agent
(3) Expelling means
(4) Physical condition

[**10:**7.3.1]

Δ **A.13.6.4.3.1** The annual maintenance of a fire extinguisher requires the services of a trained and certified technician who has the proper tools, listed parts, and appropriate manufacturer's service manual. Maintenance of fire extinguishers should not be confused with inspection, which is a quick check of the extinguishers that is performed at least every 30 days. Because the detailed maintenance procedures for various extinguisher types and models differ, the procedures specified within service manuals need to be followed. [**10:**A.7.3.1]

The following list is a sample of maintenance procedures that should be followed to determine deficiencies that require additional attention to remediate the condition of the extinguisher as appropriate for rechargeable, stored-pressure, dry chemical, and halogenated agent hand portable fire extinguishers:

(1) Visually examine the extinguisher for damage by removing the extinguisher from the hanger, bracket, or cabinet, and visually examine the extinguisher for damage, including pressure gauge, cylinder dents, repairs, general corrosion, hose or nozzle threads, handles, and levers.
(2) Verify that the hanger, bracket, or cabinet is the proper one for the extinguisher.
(3) Verify that the hanger, bracket, or cabinet is secure, undamaged, and properly mounted.
(4) Verify that the nameplate operating instructions are legible and facing outward.
(5) Confirm that the extinguisher model is not subject to recall and is not obsolete.
(6) Verify the extinguisher records to determine internal examination and hydrostatic test intervals. Thoroughly examine the cylinder for dents, damage, repairs, or corrosion.
(7) Verify the pull pin functions properly and examine for damage or corrosion by removing the pull pin.
(8) Verify that the handle and levers are undamaged and operable.
(9) Verify that the valve stem is correctly extended and not corroded or damaged.
(10) Verify that the pressure gauge or indicator is in the operable range.
(11) Verify that the gauge operating pressure corresponds with the nameplate instructions.
(12) Verify that the gauge face corresponds with the proper agent type.
(13) Verify that the gauge threads are compatible with the valve body material.
(14) Verify that the nozzle or hose assembly, or both, is unobstructed by removing and examining the nozzle.
(15) Confirm that the nozzle and hose assembly are correct for the model of extinguisher.
(16) Verify that the hose and couplings are not cut, cracked, damaged, or deformed.
(17) Examine internal valve port surfaces and threads for signs of leakage or corrosion by removing the nozzle or hose assembly and reinstalling the nozzle and hose assembly securely after examination.
(18) Verify that the hose retention band is secure and properly adjusted.
(19) Weigh the extinguisher and verify that it corresponds to the weight listed on the nameplate.
(20) Reinstall the ring pin and install a new tamper seal.
(21) Clean exposed extinguisher surfaces to remove any foreign material.
(22) Record the maintenance on the extinguisher tag or label.
(23) Return the extinguisher to the hanger, bracket, or cabinet.

[**10:**A.7.3.1]

The following list is a sample of maintenance procedures that should be followed to determine deficiencies that require additional attention to remediate the condition of the extinguisher as appropriate for carbon dioxide hand portable fire extinguishers:

(1) Visually examine the extinguisher for damage by removing the extinguisher from the hanger or cabinet, and visually examine the extinguisher for damage, including cylinder dents, repairs, general corrosion, hose or nozzle threads, handles, and levers.
(2) Verify that the bracket or cabinet is the proper one for the extinguisher.
(3) Verify that the bracket or cabinet is secure, undamaged, and properly mounted.
(4) Verify that the nameplate operating instructions are legible and facing outward.
(5) Confirm that the extinguisher model is not subject to recall and is not obsolete.
(6) Verify the extinguisher records to determine hydrostatic test intervals.
(7) Verify the pull pin functions properly and examine for damage or corrosion by removing the pull pin.

(8) Examine the handle and levers to ensure that they are undamaged and operable.
(9) Verify that the valve stem is correctly extended and not corroded or damaged.
(10) Verify that the nozzle or hose assembly, or both, is unobstructed, by removing and examining the nozzle.
(11) Confirm that the nozzle and hose assembly are correct for the model of extinguisher.
(12) Verify that the hose and couplings are not cut, cracked, damaged, or deformed.
(13) Examine the discharge port for signs of leakage or corrosion by removing the nozzle or hose assembly and reinstalling the nozzle and hose assembly securely after examination.
(14) Conduct a conductivity test on the hose assembly.
(15) Affix the conductivity test label to hose assemblies that pass the conductivity test and replace hoses that fail the conductivity test.
(16) Verify that the safety assembly is not damaged or blocked.
(17) Verify that the hose retention band is secure and properly adjusted.
(18) Weigh the extinguisher to verify that it corresponds to the weight listed on the nameplate.
(19) Reinstall the ring pin and install a new tamper seal.
(20) Clean exposed extinguisher surfaces to remove any foreign material.
(21) Record the maintenance on the extinguisher tag or label.
(22) Return the extinguisher to the hanger, bracket, or cabinet.

[**10:**A.7.3.1]

The following list is a sample of maintenance procedures and checks that are commonly associated with pressurized-water-type hand portable fire extinguishers:

(1) Visually examine the extinguisher for damage by removing the extinguisher from the hanger, bracket, or cabinet, and visually examine the extinguisher for damage, including pressure gauge, cylinder dents, repairs, general corrosion, hose or nozzle threads, handles, and levers.
(2) Verify that the hanger, bracket, or cabinet is the proper one for the extinguisher.
(3) Verify that the hanger, bracket, or cabinet is secure, undamaged, and properly mounted.
(4) Verify that the nameplate operating instructions are legible and facing outward.
(5) Confirm that the extinguisher model is not subject to recall and is not obsolete.
(6) Check the extinguisher records to determine hydrostatic test intervals.
(7) Verify that the pull pin functions properly and examine for damage or corrosion by removing the pull pin.
(8) Examine the handle and levers to ensure that they are undamaged and operable.
(9) Verify that the valve stem is correctly extended and not corroded or damaged.
(10) Verify that the pressure gauge is in the operable range.
(11) Verify that the gauge operating pressure corresponds with the nameplate instructions.
(12) Verify that the gauge face corresponds with the proper agent type.
(13) Verify that the gauge threads are compatible with the valve body material.
(14) Verify that the nozzle or hose assembly, or both, is unobstructed, by removing and examining the nozzle.
(15) Confirm that the nozzle and hose assembly are correct for the model of extinguisher.
(16) Verify that the hose and couplings are not cut, cracked, damaged, or deformed.
(17) Examine the internal valve port surfaces and threads for signs of leakage or corrosion by removing the nozzle or hose assembly and reinstalling the nozzle and hose assembly securely after examination.
(18) Verify that the hose retention band is secure and properly adjusted.
(19) Weigh the extinguisher to verify that it corresponds to the weight listed on the nameplate.
(20) Reinstall the ring pin and install a new tamper seal.
(21) Clean exposed extinguisher surfaces to remove any foreign material.
(22) Record the maintenance on the extinguisher tag or label.
(23) Return the extinguisher to the hanger, bracket, or cabinet.

[**10:**A.7.3.1]

The following list is a sample of maintenance procedures and checks that are commonly associated with cartridge-operated dry chemical and dry powder hand portable fire extinguishers:

(1) Visually examine the extinguisher for damage by removing the extinguisher from the hanger, bracket, or cabinet, and visually examine the extinguisher for damage, including pressure gauge, cylinder dents, repairs, general corrosion, hose or nozzle threads, handles, and levers.
(2) Verify that the hanger, bracket, or cabinet is the proper one for the extinguisher.
(3) Verify that the hanger, bracket, or cabinet is secure, undamaged, and properly mounted.
(4) Verify that the nameplate operating instructions are legible and facing outward.
(5) Confirm that the extinguisher model is not subject to recall and is not obsolete.
(6) Verify the extinguisher hydrostatic test records to determine the hydrostatic test interval.
(7) Invert the extinguisher and open the nozzle to ensure any pressure is relieved from the shell.
(8) Remove the cartridge guard and check the integral components for damage or corrosion.
(9) Unscrew the cartridge to examine the seal. (Replace the cartridge if the seal is punctured, damaged, or corroded.) Verify that the seal is not punctured, that it is the proper cartridge for that extinguisher, and that it has the proper manufacturer's seal.
(10) Install the shipping cap on the cartridge.
(11) Weigh the cartridge on a scale and verify the weight is within the tolerance specified in the manufacturer's service manual.

(12) Remove the discharge nozzle from its holder and lift the hose, breaking the tamper seal.
(13) Operate the puncture lever to verify proper operation.
(14) Check and clean the pressure relief vent in the cartridge receiver in accordance with manufacturer's service manual.
(15) Remove and examine the cartridge receiver gasket. Replace the gasket if brittle, compression set, cracked, cut, or missing.
(16) Lubricate the gasket in accordance with the manufacturer's manual and install.
(17) Slowly loosen the fill cap to relieve any trapped pressure and reinstall hand tight.
(18) Examine the hose, nozzle, and couplings for any damage.
(19) Operate the discharge nozzle to verify proper operation.
(20) Remove the nozzle tip in accordance with the manufacturer's service manual and verify the proper tip is installed and that it is not damaged. Install the nozzle tip in accordance with manufacturer's manual.
(21) Remove the discharge hose from the extinguisher and ensure that the hose is not obstructed.
(22) Examine the hose o-ring and replace if necessary.
(23) Verify that the hose connection is clean and not damaged.
(24) Install the hose on the extinguisher.
(25) Remove the fill cap and examine the threads and seating surfaces for any damage or corrosion.
(26) Verify that the pressure relief vent is not obstructed.
(27) Verify that the dry chemical agent is the correct type and that there are no foreign materials or caking.
(28) Examine and clean the fill cap, gasket, and indicator in accordance with manufacturer's manual.
(29) Lubricate and install the fill cap and gasket in accordance with manufacturer's manual.
(30) Secure the discharge hose in place and install the proper cartridge.
(31) Replace the cartridge guard and install new tamper seals.
(32) Record the maintenance on the extinguisher tag or label.
(33) Return the extinguisher to the hanger, bracket, or cabinet.

[**10:**A.7.3.1]

N **13.6.4.3.1.1** Fire extinguishers shall be subjected to maintenance at intervals of not more than 1 year, at the time of hydrostatic test, or when specifically indicated by an inspection discrepancy or electronic notification. [**10:**7.3.1.1]

13.6.4.3.2 Annual External Examination of All Extinguishers.

13.6.4.3.2.1 Physical Condition. An annual external visual examination of all fire extinguishers shall be made to detect obvious physical damage, corrosion, or nozzle blockage; to verify that the operating instructions are present, legible, and facing forward, and that the HMIS information is present and legible, and to determine if a 6-year interval examination or hydrostatic test is due. [**10:**7.3.2.1]

13.6.4.3.2.2* Seals or Tamper Indicators. At the time of the maintenance, the tamper seal of a rechargeable fire extinguisher shall be removed by operating the pull pin or locking device. [**10:**7.3.2.2]

A.13.6.4.3.2.2 Where a safety seal or tamper indicator is missing, it can be evidence that the fire extinguisher has been used. If a tamper seal is found to be missing from a nonrechargeable extinguisher, it should be removed from service. [**10:**A.7.3.2.2]

13.6.4.3.2.2.1 After the applicable maintenance procedures are completed, a new listed tamper seal shall be installed. [**10:**7.3.2.2.1]

13.6.4.3.2.2.2 Seals or tamper indicators on nonrechargeable-type extinguishers shall not be removed. [**10:**7.3.2.2.2]

13.6.4.3.2.3* Boots, Foot Rings, and Attachments. All removable extinguisher boots, foot rings, and attachments shall be removed to accommodate thorough annual cylinder examinations. [**10:**7.3.2.3]

A.13.6.4.3.2.3 Removable extinguisher boots and foot rings are those that are not put on by the extinguisher manufacturer with glue or welded. [**10:**A.7.3.2.3]

13.6.4.3.2.4 When subjected to temperatures at or above their listed rating, stored-pressure fire extinguishers that require a 12-year hydrostatic test shall be emptied and subjected to the applicable maintenance and recharge procedures on an annual basis. [**10:**7.3.2.4]

13.6.4.3.2.5 Corrective Action. When an external examination of any fire extinguisher reveals a deficiency, immediate corrective action shall be taken. [**10:**7.3.2.5]

13.6.4.3.3 Annual Internal Examination of Certain Types of Extinguishers.

13.6.4.3.3.1* Maintenance Intervals. Fire extinguishers shall be internally examined at intervals not exceeding those specified in Table 13.6.4.3.3.1. [**10:**7.3.3.1]

Δ **A.13.6.4.3.3.1** Persons performing maintenance operations usually come from two major groups:

(1) Fire extinguisher service agencies
(2) Trained industrial safety or maintenance personnel [**10:**A.7.3.3.1]

Fire extinguishers owned by individuals are often neglected because a periodic follow-up program is not planned. It is recommended that such owners become familiar with their fire extinguishers so they can detect telltale warnings during inspection that suggest the need for maintenance. When maintenance is indicated, it should be performed by trained persons having proper equipment. *(See 13.6.4.1.2.2.)* [**10:**A.7.3.3.1]

The purpose of a well-planned and well-executed maintenance program for a fire extinguisher is to maximize the following probabilities:

(1) That the extinguisher will operate properly between the time intervals established for maintenance examinations in the environment to which it is exposed
(2) That the extinguisher will not constitute a potential hazard to persons in its vicinity or to operators or rechargers of fire extinguishers [**10:**A.7.3.3.1]

Any replacement parts needed should be obtained from the manufacturer or a representative. [**10:**A.7.3.3.1]

TABLE 13.6.4.3.3.1 Maintenance Involving Internal Examination

Extinguisher Type	Internal Examination Interval (years)
Stored-pressure loaded stream and antifreeze	1
Pump tank water and pump tank calcium chloride–based	1
Dry chemical, cartridge- and cylinder-operated, with mild steel shells	1*
Dry powder, cartridge- and cylinder-operated, with mild steel shells	1*
Wetting agent	1
Stored-pressure water	5
AFFF (aqueous film-forming foam)	3†
FFFP (film-forming fluoroprotein foam)	3†
Stored-pressure dry chemical, with stainless steel shells	5
Carbon dioxide	5
Wet chemical	5
Dry chemical stored-pressure, with mild steel shells, brazed brass shells, and aluminum shells	6
Halogenated agents	6
Dry powder, stored-pressure, with mild steel shells	6

*Dry chemical and dry powder in cartridge- or cylinder-operated extinguishers are examined annually.

†The extinguishing agent in liquid charge-type AFFF and FFFP extinguishers is replaced every 3 years, and an internal examination (teardown) is normally conducted at that time.

[**10:** Table 7.3.3]

13.6.4.3.3.2 Loaded Stream Charge. Stored-pressure types of fire extinguishers containing a loaded stream agent shall be disassembled on an annual basis and subjected to complete maintenance. [**10:**7.3.3.2]

13.6.4.3.3.2.1 The loaded stream charge shall be permitted to be recovered and re-used, provided it is subjected to agent analysis in accordance with the extinguisher manufacturer's instructions. [**10:**7.3.3.2.1]

13.6.4.3.3.2.2 When the internal maintenance procedures are performed during periodic recharging or hydrostatic testing, the 1-year requirement shall begin from that date. [**10:**7.3.3.2.2]

13.6.4.3.3.3 Cartridge- or Cylinder-Operated Extinguishers. The extinguishing agent of cartridge- or cylinder-operated extinguishers shall be internally examined annually. [**10:**7.3.3.3]

13.6.4.3.3.4 Wetting Agent Extinguishers. Wetting agent extinguishers shall be disassembled on an annual basis and subjected to complete maintenance. [**10:**7.3.3.4]

13.6.4.3.3.5 Pump Tank Extinguishers. Pump tank extinguishers shall be internally examined annually. [**10:**7.3.3.5]

13.6.4.3.3.6 Annual internal examination shall not be required for nonrechargeable fire extinguishers, carbon dioxide fire extinguishers, or stored-pressure fire extinguishers, except for those types specified in 13.6.4.3.3.2. [**10:**7.3.3.6]

13.6.4.3.4* Annual Maintenance Record Keeping.

A.13.6.4.3.4 In addition to the required tag or label, a permanent file record should be kept for each fire extinguisher. This file record should include the following information, as applicable:

(1) Maintenance date and the name of the person and the agency performing the maintenance
(2) Date of the last recharge and the name of the person and the agency performing the recharge
(3) Hydrostatic retest date and the name of the person and the agency performing the hydrostatic test
(4) Description of dents remaining after passing of the hydrostatic test
(5) Date of the 6-year maintenance for stored-pressure dry chemical and halogenated agent types (*See 13.6.4.3.6.)*

[**10:**A.7.3.4]

It is recognized that an electronic bar coding system is often acceptable to the AHJ in lieu of a tag or label for maintenance record keeping. [**10:**A.7.3.4]

Under special circumstances, or when local requirements are in effect, additional information can be desirable or required. [**10:**A.7.3.4]

13.6.4.3.4.1 Each fire extinguisher shall have a tag or label securely attached that indicates that maintenance was performed. [**10:**7.3.4.1]

Δ **13.6.4.3.4.1.1** The tag or label, as a minimum, shall identify the following:

(1) Month and year maintenance was performed
(2) Person performing the work
(3) Name of the agency performing the work

[**10:**7.3.4.1.1]

Δ **13.6.4.3.4.2** Each extinguisher that has undergone maintenance that includes internal examination, except extinguishers identified in 13.6.4.3.3.3 and 13.6.4.3.3.5, shall have a verification-of-service collar located around the neck of the container. [**10:**7.3.4.2]

13.6.4.3.4.3 Verification-of-Service Collar (Maintenance or Recharging).

13.6.4.3.5 Corrective Action. When maintenance of any fire extinguisher reveals a deficiency, immediate corrective action shall be taken. [**10:**7.3.5]

Δ **13.6.4.3.6 Six-Year Internal Examination of Certain Types of Extinguishers.** Every 6 years, stored-pressure fire extinguishers that require a 12-year hydrostatic test shall be emptied and subjected to the applicable internal and external examination procedures as detailed in the manufacturer's service manual and NFPA 10. [**10:**7.3.6]

13.6.4.3.6.1 When the applicable maintenance procedures are performed during periodic recharging or hydrostatic testing, the 6-year requirement shall begin from that date. [**10:**7.3.6.1]

13.6.4.3.6.2* The removal of agent from halon agent fire extinguishers shall only be done using a listed halon closed recovery system. [**10:**7.3.6.2]

A.13.6.4.3.6.2 Halon removed from a fire extinguisher is kept in a closed recovery/recharge system until disposition can be made as to whether to recharge the halon back into a fire extinguisher or return unsatisfactory halon to a manufacturer for proper disposal. A listed Halon 1211 closed recovery/recharge system has the following:

(1) Clear sight glass for monitoring the cleanliness of the Halon 1211
(2) A means of determining if the acceptable water content of the halon has been exceeded
(3) A means of mechanically filtering the Halon 1211 and removing excess water

[**10:**A.7.3.6.2]

Such a recovery system also has a motor-driven pump system that permits the transfer of halon into a fire extinguisher or supply container without the need to vent the receiving container to reduce its pressure before halon transfer. Closed recovery/recharge systems also include the plumbing, valves, regulators, and safety relief devices to permit convenient, quick transfer of the Halon 1211. [**10:**A.7.3.6.2]

13.6.4.3.6.3 Nonrechargeable fire extinguishers shall not be required to have a 6-year internal examination and shall not be hydrostatically tested but shall be removed from service at a maximum interval of 12 years from the date of manufacture. [**10:**7.3.6.3]

Δ **13.6.4.3.6.3.1** Nonrechargeable halon agent fire extinguishers shall be disposed of in accordance with 13.6.4.2.3.3. [**10:**7.3.6.3.1]

13.6.4.3.6.4 Corrective Action. When an internal examination of any fire extinguisher reveals a deficiency, immediate corrective action shall be taken. [**10:**7.3.6.4]

13.6.4.3.6.5* Six-Year Internal Examination Label. Fire extinguishers that pass the applicable 6-year requirement of 13.6.4.3.6 shall have the maintenance information recorded on a durable weatherproof label that is a minimum of 2 in. × 3½ in. (51 mm × 89 mm). [**10:**7.3.6.5]

A.13.6.4.3.6.5 Labels should be printed in black with a light blue background. [**10:**A.7.3.6.5]

13.6.4.3.6.5.1 The new label shall be affixed to the shell by a heatless process, and any previous 6-year internal examination labels shall be removed. [**10:**7.3.6.5.1]

13.6.4.3.6.5.2 These labels shall be of the self-destructive type when their removal from a fire extinguisher is attempted. [**10:**7.3.6.5.2]

13.6.4.3.6.5.3 The 6-year internal examination label shall, as a minimum, identify the following:

(1) Month and year the 6-year internal examination was performed
(2) Person performing the work
(3) Name of the agency performing the work

[**10:**7.3.6.5.3]

13.6.4.4* Carbon Dioxide Hose Assembly Conductivity Test. A conductivity test shall be conducted annually on all carbon dioxide hose assemblies. [**10:**7.4]

A.13.6.4.4 Carbon dioxide hose assemblies have a continuous metal braid that connects to both couplings to minimize the static shock hazard. The reason for the conductivity test is to determine that the hose is conductive from the inlet coupling to the outlet orifice. A basic conductivity tester consists of a flashlight having an open circuit and a set of two wires with a conductor (clamps or probe) at each end. [**10:**A.7.4]

Figure A.13.6.4.4 provides a guide to the design of a conductivity test label. [**10:**A.7.4]

13.6.4.4.1 Carbon dioxide hose assemblies that fail the conductivity test shall be replaced. [**10:**7.4.1]

13.6.4.4.2 Record Keeping for Conductivity Testing of Carbon Dioxide Hose Assemblies.

13.6.4.4.2.1 Carbon dioxide hose assemblies that pass a conductivity test shall have the test information recorded on a durable weatherproof label that is a minimum of ½ in. × 3 in. (13 mm × 76 mm). [**10:**7.4.2.1]

13.6.4.4.2.2 The label shall be affixed to the hose by means of a heatless process. [**10:**7.4.2.2]

Δ **13.6.4.4.2.3** The label shall include the following information:

(1) Month and year the test was performed, indicated by perforation such as is done by a hand punch
(2) Name or initials of person performing the test and the name of the agency performing the test

[**10:**7.4.2.3]

N **13.6.4.5 Hose Station Maintenance.** Where hose stations are installed to comply with 13.6.3.2.1.5, they shall be maintained in accordance with NFPA 1962. [**10:**7.5]

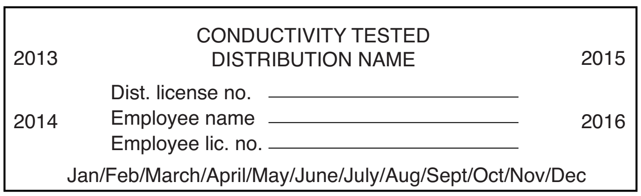

FIGURE A.13.6.4.4 *Conductivity Test Label. [**10:**Figure A.7.4]*

Paragraph 13.6.4.5 is new to the *Code*. Previous editions of the *Code* failed to emphasize the need for regular maintenance of fire hoses that are installed in lieu of fire extinguishers. NFPA 10 requires fire extinguishers to be regularly maintained. As long as fire hoses are recognized in 13.6.3.2.1.5 as an acceptable alternative for up to half of the required complement of Class A–rated fire extinguishers, it is important that NFPA 10 also require that those fire hoses be properly maintained. NFPA 1962, *Standard for the Care, Use, Inspection, Service Testing, and Replacement of Fire Hose, Couplings, Nozzles, and Fire Hose Appliances*, details the maintenance requirements for fire hoses.

13.6.4.6 Electronic Monitoring System Maintenance.

13.6.4.6.1 Electronic Monitoring. The components of the monitoring device/system shall be tested and maintained annually in accordance with the manufacturer's listed maintenance manual, with the following items included as a minimum:

(1) Power supply inspection/battery change
(2) Obstruction sensor inspection
(3) Location sensor inspection
(4) Pressure indication inspection
(5) Connection continuity inspection *(see 13.6.4.6.1.1 and 13.6.4.6.1.2)*

[**10:**7.6.1]

13.6.4.6.1.1 One hundred percent of all units shall be tested upon initial installation or reacceptance with verification of receipt of signal at the control panel or a local alarm. [**10:**7.6.1.1]

13.6.4.6.1.2 Twenty percent of units shall be tested annually on a rotating basis so that all units are tested within a 5-year period. [**10:**7.6.1.2]

13.6.4.6.2 When used in conjunction with fire alarm systems, fire extinguisher electronic monitoring devices shall be inspected and maintained in accordance with *NFPA 72* and 13.6.4.6.1. [**10:**7.6.2]

13.6.4.6.3 Corrective Action. When maintenance of any monitoring system reveals a deficiency, immediate corrective action shall be taken. [**10:**7.6.3]

13.6.4.7 Maintenance of Wheeled Extinguisher Hoses and Regulators.

13.6.4.7.1 Wheeled Unit Hoses. Discharge hoses on wheeled-type fire extinguishers shall be completely uncoiled and examined for damage annually. [**10:**7.7.1]

13.6.4.7.2* Discharge hoses on wheeled extinguishers shall be coiled in a manner to prevent kinks and to allow rapid deployment in accordance with the manufacturer's instructions. [**10:**7.7.1.1]

A.13.6.4.7.2 The following procedure permits rapid removal of the hose by one person without kinking of the hose and without obstruction of flow of the extinguishing agent:

(1) Form a standard loop over the hose supports *[see Figure A.13.6.4.7.2(a)]*.
(2) Follow with a reverse loop over the hose supports so that the hose passes behind the loop *[see Figure A.13.6.4.7.2(b)]*.
(3) Repeat steps (1) and (2), alternating standard loops and reverse loops, until all hose is coiled on the support *[see Figure A.13.6.4.7.2(c)]*.

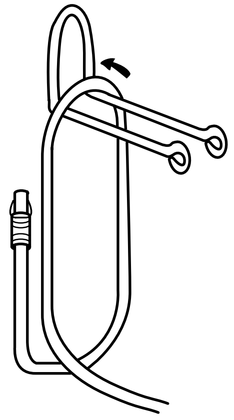

FIGURE A.13.6.4.7.2(a) *Counterclockwise Loop. [**10:**Figure A.7.7.1.1(a)]*

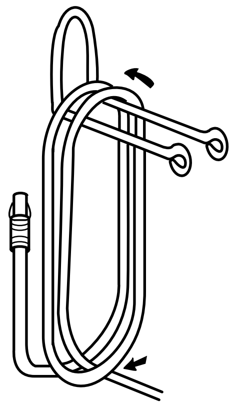

FIGURE A.13.6.4.7.2(b) *Reverse Loop. [**10:**Figure A.7.7.1.1(b)]*

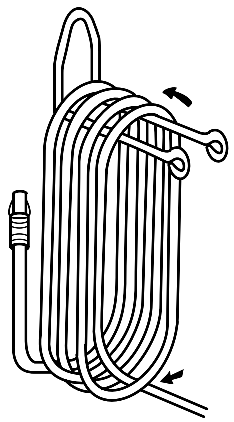

FIGURE A.13.6.4.7.2(c) *Procedures in Figure A.13.6.4.7.2(a) and Figure A.13.6.4.7.2(b) Continued. [**10:**Figure A.7.7.1.1(c)]*

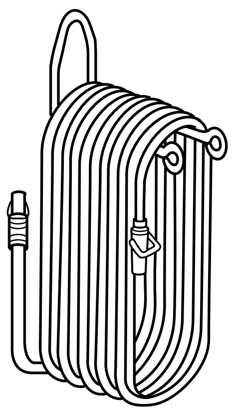

FIGURE A.13.6.4.7.2(d) *Nozzle in Downward Position. [**10:**Figure A.7.7.1.1(d)]*

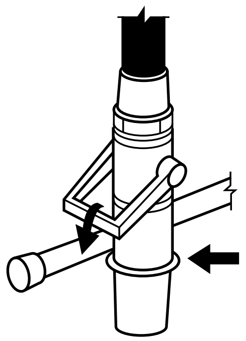

FIGURE A.13.6.4.7.2(e) *Nozzle in Holder. [**10:**Figure A.7.7.1.1(e)]*

(4) Adjust the coil so that the nozzle is in the downward position *[see Figure A.13.6.4.7.2(d)]*. Hose coiled in this manner pulls off free of twists.
(5) Place the nozzle in the holder with the handle forward in the closed position *[see Figure A.13.6.4.7.2(e)]*.

[**10:**A.7.7.1.1]

13.6.4.7.3 Pressure Regulators. Pressure regulators provided with wheeled-type fire extinguishers shall be tested annually for outlet static pressure and flow rate in accordance with the manufacturer's instructions. [**10:**7.7.2]

13.6.4.7.4 Corrective Action. When maintenance of any fire extinguisher hose or pressure regulator reveals a deficiency, immediate corrective action shall be taken. [**10:**7.7.3]

13.6.4.8 Extinguisher Recharging and Extinguishing Agents.

13.6.4.8.1* General.

A.13.6.4.8.1 General safety guidelines for recharging include the following:

(1) Make sure all pressure is vented from the fire extinguisher before attempting to remove the valve body or to fill the closure. (**Warning:** Do not depend on pressure-indicating devices to tell if the container is under pressure, because the devices could malfunction.)
(2) Use proper recharge materials when refilling a fire extinguisher. Mixing of some extinguishing agents can cause a chemical reaction, resulting in a dangerous pressure buildup in the container.
(3) The weight of agent as specified on the nameplate is critical. Overfilling could render the fire extinguisher dangerous or ineffective.
(4) Clean and properly lubricate all sealing components to prevent leakage after recharge.
(5) Check the pressure-indicating device to ascertain that it is reading properly.
(6) Most manufacturers recommend the use of dry nitrogen as an expellant gas for stored-pressure fire extinguishers. Limiting the charging pressure regulator setting to 25 psi (172 kPa) above service pressure, as 13.6.4.8.4, prevents gauge damage and loss of calibration. (**Warning:** Never connect the fire extinguisher to be charged directly to the high-pressure source. Connecting directly to the high-pressure source could cause the container to rupture, resulting in injury. Never leave a fire extinguisher connected to the regulator of a high-pressure source for an extended period of time. A defective regulator could cause the container to rupture due to excess pressure.)
(7) Use the manufacturer's recommended charging adapter to prevent damage to a valve and its components.
(8) When recharging separate expellant source fire extinguishers, make sure the filled enclosure is in place and tightened down. Replace all safety devices prior to installing replacement cartridges.
(9) Use only gas cartridges recommended by the manufacturer. Cartridge features such as pressure relief, puncturing capabilities, fill density, and thread compatibility are designed and approved to specific functional requirements.
(10) Use proper safety seals; other types, such as meter seals, could fail to break at the prescribed requirements.
(11) Regulators utilized on wheeled fire extinguishers are factory pinned at the operating pressure and should not be field adjusted.

[**10:**A.7.8.1]

The term *maintenance*, as it relates to fire extinguishers, means complete disassembly and examination. Recharging is not required in the annual maintenance of some types of extinguishers where disassembly and internal examination are not performed. Some jurisdictions require complete (internal/external) annual maintenance of a number of types of extinguishers; therefore, recharging of those types is required annually. Recharging is required after any use in order to remove any dry chemical from the sealing surfaces and hoses so the unit retains pressure. Recharging is also performed to remove water, foam, or antifreeze from internal areas of the valve to avoid corrosion. Most important, recharging must be performed to restore the extinguisher to its full fire-extinguishing potential.

13.6.4.8.1.1 All rechargeable-type fire extinguishers shall be recharged after any use or when the need is indicated by an inspection or servicing. [**10:**7.8.1.1]

13.6.4.8.1.2* When recharging is performed, the manufacturer's service manual shall be followed. *(For recharge agents, see 13.6.4.8.3.)* [**10:**7.8.1.2]

A.13.6.4.8.1.2 Some manufacturers require that their fire extinguishers be returned to the factory for recharging. [**10:**A.7.8.1.2]

13.6.4.8.1.3* The amount of recharge agent shall be verified by weighing. [**10:**7.8.1.3]

A.13.6.4.8.1.3 To determine the gross weight, the entire fire extinguisher should be weighed empty. The weight of the specified recharge agent should be added to that amount. [**10:**A.7.8.1.3]

13.6.4.8.1.3.1 For those fire extinguishers that do not have the gross weight marked on the nameplate or valve, a permanent label that indicates the gross weight shall be affixed to the cylinder. [**10:**7.8.1.3.1]

13.6.4.8.1.3.2 The added label containing the gross weight shall be a durable material of a pressure-sensitive, self-destruct type. *(For stored-pressure water-type extinguishers, see 13.6.4.8.3.10.)* [**10:**7.8.1.3.2]

13.6.4.8.1.3.3 Pump tank water and pump tank calcium chloride–based antifreeze types shall not be required to have weight marked. [**10:**7.8.1.3.3]

13.6.4.8.1.3.4* After recharging, a leak test shall be performed on stored-pressure and self-expelling types of fire extinguishers. [**10:**7.8.1.3.4]

A.13.6.4.8.1.3.4 The leak test required for stored-pressure and self-expelling types should be sufficiently sensitive to ensure that the fire extinguisher remains operable for at least 1 year. Any tamper indicators or seals need to be replaced after recharging. [**10:**A.7.8.1.3.4]

13.6.4.8.1.3.5 In no case shall an extinguisher be recharged without hydrostatic testing if it is beyond its specified hydrostatic test date. [**10:**7.8.1.3.5]

13.6.4.8.2 Extinguisher Recharging Frequency for Certain Types of Extinguishers.

13.6.4.8.2.1 Pump Tank. Every 12 months, pump tank water and pump tank calcium chloride–based antifreeze types of fire extinguishers shall be recharged with new chemicals or water as applicable. [**10:**7.8.2.1]

13.6.4.8.2.2 Wetting Agent. The agent in stored-pressure wetting agent fire extinguishers shall be replaced annually. [**10:**7.8.2.2]

13.6.4.8.2.2.1 Only the agent specified on the nameplate shall be used for recharging. [**10:**7.8.2.2.1]

13.6.4.8.2.2.2 The use of water or any other additives shall be prohibited. [**10:**7.8.2.2.2]

13.6.4.8.2.3 AFFF and FFFP.

13.6.4.8.2.3.1 The premixed agent in liquid charge–type AFFF and FFFP fire extinguishers shall be replaced at least once every 3 years. [**10:**7.8.2.3.1]

13.6.4.8.2.3.2 Only the foam agent specified on the extinguisher nameplate shall be used for recharge. [**10:**7.8.2.3.2]

13.6.4.8.2.3.3 The agent in nonpressurized AFFF and FFFP fire extinguishers that is subjected to agent analysis in accordance with manufacturer's instructions shall not be required to comply with 13.6.4.8.2.3.1. [**10:**7.8.2.3.3]

13.6.4.8.3* Recharge Agents.

A.13.6.4.8.3 On properties where fire extinguishers are maintained by the occupant, a supply of recharging agents should be kept on hand. These agents should meet the requirements of 13.6.4.8.3. [**10:**A.7.8.3]

The intent of this provision is to maintain the efficiency of each fire extinguisher as produced by the manufacturer and as labeled by one or more of the fire testing laboratories. For example, the extinguishing agent and the additives used in the various types of dry chemical fire extinguishers vary in chemical composition and in particle size and, thus, in flow characteristics. Each fire extinguisher is designed to secure maximum efficiency with the particular formulation used. Changing the agent from that specified on the fire extinguisher nameplate could affect flow rates, nozzle discharge characteristics, and the quantity of available agent (as influenced by density) and would void the label of the testing laboratory. [**10:**A.7.8.3]

Certain recharging materials deteriorate with age, exposure to excessive temperature, and exposure to moisture. Storage of recharge agents for long periods of time should be avoided. [**10:**A.7.8.3]

Dry powder used for combustible metal fires (Class D) should not become damp, because the powder will not be free flowing. In addition, when dry powder contains sufficient moisture, a hazardous reaction could result when applied to a metal fire. [**10:**A.7.8.3]

13.6.4.8.3.1 Only those agents specified on the nameplate or agents proven to have equal chemical composition, physical characteristics, and fire-extinguishing capabilities shall be used. [**10:**7.8.3.1]

13.6.4.8.3.1.1 Agents listed specifically for use with that fire extinguisher shall be considered to meet these requirements. [**10:**7.8.3.1.1]

13.6.4.8.3.2* Mixing of Dry Chemicals. Multipurpose dry chemicals shall not be mixed with alkaline-based dry chemicals. [**10:**7.8.3.2]

A.13.6.4.8.3.2 Mixing multipurpose dry chemicals with alkaline-based dry chemicals could result in a chemical reaction capable of developing sufficient pressures to rupture a fire extinguisher. Substituting a different formulation for the one originally employed could cause malfunctioning of the fire extinguisher or result in substandard performance. [**10:**A.7.8.3.2]

13.6.4.8.3.3 Topping Off.

13.6.4.8.3.3.1 The remaining dry chemical in a discharged fire extinguisher shall be permitted to be re-used, provided that it is thoroughly checked for the proper type, contamination, and condition. [**10:**7.8.3.3.1]

13.6.4.8.3.3.2 Dry chemical found to be of the wrong type or contaminated shall not be re-used. [**10:**7.8.3.3.2]

13.6.4.8.3.4 Dry Chemical Agent Re-Use.

13.6.4.8.3.4.1 The dry chemical agent shall be permitted to be re-used, provided a closed recovery system is used and the agent is stored in a sealed container to prevent contamination. [**10:**7.8.3.4.1]

13.6.4.8.3.4.2 Prior to re-use, the dry chemical shall be thoroughly checked for the proper type, contamination, and condition. [**10:**7.8.3.4.2]

13.6.4.8.3.4.3 Where doubt exists with respect to the type, contamination, or condition of the dry chemical, the dry chemical shall be discarded. [**10:**7.8.3.4.3]

13.6.4.8.3.4.4 Dry Chemical Closed Recovery System.

(A) The system shall be constructed in a manner that does not introduce foreign material into the agent being recovered. [**10:**7.8.3.4.4.1]

(B) The system shall have a means for visual inspection of the recovered agent for contaminants. [**10:**7.8.3.4.4.2]

13.6.4.8.3.5 Dry Powder.

13.6.4.8.3.5.1 Pails or drums containing dry powder agents for scoop or shovel application for use on metal fires shall be kept full and sealed with the lid provided with the container. [**10:**7.8.3.5.1]

13.6.4.8.3.5.2 The dry powder shall be replaced if found damp. *(See A.13.6.4.8.3.)* [**10:**7.8.3.5.2]

13.6.4.8.3.6* Removal of Moisture. For all non-water types of fire extinguishers, any moisture shall be removed before recharging. [**10:**7.8.3.6]

A.13.6.4.8.3.6 Moisture within a non-water-type fire extinguisher creates a serious corrosion hazard to the fire extinguisher shell and also indicates that the extinguisher is probably inoperative. Moisture could possibly enter under the following conditions:

(1) After a hydrostatic test
(2) When recharging is being performed
(3) When the valve has been removed from the cylinder
(4) Where compressed air and a moisture trap are used for pressurizing non-water types

[**10:**A.7.8.3.6]

It is extremely important to remove any water or moisture from any fire extinguisher before recharging. Excess moisture in a dry chemical fire extinguisher causes the agent to cake and lump and become unusable. It also causes corrosion to the fire extinguisher shell and valve. In carbon dioxide and halogenated fire extinguishers, excess moisture combined with the extinguishing agent causes extremely corrosive acids to form. These acids can corrode the fire extinguisher shell and valve. [**10:**A.7.8.3.6]

13.6.4.8.3.7* Halogenated Agent. Halogenated agent fire extinguishers shall be charged with only the type and weight of agent specified on the nameplate. [**10:**7.8.3.7]

A.13.6.4.8.3.7 If the fire extinguisher valve is removed for servicing, it is recommended that the fire extinguisher be purged with nitrogen or argon (as appropriate) or that a vacuum be drawn on the fire extinguisher cylinder prior to recharging. [**10:**A.7.8.3.7]

13.6.4.8.3.8 Halogenated Agent Re-Use.

13.6.4.8.3.8.1 The removal of Halon 1211 from fire extinguishers shall be done using only a listed halon closed recovery system. [**10:**7.8.3.8.1]

13.6.4.8.3.8.2 The removal of agent from other halogenated agent fire extinguishers shall be done using only a closed recovery system. [**10:**7.8.3.8.2]

13.6.4.8.3.8.3 The fire extinguisher shall be examined internally for contamination or corrosion or both. [**10:**7.8.3.8.3]

13.6.4.8.3.8.4 The halogenated agent retained in the system recovery cylinder shall be re-used only if no evidence of internal contamination is observed in the fire extinguisher cylinder. [**10:**7.8.3.8.4]

13.6.4.8.3.8.5 Halogenated agent removed from fire extinguishers that exhibits evidence of internal contamination or corrosion shall be processed in accordance with the fire extinguisher manufacturer's instructions. [**10:**7.8.3.8.5]

13.6.4.8.3.9* Carbon Dioxide.

A.13.6.4.8.3.9 The preferred source of carbon dioxide for recharging fire extinguishers is from a low-pressure [300 psi at 0°F (2068 kPa at −17.8°C)] supply, supplied either directly or via dry cylinders used as an intermediary means. Dry ice converters should not be used to recharge carbon dioxide portable fire extinguishers. [**10:**A.7.8.3.9]

13.6.4.8.3.9.1 The vapor phase of carbon dioxide shall be not less than 99.5 percent carbon dioxide. [**10:**7.8.3.9.1]

13.6.4.8.3.9.2 The water content shall be not more than 60 parts per million (ppm) by weight at –52°F (–47°C) dew point. [**10:**7.8.3.9.2]

13.6.4.8.3.9.3 Oil content shall not exceed 10 ppm by weight. [**10:**7.8.3.9.3]

13.6.4.8.3.10* Water Types. The amount of liquid agent shall be determined by using one of the following:

(1) Exact measurement by weight
(2) Exact measurement by volume
(3) Anti-overfill tube, if provided
(4) Fill mark on fire extinguisher shell, if provided

[**10:**7.8.3.10]

A.13.6.4.8.3.10 When stored-pressure fire extinguishers are recharged, overfilling results in improper discharge. [**10:**A.7.8.3.10]

13.6.4.8.3.10.1 Only the agent specified on the extinguisher nameplate shall be used for recharge. [**10:**7.8.3.10.1]

13.6.4.8.3.10.2 Only additives identified on the original nameplate shall be permitted to be added to water type extinguishers. [**10:**7.8.3.10.2]

13.6.4.8.3.11 Wet Chemical and Water Mist Agent Re-Use.

13.6.4.8.3.11.1 Wet chemical and water mist agents shall not be re-used. [**10:**7.8.3.11.1]

13.6.4.8.3.11.2 If a wet chemical or water mist extinguisher is partially discharged, all remaining wet chemical or water mist shall be discarded. [**10:**7.8.3.11.2]

13.6.4.8.3.11.3 Wet chemical or water mist agent shall be discarded and replaced at the hydrostatic test interval. [**10:**7.8.3.11.3]

(A) Only the agent specified on the extinguisher nameplate shall be used for recharge. [**10:**7.8.3.11.3.1]

13.6.4.8.4 Recharging Expellant Gas for Stored-Pressure Fire Extinguishers.

13.6.4.8.4.1 Only standard industrial-grade nitrogen with a maximum dew point of −60°F (−51°C), in accordance with CGA G-10.1. *Commodity Specification for Nitrogen*, shall be used to pressurize stored-pressure dry chemical and halogenated-type fire extinguishers that use nitrogen as a propellant. [**10:**7.8.4.8.1]

13.6.4.8.4.2 Halogenated-type fire extinguishers that require argon shall be pressurized with argon with a dew point of −65°F (−54°C) or lower. [**10:**7.8.4.8.2]

13.6.4.8.4.3 Compressed air shall be permitted to be used from special compressor systems capable of delivering air with a dew point of −60°F (−51°C) or lower. *(See Annex J of NFPA 10.)* [**10:**7.8.4.3]

13.6.4.8.4.3.1 The special compressor system shall be equipped with an automatic monitoring and alarm system to ensure that the dew point remains at or below −60°F (−51°C) at all times. [**10:**7.8.4.3.1]

13.6.4.8.4.3.2 Compressed air through moisture traps shall not be used for pressurizing even though so stated in the instructions on older fire extinguishers. [**10:**7.8.4.3.2]

13.6.4.8.4.3.3 Compressed air without moisture removal devices shall be permitted for pressurizing water extinguishers and foam hand extinguishers only. [**10:**7.8.4.3.3]

13.6.4.8.4.4* Class D, wet chemical, water mist, and halogenated agent fire extinguishers shall be repressurized only with the type of expellant gas referred to on the fire extinguisher label. [**10:**7.8.4.4]

A.13.6.4.8.4.4 Some Class D fire extinguishers are required to be pressurized with argon. [**10:**A.7.8.4.4]

13.6.4.8.4.5 A rechargeable stored-pressure-type fire extinguisher shall be pressurized only to the charging pressure specified on the fire extinguisher nameplate. [**10:**7.8.4.5]

13.6.4.8.4.5.1 The manufacturer's pressurizing adapter shall be connected to the valve assembly before the fire extinguisher is pressurized. [**10:**7.8.4.5.1]

13.6.4.8.4.5.2 A regulated source of pressure, set no higher than 25 psi (172 kPa) above the operating (service) pressure, shall be used to pressurize fire extinguishers. [**10:**7.8.4.5.2]

13.6.4.8.4.5.3 The gauge used to set the regulated source of pressure shall be calibrated at least annually. [**10:**7.8.4.5.3]

13.6.4.8.4.6* An unregulated source of pressure, such as a nitrogen cylinder without a pressure regulator, shall not be used. [**10:**7.8.4.6]

A.13.6.4.8.4.6 The reason an unregulated source of pressure is not to be used is because the fire extinguisher has the potential to be overpressurized and possibly rupture. [**10:**A.7.8.4.6]

13.6.4.8.4.7* A fire extinguisher shall not be left connected to the regulator of a high-pressure source for an extended period of time. [**10:**7.8.4.7]

A.13.6.4.8.4.7 A defective regulator could cause the container to rupture due to excess pressure. [**10:**A.7.8.4.7]

13.6.4.8.4.8 Recharge Record Keeping.

13.6.4.8.4.8.1 Each fire extinguisher shall have a tag or label attached that indicates the month and year recharging was performed, identifies the person performing the service, and identifies the name of the agency performing the work. [**10:**7.8.4.8.1]

13.6.4.8.4.8.2 Each extinguisher that has been recharged shall have a verification-of-service collar located around the neck of the container, except as identified in 13.6.4.11.4. [**10:**7.8.4.8.2]

13.6.4.9* Pressure Gauges.

A.13.6.4.9 If it becomes necessary to replace a pressure gauge on a fire extinguisher, in addition to knowing the charging pressure, it is important to know the type of extinguishing agent for which the gauge is suitable, as well as the valve body with which the gauge is compatible. This information often is available in the form of markings on the dial face. Where the marking is provided, the extinguishing agent is indicated by instructions such as "Use Dry Chemicals Only," while the valve body compatibility is indicated as follows:

(1) Gauges intended for use with aluminum or plastic valve bodies are marked with a line above the gauge manufacturer's code letter.
(2) Gauges intended for use with brass or plastic valve bodies are marked with a line below the manufacturer's code letter.
(3) Universal gauges that can be used with aluminum, brass, or plastic valve bodies are marked with lines above and below the manufacturer's code letter or by the absence of any line above or below the manufacturer's code letter.

[**10:**A.7.9]

Using the proper replacement gauge as to pressure range, extinguishing agent, and valve body compatibility is recommended to avoid or to reduce gauge-related problems. [**10:**A.7.9]

13.6.4.9.1 Replacement pressure gauges shall have the correct indicated charging (service) pressure. [**10:**7.9.1]

13.6.4.9.2 Replacement pressure gauges shall be marked for use with the agent in the fire extinguisher. [**10:**7.9.2]

13.6.4.9.3 Replacement pressure gauges shall be compatible with the fire extinguisher valve body material. [**10:**7.9.3]

13.6.4.10 Prohibition on Uses of Extinguishers and Conversion of Fire Extinguisher Types.

13.6.4.10.1 Fire extinguishers shall not be used for any purpose other than that of a fire extinguisher. [**10:**7.10.1]

13.6.4.10.2 Fire extinguishers shall not be converted from one type to another, modified, or altered. [**10:**7.10.2]

13.6.4.10.3 Fire extinguishers shall not be converted for the use of a different type of extinguishing agent. [**10:**7.10.3]

13.6.4.11* Maintenance and Recharge Service Collar. Each extinguisher that has undergone maintenance that included internal examination or that has been recharged requiring the removal of the valve assembly shall have a verification-of-service collar located around the neck of the container. [**10:**7.11]

Δ **A.13.6.4.11** A verification-of-service collar is installed to show that an extinguisher has been depressurized, the valve has been removed, and a complete maintenance has been performed. The verification-of-service collar design also requires that the valve be removed before the collar can be attached to the extinguisher. The collar provides the AHJs with a convenient visual proof that the extinguisher has been disassembled and that maintenance most likely has been performed. [**10:**A.7.11]

All extinguishers are to have the valve removed for hydrostatic testing and are to be subsequently recharged before they are returned to service. To be valid, the date on the verification-of-service collar should always be the same as or more recent than the date on the hydrostatic test label. [**10:**A.7.11]

Figure A.13.6.4.11 provides a guide to the design of a verification-of-service collar. [**10:**A.7.11]

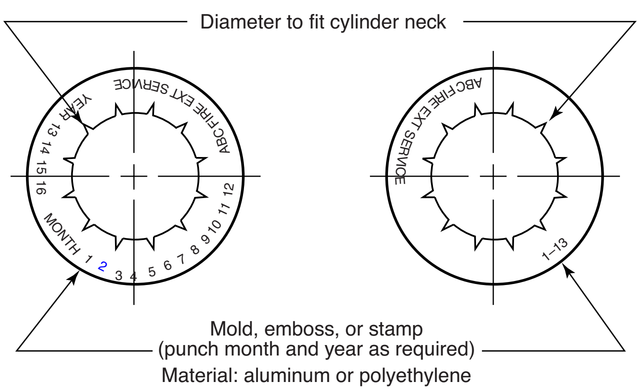

***FIGURE A.13.6.4.11** Design of a Verification-of-Service Collar. [**10:**A.7.11]*

13.6.4.11.1 The collar shall be a single circular piece of uninterrupted material forming a hole of a size that does not permit the collar assembly to move over the neck of the container unless the valve is completely removed. [**10:**7.11.1]

13.6.4.11.2 The collar shall not interfere with the operation of the fire extinguisher. [**10:**7.11.2]

13.6.4.11.3 The verification-of-service collar shall, as a minimum, identify the following:

(1) Month and year the recharging or internal examination was performed
(2) Name of the agency performing the work

[**10:**7.11.3]

13.6.4.11.4 Service Collar Exemptions.

13.6.4.11.4.1 New extinguishers requiring an initial charge in the field (such as pressurized water, AFFF, FFFP, or wet chemical extinguishers) shall not be required to have a verification-of-service collar installed. [**10:**7.11.4.1]

13.6.4.11.4.2 Liquefied gas, halogenated agent, and carbon dioxide extinguishers that have been recharged without valve removal shall not be required to have a verification-of-service collar installed following recharge. [**10:**7.11.4.2]

13.6.4.11.4.3 Cartridge- and cylinder-operated extinguishers shall not be required to have a verification-of-service collar installed. [**10:**7.11.4.3]

13.6.4.12* Weight Scales. Weight scales used for the maintenance and recharge of fire extinguishers shall have the reading increments and the accuracy necessary to verify the charge weights required in the service manuals and on the nameplates. [**10:**7.12]

Δ **A.13.6.4.12** Weight scales used for weighing a fire extinguisher with a gross weight of 60 lb (27.2 kg) or less should permit readings to 0.25 lb (0.10 kg). Weight scales used for weighing extinguishers and cartridges should permit readings consistent with the tolerances identified on the nameplate of the extinguisher or cartridge. All scales should be calibrated (tested) for accuracy. Accuracy of weight scales should be demonstrated at least daily by the use of a test weight(s) having a verified weight. The test method involves placing a test weight on the scale and reading the results. The following method should be used to calibrate weight scales daily or more frequently as needed:

(1) With nothing on the scale, "zero out" the weight scale by adjusting the weight scale calibration knob or wheel or tare/zero button so that it reads zero. A digital scale should be powered and allowed to stabilize before adjusting to read zero.
(2) Place the test weight(s) on the scale.
(3) Read the weight that is registered on the scale, and, if needed, adjust the scale by turning the calibration knob or wheel to show the weight of the test weight that is being tested. Some digital scales have an electronic push-button calibration feature to calibrate the weight during a test.

(4) Repeat the testing procedure twice after any adjustment. The weight that is registered should be exactly the same.

[**10:**A.7.12]

Weight scales that do not provide repeatable results within the tolerances specified in the manufacturer's literature should be repaired or replaced. [**10:**A.7.12]

13.6.5 Hydrostatic Testing. For hydrostatic testing of portable fire extinguishers, see Chapter 8 of NFPA 10.

13.6.5.1 Condemning Extinguishers.

13.6.5.1.1 Fails Test or Examination. When a fire extinguisher cylinder, shell, or cartridge fails a hydrostatic pressure test or fails to pass a visual examination as specified in 8.4.2 of NFPA 10, it shall be condemned or destroyed by the owner or the owner's agent. [**10:**8.8.1]

13.6.5.1.1.1 When a cylinder is required to be condemned, the retester shall notify the owner in writing that the cylinder is condemned and that it cannot be reused. [**10:**8.8.1.1]

13.6.5.1.1.2 A condemned cylinder shall not be repaired. [**10:**8.8.1.2]

13.6.5.1.2 Marking Condemned Extinguishers.

13.6.5.1.2.1 Condemned cylinders shall be stamped "CONDEMNED" on the top, head, shoulder, or neck with a steel stamp. [**10:**8.8.2.1]

13.6.5.1.2.2 No person shall remove or obliterate the "CONDEMNED" marking. [**10:**8.8.2.2]

13.6.5.1.2.3 Minimum letter height shall be ⅛ in. (3 mm). [**10:**8.8.2.3]

13.7 Detection, Alarm, and Communications Systems

13.7.1 General.

13.7.1.1 Where building fire alarm systems or automatic fire detectors are required by other sections of this *Code*, they shall be provided and installed in accordance with NFPA 70, *NFPA 72*, and Section 13.7.

Δ **13.7.1.2* Building Fire Alarm Systems.** Protected premises fire alarm systems that serve the general fire alarm needs of a building or buildings shall include one or more of the following systems or functions:

(1) Manual fire alarm signal initiation
(2) Automatic fire alarm and supervisory signal initiation
(3) Monitoring of abnormal conditions in fire suppression systems
(4) Activation of fire suppression systems
(5) Activation of emergency control functions
(6) Activation of fire alarm notification appliances
(7) In-building fire emergency voice/alarm communications
(8) Guard's tour supervisory service
(9) Process monitoring supervisory systems
(10) Activation of off-premises signals
(11) Combination systems

[**72:**23.3.3.1]

Δ **A.13.7.1.2** The following functions are included in Annex A to provide guidelines for utilizing building systems and equipment in addition to proprietary fire alarm equipment in order to provide life safety and property protection. Building functions that should be initiated or controlled during a fire alarm condition include, but should not be limited to, the following:

(1) Elevator operation consistent with ANSI/ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*
(2) Unlocking of stairwell and exit doors (see NFPA 80 and NFPA *101*)
(3) Release of fire and smoke dampers (see NFPA 90A and NFPA 90B)
(4) Monitoring and initiating of self-contained automatic fire extinguishing system(s) or suppression system(s) and equipment (see NFPA 11, NFPA 12, NFPA 12A, NFPA 13, NFPA 14, NFPA 15, NFPA 17, NFPA 17A, and NFPA 750)

[**72:**A.23.3.3.1]

13.7.1.3 All apparatus requiring rewinding or resetting to maintain normal operation shall be rewound or reset as promptly as possible after each test and alarm. [**72:**14.5.4]

13.7.1.4 The provisions of Section 13.7 shall apply only where specifically required by another section of this *Code*. [***101:***9.6.1.1]

13.7.1.4.1 Fire detection, alarm, and communications systems installed to make use of an alternative permitted by this *Code* shall be considered required systems and shall meet the provisions of this *Code* applicable to required systems. [***101:***9.6.1.2]

The provisions of 13.7.1.4.1 remind the user that a fire detection system, an alarm system, or an associated communications system that is installed to take advantage of a *Code* alternative becomes a required system and is subject to the same requirements as any other required system, including maintenance. An example of this provision is a new business occupancy that is not required to have a fire alarm system on the basis of the thresholds established in 13.7.2.25. If, for security reasons, delayed-egress electrical locking systems were to be installed, they would have to meet the provisions of 14.5.3.1. Paragraph 14.5.3.1.1(1) requires that the locks automatically release upon the activation of an approved, supervised automatic sprinkler system in accordance with Section 13.3; the activation of any heat detector; or the activation of not more than two smoke detectors of an approved, supervised automatic fire detection system installed in accordance with Section 13.7 of this *Code* and Section 9.6 of NFPA *101*. If a fire alarm system is utilized to automatically release a delayed-egress electrical locking system, it becomes a required system and must be installed and maintained in accordance with Section 13.7 of this *Code* and Section 9.6 of NFPA *101*.

Δ **13.7.1.4.2*** To ensure operational integrity, the fire alarm system shall have an approved maintenance and testing program complying with the applicable requirements of *NFPA 70* and *NFPA 72*. [***101:***9.6.1.4]

A.13.7.1.4.2 Records of conducted maintenance and testing and a copy of the certificate of compliance should be maintained. [***101:***A.9.6.1.4]

The operational integrity of a fire alarm system cannot be ensured without proper maintenance and testing. Thus, the *Code* requires that an approved — that is, acceptable to the AHJ — maintenance and testing program be operational on an ongoing basis. An important part of the program is retention of system acceptance records and subsequent operational test records, so that comparisons can be made to initial system specifications.

Δ **13.7.1.4.3** Fire alarm system impairment procedures shall comply with NFPA 72. [***101:***9.6.1.5]

A fire alarm system might be shut down or otherwise impaired for any number of reasons during the life of a building. Some impairments are preplanned, controlled, and of short duration, such as during periodic testing and maintenance. Others might be preplanned and of longer duration, such as during times of building or system rehabilitation. Emergency shutdown of the system can be the result of power failure, fire, or other physical damage and might result in a short or lengthy shutdown to repair the system. Advance planning should help ensure that the system, or most of the system, can be restored to service despite the scope of the renovation or the extent of an unexpected impairment. If the alarm system is required by the *Code* or if it was installed to make use of one of the alternatives offered by the *Code*, it must be in operable condition for the building to be considered *Code* compliant.

Instead of designating a building with an inoperative alarm system as noncompliant and prohibiting occupancy under all conditions in accordance with the provisions of 4.5.4 and 4.5.6.1, 13.7.1.4.3 mandates compliance with the fire alarm system impairment procedures specified by *NFPA 72*. In addition to notifying the building owner any time an alarm system or portion thereof is impaired, the service provider is required to notify the AHJ when an alarm system is out of service for more than 8 hours. The 8-hour criterion specified by *NFPA 72* is intended to correspond with a typical work shift, such that if the alarm system remains impaired at the end of the work day, the AHJ will be notified. If the AHJ determines the alarm system will be impaired for an extended period of time, means to mitigate the associated life safety risk can be implemented. Such means might include the establishment of a fire watch.

It is the intent of the *Code* that a fire watch result in a heightened awareness of the building's operations and environment. Individuals assigned to the fire watch should be able to recognize fire hazards and understand the procedures for occupant and fire department notification and occupant evacuation in an emergency.

When a plan to address system impairment is being developed, it is important to consider the nature of the impairment, the location, the increased hazards that are involved, and the actions necessary to mitigate the hazards. The AHJ should be involved in the development of such a plan.

See 13.3.3.6 for requirements relating to automatic sprinkler system impairments.

13.7.1.5* Impaired and Nuisance Alarm Prone Systems.

A.13.7.1.5 Requirements to address impaired fire alarm systems, and fire alarm systems prone to chronic nuisance alarms are provided in 13.7.1.5. In many situations, the problems can be corrected by ensuring the systems are maintained, serviced, and tested by an approved fire alarm service company. However, in some cases, the system problems may be attributed to aging for which suitable replacement parts are no longer available.

13.7.1.5.1 Impaired fire alarm systems shall include, but shall not be limited to, required systems that are not fully operational, are no longer monitored as required by the AHJ, or are under renovation or repair.

13.7.1.5.2 The system owner or designated representative shall immediately notify the AHJ in an approved manner when a fire alarm system is impaired.

13.7.1.5.3 The AHJ shall be authorized to require standby fire personnel or an approved fire watch in accordance with 1.7.16 at premises in which required fire alarm systems are impaired or classified as chronic nuisance alarm prone systems.

13.7.1.5.4 Fire alarm systems that have produced five or more nuisance alarms in a 365-day period shall be classified as chronic nuisance alarm prone systems.

13.7.1.5.5* The AHJ shall be authorized to require central station service be provided for chronic nuisance alarm prone systems.

A.13.7.1.5.5 This paragraph allows the AHJ to require chronic nuisance alarm prone systems to comply with the *NFPA 72*, Section 26.3 requirements for central station service. Central station service, as compared to other supervising service, requires the system to be covered by a systematic follow-up program under the control of the organization that has listed the prime contractor. This will ensure that not only is the system being maintained, serviced, and periodically tested by an approved alarm service company, but it is also under an ongoing audit program by the company that listed the central station. Many jurisdictions that require central station service on fire alarm systems also communicate directly with the listing organization concerning the systems monitored in their jurisdiction.

13.7.1.5.6* Fire alarm supervising stations and fire alarm service companies shall immediately notify the AHJ when any of the following conditions exists:

(1) A fire alarm system is impaired.
(2) Required system monitoring is no longer being provided.
(3) Required testing, service, and maintenance is no longer being provided.

(4) A fire alarm system cannot be serviced or repaired to make it fully operational.
(5) A fire alarm system cannot be serviced or repaired to eliminate chronic nuisance alarms.

A.13.7.1.5.6 It is not always practical for the AHJ to continually verify that required monitoring, testing, service, and maintenance are provided. It is also difficult for the AHJ to determine if older systems are no longer able to be serviced or repaired to keep them operational and resistant to nuisance alarms, particularly if spare parts are no longer available. Paragraph 13.7.1.5.6 requires the fire alarm companies to notify the AHJ when required services have been discontinued, or when systems can no longer be serviced and maintained in an operational condition, free from chronic nuisance alarms. It is not the intent of this paragraph to prevent system owners from getting a second opinion on the system status from another approved fire alarm service provider.

13.7.1.5.7 The system owner shall replace required fire alarm systems that cannot be serviced or repaired to eliminate system impairments or chronic nuisance alarms.

13.7.1.6* Nonrequired Coverage.

The term *nonrequired* is not the same as the terms *supplementary*, *partial*, or *selective* (see 17.5.3.2 of *NFPA 72*). Refer to the definitions of the terms *nonrequired* and *supplementary* found in 3.3.170, A.3.3.170, and 3.3.286 of *NFPA 72*.

The subparagraphs of 13.7.1.6 address circumstances in which fire detection serves purposes or achieves objectives not established by a locally adopted, minimum-compliance building code or fire code. Often, a user has specific fire protection goals or objectives that can be achieved only by using automatic fire detection. For example, a building operator might have a mission continuity objective and intends to use a special extinguishing system, actuated by automatic detection, to achieve that objective. Such a system is a nonrequired system because it is installed at the option of the operator and not because of a building or fire code requirement.

The language of the subparagraphs provides the necessary latitude in design for systems that are being installed to meet an objective other than the minimum requirements for property protection and life safety provided in the local building code. Although the requirements in 13.7.1.6.1 and 13.7.1.6.2 are specified in prescriptive terms, designs for some objectives might be best achieved through the use of the performance-based design option. The process of performance-based design involves a documented formal analysis that serves as the basis for design decisions.

A.13.7.1.6 The requirement of 13.7.1.6 recognizes there will be instances where, for example, a facility owner would want to apply detection to meet certain performance goals and to address a particular hazard or need, but that detection is not required. Once installed, of course, acceptance testing, annual testing, and ongoing maintenance in accordance with this *Code* is expected. The intent of this section is to allow the use of a single detector, or multiple detectors provided for specific protection, with spacing to meet specific fire safety objectives as determined in accordance with 17.6.1.1 and 17.7.1.1 of *NFPA 72*. [**72:**A.17.5.3.3]

13.7.1.6.1 Detection installed for reasons of achieving specific fire safety objectives, but not required by any laws, codes, or standards, shall meet all of the requirements of this *Code*, with the exception of prescriptive spacing criteria of Chapter 17 of *NFPA 72*. [**72:**17.5.3.3.1]

Even where detection is not required by some applicable law, code, or standard, detection must still comply with all the requirements of *NFPA 72*, including the specific detector location, installation, operation, and maintenance requirements for the type of detector being used. This requirement helps to ensure that purchasers of nonrequired systems receive systems that work. Decades of experience in fire alarm system design, installation, and maintenance have demonstrated that compliance with the criteria in this *Code* results in systems that have a high probability of providing consistent, reliable service. The exception permits the use of detector spacing that is different from the spacing specified in the prescriptive sections of this *Code*. With some system objectives, using the prescriptive spacings is not necessary in order to attain the performance intended for the nonrequired system.

Whenever any system is designed, 17.6.1.1, 17.7.1.1, and 17.8.1.1 of *NFPA 72* require that the objectives for the system be stipulated in the design documentation. Consequently, these paragraphs apply to nonrequired systems. The detection spacing selected must be substantiated in the design documentation to show that design objectives for the system will be satisfied when the detectors are selected and installed on the spacing selected.

13.7.1.6.2 Where nonrequired detectors are installed for achieving specific fire safety objectives, additional detectors not necessary to achieve the objectives shall not be required. [**72:**17.5.3.3.2]

Generally, the objective of nonrequired coverage is to attain an early warning of a fire involving a valuable asset but not necessarily some other portion of the compartment. Under these circumstances, providing detection for the portion of the compartment where the asset is actually located, rather than throughout the entire compartment or building, might be sufficient. Exhibit 13.33 and Exhibit 13.34 represent special application detection devices.

13.7.1.7 Signal Initiation.

Δ **13.7.1.7.1** Where required by other sections of this *Code*, actuation of the fire alarm system shall occur by any or all of the following means of initiation, but shall not be limited to such means:

(1) Manual fire alarm initiation
(2) Automatic detection
(3) Extinguishing system operation

[***101:***9.6.2.1]

The capability for manual fire alarm initiation is a requirement common to all occupancies that require the installation of a fire

Exhibit 13.33

Exhibit 13.34

Line-type heat detector installed in a cable tray application. (Source: The Protectowire Co., Inc., Pembroke, MA)

alarm system. Initiation by automatic detection or extinguishing system operation is permitted to serve in lieu of manual initiation for some occupancies. In some cases, an occupancy chapter might require initiation by automatic detection or extinguishing system operation. For example, new educational occupancies are not always required to have an automatic sprinkler system, depending on their size; however, if such a system is installed, 13.7.2.3.2.2 requires automatic alarm system initiation by operation of the sprinkler system in addition to the manual means. In new health care occupancies, automatic sprinklers are required, and 13.7.2.7.2.1 states that initiation of the alarm system is to be by manual means and by sprinkler system waterflow alarms. In new Class A mercantile occupancies, a fire alarm system and an automatic sprinkler system are required. However, 13.7.2.23.2(1) requires only alarm initiation by manual means. Alarm initiation by means of sprinkler system activation is permitted by 13.7.2.23.2(3) to serve in lieu of manual initiation, but it is not required.

Where both manual and automatic means for alarm system initiation are used, they should be complementary. If one system becomes inoperative — for example, failure of the manual initiation circuit — the second should continue to function properly and initiate the alarm upon automatic detection of fire or smoke.

13.7.1.7.2 Manual fire alarm boxes shall be used only for fire-protective signaling purposes. Combination fire alarm and guard's tour stations shall be permitted. [***101***:9.6.2.2]

13.7.1.7.3 A manual fire alarm box shall be provided as follows, unless modified by another section of this *Code*:

(1) For new alarm system installations, the manual fire alarm box shall be located within 60 in. (1525 mm) of exit doorways.
(2) For existing alarm system installations, the manual fire alarm box either shall be provided in the natural exit access path near each required exit or within 60 in. (1525 mm) of exit doorways.

[***101***:9.6.2.3]

13.7.1.7.4 Manual fire alarm boxes shall be mounted on both sides of grouped openings over 40 ft (12.2 m) in width, and within 60 in. (1525 mm) of each side of the opening. [***101***:9.6.2.4]

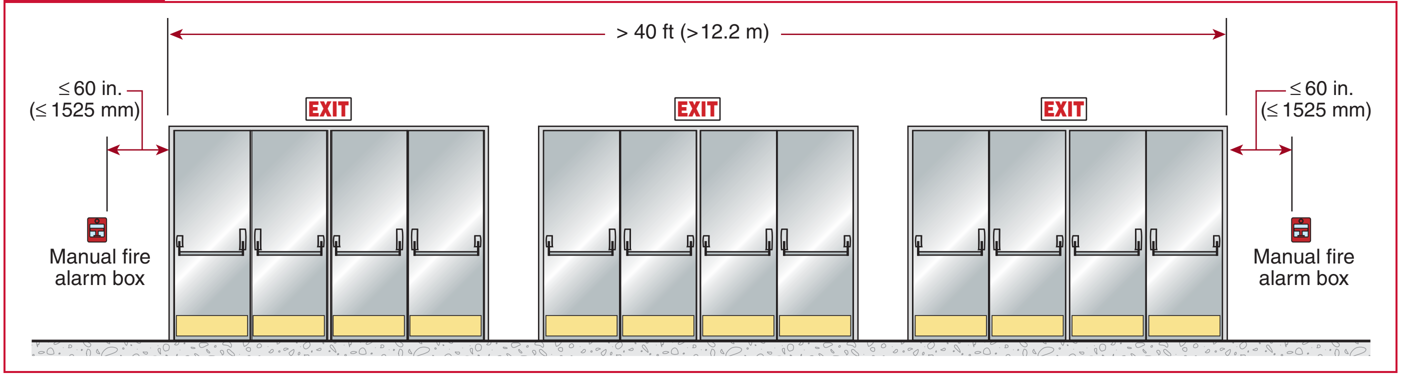
Prior to the 2009 edition of the *Code,* manual fire alarm boxes were only required to be located near each required exit in the natural exit access path; such arrangement is still permitted by 13.7.1.7.3(2) for existing installations. For new installations, manual fire alarm boxes must be located within 60 in. (1525 mm) of exit doors, which includes doors directly to the outside and doors to exit stair enclosures and exit passageways. See Exhibit 13.35 for an example of the application of 13.7.1.7.4 to manual fire alarm boxes at grouped openings.

13.7.1.7.5* Additional manual fire alarm boxes shall be located so that, on any given floor in any part of the building, no horizontal distance on that floor exceeding 200 ft (61 m) shall need to be traversed to reach a manual fire alarm box. [***101***:9.6.2.5]

A.13.7.1.7.5 It is not the intent of 13.7.1.7.5 to require manual fire alarm boxes to be attached to movable partitions or to equipment, nor is it the intent to require the installation of permanent structures for mounting purposes only. [***101***:A.9.6.2.5]

In a large open area, such as an exhibit hall, it would be impractical to require the installation of manual fire alarm boxes on

Exhibit 13.35



Locations of manual fire alarm boxes at grouped openings.

mounting posts in the middle of the floor. However, it would be reasonable to apply the maximum spacing requirements to boxes located on the perimeter wall of the space.

13.7.1.7.6* For fire alarm systems using automatic fire detection or waterflow detection devices to initiate the fire alarm system in accordance with Chapters 11 through 43 of NFPA *101*, not less than one manual fire alarm box, located as required by the AHJ, shall be provided to initiate a fire alarm signal. [***101:***9.6.2.6]

A.13.7.1.7.6 The manual fire alarm box required by 13.7.1.7.6 is intended to provide a means to manually activate the fire alarm system when the automatic fire detection system or waterflow devices are out of service due to maintenance or testing, or where human discovery of the fire precedes automatic sprinkler system or automatic detection system activation. Where the fire alarm system is connected to a monitoring facility, the manual fire alarm box required by 13.7.1.7.6 should be connected to a separate circuit that is not placed "on test" when the detection or sprinkler system is placed on test. The manual fire alarm box should be located in an area that is accessible to occupants of the building and should not be locked. [***101:***A.9.6.2.6]

13.7.1.7.7* Manual fire alarm boxes shall be accessible, unobstructed, and visible. [***101:***9.6.2.7]

A.13.7.1.7.7 Manual fire alarm boxes can include those with key-operated locks for detention areas or psychiatric hospitals, manual fire alarm boxes in areas where explosive vapors or dusts might be a hazard, or manual fire alarm boxes in areas with corrosive atmospheres. The appearance of manual fire alarm boxes for special uses often differs from those used in areas of normal occupancy. Manual fire alarm boxes, such as those with locks, that are located in areas where the general public has limited access might need to have signage advising persons to seek assistance from staff in the event a fire is noted. [***101:***A.9.6.2.7]

Paragraphs 13.7.1.7.3 through 13.7.1.7.7 establish the criteria for the placement of manual fire alarm boxes. The intent is to provide maximum visibility and easy access to increase the probability that building occupants will initiate an alarm as they exit the building. If alarm boxes are not located conveniently or are obstructed from view, it is unlikely that an occupant will look for one. A manual fire alarm box is shown in Exhibit 13.36.

The requirement of 13.7.1.7.6 is also found in *NFPA 72*. This requirement affects initiation arrangement for occupancies that permit alarm initiation by automatic detection or extinguishing system operation in lieu of manual initiation. For example, a business occupancy using either 13.7.2.25.2(2) or (3) for alarm initiation would still be required to have one manual fire alarm box in the building at a location approved by the AHJ. The single required fire alarm box is intended to be utilized to initiate the required fire alarm to provide occupant notification in the event the automatic initiation circuit is out of service for testing, maintenance, or repair. It is not necessarily intended to be accessible to the general public, although it might be if so required by the AHJ.

13.7.1.7.8 Where a sprinkler system provides automatic detection and alarm system initiation, it shall be provided with an approved

Exhibit 13.36

Manual fire alarm box. (Courtesy of The Protectowire Co., Inc., Pembroke, MA) alarm initiation device that operates when the flow of water is equal to or greater than that from a single automatic sprinkler. [*101:*9.6.2.8]

13.7.1.7.9 Where a total (complete) coverage smoke detection system is required by another section of this *Code*, automatic detection of smoke in accordance with *NFPA 72* shall be provided in all occupiable areas in environments that are suitable for proper smoke detector operation. [*101:*9.6.2.9]

13.7.1.8 Smoke Alarms.

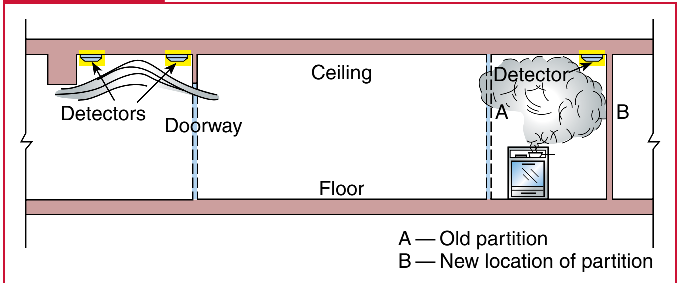
Smoke alarms need to be positioned correctly. If they are too close to a wall/ceiling intersection, particularly over a door, air currents might cause heat and smoke to bypass the unit completely. Likewise, the location of the alarms with respect to a dropped beam or other construction can have a similar nullifying effect. Problems can arise where partitions are moved without regard to the location of existing detectors. These problems are illustrated in Exhibit 13.37. *NFPA 72* provides extensive guidance in this area.

The terms *smoke alarm* and *smoke detector* are frequently, and incorrectly, used interchangeably. A smoke alarm is a device that, upon the presence of smoke, sounds an integral alarm. Smoke alarms are typically powered by the building electrical system and might be provided with battery backup; in some cases, such as in existing one- and two-family dwellings, they are permitted to be powered solely by batteries. Smoke alarms are typically found within dwelling units and within sleeping rooms of lodging or rooming houses and hotels and dormitories, among other occupancy locations.

Smoke alarms can be of either the single-station type or the multiple-station type. The term *single station* means that, when a particular smoke alarm senses smoke, only that device sounds its integral sounding alarm. The term *multiple-station* refers to smoke alarms that are interconnected such that, when one alarm senses smoke, all the interconnected devices sound their integral alarms. Multiple-station smoke alarms are typically interconnected within individual dwelling units to alert sleeping occupants located in different rooms to a fire in the dwelling.

A smoke detector is a component of a fire alarm system. In the presence of smoke, a smoke detector sends an electronic signal to the fire alarm control unit, which, in turn, initiates a predetermined action (such as activating the building evacuation alarm). Smoke detectors usually receive their power from the fire alarm system and contain no integral sounding devices.

Exhibit 13.37



Detector location problems to be avoided.

In an occupancy such as a hotel, it might be desirable to protect the guest rooms with system smoke detectors rather than single-station smoke alarms. The *Code*, however, prohibits the guest room smoke detectors from sounding the general building evacuation alarm (see 13.7.1.8.9). Provided that the system smoke detectors are arranged to function like single- or multiple-station smoke alarms by sounding an alarm only within the protected guest room or suite, and to perhaps annunciate a supervisory signal at the front desk, 13.7.1.8.6 permits system smoke detectors to be used in the guest rooms in lieu of single- or multiple-station smoke alarms. The use of such system smoke detectors might provide an enhanced level of reliability, since the wiring connecting the detectors to the fire alarm control unit will be supervised for integrity in accordance with *NFPA 72*.

13.7.1.8.1 Where required by another section of this *Code*, single-station and multiple-station smoke alarms shall be in accordance with *NFPA 72* unless otherwise provided in 13.7.1.8.3, 13.7.1.8.4, 13.7.1.8.5, or 13.7.1.8.6. [*101:*9.6.2.10.1]

13.7.1.8.2 Where automatic smoke detection is required by Chapters 11 through 43 of NFPA *101*, smoke alarms shall not be used as a substitute. [*101:*9.6.2.10.2]

13.7.1.8.3* The interconnection of smoke alarms shall apply only to new construction as provided in 13.7.1.8.8. [*101:*9.6.2.10.3]

Δ **A.13.7.1.8.3** *NFPA 72* mandates smoke alarms in all sleeping rooms, and interconnection of smoke alarms is required for both new and existing installations. Per 13.7.1.8.1, the residential occupancy requirements determine whether smoke alarms are needed within sleeping rooms. Paragraph 13.7.1.8.3 limits the requirement for interconnection of smoke alarms to those in new construction. This *Code* does not intend to require compliant, existing smoke alarm installations to be interconnected. This *Code* is periodically revised to add retrospective requirements only where the need is clearly substantiated. [*101:*A.9.6.2.10.3]

Δ **13.7.1.8.4** Smoke alarms and smoke detectors shall not be installed within an area of exclusion determined by a 10 ft (3.0 m) radial distance along a horizontal flow path from a stationary or fixed cooking appliance, unless listed for installation in close proximity to cooking appliances. Smoke alarms and smoke detectors installed between 10 ft (3.0 m) and 20 ft (6.1 m) along a horizontal flow path from a stationary or fixed cooking appliance shall be equipped with an alarm-silencing means or use photoelectric detection.

Exception: Smoke alarms or smoke detectors that use photoelectric detection shall be permitted for installation at a radial distance greater than 6 ft (1.8 m) from any stationary or fixed cooking appliance when the following conditions are met:

(1) The kitchen or cooking area and adjacent spaces have no clear interior partitions or headers and
(2) The 10 ft (3.0 m) area of exclusion would prohibit the placement of a smoke alarm or smoke detector required by other sections of NFPA 72.

*[**72:**29.8.3.4(4)]*

13.7.1.8.5 Smoke alarms and smoke detectors shall not be installed within a 36 in. (910 mm) horizontal path from a door to a bathroom containing a shower or tub unless listed for installation in close proximity to such locations. [**72:**29.8.3.4(6)]

Paragraph 13.7.1.8.5 clarifies that devices listed for installation in close proximity of bathroom doors are permitted within the 36 in. (910 mm) exclusion distance. This language is consistent with the general provisions for equivalency in Section 1.4, which permits for the application of technologies that can meet the intended performance goals without being overly restrictive and inadvertently barring the use of capable equipment.

13.7.1.8.6 System smoke detectors in accordance with *NFPA 72* and arranged to function in the same manner as single-station or multiple-station smoke alarms shall be permitted in lieu of smoke alarms. [***101:***9.6.2.10.7]

13.7.1.8.7 Smoke alarms, other than battery-operated smoke alarms as permitted by other sections of this *Code*, shall be powered in accordance with the requirements of *NFPA 72*. [***101:***9.6.2.10.8]

Single-station and multiple-station smoke alarms, unless exempted by 13.7.1.8.7, must be powered as required by *NFPA 72*. In general, they must be powered by the building electrical system; they must not rely solely on battery power. This provision is based on the experience that battery-operated smoke alarms do not provide the reliability with respect to uninterrupted power supply that building electrical system power provides. Batteries are often removed to avoid nuisance alarms caused by cooking or steam from showers, or they may be removed for use in other devices such as radios and electronic toys; dead batteries often are not replaced. However, 13.7.1.8.7 allows other sections of the *Code* to permit battery-operated, single-station smoke alarms. The use of battery-operated smoke alarms is permitted in existing one- and two-family dwellings; in existing lodging or rooming houses; and, under certain conditions, in existing residential board and care facilities.

It is not the intent of 13.7.1.8.7 to prohibit low-power wireless technology where a battery-operated alarm reports by radio transmission to a fire alarm control unit if such a system complies with *NFPA 72*. In turn, *NFPA 72* requires such systems to indicate a missing battery or low battery power condition at the remotely located alarm system panel. Compliance with the provisions of *NFPA 72* applicable to low-power wireless systems increases the power source reliability to a level comparable to that provided by connection to the building electrical service.

Δ **13.7.1.8.8*** In new construction, where two or more smoke alarms are required within a dwelling unit, suite of rooms, or similar area, they shall be arranged so that operation of any smoke alarm shall cause the alarm in all smoke alarms within the dwelling unit, suite of rooms, or similar area to sound, unless otherwise permitted by one of the following:

(1) The requirement of 13.7.1.8.8 shall not apply where permitted by another section of this *Code*.

(2) The requirement of 13.7.1.8.8 shall not apply to configurations that provide equivalent distribution of the alarm signal. [***101:***9.6.2.10.9]

A.13.7.1.8.8 A dwelling unit is that structure, area, room, or combination of rooms, including hotel rooms/suites, in which a family or individual lives. A dwelling unit includes living areas only and not common usage areas in multifamily buildings, such as corridors, lobbies, and basements. [***101:***A.9.6.2.10.8]

13.7.1.8.9 The alarms described in 13.7.1.8.8 shall sound only within an individual dwelling unit, suite of rooms, or similar area and shall not actuate the building fire alarm system, unless otherwise permitted by the AHJ. [***101:***9.6.2.10.10]

13.7.1.8.10 Smoke alarms shall be permitted to be connected to the building fire alarm system for the purpose of annunciation in accordance with *NFPA 72*. [***101:***9.6.2.10.11]

The intent behind requiring smoke alarms within individual living units without requiring connection to the building fire alarm system is to provide notification of a smoke condition within a guest room, guest suite, or dwelling unit to its occupants. Once the occupants escape from their unit to the building's common areas, they can use the manual fire alarm boxes to sound the building alarm to notify the remaining building occupants of the emergency.

Interconnection of dwelling unit smoke detectors to the building fire alarm system can result in numerous nuisance alarms due to the detection of cooking vapors or steam from showers. Nuisance alarms can lead to complacency or, worse, the deliberate disablement of the system and the resulting lack of early warning. Thus, where a complete fire detection (versus smoke detection) system is required, it usually includes system smoke detection within building common areas and system heat detection within individual dwelling units. Single- or multiple-station smoke alarms are then still necessary within each dwelling unit to afford the occupants of each unit early warning of smoke conditions within their unit.

13.7.1.9 Occupant Notification.

13.7.1.9.1 Occupant notification shall be provided to alert occupants of a fire or other emergency where required by other sections of this *Code*. [***101:***9.6.3.1]

13.7.1.9.2 Occupant notification shall be in accordance with 13.7.1.9.3 through 13.7.1.9.10.2, unless otherwise provided in 13.7.1.9.2.1 through 13.7.1.9.2.4. [***101:***9.6.3.2]

Note that 13.7.1.9.5 requires occupant notification to be provided by audible and visible signals. Thus, where an occupancy chapter requires an alarm system that provides occupant notification in accordance with 13.7.1.9, visible signals, as well as the traditional audible signals, must be provided. Several exemptions to the requirement for visible signals are provided in 13.7.1.9.5.1 through 13.7.1.9.5.8. For example, existing alarm systems are exempt from the requirement for visible signals per 13.7.1.9.5.3.

13.7.1.9.2.1* Elevator lobby, hoistway, and associated machine room smoke detectors used solely for elevator recall, and heat detectors used solely for elevator power shutdown, shall not be required to activate the building evacuation alarm if the power supply and installation wiring to such detectors are monitored by the building fire alarm system, and if the activation of such detectors initiates a supervisory signal at a constantly attended location. [***101:***9.6.3.2.1]

A.13.7.1.9.2.1 Elevator lobbies have been considered areas subject to unwanted alarms due to factors such as low ceilings and smoking. In the past several years, new features have become available to reduce this problem. These features are, however, not necessarily included in any specific installation. [***101:***A.9.6.3.2.1]

13.7.1.9.2.2* Smoke detectors used solely for closing dampers or heating, ventilating, and air-conditioning system shutdown shall not be required to activate the building evacuation alarm, provided that the power supply and installation wiring to the detectors are monitored by the building fire alarm system, and the activation of the detectors initiates a supervisory signal at a constantly attended location. [***101:***9.6.3.2.2]

A.13.7.1.9.2.2 The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm. [***101:***A.9.6.3.2.2]

13.7.1.9.2.3* Smoke detectors located at doors for the exclusive operation of automatic door release shall not be required to activate the building evacuation alarm, provided that the power supply and installation wiring to the detectors are monitored by the building fire alarm system, and the activation of the detectors initiates a supervisory signal at a constantly attended location. [***101:***9.6.3.2.3]

A.13.7.1.9.2.3 The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm. [***101:***A.9.6.3.2.3]

13.7.1.9.2.4 Detectors in accordance with 22.3.4.3.1(2) and 23.3.4.3.1(2) of NFPA *101* shall not be required to activate the building evacuation alarm. [***101:***9.6.3.2.4]

The provisions of 13.7.1.9.2.1 through 13.7.1.9.2.4 reaffirm that not all detectors are required to sound the building alarm simply because they are installed on the premises. Detectors used for releasing service, such as for the release of an automatic door hold-open device that allows a door to be self-closing in the presence of smoke, need only perform their intended function as long as the detector wiring is monitored and a supervisory signal is annunciated at a constantly attended location when the detectors activate. In areas where smoke detection — complete with occupant notification via the building alarm system — is needed to provide the intended level of life safety, the *Code* specifically requires either a complete or a partial smoke detection system. Interconnection with the building alarm should not be mandated in the hope of receiving additional detection coverage; such a detector might have been installed for another purpose, such as releasing service.

New health care occupancies, as specified in 13.7.2.7.3.1, are prohibited from using 13.7.1.9.2.3. Thus, if a smoke detector is installed as part of an automatic door release system (see 14.5.4.2), the activation of the detector must result in occupant notification through the building fire alarm system.

13.7.1.9.3 Where permitted by Chapters 11 through 43 of NFPA *101*, a presignal system shall be permitted where the initial fire alarm signal is automatically transmitted without delay to a municipal fire department, to a fire brigade (if provided), and to an on-site staff person trained to respond to a fire emergency. [***101:***9.6.3.3]

Instead of immediately and automatically sounding a general alarm throughout the building, a presignal system delays the general alarm by sounding an alarm only at an approved and constantly attended area. This area could be, for example, a fire brigade station, a guard station, or similar location with staff trained to investigate the signal's origin and subsequently activate a general alarm if necessary.

A delay in sounding the general alarm is inherent in a presignal system, but the delay might do more harm than good in those occupancies with populations that are difficult to evacuate or protect. Therefore, the *Code* requires an occupancy to specifically recognize a presignal system to permit its use.

A presignal system used in accordance with the provisions of 13.7.1.9.3 is permitted to delay only the general occupant notification and must, at time of initiation, achieve immediate and automatic notification of emergency forces.

13.7.1.9.4 Where permitted by Chapters 11 through 43 of NFPA *101*, a positive alarm sequence shall be permitted, provided that it is in accordance with *NFPA 72*. [***101:***9.6.3.4]

Positive alarm sequence offers relief from nuisance alarms in buildings equipped with detection technology by permitting a delay in occupant notification. The detector senses smoke and automatically, without delay, sends an alarm signal to a constantly attended location, so that trained staff can investigate the origin of the signal. Positive alarm sequence includes the following features:

1. The signal received at the attended location must be acknowledged within 15 seconds, or immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
2. Trained personnel have up to 180 seconds during the alarm investigation phase to evaluate the fire condition and reset the system; if the system is not reset within 180 seconds, immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
3. If a second automatic fire detector is actuated during the investigation phase, immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.

4. If any other initiating device, such as a manual fire alarm box, is actuated during the investigation phase, immediate activation of notification signals in accordance with the building evacuation or relocation plan and remote signals must occur.
5. The system must provide a means to bypass the positive alarm sequence.

Positive alarm sequence is permitted where another section of this *Code* or NFPA *101* specifically allows it. The only occupancies that do not permit occupant notification by positive alarm sequence are new and existing residential board and care occupancies.

13.7.1.9.5 Unless otherwise provided in 13.7.1.9.5.1 through 13.7.1.9.5.8, notification signals for occupants to evacuate shall be by audible and visible signals in accordance with *NFPA 72* and ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, or other means of notification acceptable to the AHJ. [***101:***9.6.3.5]

13.7.1.9.5.1 Areas not subject to occupancy by persons who are hearing impaired shall not be required to comply with the provisions for visible signals. [***101:***9.6.3.5.1]

In addition to audible alarms, visible alarm devices are needed in buildings occupied by persons who are hearing impaired. The provision of 13.7.1.9.5.1 recognizes that not all buildings are subject to occupancy by those who are hearing impaired. For example, in a high hazard industrial occupancy where, due to employee safety concerns, an adequate hearing level has been judged to be a legitimate condition of employment, there should be no life safety need for visible signals in addition to the audible signals. As the provisions of the *Americans with Disabilities Act and Architectural Barriers Act Accessibility Guidelines for Buildings and Facilities* receive wider implementation or are expanded in scope, few locations will exist where it is certain that persons with hearing impairments will not be present.

13.7.1.9.5.2 Visible-only signals shall be provided where specifically permitted in health care occupancies in accordance with Chapters 18 and 19 of NFPA *101*. [***101:***9.6.3.5.2]

13.7.1.9.5.3 Existing alarm systems shall not be required to comply with the provision for visible signals. [***101:***9.6.3.5.3]

Δ **13.7.1.9.5.4** Visible signals shall not be required in lodging or rooming houses in accordance with Chapter 26 of NFPA *101*. [***101:***9.6.3.5.4]

13.7.1.9.5.5 Visible signals shall not be required in exit stair enclosures. [***101:***9.6.3.5.5]

13.7.1.9.5.6 Visible signals shall not be required in elevator cars. [***101:***9.6.3.5.6]

Visible occupant notification appliances are not required to be installed in exit stairs or elevator cars as noted in 13.7.1.9.5.5 and 13.7.1.9.5.6, respectively. These provisions recognize that, upon entering an exit stair, occupants have reached a safe location and are in the process of egressing the building. Notification appliances in exit stair enclosures can create confusion and slow down the evacuation process. Likewise, if occupants are in an elevator and the building alarm activates, they will become aware of the alarm condition when the doors open and will proceed to egress the building. See also 13.7.1.9.6.4 and 13.7.1.9.6.5 for parallel provisions addressing audible notification appliances.

13.7.1.9.5.7* Public mode visual notification appliances in accordance with *NFPA 72* shall not be required in designated areas as permitted by Chapters 11 through 43 of NFPA *101*, provided that they are replaced with approved alternative visible means. [***101:***9.6.3.5.7]

A.13.7.1.9.5.7 Visual notification appliances installed in large volume spaces, such as arenas, stadiums, mall concourses and atriums, can be alternative devices which are not listed as visible notification appliances for fire alarm systems provided that the notification objective of the visual signal is reasonably achieved. Examples of alternative devices include, but are not limited to, scoreboards, message boards, and other electronic devices that meet the performance objectives of visible fire alarm appliances in large volume spaces. [***101:***A.9.6.3.5.7]

It is the intent to permit the omission of visible notification appliances as identified in 13.7.1.9.5.7 provided that the adjacent areas that have not been specifically designated as exempt are provided with visible notification as required by 13.7.1.9.5. [***101:***A.9.6.3.5.7]

13.7.1.9.5.8* Where visible signals are not required, as permitted by 13.7.1.9.5.7, documentation of such omission shall be maintained in accordance with 9.7.7 of NFPA *101*. [***101:***9.6.3.5.8]

A.13.7.1.9.5.8 Documentation should be maintained with the as-built drawings so that inspection and testing personnel understand that the visible appliances have been exempted from certain areas and, therefore, can note the deviation on the acceptance test documentation and ongoing inspection reports. This will provide inspection and testing personnel with necessary details regarding the omission of visible notification appliances. [***101:***A.9.6.3.5.8]

In large-volume spaces, such as stadiums, standard visual alarm notification appliances (strobes) might not prove to be effective for hearing-impaired occupants. The provisions of 13.7.1.9.5.7 and 13.7.1.9.5.8 permit alternative means of visual notification, provided that permission is granted by the applicable occupancy. Such alternative means of visual notification might be provided by electronic signage or video displays strategically located throughout the space or by the electronic scoreboards provided within a stadium or arena. It is anticipated that, in such occupancies, hearing-impaired occupants not only will see the messages but will take cues from other occupants responding to the audible alarm notification.

13.7.1.9.6 The general evacuation alarm signal shall operate in accordance with one of the methods prescribed by 13.7.1.9.6.1 through 13.7.1.9.6.3. [***101:***9.6.3.6]

13.7.1.9.6.1 The general evacuation alarm signal shall operate throughout the entire building other than the locations described in 13.7.1.9.6.4 and 13.7.1.9.6.5. [***101:***9.6.3.6.1]

13.7.1.9.6.2* Where total evacuation of occupants is impractical due to building configuration, only the occupants in the affected zones shall be initially notified, and provisions shall be made to selectively notify occupants in other zones to afford orderly evacuation of the entire building, provided that such arrangement is approved by the AHJ. [***101:***9.6.3.6.2]

A.13.7.1.9.6.2 To approve an evacuation plan to selectively notify building occupants, the AHJ should consider several building parameters, including building compartmentation, detection and suppression system zones, occupant loads, and the number and arrangement of the means of egress.

In high-rise buildings, it is typical to evacuate the fire floor, the floor(s) above, and the floor immediately below. Other areas are then evacuated as the fire develops. [***101:***A.9.6.3.6.2]

The provision of 13.7.1.9.6.2 typically applies to high-rise buildings. It provides for zoned, staged evacuation. This provision anticipates that the portions of the building that do not receive the initial alarm are separated from the areas of immediate emergency by adequate fire resistance–rated construction, such as the 2-hour fire separation that is usually provided between floors of high-rise buildings.

The use of staged evacuation requires occupants to be regularly trained and to have a basic understanding of the building's life safety systems and features. After having witnessed the collapse of the World Trade Center on September 11, 2001, many building occupants might not be comfortable remaining in a high-rise building under any fire condition. By conducting routine training, their comfort level can be increased by raising their awareness of how buildings are designed to limit the spread of fire from the area of origin through compartmentation and the installation of automatic sprinkler systems. This training becomes very important, since the exit stairs in most existing high-rise buildings are not designed to accommodate the simultaneous evacuation of the entire building population.

13.7.1.9.6.3 Where occupants are incapable of evacuating themselves because of age, physical or mental disabilities, or physical restraint, all of the following shall apply:

(1) The private operating mode as described in *NFPA 72* shall be permitted to be used.
(2) Only the attendants and other personnel required to evacuate occupants from a zone, area, floor, or building shall be required to be notified.
(3) Notification of personnel as specified in 13.7.1.9.6.3(2) shall include means to readily identify the zone, area, floor, or building in need of evacuation.

[***101:***9.6.3.6.3]

The provisions of 13.7.1.9.6.3, which address the private operating mode for occupant notification, frequently apply to health care occupancies and detention and correctional occupancies. It is common in these occupancies to use coded messages or a similar method to announce the occurrence and location of a fire emergency throughout the facility. This allows all members of the emergency response team, regardless of current location within a potentially sprawling facility, to respond to their assigned emergency duties.

NFPA 72 modifies the requirements for the placement of visible notification appliances where the private operating mode is utilized. For example, it might not be necessary to locate visible notification appliances in the patient rooms of a hospital or nursing home, since notification is intended to be provided via a coded message to staff, who will initiate the emergency plan. In such a case, visible signals might be limited to those areas subject to occupancy by the general public (such as lobbies, corridors, cafeterias, public restrooms, and other similar spaces). The AHJ ultimately determines where visible notification appliances must be located.

Δ **13.7.1.9.6.4** The general evacuation signal shall not be required in exit stair enclosures. [***101:***9.6.3.6.4]

Δ **13.7.1.9.6.5** The general evacuation signal shall not be required in elevator cars. [***101:***9.6.3.6.5]

13.7.1.9.7 Audible alarm notification appliances shall be of such character and so distributed as to be effectively heard above the average ambient sound level that exists under normal conditions of occupancy. [***101:***9.6.3.7]

The AHJ should review carefully the types and locations of fire alarm notification appliances. Given that audibility above ambient sound level is of primary importance and that each additional sounding device adds cost to a system, a balance should be maintained so that excessive costs are not incurred, while the installation of sufficient devices for adequate audibility is ensured. The provision of sufficient devices is extremely important in hotels and apartment buildings. Sounding devices located in corridors might not be audible within living units or guest rooms, especially in newer construction, due to the increased use of acoustical insulation for sound isolation.

In newer hotels, it has become common to install alarm notification appliances within each guest room to meet the audibility requirements of *NFPA 72*. With water running in the bathroom, the television operating on high volume, and the air-conditioning system in use, the horn or speaker within the room achieves the required occupant notification, whereas a similar device located in the corridor alone might not. Additionally, the alarm device often used is a speaker that can produce an alarm tone or deliver a specific voice message. A speaker device is particularly useful in a high-rise building; although it is important to get an initial message to all rooms, there could be a need to send different messages to different parts of the building as part of a zoned or staged evacuation plan. See the commentary following A.13.7.1.9.6.2 for additional information on staged evacuation.

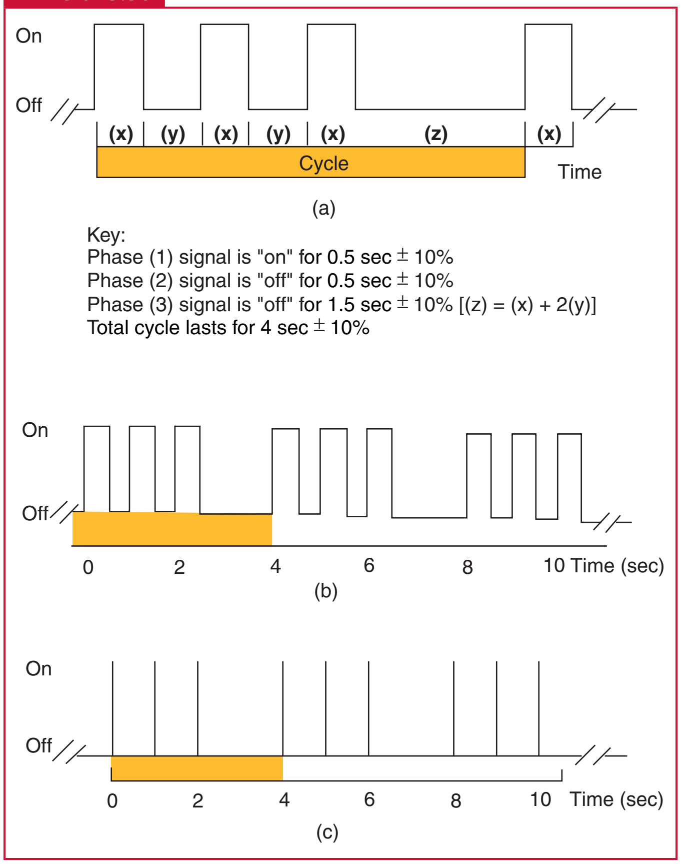
13.7.1.9.8 Audible alarm notification appliances shall produce signals that are distinctive from audible signals used for other purposes in a given building. [***101:***9.6.3.8]

Where an evacuation alarm signal is required by this *Code* or NFPA *101*, the standard fire alarm evacuation signal described in *NFPA 72* should be used. The standard fire alarm evacuation signal is a three-pulse temporal pattern using any appropriate sound. This signal is illustrated in Exhibit 13.38. The pattern consists of an "on" phase (1) lasting 0.5 second followed by an "off" phase (2) lasting 0.5 second, for three successive "on" periods; these are followed by an "off" phase (3) lasting 1.5 seconds. The signal should be repeated for a period appropriate for the purposes of evacuation of the building, but for not less than 180 seconds. A single-stroke bell or chime sounded at "on" intervals lasting 1 second, with a 2-second "off" interval after each third "on" stroke, is permitted.

13.7.1.9.9 Automatically transmitted or live voice evacuation or relocation instructions shall be permitted to be used to notify occupants and shall comply with either 13.7.1.9.9.1 or 13.7.1.9.9.2. [***101:***9.6.3.9]

13.7.1.9.9.1 Automatically transmitted or live voice evacuation or relocation instructions shall be in accordance with *NFPA 72*. [***101:***9.6.3.9.1]

Exhibit 13.38



Standard fire alarm evacuation signal.

13.7.1.9.9.2 Where permitted by Chapters 11 through 43 of NFPA *101*, automatically transmitted or live voice announcements shall be permitted to be made via a voice communication or public address system that complies with all of the following:

(1) Occupant notification, either live or recorded, shall be initiated at a constantly attended receiving station by personnel trained to respond to an emergency.
(2) An approved secondary power supply shall be provided for other than existing, previously approved systems.
(3) The system shall be audible above the expected ambient noise level.
(4) Emergency announcements shall take precedence over any other use.

[***101:***9.6.3.9.2]

13.7.1.9.10 Unless otherwise permitted by another section of this *Code*, audible and visible fire alarm notification appliances shall comply with either 13.7.1.9.10.1 or 13.7.1.9.10.2. [***101:***9.6.3.10]

13.7.1.9.10.1 Audible and visible fire alarm notification appliances shall be used only for fire alarm system or other emergency purposes. [***101:***9.6.3.10.1]

13.7.1.9.10.2 Emergency voice/alarm communication systems shall be permitted to be used for other purposes in accordance with *NFPA 72*. [***101:***9.6.3.10.2]

The provision of 13.7.1.9.10.2 permits a voice communication system to be used for some other purpose in accordance with *NFPA 72*. The system designer or building operator and the AHJ should determine how susceptible the system is to deliberate tampering. For example, in a business occupancy where a combination emergency voice communication and daily background music system is installed with a speaker located in the ceiling directly over an employee's desk, it should be predicted that the constant background music might irritate the employee to the point that the employee might muffle or otherwise disable the speaker. Therefore, the requirement that the fire alarm system take precedence over all other signals becomes futile; a disabled speaker cannot deliver the required emergency message.

13.7.1.10 Emergency Forces Notification.

13.7.1.10.1 Where required by another section of this *Code*, emergency forces notification shall be provided to alert the municipal fire department and fire brigade (if provided) of fire or other emergency. [***101:***9.6.4.1]

Δ **13.7.1.10.2** Where emergency forces notification is required by another section of this *Code*, the fire alarm system shall be arranged to transmit the alarm automatically via any of the following means acceptable to the AHJ and shall be in accordance with *NFPA 72*:

(1) Auxiliary fire alarm system
(2) Central station fire alarm system
(3) Proprietary supervising station fire alarm system
(4) Remote supervising station fire alarm system

[***101:***9.6.4.2]

The following paragraphs help differentiate among the four alarm transmission methods for fire department notification specified in 13.7.1.10.2.

1. *Auxiliary fire alarm system.* An auxiliary fire alarm system is a system connected to a municipal fire alarm system for transmitting a fire alarm to the public fire service communications center. Fire alarms from an auxiliary alarm system are received at the public fire service communications center on the same equipment and by the same methods as alarms transmitted manually from municipal fire alarm boxes located on streets.

2. *Central station fire alarm system.* A central station fire alarm system is a system or group of systems in which the operations of circuits and devices are signaled automatically to, recorded in, maintained by, and supervised from a listed central station staffed by competent and experienced servers and operators. Upon receipt of a signal, the staff takes such action as is required. Such service is controlled and operated by a person or firm whose business is the furnishing, maintaining, and monitoring of supervised fire alarm systems.

3. *Proprietary supervising station fire alarm system.* A proprietary supervising station fire alarm system is an installation of fire alarm systems that serves contiguous or noncontiguous properties, under one ownership, from a proprietary supervising station located at the protected property where trained, competent personnel are in constant attendance. This system includes the proprietary supervising station; power supplies; signal initiating devices; initiating device circuits (IDCs); signal notification appliances; equipment for the automatic, permanent, visual recording of signals; and equipment for initiating the operation of emergency building control services.

4. *Remote supervising station fire alarm system.* A remote supervising station fire alarm system is a system installed to transmit alarm, supervisory, and trouble signals from one or more protected premises to a remote supervising station location at which appropriate action is taken.

Δ **13.7.1.10.3** For existing installations where none of the means of notification specified in 13.7.1.10.2(1) through 13.7.1.10.2(4) are available, an approved plan for notification of the municipal fire department shall be permitted. [***101:***9.6.4.3]

The extensive availability of reliable communications systems has limited the necessity for the provision of 13.7.1.10.3 (formerly permitted for all occupancies) to existing installations only.

13.7.1.10.4 For other than existing installations, where fire alarm systems are required to provide emergency forces notification, supervisory signals and trouble signals shall sound and be visibly displayed either at an approved, remotely located receiving facility or at a location within the protected building that is constantly attended by qualified personnel. [***101:***9.6.4.4]

13.7.1.11 Fire Safety Functions.

13.7.1.11.1 Emergency control functions shall be installed in accordance with the requirements of *NFPA 72*. [***101:***9.6.5.1]

13.7.1.11.2 Where required by another section of this *Code*, the following functions shall be actuated:

(1) Release of hold-open devices for doors or other opening protectives

Doors are permitted by 14.5.4.2 to be automatic-closing if (among other requirements) the detection of smoke automatically releases the device holding the door open, thus allowing the door to become self-closing. The provisions of 14.5.4.2 do not require the building alarm system to release the doors. The health care occupancy chapters of NFPA *101* are more stringent on the subject and require that the automatic closing of doors must also occur upon initiation of the building's required fire alarm system (see 18.2.2.2.8 and 19.2.2.2.8 of NFPA *101*). This is an example of an occupancy chapter of NFPA *101* mandating the application of 13.7.1.11.2(1) as a requirement that is needed in addition to the provisions of 14.5.4.2.

(2) Stairwell or elevator shaft pressurization
(3) Smoke management or smoke control systems

Manual fire alarm boxes generally should not be used to activate smoke control systems, other than stair tower pressurization systems, due to the likelihood of a person signaling an alarm from a location outside the smoke zone of fire origin. Such alarm initiation could put the smoke management system in an undesirable mode of operation and cause it to spread smoke from one zone to another, rather than restrict it. The installation of smoke control systems is addressed by NFPA 92, *Standard for Smoke Control Systems*.

(4) Unlocking of doors

For an example of a *Code* requirement for the activation of the alarm system to unlock a door, see the provisions for delayed-egress electrical locking systems addressed by 14.5.3.1.

(5) Elevator recall and shutdown

ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, and ASME A17.3, *Safety Code for Existing Elevators and Escalators* (which are referenced mandatorily by Section 11.3), prohibit the recall of elevators by detectors, other than those installed in elevator lobbies, hoistways, and associated elevator machine rooms. Recall by other detectors can lead to numerous nuisance recalls under conditions where it would be safe to operate elevators. To avoid taking elevators out of service every time any building smoke detector activates, the recall feature is sometimes deliberately disabled. ASME A17.1/CSA B44 and ASME A17.3 impose the recall restriction to ensure that the elevator recall feature remains operational. The elevator lobby, hoistway, and machine room detectors are permitted to be part of the building fire alarm system, provided that only the activation of those detectors initiates elevator recall.

(6) HVAC shutdown
[***101:***9.6.5.2]

13.7.1.12 Location of Controls. Operator controls, alarm indicators, and manual communications capability shall be installed at a convenient location acceptable to the AHJ. [***101:***9.6.6]

At times it is not practical, either physically or from a security standpoint, to locate fire alarm system controls adjacent to an entrance. For example, controls for proprietary fire alarm systems designed in accordance with *NFPA 72,* for reasons of security, often need to be located away from public areas. Thus, the *Code* does not require that controls be located adjacent to an entrance. However, because the controls are intended to be used by the fire department, they need to be located as approved by the AHJ. Where the fire department does not serve as the AHJ, it should be consulted to determine an acceptable location.

13.7.1.13 Annunciation and Annunciation Zoning.

The provisions of 13.7.1.13 establish requirements for fire alarm annunciation, which are then referenced by other sections of the *Code* as part of the overall life safety package needed for specific occupancies. Alarm annunciation allows trained individuals — such as building engineers, security and safety officers, and responding fire service personnel — to read the indicator lamps or alphanumeric displays of an annunciator panel to identify circuits, associated building locations, and conditions that warrant attention or investigation.

13.7.1.13.1 Where alarm annunciation is required by another section of this *Code*, it shall comply with 13.7.1.13.2 through 13.7.1.13.13. [***101:***9.6.7.1]

13.7.1.13.2 Alarm Annunciation. Where required by other governing laws, codes, or standards, the location of an operated initiating device shall be annunciated by visible means. [**72:**10.17.1.1]

13.7.1.13.2.1 Visible annunciation of the location of an operated initiating device shall be by an indicator lamp, alphanumeric display, printout, or other approved means. [**72:**10.17.1.1.1]

13.7.1.13.2.2 The visible annunciation of the location of operated initiating devices shall not be canceled by the means used to deactivate alarm notification appliances. [**72:**10.17.1.1.2]

13.7.1.13.3 Supervisory and Trouble Annunciation. Where required by other governing laws, codes, or standards, supervisory and/or trouble conditions shall be annunciated by visible means. [**72:**10.17.2.1]

13.7.1.13.3.1 Visible annunciation shall be by an indicator lamp, an alphanumeric display, a printout, or other means. [**72:**10.17.2.1.1]

13.7.1.13.3.2 The visible annunciation of supervisory and/or trouble conditions shall not be canceled by the means used to deactivate supervisory or trouble notification appliances. [**72:**10.17.2.1.2]

13.7.1.13.4* Annunciator Access and Location.

A.13.7.1.13.4 The primary purpose of annunciation is to enable responding personnel to quickly and accurately determine the status of equipment or emergency control functions that might affect the safety of occupants. [**72:**A.10.17.3]

The AHJ determines the type and location of any required annunciation. Common locations for annunciation are lobbies, guards' desks, and fire command centers. *NFPA 72* does not prescribe requirements for the location of the fire alarm control unit. However, if annunciation is required and the fire alarm control unit is being used as the means for annunciation, it must be located in accordance with 13.7.1.13.4.1 and 13.7.1.13.4.2.

13.7.1.13.4.1 All required annunciation means shall be readily accessible to responding personnel. [**72:**10.17.3.1]

13.7.1.13.4.2 All required annunciation means shall be located as required by the AHJ to facilitate an efficient response to the situation. [**72:**10.17.3.2]

13.7.1.13.5 Alarm Annunciation Display. Visible annunciators shall be capable of displaying all zones in alarm. [**72:**10.17.4]

13.7.1.13.5.1 If all zones in alarm are not displayed simultaneously, the zone of origin shall be displayed. [**72:**10.17.4.1]

13.7.1.13.5.2 If all zones in alarm are not displayed simultaneously, there shall be an indication that other zones are in alarm. [**72:**10.17.4.2]

The requirement in 13.7.1.13.5 ensures that where systems require scrolling to view all the zones in alarm, the system will display the zone of origin and provide an indication that more alarms can be viewed than are currently displayed. The intent is to aid emergency responders in quickly obtaining complete information from the system. The zone of origin must always be displayed. Although the arrangement of the display is not prescribed, *Code* users should be aware of the standard emergency service interface requirements of Section 18.11 of *NFPA* 72 and the related guidance in A.18.11.

13.7.1.13.6* Annunciation Zoning.

A.13.7.1.13.6 Fire alarm system annunciation should, as a minimum, be sufficiently specific to identify a fire alarm signal in accordance with the following:

(1) If a floor exceeds 22,500 ft^2 (2090 m^2) in area, the floor should be subdivided into detection zones of 22,500 ft^2 (2090 m^2) or less, consistent with the existing smoke and fire barriers on the floor.
(2) If a floor exceeds 22,500 ft^2 (2090 m^2) in area and is undivided by smoke or fire barriers, detection zoning should be determined on a case-by-case basis in consultation with the AHJ.
(3) Waterflow switches on sprinkler systems that serve multiple floors, areas exceeding 22,500 ft^2 (2090 m^2), or areas inconsistent with the established detection system zoning should be annunciated individually.
(4) In-duct smoke detectors on air-handling systems that serve multiple floors, areas exceeding 22,500 ft^2 (2090 m^2), or areas inconsistent with the established detection system zoning should be annunciated individually.
(5) If a floor area exceeds 22,500 ft^2 (2090 m^2), additional zoning should be provided. The length of any zone should not exceed 300 ft (91 m) in any direction. If the building is provided with

automatic sprinklers throughout, the area of the alarm zone should be permitted to coincide with the allowable area of the sprinkler zone.
[**72:**A.10.17.5]

The provisions of 13.7.1.13.6 specify the minimum zoning required. Fire alarm system notification zones, which are addressed by these requirements, should correlate with building smoke and fire zones. This correlation is especially important if an in-building fire emergency voice/alarm communications system is used to selectively or partially evacuate occupants or to relocate occupants to areas of refuge during a fire. Definitions for the terms *zone*, *notification zone,* and *signaling zone* can be found in Chapter 3 of *NFPA 72*. In addition, refer to the requirements in 23.8.6.3 of *NFPA 72* for notification zones and the requirements in 24.4.9 of *NFPA 72* for signaling zones.

Additional zoning requirements may exist in the governing building codes, NFPA *101*, *NFPA 5000*®, and local ordinances. These higher-level documents often require each floor of a building to be zoned separately for smoke detectors, waterflow switches, manual fire alarm boxes, and other initiating devices. The zoning recommendations found in A.13.7.1.13.6 parallel the annunciation zoning requirements found in NFPA *101* and the model building codes. *NFPA 72*, as a minimum installation standard, does not require that an addressable system control unit be used. Conventional (zone or nonaddressable) alarm control units are often adequate to meet the annunciation zoning requirements. Local codes or ordinances might be more specific.

13.7.1.13.6.1 For the purpose of alarm annunciation, each floor of the building shall be considered as a separate zone. [**72:**10.19.5.1]

13.7.1.13.6.2 For the purposes of alarm annunciation, if a floor of the building is subdivided into multiple zones by fire or smoke barriers and the fire plan for the protected premises allows relocation of occupants from the zone of origin to another zone on the same floor, each zone on the floor shall be annunciated separately. [**72:**10.17.5.2]

13.7.1.13.6.3 Where the system serves more than one building, each building shall be annunciated separately. [**72:**10.17.5.3]

13.7.1.13.7 Alarm annunciation at the control center shall be by means of audible and visible indicators. [***101:***9.6.7.2]

Alarm annunciation at the control center, as specified in 13.7.1.13.7, must be by means of audible as well as visible indicators to capture the attention of the trained attendant, who might have numerous job functions within or near the control center that might distract attention from the annunciator panel.

Where a control center is not required or otherwise provided, the annunciator panel should be located in or near a public space, such as an entrance lobby, so that trouble and supervisory signals will get the attention of a passerby, who can then notify the building's maintenance staff.

13.7.1.13.8 For the purposes of alarm annunciation, each floor of the building, other than floors of existing buildings, shall be considered as not less than one zone, unless otherwise permitted by 13.7.1.13.9.4, 13.7.1.13.9.5, 13.7.1.13.9.6 or as another section of this *Code*. [***101:***9.6.7.3]

13.7.1.13.9 Where a floor area exceeds 22,500 ft^2 (2090 m^2), additional fire alarm zoning shall be provided, and the length of any single fire alarm zone shall not exceed 300 ft (91 m) in any direction, except as provided in 13.7.1.13.9.1 through 13.7.1.13.9.6 or otherwise modified by another section of this *Code*. [***101:***9.6.7.4]

13.7.1.13.9.1 Where permitted by another section of this *Code*, fire alarm zones shall be permitted to exceed 22,500 ft^2 (2090 m^2), and the length of a zone shall be permitted to exceed 300 ft (91 m) in any direction. [***101:***9.6.7.4.1]

13.7.1.13.9.2 Where the building is protected by an automatic sprinkler system in accordance with NFPA 13, the area of the fire alarm zone shall be permitted to coincide with the allowable area of the sprinkler system. [***101:***9.6.7.4.2]

13.7.1.13.9.3 Where the building is protected by a water mist system in accordance with 9.8.1 and Table 9.8.1 of NFPA *101*, the area of the fire alarm zone shall be permitted to coincide with the allowable area of the water mist system. [***101:***9.6.7.4.3]

13.7.1.13.9.4 Unless otherwise prohibited by another section of this *Code*, where a building not exceeding four stories in height is protected by an automatic water mist system in accordance with 9.7.3 of NFPA *101*, the water mist system shall be permitted to be annunciated on the fire alarm system as a single zone. [***101:***9.6.7.4.4]

13.7.1.13.9.5 Unless otherwise prohibited by another section of this *Code*, where a building not exceeding four stories in height is protected by an automatic sprinkler system in accordance with NFPA 13, the sprinkler system shall be permitted to be annunciated on the fire alarm system as a single zone. [***101:***9.6.7.4.5]

The provision of 13.7.1.13.9.5 permits the waterflow from a sprinkler system that meets the requirements of NFPA 13 to be annunciated as a single zone in buildings up to four stories in height, unless the applicable occupancy chapters prohibit such arrangement. Lacking this provision, sprinkler systems would have to be arranged so that every floor would be provided with a waterflow switch to permit each floor to be annunciated as separate zones. Such a requirement would limit the sprinkler system design flexibility and would prohibit the use of the so-called birdcage design in which multiple vertical risers act as loops for hydraulic efficiency. The only occupancy chapter of NFPA *101* that prohibits the use of this provision is Chapter 18, New Health Care Occupancies).

13.7.1.13.9.6 Where the building is protected by an automatic sprinkler system in accordance with NFPA 13D or NFPA 13R, the sprinkler system shall be permitted to be annunciated on the fire alarm system as a single zone. [***101:***9.6.7.4.6]

Paragraphs 13.7.1.13.9.1 through 13.7.1.13.9.6 provide a choice of zone locations and zone sizes for meaningful annunciation. In a new, multiple-story building required to have alarm annunciation by another section of the *Code*, 13.7.1.13.8 would not permit two or more floors to be considered as a single zone, unless the building were a residential occupancy sprinklered in accordance with NFPA 13R, NFPA 13D, or as otherwise permitted by 13.7.1.13.9.5, in which case the sprinkler system would be permitted to be annunciated as a single zone. In buildings other than those sprinklered in accordance with NFPA 13 (up to four stories, other than new health care), NFPA 13R, or NFPA 13D, floors must be annunciated separately; otherwise an alarm condition would be annunciated as originating in a zone that includes multiple floors and, thus, would not identify the specific location of the fire. Such a situation might delay the investigation and associated emergency response effort. Existing alarm annunciation systems are exempted from the requirement of 13.7.1.13.8, so as not to unfairly render existing *Code*-complying installations abruptly noncompliant, thereby avoiding the need for major alterations or a complete replacement of the alarm system.

Residential sprinkler systems in accordance with NFPA 13R and NFPA 13D commonly utilize a birdcage piping configuration, in which the sprinkler branch lines are run vertically through the building, rather than horizontally, providing an economical design alternative. (The resulting piping network resembles a birdcage, thus the name.) With such a configuration, however, it is not practical to provide waterflow devices for every floor, since each branch line typically serves multiple floors. Therefore, a single waterflow device is provided on the supply piping ahead of the branch lines, resulting in the sprinkler system being annunciated as a single zone. Although such an arrangement might increase the time required for emergency responders to locate the fire, it is considered a reasonable alternative for residential occupancies not exceeding four stories in height utilizing sprinkler systems compliant with NFPA 13R or NFPA 13D.

It is further specified in 13.7.1.13.9 that no one zone, for alarm annunciation purposes, even if located entirely on one floor of the building, is permitted to be so large that it delays identification of the location from which the alarm was initiated. The permitted zone size, 22,500 ft^2 (2090 m^2), is intended to coordinate with the maximum permitted smoke compartment size in health care and detention and correctional occupancies. The maximum zone area and zone dimensional criteria are modified by 13.7.1.13.9.2 for fully sprinklered buildings, allowing the alarm system zoning to coincide with the area of the sprinkler system zone. Depending on the sprinkler system's design, this might result in a zone as large as 52,000 ft^2 (4831 m^2). This requirement helps to achieve consistency in reporting alarms from signaling system devices and from sprinkler system waterflow to the alarm annunciator. Although a sprinkler system might be designed and installed by parties other than those who design and install fire alarm systems, the coordination of these two systems is needed during the design phase to ensure that they complement each other.

13.7.1.13.10 A system trouble signal shall be annunciated by means of audible and visible indicators. in accordance with *NFPA 72*. [***101:***9.6.7.5]

13.7.1.13.11 A system supervisory signal shall be annunciated by means of audible and visible indicators in accordance with *NFPA 72*. [***101:***9.6.7.6]

Alarm system trouble signals and supervisory signals must be annunciated by both audible and visible indicators in accordance with 13.7.1.13.10 and 13.7.1.13.11 to help ensure that personnel will respond to the indication. Trouble signals indicate such conditions as a circuit break or ground occurring in the fire alarm system wiring. Supervisory signals indicate conditions that would adversely affect the operation of a fire suppression system, such as a closed control valve on an automatic sprinkler system. Supervisory signals can also be associated with the supervision of other extinguishing systems and equipment.

13.7.1.13.12 Where the system serves more than one building, each building shall be annunciated separately. [***101:***9.6.7.7]

13.7.1.13.13 Where permitted by another section of this *Code*, the alarm zone shall be permitted to coincide with the permitted area for smoke compartments. [***101:***9.6.7.8]

Δ **13.7.1.14 Carbon Monoxide (CO) Detection and Warning Equipment.** Where required by another section of this *Code*, carbon monoxide (CO) detection and warning equipment shall be provided in accordance with NFPA 720. [***101:***9.12]

Paragraph 13.7.1.14 provides a reference to NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment,* where such equipment is mandated by another section of the *Code*. It is noted that not all occupancies are required to be provided with CO detection and warning equipment. Such equipment is not currently required by the *Code* to be installed in any existing occupancy; its use is generally limited to new occupancies in which occupants might be asleep or otherwise have decreased capability of self-preservation and where vehicles, combustion equipment, or appliances are present. The occupancies requiring CO detection and warning equipment are as follows:

1. New assembly occupancies (13.7.2.1.4)
2. New educational occupancies (13.7.2.3.4)
3. New day-care homes (13.7.2.5.6.4)
4. New and existing health care occupancies containing fireplaces (18.5.2.3 and 19.5.2.3 of NFPA *101*)
5. New one- and two-family dwellings (13.7.2.13.2)
6. New lodging or rooming houses (13.7.2.14.6)
7. New hotels and dormitories (13.7.2.15.6)
8. New apartment buildings (13.7.2.17.6)
9. New residential board and care occupancies (32.2.3.4.4 and 32.3.3.4.9 of NFPA *101*)

Exhibit 13.39 illustrates an example of a CO alarm. It is important to note that all CO detectors and alarms have a limited service life, typically about 5 to 10 years. CO detection equipment must be replaced at the end of its service life; the recommended replacement date is required by NFPA 720 to be marked on the device.

Exhibit 13.39

Carbon monoxide alarm. (© Danny Hooks, Dreamstime.com)

The requirements for CO detection and warning equipment are not based on safety to life from fire considerations. Rather, they are intended to mitigate the risk to building occupants posed by exposure to CO gas, which is a natural product of incomplete combustion of hydrocarbon fuels. Where combustion gases from equipment in a building (such as a fuel-fired furnace) are not properly vented, or where CO gas infiltrates a building from a space like an attached garage, occupants are at risk of CO poisoning. CO gas is sometimes referred to as the silent killer because it is colorless and odorless. Without CO detection and warning equipment, its presence is virtually impossible to detect.

According to the Centers for Disease Control and Prevention (CDC), approximately 15,200 people were treated annually during 2001–2003 in emergency departments for unintentional, non-fire–related CO exposure. During 2001–2002, an estimated 480 people died annually as a result of such exposure. In 2005, municipal fire departments responded to an estimated 61,100 non-fire CO incidents where CO was present. The cold weather months of December and January are the peak months for non-fire CO incidents, and 89 percent of non-fire CO incidents took place in the home.

NFPA 720 is formatted much like *NFPA 72* and contains requirements for CO detection systems (analogous to fire alarm systems) as well as single- and multiple-station CO alarms (analogous to smoke alarms). NFPA 720 was first published in 1998 and was titled *Recommended Practice for the Installation of Household Carbon Monoxide (CO) Warning Equipment.* In 2005, it was revised as a standard; however, its scope was still limited to dwelling units. For the 2009 edition, the scope of NFPA 720 was significantly expanded to include occupancies other than residential dwelling units. The expanded requirements were based on the Fire Protection Research Foundation report "Development of a Technical Basis for Carbon Monoxide Detector Siting." Where NFPA 720 is applied via adoption of this *Code*, and where the requirements of this *Code* differ from the requirements of NFPA 720, the requirements of this *Code* should apply. Where both this *Code* and NFPA 720 are separately adopted and enforced, the more stringent requirements should be followed so as to meet the minimum requirements of both documents.

N **13.7.1.15* Risk Analysis for Mass Notification Systems.**

N **A.13.7.1.15** This section does not require mass notification systems, it only provides direction for the risk analysis. Where the risk analysis and resulting action plan identifies a need for a mass notification system, *NFPA 72* should be used for design and installation requirements. [***101:***A.9.14]

Paragraphs 13.7.1.15 through 13.7.1.15.4, which are new to the 2018 edition of the *Code*, provide criteria for completing a risk analysis to determine whether a building or a collection of buildings, such as a university campus, requires a mass notification system (MNS) to warn individuals of an emergency, including, but not limited to, weather emergencies (e.g., floods and tornadoes), hazardous materials releases (e.g., an accident involving a tank truck containing a hazardous chemical), and acts of violence (e.g., an active-shooter or terrorist attack).

An in-building MNSs is a system used to provide information and instructions to people in a building(s) or other space using intelligible voice communications and including visible signals, text, graphics, tactile, or other communication methods, as defined in *NFPA 72*. An in-building MNS is similar in concept to a fire alarm system that includes an in-building fire emergency voice/alarm communications system. The only purpose of an in-building fire emergency voice/alarm communications system is for fire emergencies; the in-building MNS has a much broader set of potential applications and is likely to be subject to a much more complex set of potential design conditions and operation scenarios, which could also include fire emergencies.

A wide-area MNS is generally installed to provide real-time information to outdoor areas and could have the capability to communicate with other notification systems provided for a campus, military base, municipality, or similar single area or multiple contiguous areas, as defined in *NFPA 72*. A wide-area MNS is a one-way emergency communications system that is intended to communicate to outdoor areas such as those on a college or military campus. The primary means of communication is via high power speaker arrays.

The distributed-recipient MNS, or DRMNS, is a system meant to communicate directly to targeted individuals and groups that might not be in a contiguous area, as defined in *NFPA 72*. DRMNSs are normally one-way emergency communications systems that are intended to communicate with a wide range of targeted individuals and groups. Methods of communication include a variety of means such as reverse 911, SMS text messaging, and email.

N **13.7.1.15.1 Where Required.**

N **13.7.1.15.1.1** Where required by another section of this *Code*, a risk analysis for mass notification systems shall be provided in accordance with the requirements of Chapter 24 of *NFPA 72* and the provisions of 13.7.1.15.2 through 13.7.1.15.4. [***101:***9.14.1.1]

N **13.7.1.15.1.2** Where a mass notification system is required by the risk analysis in 13.7.1.15.1.1, the system shall be in accordance with the requirements of Chapter 24 of *NFPA 72*. [***101:***9.14.1.2]

A risk analysis to determine the need for an MNS is required where specified by the applicable occupancies. Occupancies and special structures that require an MNS risk analysis include the following:

- New high-rise buildings with a total occupant load of 5000 or more persons or where the floor of an occupiable story is greater than 420 ft (128 m) above the lowest level of fire department vehicle access (11.8.4.3 of NFPA *101*)
- New assembly occupancies with an occupant load of 500 or more (13.7.2.1.5)
- New educational occupancies (13.7.2.3.5)
- New grade K–12, college, and university dormitories with an occupant load of greater than 100 (13.7.2.15.7)
- New mall structures (36.4.4.7.5 of NFPA *101*)
- New business occupancies requiring a fire alarm system (see 13.7.2.25.5.1) and those containing a classroom where the building is owned, rented, leased, or operated by a college or university (13.7.2.25.5.2)
- Neither *NFPA 72* nor this *Code* requires the installation of an MNS. The decision to install an MNS is typically owner-driven based on the results of the risk analysis required by 13.7.1.15 and the occupancy chapters. If the owner determines an MNS is needed, it must meet the requirements of *NFPA 72*.

N **13.7.1.15.2 Purpose.**

N **13.7.1.15.2.1** The purpose of the mass notification system shall be to communicate information about emergencies including, but not limited to, fire, human-caused events (accidental and intentional), other dangerous situations, accidents, and natural disasters. [***101:***9.14.2.1]

N **13.7.1.15.2.2** The purpose of the emergency action plan for the mass notification system shall be to identify the mass notification system design and performance requirements in accordance with the results of the risk analysis. [***101:***9.14.2.2]

N **13.7.1.15.3 Documentation.**

N **13.7.1.15.3.1** The emergency action plan, risk assessment report, and accompanying documentation shall be submitted to the authority having jurisdiction by the registered design professional (RDP). The format and content of the documentation shall be acceptable to the authority having jurisdiction. [***101:***9.14.3.1]

N **13.7.1.15.3.2*** Where required by the authority having jurisdiction, an independent review of the emergency action plan, risk assessment, and the accompanying documentation by one or more individuals possessing expertise in risk characterization for accidental and intentional hazards shall be performed. [***101:***9.14.3.2]

N **A.13.7.1.15.3.2** These peer reviews should focus on the assumptions and methods of analysis used and on the findings. Peer reviewers should submit written assessment reports to the authority having jurisdiction. [***101:***A.9.14.3.2]

The independent, third-party review described in 13.7.1.15.3.2, if required by the AHJ, is performed at the owner's expense. See 1.15 for additional details on technical assistance.

N **13.7.1.15.4 Emergency Action Plan.** The completed emergency action plan in accordance with Section 4.8 of NFPA *101* shall be used for the design of the mass notification/emergency communications system. [***101:***9.14.4]

13.7.2 Where Required and Occupancy Requirements.

13.7.2.1 New Assembly Occupancies.

13.7.2.1.1 General.

13.7.2.1.1.1 New assembly occupancies with occupant loads of more than 300 and all theaters with more than one audience-viewing room shall be provided with an approved fire alarm system in accordance with Section 13.7 and 13.7.2.1, unless otherwise permitted by 13.7.2.1.1.2. [***101:***12.3.4.1.1]

13.7.2.1.1.2 New assembly occupancies that are a part of a multiple occupancy protected as a mixed occupancy *(see 6.1.14)* shall be permitted to be served by a common fire alarm system, provided that the individual requirements of each occupancy are met. [***101:***12.3.4.1.2]

13.7.2.1.2 Initiation.

13.7.2.1.2.1 Initiation of the required fire alarm system shall be by both of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1), unless otherwise permitted by one of the following:
   (a) The requirement of 13.7.2.1.2.1(1) shall not apply where initiation is by means of an approved automatic fire detection system in accordance with 13.7.1.7.1(2) that provides fire detection throughout the building.
   (b) The requirement of 13.7.2.1.2.1(1) shall not apply where initiation is by means of an approved automatic sprinkler system in accordance with 13.7.1.7.1(3) that provides fire detection and protection throughout the building.

(2) Where automatic sprinklers are provided, initiation of the fire alarm system by sprinkler system waterflow, even where manual fire alarm boxes are provided in accordance with 13.7.2.1.2.1(1)

[***101:***12.3.4.2.1]

13.7.2.1.2.2 The initiating device shall be capable of transmitting an alarm to a receiving station, located within the building, that is constantly attended when the assembly occupancy is occupied. [***101:***12.3.4.2.2]

13.7.2.1.2.3* In new assembly occupancies with occupant loads of more than 300, automatic detection shall be provided in all hazardous areas that are not normally occupied, unless such areas are protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***12.3.4.2.3]

A.13.7.2.1.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. When the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone. The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent. [***101:***A.12.3.4.2.3]

13.7.2.1.3 Notification. The required fire alarm system shall activate an audible and visible alarm in a constantly attended receiving station within the building when occupied for purposes of initiating emergency action. [***101:***12.3.4.3]

13.7.2.1.3.1 Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***12.3.4.3.1]

13.7.2.1.3.2 Reserved.

13.7.2.1.3.3 Occupant notification shall be by means of voice announcements in accordance with 13.7.1.9.9, initiated by the person in the constantly attended receiving station. [***101:***12.3.4.3.3]

13.7.2.1.3.4 Occupant notification shall be by means of visible signals in accordance with 13.7.1.9.5, initiated by the person in the constantly attended receiving station, unless otherwise permitted by 13.7.2.1.3.5. [***101:***12.3.4.3.4]

13.7.2.1.3.5* Visible signals shall not be required in the assembly seating area, or the floor area used for the contest, performance, or entertainment, where the occupant load exceeds 1000 and an approved, alternative visible means of occupant notification is provided. *(See 13.7.1.9.5.7.)* [***101:***12.3.4.3.5]

A.13.7.2.1.3.5 Examples of devices that might be used to provide alternative visible means include scoreboards, message boards, and other electronic devices. [***101:***A.12.3.4.3.5]

13.7.2.1.3.6 The announcement shall be permitted to be made via a voice communication or public address system in accordance with 13.7.1.9.9.2. [***101:***12.3.4.3.6]

Δ **13.7.2.1.3.7** Where the AHJ determines that a constantly attended receiving station is impractical, both of the following shall be provided:

(1) Automatically transmitted evacuation or relocation instructions shall be provided in accordance with *NFPA 72*.
(2) The system shall be monitored by a supervising station in accordance with *NFPA 72*.

[***101:***12.3.4.3.7]

N **13.7.2.1.4 Carbon Monoxide Detection.**

N **13.7.2.1.4.1** New assembly occupancies shall be provided with carbon monoxide detection and warning equipment in accordance with 13.7.1.14 in the locations specified as follows:

(1) On the ceilings of rooms containing permanently installed fuel-burning appliances or fuel-burning fireplaces
(2) Centrally located within occupiable spaces served by the first supply air register from permanently installed fuel-burning HVAC systems
(3)* Centrally located within occupiable spaces adjacent to an attached garage

[***101:***12.3.4.4.1]

N **A.13.7.2.1.4.1(3)** The intent is to require CO detectors in occupiable spaces immediately adjacent, vertically or horizontally, to attached garages, regardless of the presence of openings between the garage and the adjacent occupiable spaces. Other occupiable spaces that are not adjacent to the attached garage do not require CO detectors. [***101:***A.12.3.4.4.1]

N **13.7.2.1.4.2** Carbon monoxide detectors as specified in 13.7.2.1.4.1 shall not be required in the following locations:

(1) Garages
(2) Occupiable spaces with attached garages that are open parking structures as defined in 3.3.192.26.3.
(3) Occupiable spaces with attached garages that are mechanically ventilated in accordance with the mechanical code

[***101:***12.3.4.4.2]

N **13.7.2.1.5 Risk Analysis for Mass Notification Systems.** A risk analysis in accordance with 13.7.1.15 shall be performed for new assembly occupancies with an occupant load of 500 or more to determine if a mass notification system is required. [***101:***12.3.4.5]

13.7.2.2 Existing Assembly Occupancies.

13.7.2.2.1 General.

13.7.2.2.1.1 Existing assembly occupancies with occupant loads of more than 300 and all theaters with more than one audience-viewing room shall be provided with an approved fire alarm system in accordance with Section 13.7 and 13.7.2.2, unless otherwise permitted by 13.7.2.2.1.2, 13.7.2.2.1.3, or 13.7.2.2.1.4. [***101:***13.3.4.1.1]

13.7.2.2.1.2 Existing assembly occupancies that are a part of a multiple occupancy protected as a mixed occupancy *(see 6.1.14)* shall be permitted to be served by a common fire alarm system, provided that the individual requirements of each occupancy are met. [***101:***13.3.4.1.2]

13.7.2.2.1.3 Voice communication or public address systems complying with 13.7.2.2.3.6 shall not be required to comply with Section 13.7. [***101:***13.3.4.1.3]

13.7.2.2.1.4 The requirement of 13.7.2.2.1.1 shall not apply to existing assembly occupancies where, in the judgment of the AHJ, adequate alternative provisions exist or are provided for the discovery of a fire and for alerting the occupants promptly. [***101:***13.3.4.1.4]

13.7.2.2.2 Initiation.

13.7.2.2.2.1 Initiation of the required fire alarm system shall be by both of the following means, and the system shall be provided with an emergency power source:

(1) Manual means in accordance with 13.7.1.7.1(1), unless otherwise permitted by one of the following:
    (a) The requirement of 13.7.2.2.2.1(1) shall not apply where initiation is by means of an approved automatic fire

detection system in accordance with 13.7.1.7.1(2) that provides fire detection throughout the building.

(b) The requirement of 13.7.2.2.2.1(1) shall not apply where initiation is by means of an approved automatic sprinkler system in accordance with 13.7.1.7.1(3) that provides fire detection and protection throughout the building.

(2) Where automatic sprinklers are provided, initiation of the fire alarm system by sprinkler system waterflow, even where manual fire alarm boxes are provided in accordance with 13.7.2.2.2.1(1)

[***101:***13.3.4.2.1]

13.7.2.2.2.2 The initiating device shall be capable of transmitting an alarm to a receiving station, located within the building, that is constantly attended when the assembly occupancy is occupied. [***101:***13.3.4.2.2]

13.7.2.2.2.3* In existing assembly occupancies with occupant loads of more than 300, automatic detection shall be provided in all hazardous areas that are not normally occupied, unless such areas are protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***13.3.4.2.3]

A.13.7.2.2.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. Where the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone. The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent. [***101:***A.13.3.4.2.3]

13.7.2.2.3 Notification. The required fire alarm system shall activate an audible alarm in a constantly attended receiving station within the building when occupied for purposes of initiating emergency action. [***101:***13.3.4.3]

13.7.2.2.3.1 Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***13.3.4.3.1]

13.7.2.2.3.2 A presignal system in accordance with 13.7.1.9.3 shall be permitted. [***101:***13.3.4.3.2]

13.7.2.2.3.3 Occupant notification shall be by means of voice announcements in accordance with 13.7.1.9.9 initiated by the person in the constantly attended receiving station. [***101:***13.3.4.3.3]

13.7.2.2.3.4 Reserved.

13.7.2.2.3.5 Reserved.

13.7.2.2.3.6 The announcement shall be permitted to be made via a voice communication or public address system in accordance with 13.7.1.9.9.2. [***101:***13.3.4.3.6]

Δ **13.7.2.2.3.7** Where the AHJ determines that a constantly attended receiving station is impractical, automatically transmitted evacuation or relocation instructions shall be provided in accordance with *NFPA 72*. [***101:***13.3.4.3.7]

Paragraphs 13.7.2.1.1.2 and 13.7.2.2.1.2 clarify that a common alarm system can be used within a building that houses occupancies in addition to an assembly occupancy, provided that the system meets the alarm requirements applicable to each of those occupancies. Those provisions permit an assembly occupancy in a school, hotel, hospital, mall structure, or another building to be served by the same fire alarm as the predominant occupancy, provided that it also meets the requirements applicable to alarm systems in an assembly occupancy.

Paragraph 13.7.2.2.1.3 permits an existing voice communication system or public address system installed to comply with 13.7.2.2.3.6 to be exempt from the installation requirements of *NFPA 72*, including electrical supervision and secondary power. In *Code* editions through 2006, alarm systems in new assembly occupancies were afforded the same exemption under the belief that the daily use of the voice communication system would provide adequate self-supervision and sufficient need to keep the system in good working order. Subsequent editions require new alarm systems in assembly occupancies to provide occupant notification by means of voice announcements in accordance with 13.7.1.9.9. The provisions of 13.7.1.9.9 permit automatically transmitted or live voice evacuation or relocation instructions, used to notify occupants, to comply with either *NFPA 72* or the criteria of 13.7.1.9.9.2, which require secondary power, among other features. Paragraph 13.7.1.9.9 is meant to be used for facilities such as large assembly venues in which the configuration (e.g., large-volume spaces), function, and human behavior (including elevated levels of occupant-generated noise) present challenges with respect to effective occupant notification by standard means in accordance with *NFPA 72*. Because the routine operation of large-venue assembly occupancies demands highly reliant, acoustically capable, and sufficiently audible public address systems, properly trained staff can be relied on to use these public address systems to effect occupant notification.

Paragraph 13.7.2.2.1.4, which applies only to existing assembly occupancies, specifically allows the AHJ to permit the continued use of existing alternative means for discovering fire and alerting occupants — even if such means do not meet the myriad requirements of *NFPA 72*.

13.7.2.3 New Educational Occupancies.

13.7.2.3.1 General.

13.7.2.3.1.1 New educational occupancies shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.3. [***101:***14.3.4.1.1]

13.7.2.3.1.2 The requirement of 13.7.2.3.1.1 shall not apply to buildings meeting all of the following criteria:

(1) Buildings having an area not exceeding 1000 ft^2 (93 m^2)
(2) Buildings containing a single classroom
(3) Buildings located not less than 30 ft (9.1 m) from another building

[***101:***14.3.4.1.2]

The limited-size, single-classroom building addressed by 13.7.2.3.1.2 and 13.7.2.4.1.2 does not need an alarm system, because the fire will be immediately obvious to the occupants. Emergency egress can begin upon first notice of fire. A fire within a building located at least 30 ft (9.1 m) from another building should not prove to be detrimental to the occupants of the other building if egress is delayed because no alarm system is provided.

13.7.2.3.2 Initiation.

Δ **13.7.2.3.2.1 General.** Initiation of the required fire alarm system, other than as permitted by 13.7.2.3.2.3, shall be by manual means in accordance with 13.7.1.7.1(1). [***101:***14.3.4.2.1]

13.7.2.3.2.2 Automatic Initiation. In buildings provided with automatic sprinkler protection, the operation of the sprinkler system shall automatically activate the fire alarm system in addition to the initiation means required in 13.7.2.3.2.1. [***101:***14.3.4.2.2]

13.7.2.3.2.3 Alternative Protection System. Manual fire alarm boxes shall be permitted to be eliminated in accordance with 13.7.2.3.2.3.1 or 13.7.2.3.2.3.2. [***101:***14.3.4.2.3]

13.7.2.3.2.3.1* Manual fire alarm boxes shall be permitted to be eliminated where all of the following conditions apply:

(1) Interior corridors are protected by smoke detectors in accordance with Section 13.7.
(2) Auditoriums, cafeterias, and gymnasiums are protected by heat-detection devices or other approved detection devices.
(3) Shops and laboratories involving dusts or vapors are protected by heat-detection devices or other approved detection devices.
(4) Provision is made at a central point to manually activate the evacuation signal or to evacuate only affected areas.

[***101:***14.3.4.2.3.1]

A.13.7.2.3.2.3.1 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal. [***101:***A.14.3.4.2.3.1]

13.7.2.3.2.3.2* Manual fire alarm boxes shall be permitted to be eliminated where both of the following conditions apply:

(1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.
(2) Provision is made at a central point to manually activate the evacuation signal or to evacuate only affected areas.

[***101:***14.3.4.2.3.2]

A.13.7.2.3.2.3.2 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal. [***101:***A.14.3.4.2.3.2]

Exhibit 13.40 shows a manual fire alarm box for initiation of the building fire alarm system. The cover is intended to help avoid accidental initiations due to unintended contact with the box. Where additional means of preventing unintended or nuisance alarms is needed, the provisions of 13.7.2.3.2.3 and 13.7.2.4.2.3 offer alternatives.

Exhibit 13.40

Manual fire alarm box with protective cover.

Paragraphs 13.7.2.3.2.3 and 13.7.2.4.2.3 provide alternatives to the manual fire alarm boxes required by 13.7.2.3.2.1 and 13.7.2.4.2.1. These alternatives are offered as a means to avoid the nuisance alarms initiated through unauthorized use of the building manual fire alarm boxes. By relying on the automatic initiation that is provided by the detection systems addressed in 13.7.2.3.2.3.1(1) and 13.7.2.4.23,1(1) through 13.7.2.3.2.3.1(3) and 13.7.2.4.2.3.1(3), equivalent protection is provided. By relying on the fire control that is provided by the automatic sprinkler system addressed in 13.7.2.3.2.3.2 and 13.7.2.4.2.3.2, equivalent protection is provided.

Paragraph 13.7.2.4.2.1(2) — which applies only to existing educational occupancies — recognizes an alternative to a dedicated fire alarm system. Where there is a two-way communication system between classrooms and a constantly attended location where a general alarm can be sounded, the requirement for an alarm system — and its requisite manual fire alarm boxes — is exempted. To use this exemption, the AHJ must designate those manual fire alarm boxes that are not required. For the purposes of this provision, a "constantly attended" location is a location that is attended while the school building is in use as a school. Compliance might involve providing personnel at this location during night classes, when the regular school office staff is not present. The exemption is not permitted for new construction due to reliability concerns.

13.7.2.3.3 Notification.

13.7.2.3.3.1 Occupant Notification.

13.7.2.3.3.1.1 Occupant notification shall be accomplished automatically in accordance with 13.7.1.9. [***101:***14.3.4.3.1.1]

13.7.2.3.3.1.2 The occupant notification required by 13.7.2.3.3.1.1 shall utilize an emergency voice/alarm communication system in accordance with 13.7.1.9 where the building has an occupant load of more than 100. [***101:***14.3.4.3.1.2]

13.7.2.3.3.1.3 Positive alarm sequence shall be permitted in accordance with 13.7.1.9.4. [***101:***14.3.4.3.1.3]

13.7.2.3.3.1.4 In accordance with 13.7.1.9.10.2, the emergency voice/alarm communication system shall be permitted to be used for other emergency signaling or for class changes. [***101:***14.3.4.3.1.4]

13.7.2.3.3.1.5 To prevent students from being returned to a building that is burning, the recall signal shall be separate and distinct from any other signals, and such signal shall be permitted to be given by use of distinctively colored flags or banners. [***101:***14.3.4.3.1.5]

13.7.2.3.3.1.6 If the recall signal required by 13.7.2.3.3.1.5 is electric, the push buttons or other controls shall be kept under lock, the key for which shall be in the possession of the principal or another designated person in order to prevent a recall at a time when there is an actual fire. [***101:***14.3.4.3.1.6]

13.7.2.3.3.1.7 Regardless of the method of recall signal, the means of giving the recall signal shall be kept under lock. [***101:***14.3.4.3.1.7]

13.7.2.3.3.2 Emergency Forces Notification. Emergency forces notification shall be accomplished in accordance with 13.7.1.10. [***101:***14.3.4.3.2]

13.7.2.3.4 Carbon Monoxide Alarms and Carbon Monoxide Detection Systems.

Δ **13.7.2.3.4.1** Carbon monoxide detectors in accordance with 13.7.1.14 shall be provided in new educational occupancies in the locations specified as follows:

(1) Carbon monoxide detectors shall be installed on the ceilings of rooms containing permanently installed fuel-burning appliances.
(2) Carbon monoxide detectors shall be installed centrally located within occupiable spaces served by the first supply air register from a permanently installed, fuel-burning HVAC system.
(3) Carbon monoxide detectors shall be installed centrally located within occupiable spaces adjacent to a communicating attached garage.
(4) Carbon monoxide detectors shall be installed centrally located within occupiable spaces adjacent to an attached garage with a separation wall constructed of gypsum wallboard.

[***101:***14.3.4.4.1]

13.7.2.3.4.2 Carbon monoxide alarms and carbon monoxide detectors as specified in 13.7.2.3.4.1 shall not be required in the following locations:

(1) Garages
(2) Occupiable spaces with communicating attached garages that are open parking structures as defined in 3.3.192.26.3
(3) Occupiable spaces with communicating attached garages that are mechanically ventilated in accordance with the applicable mechanical code
(4) Occupiable spaces that are separated from attached garages by walls constructed of gypsum wallboard where the garage is an open parking structure as defined in 3.3.192.26.3
(5) Occupiable spaces that are separated from attached garages by walls constructed of gypsum wallboard where the garage is mechanically ventilated in accordance with the mechanical code

[***101:***14.3.4.4.3]

N **13.7.2.3.5 Risk Analysis for Mass Notification Systems.** A risk analysis in accordance with 13.7.1.15 shall be performed to determine if a mass notification system is required. [***101:***14.3.4.5]

Paragraph 13.7.1.15 is new for the 2018 edition of the *Code*. By reference to this new paragraph, new educational occupancies require that a risk analysis be conducted in accordance with Chapter 24 of *NFPA 72* to determine if an MNS is necessary. See the commentary associated with 13.7.1.15 for more information.

13.7.2.4 Existing Educational Occupancies.

13.7.2.4.1 General.

13.7.2.4.1.1 Existing educational occupancies shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.4. [***101:***15.3.4.1.1]

13.7.2.4.1.2 The requirement of 13.7.2.4.1.1 shall not apply to buildings meeting all of the following criteria:

(1) Buildings having an area not exceeding 1000 ft^2 (93 m^2)
(2) Buildings containing a single classroom
(3) Buildings located not less than 30 ft (9.1 m) from another building

[***101:***15.3.4.1.2]

See the commentary following 13.7.2.3.1.2(3).

13.7.2.4.2 Initiation.

Δ **13.7.2.4.2.1 General.** Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7(1), unless otherwise permitted by one of the following:

(1) Manual fire alarm boxes shall not be required where permitted by 13.7.2.4.2.3.
(2) In buildings where all normally occupied spaces are provided with a two-way communication system between such spaces and a constantly attended receiving station from where a general evacuation alarm can be sounded, the manual fire alarm boxes shall not be required, except in locations specifically designated by the AHJ.

[***101:***15.3.4.2.1]

13.7.2.4.2.2 Automatic Initiation. In buildings provided with automatic sprinkler protection, the operation of the sprinkler system shall automatically activate the fire alarm system in addition to the initiation means required in 13.7.2.4.2.1. [***101:***15.3.4.2.2]

13.7.2.4.2.3 Alternative Protection System. Manual fire alarm boxes shall be permitted to be eliminated in accordance with 13.7.2.4.2.3.1 or 13.7.2.4.2.3.2. [***101:***15.3.4.2.3]

Δ **13.7.2.4.2.3.1*** Manual fire alarm boxes shall be permitted to be eliminated where all of the following conditions apply:

(1) Interior corridors are protected by smoke detectors using an alarm verification system as described in *NFPA 72*.
(2) Auditoriums, cafeterias, and gymnasiums are protected by heat-detection devices or other approved detection devices.
(3) Shops and laboratories involving dusts or vapors are protected by heat-detection devices or other approved detection devices.
(4) Provision is made at a central point to manually activate the evacuation signal or to evacuate only affected areas.

[***101:***15.3.4.2.3.1]

A.13.7.2.4.2.3.1 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal. [***101:***A.15.3.4.2.3.1]

13.7.2.4.2.3.2* Manual fire alarm boxes shall be permitted to be eliminated where both of the following conditions apply:

(1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.
(2) Provision is made at a central point to manually activate the evacuation signal or to evacuate only affected areas.

[***101:***15.3.4.2.3.2]

A.13.7.2.4.2.3.2 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal. [***101:***A.15.3.4.2.3.2]

13.7.2.4.3 Notification.

13.7.2.4.3.1 Occupant Notification.

13.7.2.4.3.1.1* Occupant notification shall be accomplished automatically in accordance with 13.7.1.9. [***101:***14.3.4.3.1.1]

Δ **A.13.7.2.4.3.1.1** The audible occupant notification signal for evacuation of an educational occupancy building should be the distinctive three-pulse temporal pattern fire alarm evacuation signal that is required of new systems by *NFPA 72*. The temporal pattern will help educate students to recognize the need to evacuate when they are in other occupancies. Existing fire alarm systems should be modified, as feasible, to sound the three-pulse temporal pattern. [***101:***A.15.3.4.3.1.1]

13.7.2.4.3.1.2 Reserved.

13.7.2.4.3.1.3 Positive alarm sequence shall be permitted in accordance with 13.7.1.9.4. [***101:***15.3.4.3.1.3]

13.7.2.4.3.1.4 Where acceptable to the AHJ, the fire alarm system shall be permitted to be used for other emergency signaling or for class changes, provided that the fire alarm is distinctive in signal and overrides all other use. [***101:***15.3.4.3.1.4]

13.7.2.4.3.1.5 To prevent students from being returned to a building that is burning, the recall signal shall be separate and distinct from any other signals, and such signal shall be permitted to be given by use of distinctively colored flags or banners. [***101:***15.3.4.3.1.5]

13.7.2.4.3.1.6 If the recall signal required by 13.7.2.4.3.1.5 is electric, the push buttons or other controls shall be kept under lock, the key for which shall be in the possession of the principal or another designated person in order to prevent a recall at a time when there is an actual fire. [***101:***15.3.4.3.1.6]

13.7.2.4.3.1.7 Regardless of the method of recall signal, the means of giving the recall signal shall be kept under lock. [***101:***15.3.4.3.1.7]

13.7.2.4.3.2 Emergency Forces Notification.

13.7.2.4.3.2.1 Wherever any of the school authorities determine that an actual fire exists, they shall immediately call the local fire department using the public fire alarm system or other available facilities. [***101:***15.3.4.3.2.1]

13.7.2.4.3.2.2 Emergency forces notification shall be accomplished in accordance with 13.7.1.10 where the existing fire alarm system is replaced. [***101:***15.3.4.3.2.2]

The provision of 13.7.2.4.3.2.2 imposes a requirement for emergency forces notification in accordance with 13.7.1.10 in existing buildings only where the fire alarm system is replaced.

13.7.2.5 New Day-Care Occupancies.

13.7.2.5.1 General. New day-care occupancies, other than day-care occupancies housed in one room having at least one door opening directly to the outside at grade plane or to an exterior exit access balcony in accordance with 14.10.3, shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.5. [***101:***16.3.4.1]

13.7.2.5.2 Initiation. Initiation of the required fire alarm system shall be by manual means and by operation of any required smoke detectors and required sprinkler systems. *(See 13.7.2.5.5.)* [***101:***16.3.4.2]

13.7.2.5.3 Occupant Notification.

13.7.2.5.3.1 Occupant notification shall be in accordance with 13.7.1.9. [***101:***16.3.4.3.1]

13.7.2.5.3.2 Positive alarm sequence shall be permitted in accordance with 13.7.1.9.4. [***101:***16.3.4.3.2]

13.7.2.5.3.3 Private operating mode in accordance with 13.7.1.9.6.3 shall be permitted. [***101:***16.3.4.3.3]

13.7.2.5.4 Emergency Forces Notification. Emergency forces notification shall be accomplished in accordance with 13.7.1.10. [***101:***16.3.4.4].

13.7.2.5.5 Detection. A smoke detection system in accordance with 13.7.1 shall be installed in new day-care occupancies, other than those housed in one room having at least one door opening directly to the outside at grade plane or to an exterior exit access balcony in accordance with 14.10.3, and such system shall comply with both of the following:

(1) Detectors shall be installed on each story in front of the doors to the stairways and in the corridors of all floors occupied by the day-care occupancy.
(2) Detectors shall be installed in lounges, recreation areas, and sleeping rooms in the day-care occupancy.

[***101:***16.3.4.5]

New day-care centers, other than those housed in a single room having a door opening directly to the outside at grade plane or to an exterior exit access balcony, are required to have a fire alarm system. Existing day-care centers, other than those housed in a single room, are required to have a fire alarm system. The alarm system is for purposes of occupant notification and fire department notification. Existing day-care centers are exempt from the fire department notification requirement if there are 100 or fewer clients.

Neither new nor existing day-care centers are permitted to use a presignal system (see 13.7.1.9.3). A delay in occupant notification is permitted only if positive alarm sequence in accordance with 13.7.1.9.4 is provided. Positive alarm sequence includes some fail-safe features not found in presignal systems. For example, if the person staffing the control panel does not acknowledge the signal, general occupant notification occurs automatically. Also, if a second initiation device reports a fire condition to the control panel, the delay ends and general occupant notification occurs immediately.

Some day-care centers include provisions for clients to nap. Also, parents who work at night might place their children in day-care centers for the purpose of sleeping through the night. Regardless of whether occupants sleep in the center, the smoke detectors required by 13.7.2.5.5 and 13.7.2.6.5 will provide critical extra time to evacuate clients. The requirement for smoke detection does not apply to new day-care centers housed in a single room having a door opening directly to the outside at grade plane or to an exterior exit access balcony, in which case a fire will be obvious to all occupants simultaneously. Similarly, the requirement for smoke detection does not apply to existing day-care centers housed in a single room or where the clients are capable of self-preservation and there are no sleeping facilities.

N **13.7.2.5.6 New Day-Care Homes.**

N **13.7.2.5.6.1** Smoke alarms shall be installed within day-care homes in accordance with 13.7.1.8. [***101:***16.6.3.4.1]

N **13.7.2.5.6.2** Where a day-care home is located within a building of another occupancy, such as in an apartment building or office building, any corridors serving the day-care home shall be provided with a smoke detection system in accordance with 13.7.1.4. [***101:***16.6.3.4.2]

N **13.7.2.5.6.3** Single-station or multiple-station smoke alarms or smoke detectors shall be provided in all rooms used for sleeping in accordance with 13.7.1.8. [***101:***16.6.3.4.4]

N **13.7.2.5.6.4** Single-station or multiple-station carbon monoxide alarms or detectors shall be provided in accordance with 13.7.1.14 in day-care homes where client sleeping occurs and one or both of the following conditions exist:

(1) Fuel-fired equipment is present.
(2) An enclosed parking structure is attached to the day-care home.

[***101:***16.6.3.4.6]

13.7.2.6 Existing Day-Care Occupancies.

13.7.2.6.1 General. Existing day-care occupancies, other than day-care occupancies housed in one room, shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.6. [***101:***17.3.4.1]

13.7.2.6.2 Initiation. Initiation of the required fire alarm system shall be by manual means and by operation of any required smoke detectors and required sprinkler systems. *(See 13.7.2.6.5.)* [***101:***17.3.4.2]

13.7.2.6.3 Occupant Notification.

13.7.2.6.3.1 Occupant notification shall be in accordance with 13.7.1.9. [***101:***17.3.4.3.1]

13.7.2.6.3.2 Positive alarm sequence shall be permitted in accordance with 13.7.1.9.4. [***101:***17.3.4.3.2]

13.7.2.6.3.3 Private operating mode in accordance with 13.7.1.9.6.3 shall be permitted. [***101:***17.3.4.3.3]

13.7.2.6.4 Emergency Forces Notification.

13.7.2.6.4.1 Emergency forces notification, other than for day-care occupancies with not more than 100 clients, shall be accomplished in accordance with 13.7.1.10. [***101:***17.3.4.4.1]

13.7.2.6.4.2 Emergency forces notification shall be accomplished in accordance with 13.7.1.10 where the existing fire alarm system is replaced. [***101:***17.3.4.4.2]

13.7.2.6.5 Detection. A smoke detection system in accordance with 13.7.1 shall be installed in existing day-care occupancies, other than those housed in one room or those housing clients capable of self-preservation where no sleeping facilities are provided, and such system shall comply with both of the following:

(1) Detectors shall be installed on each story in front of the doors to the stairways and in the corridors of all floors occupied by the day-care occupancy.
(2) Detectors shall be installed in lounges, recreation areas, and sleeping rooms in the day-care occupancy.

[***101:***17.3.4.5]

See the commentary following 13.7.2.5.5.

N **13.7.2.6.6 Existing Day-Care Homes.**

N **13.7.2.6.6.1** Smoke alarms shall be installed within day-care homes in accordance with 13.7.1.8. [***101:***17.6.3.4.1]

N **13.7.2.6.6.2** Where a day-care home is located within a building of another occupancy, such as in an apartment building or office building, any corridors serving the day-care home shall be provided with a smoke detection system in accordance with 13.7.1.7. [*101:*17.6.3.4.2]

N **13.7.2.6.6.3** Single-station or multiple-station smoke alarms or smoke detectors shall be provided in all rooms used for sleeping in accordance with 13.7.1.8, other than as permitted by 13.7.2.6.6.4. [*101:*17.6.3.4.4]

N **13.7.2.6.6.4** Approved existing battery-powered smoke alarms, rather than house electrical service–powered smoke alarms required by 13.7.2.6.6.3, shall be permitted where the facility has testing, maintenance, and battery replacement programs that ensure reliability of power to the smoke alarms. [*101:*17.6.3.4.5]

13.7.2.7 New Health Care Occupancies.

13.7.2.7.1 General. New health care occupancies shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.7. [*101:*18.3.4.1]

13.7.2.7.2* Initiation.

A.13.7.2.7.2 It is not the intent of this *Code* to require single-station smoke alarms that might be required by local codes to be connected to or to initiate the building fire alarm system. [*101:*A.18.3.4.2]

13.7.2.7.2.1 Initiation of the required fire alarm systems shall be by manual means in accordance with 13.7.1.7 and by means of any required sprinkler system waterflow alarms, detection devices, or detection systems, unless otherwise permitted by 13.7.2.7.2.2 and 13.7.2.7.2.3. [*101:*18.3.4.2.1]

13.7.2.7.2.2 Manual fire alarm boxes in patient sleeping areas shall not be required at exits if located at all nurses' control stations or other continuously attended staff location, provided that both of the following criteria are met:

(1) Such manual fire alarm boxes are visible and continuously accessible.
(2) Travel distances required by 13.7.1.7.5 are not exceeded.

[*101:*18.3.4.2.2]

13.7.2.7.2.3 The system smoke detector installed in accordance with 18.3.2.5.3(13) of NFPA *101* shall not be required to initiate the fire alarm system. [*101:*18.3.4.2.3]

13.7.2.7.3 Notification. Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [*101:*18.3.4.3]

13.7.2.7.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 13.7.1.9, unless otherwise modified by the following:

(1) Paragraph 13.7.1.9.2.3 shall not be permitted to be used.
(2)* In lieu of audible alarm signals, visible alarm-indicating appliances shall be permitted to be used in critical care areas.

A.13.7.2.7.3.1(2) It is the intent of this provision to permit a visible fire alarm signal instead of an audible signal to reduce interference between the fire alarm and medical equipment monitoring alarms. [*101:*A.18.3.4.3.1(2)]

(3) The provision of 18.3.2.5.3(13)(c) of NFPA *101* shall be permitted to be used.

[*101:*18.3.4.3.1]

13.7.2.7.3.2 Emergency Forces Notification.

13.7.2.7.3.2.1 Emergency forces notification shall be accomplished in accordance with 13.7.1.10, except that the provision of 18.3.2.5.3(13)(d) of NFPA *101* shall be permitted to be used. [*101:*18.3.4.3.2.1]

13.7.2.7.3.2.2 Reserved.

13.7.2.7.3.3 Annunciation and Annunciation Zoning.

13.7.2.7.3.3.1 Annunciation and annunciation zoning shall be provided in accordance with 13.7.1.13, unless otherwise permitted by 13.7.2.7.3.3.2 or 13.7.2.7.3.3.3. [*101:*18.3.4.3.3.1]

13.7.2.7.3.3.2 The alarm zone shall be permitted to coincide with the permitted area for smoke compartments. [*101:*18.3.4.3.3.2]

13.7.2.7.3.3.3 The provision of 13.7.1.13.9.2, which permits sprinkler system waterflow to be annunciated as a single building zone, shall be prohibited. [*101:*18.3.4.3.3.3]

13.7.2.7.4 Emergency Control Functions. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically any control functions to be performed by that device. *(See 13.7.1.11.)* [*101:*18.3.4.4]

13.7.2.7.5 Detection.

13.7.2.7.5.1 General. Detection systems, where required, shall be in accordance with Section 13.7. [*101:*18.3.4.5.1]

13.7.2.7.5.2 Detection in Spaces Open to Corridors. See 18.3.6.1 of NFPA *101*. [*101:*18.3.4.5.2]

13.7.2.7.5.3* Nursing Homes. An approved automatic smoke detection system shall be installed in corridors throughout smoke compartments containing patient sleeping rooms and in spaces open to corridors as permitted in nursing homes by 18.3.6.1 of NFPA *101*, unless otherwise permitted by one of the following:

(1) Corridor systems shall not be required where each patient sleeping room is protected by an approved smoke detection system.
(2) Corridor systems shall not be required where patient room doors are equipped with automatic door-closing devices with integral smoke detectors on the room side installed in accordance with their listing, provided that the integral detectors provide occupant notification.

[*101:*18.3.4.5.3]

A.13.7.2.7.5.3 The requirement for smoke detectors in spaces open to the corridors eliminates the requirements of 18.3.6.1 (1)(c), (2)(b), and (5)(b) of NFPA *101* for direct supervision by the facility staff of nursing homes. [*101:*A.18.3.4.5.3]

13.7.2.8 Existing Health Care Occupancies.

13.7.2.8.1 General. Existing health care occupancies shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.8. [***101:***19.3.4.1]

13.7.2.8.2* Initiation.

A.13.7.2.8.2 It is not the intent of this *Code* to require single-station smoke alarms, which might be required by local codes, to be connected to or to initiate the building fire alarm system. [***101:***A.19.3.4.2]

13.7.2.8.2.1 Initiation of the required fire alarm systems shall be by manual means in accordance with 13.7.1.7 and by means of any required sprinkler system waterflow alarms, detection devices, or detection systems, unless otherwise permitted by 13.7.2.8.2.2 through 13.7.2.8.2.5. [***101:***19.3.4.2.1]

13.7.2.8.2.2 Manual fire alarm boxes in patient sleeping areas shall not be required at exits if located at all nurses' control stations or other continuously attended staff location, provided that both of the following criteria are met:

(1) Such manual fire alarm boxes are visible and continuously accessible.
(2) Travel distances required by 13.7.1.7.5 are not exceeded.

[***101:***19.3.4.2.2]

13.7.2.8.2.3 The system smoke detector installed in accordance with 19.3.2.5.3(13) of NFPA *101* shall not be required to initiate the fire alarm system. [***101:***19.3.4.2.3]

13.7.2.8.2.4 Fixed extinguishing systems protecting commercial cooking equipment in kitchens that are protected by a complete automatic sprinkler system shall not be required to initiate the fire alarm system. [***101:***19.3.4.2.4]

13.7.2.8.2.5 Detectors required by 19.7.5.3 and 19.7.5.5 of NFPA *101* shall not be required to initiate the fire alarm system. [***101:***19.3.4.2.5]

13.7.2.8.3 Notification. Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted in health care occupancies protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13. [***101:***19.3.4.3]

13.7.2.8.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 13.7.1.9, unless otherwise modified by the following:

(1)* In lieu of audible alarm signals, visible alarm-indicating appliances shall be permitted to be used in critical care areas

A.13.7.2.8.3.1(1) It is the intent of this provision to permit a visible fire alarm signal instead of an audible signal to reduce interference between the fire alarm and medical equipment monitoring alarms. [***101:***A.19.3.4.3.1(1)]

(2) Where visual devices have been installed in patient sleeping areas in place of an audible alarm, they shall be permitted where approved by the AHJ.
(3) The provision of 19.3.2.5.3(13)(c) of NFPA *101* shall be permitted to be used.

[***101:***19.3.4.3.1]

13.7.2.8.3.2 Emergency Forces Notification.

13.7.2.8.3.2.1 Emergency forces notification shall be accomplished in accordance with 13.7.1.10, except that the provision of 19.3.2.5.3(13)(d) of NFPA *101* shall be permitted to be used. [***101:***19.3.4.3.2.1]

13.7.2.8.3.2.2 Smoke detection devices or smoke detection systems equipped with reconfirmation features shall not be required to automatically notify the fire department, unless the alarm condition is reconfirmed after a period not exceeding 120 seconds. [***101:***19.3.4.3.2.2]

13.7.2.8.3.3 Reserved.

13.7.2.8.4 Emergency Control Functions. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically any control functions to be performed by that device. *(See 13.7.1.11.)* [***101:***19.3.4.4]

13.7.2.8.5 Detection.

13.7.2.8.5.1 Corridors. An approved automatic smoke detection system in accordance with Section 13.7 shall be installed in all corridors of limited care facilities, unless otherwise permitted by one of the following:

(1) Where each patient sleeping room is protected by an approved smoke detection system, and a smoke detector is provided at smoke barriers and horizontal exits in accordance with Section 13.7, the corridor smoke detection system shall not be required on the patient sleeping room floors.
(2) Smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.12.8 shall be permitted.

[***101:***19.3.4.5.1]

13.7.2.8.5.2 Detection in Spaces Open to Corridors. See 19.3.6.1 of NFPA *101*. [***101***:19.3.4.5.2]

A manual fire alarm system is required in new and existing health care occupancies by 13.7.2.7.1, 13.7.2.7.2, 13.7.2.8.1, and 13.7.2.8.2. Manual fire alarm boxes are normally located along the natural routes of egress and are also located to cover all portions of the building. Paragraphs 13.7.2.7.2.2 and 13.7.2.8.2.2 permit manual fire alarm boxes, under certain conditions, to be located only at continuously attended staff positions in sleeping areas. This arrangement provides the opportunity for prompt notification of fire without requiring staff to leave their normal workstations. In new installations, it would normally be desirable to have manual fire alarm boxes at all attended staff locations and at entrances to exits, because the additional cost of the extra fire alarm boxes would be minimal. However, the exemptions recognize that the fire alarm boxes located near the exits might lead to nuisance alarms if patients misuse them.

Manual fire alarm boxes should be located so that those qualified to send an alarm can summon aid without having to leave their zone of ordinary activity or pass out of the sight and hearing of people immediately exposed to, or in direct view of, a fire. The operation of a manual fire alarm box should automatically summon attendants who can assist in removing physically helpless occupants and controlling mentally disabled occupants.

Paragraph 13.7.2.8.2.5 addresses smoke detectors installed for a special purpose — to provide an exemption to paragraphs 19.7.5.3 and 19.7.5.5 of NFPA *101*, which require that newly introduced upholstered furniture and mattresses be resistant to cigarette ignition and have limited rates of heat release. Paragraph 13.7.2.8.2.5 exempts such smoke detectors from having to initiate the building alarm system.

Paragraphs 13.7.2.7.3 and 13.7.2.8.3 permit positive alarm sequence in sprinklered health care occupancies. The criteria for positive alarm sequence are detailed in *NFPA 72*. See the commentary following 13.7.1.9.4 for details on positive alarm sequence.

Although 13.7.2.7.3.1 and 13.7.2.8.3.1 require occupant notification, coded messages are permitted to be used to notify staff and trained responders. As part of their emergency duties, staff will then keep patients and visitors informed of expected actions.

Paragraph 13.7.2.7.3.1(1) specifically prohibits new health care occupancies from using 13.7.1.9.2.3, which exempts detectors at doors used for the exclusive operation of automatic door release from the requirements for occupant notification. Note that the use of 13.7.1.9.2.1, which exempts detectors used for recalling elevators from initiating occupant notification, and 13.7.1.9.2.2, which exempts detectors used for closing dampers from initiating occupant notification, is permitted. Although such detectors must be arranged to initiate the health care occupancy alarm system in accordance with 13.7.2.7.2.1, subsequent automatic occupant notification is not required.

Emergency forces notification is addressed in 13.7.2.7.3.2 and 13.7.2.8.3.2. Paragraph 13.7.2.8.3.2.2 permits the continued use of an existing alarm system feature that delays fire department notification for up to 120 seconds where smoke detectors or smoke detection systems are equipped with a reconfirmation feature. However, staff notification, as required by 13.7.2.8.3.1, cannot be delayed by the existing smoke detection system with reconfirmation feature.

The alarm must automatically transmit to a point outside the facility. If the fire department legally committed to serve the facility does not permit automatic alarm transmission, arrangements must be made for the prompt notification of the fire department or such other assistance as may be available in the case of fire or other emergency. Paragraph 13.7.1.10.2 lists various acceptable methods for automatically notifying the fire department. The fire department should also be called manually to verify and confirm the automatic transmission of the alarm. In larger facilities, this might be the responsibility of the facility telephone operator; in smaller facilities, it might be the responsibility of the nursing staff.

Exhibit 13.41

Alarm system annunciator panel.

The provision of 13.7.2.7.3.3 requires annunciation and annunciation zoning for new fire alarm systems. Exhibit 13.41 shows an alarm system annunciator panel positioned on the wall of a minor entrance to a hospital. The minor entrance is the location by which the fire department enters the building when responding to a call for assistance. The hospital facility floor plan is attached to the wall in the vicinity of the annunciator panel so that the abbreviated zone identifiers displayed at the annunciator panel can be converted to visual cues as to the section of the building from which the alarm signal was received.

The provision of 13.7.2.7.3.3.3 prohibits sprinkler system waterflow from being annunciated as a single building zone. The prohibition was written in reaction to the addition of 13.7.1.13.9.2, which permits such single-zone annunciation so as not to prohibit a so-called sprinkler system birdcage piping configuration, in which the sprinkler branch lines are run vertically through the building, rather than horizontally, providing an economical installation alternative. (The resulting piping network resembles a birdcage, hence the name.) With such a piping configuration, it is not practical to provide waterflow devices for every floor, since each branch line typically serves multiple floors. Therefore, a single waterflow device is provided on the supply piping ahead of the branch lines, resulting in the sprinkler system being annunciated as a single zone. Such an arrangement has the potential to increase the time required for emergency responders to locate the fire and is inconsistent with the protection level mandated for health care occupancies.

Paragraph 13.7.2.8.5.1 requires smoke detectors in the corridors of existing limited care facilities. Staffing levels in hospitals and nursing homes reasonably ensure discovery of a fire at an early stage. In existing hospitals and nursing homes, it is considered reasonable to rely on staff to sound the alarm.

Paragraph 13.7.2.7.5.3 requires corridor smoke detection systems in new nursing homes. The justification for the creation of this requirement stated that corridor smoke detectors are needed for redundancy, since, in some fire scenarios, the corridor detector might be the first device to provide notification of fire, and the cost of installing a corridor smoke detection system as part of new construction is minor.

13.7.2.9 New Ambulatory Health Care Occupancies.

13.7.2.9.1 General. New ambulatory health care facilities shall be provided with fire alarm systems in accordance with Section 13.7 and 13.7.2.9, except as modified by 13.7.2.9.2 through 13.7.2.9.4. [***101:***20.3.4.1]

13.7.2.9.2 Initiation. Initiation of the required fire alarm systems shall be by manual means in accordance with 13.7.1.7 and by means of any detection devices or detection systems required. [***101:***20.3.4.2]

13.7.2.9.3 Notification. Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***20.3.4.3]

13.7.2.9.3.1 Occupant Notification. Occupant notification shall be accomplished automatically, without delay, in accordance with 13.7.1.9 upon operation of any fire alarm activating device. [***101:***20.3.4.3.1]

13.7.2.9.3.2 Emergency Forces Notification.

13.7.2.9.3.2.1 Emergency forces notification shall be accomplished in accordance with 13.7.1.10. [***101:***20.3.4.3.2.1]

13.7.2.9.3.2.2 Reserved.

13.7.2.9.4 Emergency Control Functions. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically, without delay, any control functions required to be performed by that device. *(See 13.7.1.11.)* [***101:***20.3.4.4]

13.7.2.10 Existing Ambulatory Health Care Occupancies.

13.7.2.10.1 General. Existing ambulatory health care facilities shall be provided with fire alarm systems in accordance with Section 13.7 and 13.7.2.10, except as modified by 13.7.2.10.2 through 13.7.2.10.4. [***101:***21.3.4.1]

13.7.2.10.2 Initiation. Initiation of the required fire alarm systems shall be by manual means in accordance with 13.7.1.7 and by means of any detection devices or detection systems required. [***101:***21.3.4.2]

13.7.2.10.3 Notification. Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***21.3.4.3]

13.7.2.10.3.1 Occupant Notification. Occupant notification shall be accomplished automatically, without delay, in accordance with 13.7.1.9 upon operation of any fire alarm activating device. [***101:***21.3.4.3.1]

13.7.2.10.3.2 Emergency Forces Notification.

13.7.2.10.3.2.1 Emergency forces notification shall be accomplished in accordance with 13.7.1.10. [***101:***21.3.4.3.2.1]

13.7.2.10.3.2.2 Smoke detection devices or smoke detection systems equipped with reconfirmation features shall not be required to automatically notify the fire department, unless the alarm condition is reconfirmed after a period not exceeding 120 seconds. [***101:***21.3.4.3.2.2]

13.7.2.10.4 Emergency Control Functions. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically, without delay, any control functions required to be performed by that device. *(See 13.7.1.11.)* [***101:***21.3.4.4]

Paragraphs 13.7.2.9.1 through 13.7.2.9.4 and 13.7.2.10.1 through and 13.7.2.10.4 address required fire alarm equipment. Reliability is of prime importance; therefore, electrical supervision of the system and system components is specified via the references to Section 13.7. In the event of circuit fault, component failure, or other trouble, a continuous trouble indication signal is required and should be provided at a constantly attended location.

Paragraphs 13.7.2.9.1, 13.7.2.9.2, 13.7.2.10.1, and 13.7.2.10.2 require a manual fire alarm system. Manual fire alarm boxes should be located along the natural routes of egress and cover all portions of the building (see 13.7.1.7.3 and 13.7.1.7.5). They should be located so that those qualified to send an alarm can summon aid without having to leave their zone of ordinary activities or pass beyond the view and hearing of people immediately exposed to, or in direct view of, a fire. The operation of a manual fire alarm box should automatically summon attendants to assist in moving occupants.

Actuation of any required fire or smoke detector, activation of a required sprinkler system, or operation of a manual fire alarm box must automatically, without delay, initiate the alarm system and sound audible alarm devices within the building. Presignal systems are not permitted (see 13.7.1.9.3); positive alarm sequence is permitted (see 13.7.1.9.4).

The criteria for positive alarm sequence are detailed in *NFPA 72* and include the following:

1. The signal from an automatic fire detection device selected for positive alarm sequence operation must be acknowledged at the control unit by trained personnel within 15 seconds of annunciation in order to initiate the alarm investigation phase.
2. If the signal is not acknowledged within 15 seconds, notification signals in accordance with the building evacuation or relocation plan and remote signals must be automatically and immediately activated (i.e., immediate occupant notification and emergency forces notification must occur).
3. If the signal is acknowledged within 15 seconds, trained personnel have up to 180 seconds during the alarm investigation phase to evaluate the fire condition and reset the system.

4. If the system is not reset during the investigation phase, notification signals in accordance with the building evacuation or relocation plan and remote signals must be automatically and immediately activated (i.e., immediate occupant notification and emergency forces notification must occur).
5. If a second automatic fire detector selected for positive alarm sequence is actuated during the alarm investigation phase, notification signals in accordance with the building evacuation or relocation plan and remote signals must be automatically and immediately activated (i.e., immediate occupant notification and emergency forces notification must occur).
6. If any other initiating device is actuated (e.g., a manual fire alarm box), notification signals in accordance with the building evacuation or relocation plan and remote signals must be automatically and immediately activated (i.e., immediate occupant notification and emergency forces notification must occur).

The alarm must automatically transmit to a point outside the facility. If automatic transmission of the alarm to the fire department legally committed to serve the facility is not permitted, arrangements must be made for the prompt notification of the fire department or such other assistance as is available in the case of fire or other emergency. Paragraph 13.7.1.10.2 lists various methods acceptable for automatically notifying the fire department. The fire department should also be called manually to verify and confirm the automatic transmission of the alarm. In larger facilities, this might be the responsibility of the facility telephone operator. In smaller facilities, it might be the responsibility of the medical staff. Actuation of the fire alarm must initiate the operation of audible alerting devices that sound throughout the affected zone or building.

13.7.2.11 New Detention and Correctional Occupancies.

Δ **13.7.2.11.1 General.** New detention and correctional occupancies shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.11, except as modified by 13.7.2.11.2 through 13.7.2.11.4.3. [***101:***22.3.4.1]

13.7.2.11.2 Initiation. Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7, by means of any required detection devices or detection systems, and by means of waterflow alarm in the sprinkler system required by 13.3.2.13.1, unless otherwise permitted by the following:

(1) Manual fire alarm boxes shall be permitted to be locked, provided that staff is present within the area when it is occupied and staff has keys readily available to unlock the boxes.
(2) Manual fire alarm boxes shall be permitted to be located in a staff location, provided that both of the following criteria are met:
    (a) The staff location is attended when the building is occupied.
    (b) The staff attendant has direct supervision of the sleeping area.

[***101:***22.3.4.2]

13.7.2.11.3 Notification.

13.7.2.11.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 13.7.1.9, and the following also shall apply:

(1) A positive alarm sequence shall be permitted in accordance with 13.7.1.9.4.
(2)* Any smoke detectors required by this chapter shall be permitted to be arranged to alarm at a constantly attended location only and shall not be required to accomplish general occupant notification.

[***101:***22.3.4.3.1]

A.13.7.2.11.3.1(2) The staff at the constantly attended location should have the capability to promptly initiate the general alarm function and contact the fire department or have direct communication with a control room or other location that can initiate the general alarm function and contact the fire department. [***101:***A.22.3.4.3.1(2)]

13.7.2.11.3.2 Emergency Forces Notification.

13.7.2.11.3.2.1 Fire department notification shall be accomplished in accordance with 13.7.1.10, unless otherwise permitted by one of the following:

(1) A positive alarm sequence shall be permitted in accordance with 13.7.1.9.4.
(2) Any smoke detectors required by this chapter shall not be required to transmit an alarm to the fire department.
(3) This requirement shall not apply where staff is provided at a constantly attended location that meets one of the following criteria:
    (a) It has the capability to promptly notify the fire department.
    (b) It has direct communication with a control room having direct access to the fire department.

[***101:***22.3.4.3.2.1]

13.7.2.11.3.2.2 Where the provision of 13.7.2.11.3.2.1(3) is utilized, the fire plan, as required by 20.7.2.1.3, shall include procedures for logging of alarms and immediate notification of the fire department. [***101:***22.3.4.3.2.2]

13.7.2.11.4* Detection. An approved automatic smoke detection system shall be in accordance with Section 13.7, as modified by 13.7.2.11.4.1 through 13.7.2.11.4.3, throughout all resident sleeping areas and adjacent day rooms, activity rooms, or contiguous common spaces. [***101:***22.3.4.4]

A.13.7.2.11.4 Examples of contiguous common spaces are galleries and corridors. [***101:***A.22.3.4.4]

13.7.2.11.4.1 Smoke detectors shall not be required in sleeping rooms with four or fewer occupants. [***101:***22.3.4.4.1]

13.7.2.11.4.2 Other arrangements and positioning of smoke detectors shall be permitted to prevent damage or tampering, or for other purposes. [***101:***22.3.4.4.2]

13.7.2.11.4.2.1 Other arrangements, as specified in 13.7.2.11.4.2, shall be capable of detecting any fire, and the placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangements required by the installation standards referenced in Section 13.7. [***101:***22.3.4.4.2.1]

13.7.2.11.4.2.2 Detectors shall be permitted to be located in exhaust ducts from cells, behind grilles, or in other locations. [***101***:22.3.4.4.2.2]

13.7.2.11.4.2.3 The equivalent performance of the design permitted by 13.7.2.11.4.2.2 shall be acceptable to the AHJ in accordance with the equivalency concepts specified in Section 1.4. [***101:***22.3.4.4.2.3]

13.7.2.11.4.3* Smoke detectors shall not be required in Use Condition II open dormitories where staff is present within the dormitory whenever the dormitory is occupied. [***101:***22.3.4.4.3]

A.13.7.2.11.4.3 An open dormitory is a dormitory that is arranged to allow staff to observe the entire dormitory area at one time. [***101:***A.22.3.4.4.3]

13.7.2.12 Existing Detention and Correctional Occupancies.

13.7.2.12.1 General. Existing detention and correctional occupancies shall be provided with a fire alarm system in accordance with Section 13.7 and 13.7.2.12, except as modified by 13.7.2.12.2 through 13.7.2.12.4.4. [***101:***23.3.4.1]

13.7.2.12.2 Initiation. Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7 and by means of any required detection devices or detection systems, unless otherwise permitted by the following:

(1) Manual fire alarm boxes shall be permitted to be locked, provided that staff is present within the area when it is occupied and staff has keys readily available to unlock the boxes.
(2) Manual fire alarm boxes shall be permitted to be located in a staff location, provided that both of the following criteria are met:
    (a) The staff location is attended when the building is occupied.
    (b) The staff attendant has direct supervision of the sleeping area.

[***101:***23.3.4.2]

13.7.2.12.3 Notification.

13.7.2.12.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 13.7.1.9, and the following also shall apply:

(1) A positive alarm sequence shall be permitted in accordance with 13.7.1.9.4.
(2)* Any smoke detectors required by this chapter shall be permitted to be arranged to alarm at a constantly attended location only and shall not be required to accomplish general occupant notification.

[***101:***23.3.4.3.1]

A.13.7.2.12.3.1(2) The staff at the constantly attended location should have the capability to promptly initiate the general alarm function and contact the fire department or have direct communication with a control room or other location that can initiate the general alarm function and contact the fire department. [***101:***A.23.3.4.3.1(2)]

13.7.2.12.3.2 Emergency Forces Notification.

13.7.2.12.3.2.1 Fire department notification shall be accomplished in accordance with 13.7.1.10, unless otherwise permitted by one of the following:

(1) A positive alarm sequence shall be permitted in accordance with 13.7.1.9.4.
(2) Any smoke detectors required by this chapter shall not be required to transmit an alarm to the fire department.
(3) This requirement shall not apply where staff is provided at a constantly attended location that meets one of the following criteria:
    (a) It has the capability to promptly notify the fire department.
    (b) It has direct communication with a control room having direct access to the fire department.

[***101:***23.3.4.3.2.1]

13.7.2.12.3.2.2 Where the provision of 13.7.2.12.3.2.1(3) is utilized, the fire plan, as required by 20.7.2.1.3, shall include procedures for logging of alarms and immediate notification of the fire department. [***101:***23.3.4.3.2.2]

13.7.2.12.4 Detection. An approved automatic smoke detection system shall be in accordance with Section 13.7, as modified by 13.7.2.12.4.1 through 13.7.2.12.4.4, throughout all resident housing areas. [***101:***23.3.4.4]

13.7.2.12.4.1 Smoke detectors shall not be required in sleeping rooms with four or fewer occupants in Use Condition II or Use Condition III. [***101:***23.3.4.4.1]

13.7.2.12.4.2 Other arrangements and positioning of smoke detectors shall be permitted to prevent damage or tampering, or for other purposes. [***101:***23.3.4.4.2]

13.7.2.12.4.2.1 Other arrangements, as specified in 13.7.2.12.4.2, shall be capable of detecting any fire, and the placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangements required by the installation standards referenced in Section 13.7. [***101:***23.3.4.4.2.1]

13.7.2.12.4.2.2 Detectors shall be permitted to be located in exhaust ducts from cells, behind grilles, or in other locations. [***101:***23.3.4.4.2.2]

Δ **13.7.2.12.4.2.3** The equivalent performance of the design permitted by 13.7.2.12.4.2.2 shall be acceptable to the AHJ in accordance with the equivalency concepts specified in Section 1.4. [***101:***23.3.4.4.2.3]

13.7.2.12.4.3* Smoke detectors shall not be required in Use Condition II open dormitories where staff is present within the dormitory whenever the dormitory is occupied and the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.14.2. [***101:***23.3.4.4.3]

A.13.7.2.12.4.3 An open dormitory is a dormitory that is arranged to allow staff to observe the entire dormitory area at one time. [***101:***A.23.3.4.4.3]

13.7.2.12.4.4 In smoke compartments protected throughout by an approved automatic sprinkler system in accordance with 13.3.2.14.2, smoke detectors shall not be required, except in corridors, common spaces, and sleeping rooms with more than four occupants. [***101:***23.3.4.4.4]

Given that new detention and correctional facilities must be sprinklered, 13.7.2.12.2 requires a waterflow alarm as one of the means for initiating the fire alarm system.

Paragraph 13.7.1.9.3 requires specific occupancy chapter permission for a presignal system to be used. The provision of 13.7.2.11.3.1 and 13.7.2.12.3.1 has the effect of prohibiting the use of presignal systems by not specifically allowing them. Rather, notification must be provided without delay in accordance with 13.7.1.9, or the more reliable form of presignal — called positive alarm sequence — can be used if complying with 13.7.1.9.4. However, to avoid numerous nuisance alarms, smoke detectors are exempted from sounding a general alarm.

Where the fire department is not equipped to receive alarms or where direct transmission to the fire department is not permitted, the provisions of 13.7.2.11.3.2 and 13.7.2.12.3.2 require that arrangements be made for the prompt notification of the fire department. One means of notification is by an approved central station alarm system. The provisions of 13.7.1.10 provide several options for notifying the fire department automatically. Where smoke detectors are provided, they are not required to sound the fire alarm or to transmit a signal to the fire department, but they are required to sound an alarm at a constantly attended location, unless otherwise specified.

Paragraphs 13.7.2.11.4.3 and 13.7.2.12.3.4 are exemptions to the smoke detection system requirement. They apply to Use Condition II open dormitories where staff are present within the dormitory whenever the dormitory is occupied. Note that Use Condition II facilities must allow free movement from sleeping areas to another smoke compartment. The concept employed is one of relying on awake and alert staff within the dormitory to act as human fire detectors, providing early warning, and allowing residents to move into a safe smoke compartment.

13.7.2.13 New and Existing One- and Two-Family Dwellings.

13.7.2.13.1 Smoke alarms or a smoke detection system shall be provided in accordance with either 13.7.2.13.1.1 or 13.7.2.13.1.2, as modified by 13.7.2.13.1.3. [***101:***24.3.4.1]

13.7.2.13.1.1* Smoke alarms shall be installed in accordance with 13.7.1.8 in all of the following locations:

(1) All sleeping rooms
(2)* Outside of each separate sleeping area, in the immediate vicinity of the sleeping rooms

Δ **A.13.7.2.13.1.1** Paragraph 11.5.1.3 of *NFPA 72* contains related requirements. They specify that, where the interior floor area for a given level of a dwelling unit, excluding garage areas, is greater than 1000 ft² (93 m²), smoke alarms are to be installed as follows:

(1) All points on the ceiling are to have a smoke alarm within a distance of 30 ft (9.1 m), measured along a path of travel, or to have one smoke alarm per 500 ft² (46.5 m²) of floor area, which is calculated by dividing the total interior floor area per level by 500 ft² (46.5 m²).
(2) Where dwelling units include great rooms or vaulted/cathedral ceilings extending over multiple floors, smoke alarms located on the upper floor that are intended to protect the aforementioned area are permitted to be considered as part of the lower floor(s) protection scheme used to meet the requirements of A.13.7.2.13.1.1(1).

[***101:***A.24.3.4.1.1]

Δ **A.13.7.2.13.1.1(2)** Paragraphs 11.5.1.1(2) and 11.5.1.2 of *NFPA 72* contain related requirements. The requirement of 11.5.1.1(2) specifies that an alarm is to be installed outside of each separate dwelling unit sleeping area, within 21 ft (6.4 m) of any door to a sleeping room, with the distance measured along a path of travel. The requirement in 11.5.1.2 of *NFPA 72* specifies that, where the area addressed in 11.5.1.1(2) of *NFPA 72* is separated from the adjacent living areas by a door, a smoke alarm is to be installed in the area between the door and the sleeping rooms, and additional alarms are to be installed on the living area side of the door. [***101:***A.24.3.4.1.1(2)]

(3) On each level of the dwelling unit, including basements

[***101:***24.3.4.1.1]

13.7.2.13.1.2 Dwelling units shall be protected by an approved smoke detection system in accordance with Section 13.7 and equipped with an approved means of occupant notification. [***101:***24.3.4.1.2]

13.7.2.13.1.3 In existing one- and two-family dwellings, approved smoke alarms powered by batteries shall be permitted. [***101:***24.3.4.1.3]

The reference to 13.7.1.8 in 13.7.2.13.1.1 requires smoke alarms to be hardwired into the electrical system of the home, to be plug-in alarms, or to meet the other power requirements of *NFPA 72*. The provision of 13.7.2.13.1.3, which permits battery-powered smoke alarms in existing dwellings, gives dwelling occupants relief from retrofit requirements while providing needed protection. However, occupants of dwellings that use battery-operated smoke alarms must ensure that those alarms are tested and maintained properly. NFPA analysis has shown that 30 percent of smoke alarms were inoperative in homes with smoke alarms that had experienced fire. The primary reason for smoke alarm failure is that the battery was removed to avoid nuisance alarms. NFPA public education programs, such as the *Learn Not to Burn*® program, are effective tools for promoting the importance of working smoke alarms.

Note that the *Code* requires smoke alarms to be located in sleeping rooms of both new and existing one- and two-family dwellings. In existing dwellings, the smoke alarms are permitted to be powered by replaceable batteries as indicated in 13.7.2.13.1.3.

13.7.2.13.2 Carbon Monoxide and Carbon Monoxide Detection Systems.

13.7.2.13.2.1 Carbon monoxide alarms or carbon monoxide detectors in accordance with 13.7.1.14 and 13.7.2.13.2 shall be provided in new one- and two-family dwellings where either of the following conditions exists:

(1) Dwelling units with communicating attached garages, unless otherwise exempted by 13.7.2.13.2.3
(2) Dwelling units containing fuel-burning appliances or fuel-burning fireplaces

[***101:***24.3.4.2.1]

13.7.2.13.2.2* Where required by 13.7.2.13.2.1, carbon monoxide alarms or carbon monoxide detectors shall be installed in the following locations:

(1) Outside of each separate dwelling unit sleeping area in the immediate vicinity of the sleeping rooms
(2) On every occupiable level of a dwelling unit, including basements, and excluding attics and crawl spaces

[***101:***24.3.4.2.2]

Δ **A.13.7.2.13.2.2** The placement requirements of NFPA 720 are modified specifically for one- and two-family dwellings as required by this *Code* and do not affect other regulations within a jurisdiction. [***101:***A.24.3.4.2.2]

13.7.2.13.2.3 Carbon monoxide alarms and carbon monoxide detectors as specified in 13.7.2.13.2.1(1) shall not be required in the following locations:

(1) In garages
(2) Within dwelling units with communicating attached garages that are open parking structures as defined by the building code
(3) Within dwelling units with communicating attached garages that are mechanically ventilated in accordance with the mechanical code

[***101:***24.3.4.2.3]

The provisions of 13.7.2.13.2 mandate the installation of CO detectors or CO alarms in new dwellings where there is a potential for accidental CO poisoning from a vehicle in an attached, communicating garage (i.e., a garage with an opening to the dwelling unit) or from fuel-burning appliances, such as a gas- or an oil-fired furnace or a fuel-burning fireplace. The reference to 13.7.1.14 in 13.7.2.13.2.1 requires compliance with NFPA 720. NFPA 720, which is modeled after *NFPA 72*, contains the detailed installation requirements for CO alarms, including those for power supply. The required locations for CO alarms in dwellings are nearly identical to those for smoke alarms, except CO alarms are not required in sleeping rooms. Also, like smoke alarms, where more than one CO alarm is required in a dwelling, they must be interconnected so that, when one activates, all CO alarms in the dwelling sound their alarms.

Exhibit 13.42

Combination CO and smoke alarm.

Although not mandated in existing dwellings, the installation of CO alarms is recommended if CO poisoning is a possibility. See the commentary following 13.7.1.14 for additional details. Exhibit 13.42 depicts a typical battery-powered combination CO and smoke alarm on display for sale at a retail store.

It is important to note that the typical service life of a CO alarm varies from about 5 to 10 years. CO alarms must be replaced by the date indicated on the device to ensure proper operation.

13.7.2.14 New and Existing Lodging or Rooming Houses.

13.7.2.14.1 General.

13.7.2.14.1.1 New and existing lodging and rooming houses, other than those meeting 13.7.2.14.1.2, shall be provided with a fire alarm system in accordance with Section 13.7. [***101:***26.3.4.1.1]

13.7.2.14.1.2 A fire alarm system in accordance with Section 13.7 shall not be required in existing lodging and rooming houses that have an existing smoke detection system meeting or exceeding the requirements of 13.7.2.14.5.1 where that detection system includes not less than one manual fire alarm box per floor arranged to initiate the smoke detection alarm. [***101:***26.3.4.1.2]

In existing lodging or rooming houses, 13.7.2.14.1.2 permits existing multiple-station smoke alarms and a manual fire alarm box arranged as a system to substitute for a standard fire alarm system in accordance with *NFPA 72*.

Δ **13.7.2.14.2 Initiation.** Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7, or by alarm initiation in accordance with 13.7.1.7.1(3) in buildings protected throughout by an approved automatic sprinkler system in accordance with 13.3.2.19. [***101:***26.3.4.2]

13.7.2.14.3 Notification. Occupant notification shall be provided automatically in accordance with 13.7.1.9, as modified by 13.7.2.14.3.1 and 13.7.2.14.3.2. [***101:***26.3.4.3]

13.7.2.14.3.1* Visible signals for the hearing impaired shall not be required where the proprietor resides in the building and there are five or fewer rooms for rent. [*101:*26.3.4.3.1]

A.13.7.2.14.3.1 The proprietor is the owner or owner's agent with responsible charge. [*101:*A.26.3.4.3.1]

13.7.2.14.3.2 Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [*101:*26.3.4.3.2]

13.7.2.14.4 Detection. (Reserved)

13.7.2.14.5 Smoke Alarms.

Δ **13.7.2.14.5.1** Approved smoke alarms, other than existing smoke alarms meeting the requirements of 13.7.2.14.5.3, shall be installed in accordance with 13.7.1.8 in every sleeping room. [*101:*26.3.4.5.1]

13.7.2.14.5.2 In other than existing buildings, the smoke alarms required by 13.7.2.14.5.1 shall be interconnected in accordance with 13.7.1.8.3. [*101:*26.3.4.5.2]

13.7.2.14.5.3 Existing battery-powered smoke alarms, rather than house electric-powered smoke alarms, shall be permitted where the facility has demonstrated to the AHJ that the testing, maintenance, and battery replacement programs will ensure reliability of power to the smoke alarms. [*101:*26.3.4.5.3]

Paragraph 13.7.2.14.5.1 requires the installation of a smoke alarm in each sleeping room. This requirement applies retroactively to existing lodging or rooming houses, as well as to new construction.

While 13.7.2.14.5.3 permits existing battery-powered smoke alarms to remain in place if approved by the AHJ, newly installed smoke alarms must be powered by the building electrical service or in accordance with the other options specified by *NFPA 72*. This requirement applies to both new and existing lodging or rooming houses in accordance with 13.7.1.8.7.

13.7.2.14.6 Carbon Monoxide Alarms and Carbon Monoxide Detection Systems.

13.7.2.14.6.1 Carbon monoxide alarms or carbon monoxide detectors in accordance with 13.7.1.14 and 13.7.2.14.6 shall be provided in new lodging or rooming houses where either of the following conditions exists:

(1) Lodging or rooming houses with communicating attached garages, unless otherwise exempted by 13.7.2.14.6.3
(2) Lodging or rooming houses containing fuel-burning appliances or fuel-burning fireplaces

[*101:*26.3.4.6.1]

13.7.2.14.6.2* Where required by 13.7.2.14.6.1, carbon monoxide alarms or carbon monoxide detectors shall be installed in the following locations:

(1) Outside of each separate sleeping area in the immediate vicinity of the sleeping rooms
(2) On every occupiable level, including basements, and excluding attics and crawl spaces

[*101:*26.3.4.6.2]

Δ **A.13.7.2.14.6.2** The placement requirements of NFPA 720 are modified to accommodate lodging or rooming house occupancies that are part of multiple occupancy buildings (e.g., an on-call physicians' sleeping room in a hospital). The placement requirements of NFPA 720 are modified specifically for lodging or rooming houses as required by this *Code* and do not affect other regulations within a jurisdiction. [*101:*A.26.3.4.6.2]

13.7.2.14.6.3 Carbon monoxide alarms and carbon monoxide detectors as specified in 13.7.2.14.6.1(1) shall not be required in the following locations:

(1) In garages
(2) Within lodging or rooming houses with communicating attached garages that are open parking structures as defined by the building code
(3) Within lodging or rooming houses with communicating attached garages that are mechanically ventilated in accordance with the mechanical code

[*101:*26.3.4.6.3]

The provisions of 13.7.2.14.6 mandate the installation of CO detectors or CO alarms in new lodging or rooming houses where the potential for accidental CO poisoning from a vehicle in an attached, communicating garage (i.e., a garage with an opening to the lodging or rooming house) or from fuel-burning appliances, such as a gas- or an oil-fired furnace or a fuel-burning fireplace, exists. The reference to 13.7.1.14 in 13.7.2.14.6.1 requires compliance with NFPA 720. NFPA 720, which is modeled after *NFPA 72,* contains the detailed installation requirements for CO alarms, including those for power supply. The required locations for CO alarms in dwellings are nearly identical to those for smoke alarms, except CO alarms are not required in sleeping rooms. Also, like smoke alarms, where more than one CO alarm is required in a lodging or rooming house, they must be interconnected so that, when one activates, all CO alarms in the lodging or rooming house sound their alarms.

Although not mandated in existing lodging or rooming houses, the installation of CO alarms is recommended if CO poisoning is a possibility. It is important to note the typical service life of a CO alarm varies from about 5 to 10 years. CO alarms must be replaced by the date indicated on the device to ensure proper operation. See the commentary following 13.7.1.14 for additional details.

13.7.2.15 New Hotels and Dormitories.

13.7.2.15.1 General. A fire alarm system in accordance with Section 13.7, except as modified by 13.7.2.15.2 through 13.7.2.15.6, shall be provided. [*101:*28.3.4.1]

13.7.2.15.2 Initiation. The required fire alarm system shall be initiated by each of the following:

(1) Manual means in accordance with 13.7.1.7
(2) Manual fire alarm box located at the hotel desk or other convenient central control point under continuous supervision by responsible employees

(3) Required automatic sprinkler system
(4) Required automatic detection system other than sleeping room smoke detectors

[***101:***28.3.4.2]

13.7.2.15.3 Notification.

13.7.2.15.3.1* Occupant notification shall be provided automatically in accordance with 13.7.1.9. [***101:***28.3.4.3.1]

A.13.7.2.15.3.1 Visible signaling appliances might be governed by provisions of federal regulations in 28 CFR 36, Appendix A, "Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities," Section 4.28, Alarms. [***101:***A.28.3.4.3.1]

13.7.2.15.3.2 Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***28.3.4.3.2]

13.7.2.15.3.3* Guest rooms and guest suites specifically required and equipped to accommodate hearing-impaired individuals shall be provided with a visible notification appliance. [***101:***28.3.4.3.3]

A.13.7.2.15.3.3 A quantity of such rooms and suites might be required to be equipped to accommodate hearing-impaired individuals based on the total number of rooms in a transient lodging facility. *(See 28 CFR 36, Appendix A, "Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities.")* [***101:***A.28.3.4.3.3]

13.7.2.15.3.4 In occupiable areas, other than guest rooms and guest suites, visible notification appliances shall be provided. [***101:***28.3.4.3.4]

13.7.2.15.3.5 Annunciation and annunciation zoning in accordance with 13.7.1.13 shall be provided in buildings three or more stories in height or having more than 50 guest rooms or guest suites. Annunciation shall be provided at a location readily accessible from the primary point of entry for emergency response personnel. [***101:***28.3.4.3.5]

13.7.2.15.3.6 Emergency forces notification shall be provided in accordance with 13.7.1.10. [***101:***28.3.4.3.6]

13.7.2.15.4 Detection. A corridor smoke detection system in accordance with Section 13.7 shall be provided in buildings other than those protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.7.2.15. [***101:***28.3.4.5]

13.7.2.15.5* Smoke Alarms. Smoke alarms shall be installed in accordance with 13.7.1.8 in every guest room and every living area and sleeping room within a guest suite. [***101:***28.3.4.6]

A.13.7.2.15.5 Caution needs to be exercised in locating smoke alarms with regard to their proximity to bathrooms, cooking facilities, and HVAC outlets in order to prevent nuisance alarms. [***101:***A.28.3.4.5]

13.7.2.15.6 Carbon Monoxide Alarms and Carbon Monoxide Detection Systems.

13.7.2.15.6.1 Carbon monoxide alarms or carbon monoxide detectors in accordance with 13.7.1.14 and 13.7.2.15.6 shall be provided in new hotels and dormitories where either of the following conditions exists:

(1) Guest rooms or guest suites with communicating attached garages, unless otherwise exempted by 13.7.2.15.6.3
(2) Guest rooms or guest suites containing a permanently installed fuel-burning appliance or fuel-burning fireplace

[***101:***28.3.4.7.1]

13.7.2.15.6.2 Where required by 13.7.2.15.6.1, carbon monoxide alarms or carbon monoxide detectors shall be installed in the following locations:

(1) Outside of each separate guest room or guest suite sleeping area in the immediate vicinity of the sleeping rooms
(2) On every occupiable level of a guest room and guest suite

[***101:***28.3.4.7.2]

Δ **13.7.2.15.6.3** Carbon monoxide alarms and carbon monoxide detectors as specified in 13.7.2.15.6.1(1) shall not be required in the following locations:

(1) In garages
(2) Within guest rooms or guest suites with communicating attached garages that are open parking structures as defined by the building code
(3) Within guest rooms or guest suites with communicating attached garages that are mechanically ventilated in accordance with the mechanical code

[***101:***28.3.4.7.3]

Δ **13.7.2.15.6.4** Where fuel-burning appliances or fuel-burning fireplaces are installed outside guest rooms or guest suites, carbon monoxide detectors shall be installed in accordance with the manufacturer's published instructions in the locations specified as follows:

(1) On the ceilings of rooms containing permanently installed fuel-burning appliances or fuel-burning fireplaces
(2) Centrally located within occupiable spaces served by the first supply air register from a permanently installed, fuel-burning HVAC system
(3) Centrally located within occupiable spaces adjacent to a communicating attached garage

[***101:***28.3.4.7.4]

The provisions of 13.7.2.15.6 mandate the installation of CO detectors or CO alarms in new hotels and dormitories where the potential for accidental CO poisoning from a vehicle in an attached, communicating garage (i.e., a garage with an opening directly to the hotel or dormitory occupancy) or from fuel-burning appliances, such as a gas- or an oil-fired furnace or a fuel-burning fireplace, exists. The reference to 13.7.1.14 in 13.7.2.15.6.1 requires compliance with NFPA 720. NFPA 720, which is modeled after *NFPA 72,* contains the detailed installation requirements for CO alarms, including those for power supply. Like smoke alarms, where more than one CO alarm is required in a hotel or dormitory, they must be interconnected so that, when one activates, all CO alarms in the hotel or dormitory sound their alarms.

Although not mandated in existing hotels and dormitories, the installation of CO alarms is recommended if there is a potential for CO poisoning. It is important to note that the typical service life of a CO alarm varies from about 5 to 10 years. CO alarms must be replaced by the date indicated on the device to ensure proper operation. See the commentary following 13.7.1.14 for additional details.

N **13.7.2.15.6.5** Where carbon monoxide detectors are installed in accordance with 13.7.2.15.6.4(1), the alarm signal shall be automatically transmitted to an approved on-site location or to an off-premises location in accordance with NFPA 720. [***101:***28.3.4.7.5]

N **13.7.2.15.7 Risk Analysis for Mass Notification.**

N **13.7.2.15.7.1** A risk analysis in accordance with 13.7.1.15 shall be performed for grade K through 12, college, or university dormitories with an occupant load greater than 100 to determine if a mass notification system is required. [***101:***28.3.4.4.1]

N **13.7.2.15.7.2** Applicable portions of an existing risk analysis shall be permitted to be used when a new building is added to the campus. [***101:***28.3.4.4.2]

13.7.2.16 Existing Hotels and Dormitories.

13.7.2.16.1 General. A fire alarm system in accordance with Section 13.7, except as modified by 13.7.2.16.2 through 13.7.2.16.3.5, shall be provided in buildings, other than those where each guest room has exterior exit access in accordance with 14.10.3 and the building is three or fewer stories in height. [***101:***29.3.4.1]

13.7.2.16.2 Initiation. The required fire alarm system shall be initiated by each of the following:

(1) Manual means in accordance with 13.7.1.7, unless there are other effective means to activate the fire alarm system, such as complete automatic sprinkler or automatic detection systems, with manual fire alarm box in accordance with 13.7.2.16.2(2) required
(2) Manual fire alarm box located at the hotel desk or other convenient central control point under continuous supervision by responsible employees
(3) Required automatic sprinkler system
(4) Required automatic detection system other than sleeping room smoke detectors

[***101:***29.3.4.2]

13.7.2.16.3 Notification.

13.7.2.16.3.1 Occupant notification shall be provided automatically in accordance with 13.7.1.9. [***101:***29.3.4.3.1]

13.7.2.16.3.2 Positive alarm sequence in accordance with 13.7.1.9.4, and a presignal system in accordance with 13.7.1.9.3, shall be permitted. [***101:***29.3.4.3.2]

13.7.2.16.3.3 Reserved.

13.7.2.16.3.4 Reserved.

13.7.2.16.3.5 Reserved.

13.7.2.16.3.6* Where the existing fire alarm system does not provide for automatic emergency forces notification in accordance with 13.7.1.10, provisions shall be made for the immediate notification of the public fire department by telephone or other means in case of fire, and, where there is no public fire department, notification shall be made to the private fire brigade. [***101:***29.3.4.3.6]

A.13.7.2.16.3.6 The provision for immediate notification of the public fire department is intended to include, but is not limited to, all of the arrangements in 13.7.1.10.2. Other arrangements that depend on a clerk or other member of the staff to notify the fire department might also be permitted. In such cases, however, it is essential that a trained staff member and an immediately available means of calling the fire department are continuously available. If a telephone is to be used, it should not be of any type or arrangement that requires a coin or the unlocking of a device to contact the fire department. [***101:***A.29.3.4.3.6]

13.7.2.16.3.7 Where a new fire alarm system is installed or the existing fire alarm system is replaced, emergency forces notification shall be provided in accordance with 13.7.1.10. [***101:***29.3.4.3.7]

13.7.2.16.4 Detection. (Reserved)

13.7.2.16.5* Smoke Alarms. An approved single-station smoke alarm shall be installed in accordance with 13.7.1.8 in every guest room and every living area and sleeping room within a guest suite. [***101:***29.3.4.5]

A.13.7.2.16.5 Caution needs to be exercised in locating smoke alarms with regard to their proximity to bathrooms, cooking facilities, and HVAC outlets in order to prevent nuisance alarms. [***101***:A.29.3.4.5]

13.7.2.16.5.1 The smoke alarms shall not be required to be interconnected. [***101:***29.3.4.5.1]

13.7.2.16.5.2 Single-station smoke alarms without a secondary (standby) power source shall be permitted. [***101:***29.3.4.5.2]

13.7.2.17 New Apartment Buildings.

13.7.2.17.1 General.

13.7.2.17.1.1 New apartment buildings four or more stories in height or with more than 11 dwelling units, other than those meeting the requirements of 13.7.2.17.1.2, shall be provided with a fire alarm system in accordance with Section 13.7, except as modified by 13.7.2.17.2 through 13.7.2.17.5. [***101:***30.3.4.1.1]

13.7.2.17.1.2 A fire alarm system shall not be required in buildings where each dwelling unit is separated from other contiguous dwelling units by fire barriers *(see Section 12.7)* having a minimum 1-hour fire resistance rating, and where each dwelling unit has either its own independent exit or its own independent stairway or ramp discharging at the finished ground level. [***101:***30.3.4.1.2]

The intent of 13.7.2.17.1.2 is to exempt townhouse-type apartment buildings from the requirement for a fire alarm system, because, during a fire, each apartment unit retains safe egress routes for longer than is typical of apartment buildings with interior exit access corridors. The safe egress route helps to ensure that any delay in occupant notification resulting from the absence of an alarm system can be tolerated without undue risk.

13.7.2.17.2 Initiation.

13.7.2.17.2.1 Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7, unless the building complies with 13.7.2.17.2.2. [***101:***30.3.4.2.1]

13.7.2.17.2.2 Initiation of the required fire alarm system by manual means shall not be required in buildings four or fewer stories in height, containing not more than 16 dwelling units, and protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 13.3.2.17. [***101:***30.3.4.2.2]

13.7.2.17.2.3 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 13.3.2.17, required fire alarm systems shall be initiated upon operation of the automatic sprinkler system. [***101:***30.3.4.2.3]

13.7.2.17.3 Notification.

13.7.2.17.3.1 Occupant notification shall be provided automatically in accordance with Section 13.7, and both of the following shall also apply:

(1) Visible signals shall be installed in units designed for the hearing impaired.
(2) Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted.

[***101:***30.3.4.3.1]

13.7.2.17.3.2 Annunciation, and annunciation zoning, in accordance with 13.7.1.13 shall be provided, unless the building complies with either 13.7.2.17.3.3 or 13.7.2.17.3.4. Annunciation shall be provided at a location readily accessible from the primary point of entry for emergency response personnel. [***101:***30.3.4.3.2]

13.7.2.17.3.3 Annunciation, and annunciation zoning, shall not be required in buildings two or fewer stories in height and having not more than 50 dwelling units. [***101:***30.3.4.3.3]

13.7.2.17.3.4 Annunciation, and annunciation zoning, shall not be required in buildings four or fewer stories in height containing not more than 16 dwelling units and protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 13.3.2.17. [***101:***30.3.4.3.4]

13.7.2.17.3.5 Emergency forces notification shall be accomplished in accordance with 13.7.1.10. [***101:***30.3.4.3.5]

13.7.2.17.4 Detection. (Reserved)

13.7.2.17.5* Smoke Alarms. Smoke alarms shall be installed in accordance with 13.7.1.8 in every sleeping area, outside every sleeping area in the immediate vicinity of the bedrooms, and on all levels of the dwelling unit, including basements. [***101:***30.3.4.5]

A.13.7.2.17.5 Previous editions of NFPA *101* permitted the single-station smoke alarm required by 13.7.2.17.5 to be omitted from each apartment where a complete automatic smoke detection system was installed throughout the building. With such a system, when one detector is activated, an alarm is sounded throughout the building. Experience with complete smoke detection systems in apartment buildings has shown that numerous nuisance alarms are likely to occur. Where there is a problem with frequent nuisance alarms, occupants ignore the alarm, or the system is either disconnected or otherwise rendered inoperative. [***101:***A.30.3.4.5]

The smoke alarm(s) required by 13.7.2.17.5 should be located in the hall area(s) that provides access to rooms used for sleeping. In multilevel apartment units, the smoke alarm covering the upper level should normally be located at the top of the stairs. The smoke alarm(s) should be mounted on the ceiling or on the wall; *NFPA 72* provides detailed smoke alarm placement requirements. Smoke alarms should be remotely located from cooking areas. Where unusual factors such as room configuration, air movement, or stagnant air pockets must be considered, the AHJ and the designer should determine the placement of the smoke alarms.

In addition to requiring smoke alarms outside of sleeping rooms, the *Code* requires all new apartment buildings to be provided with smoke alarms within sleeping rooms as well, regardless of sprinkler protection. Note that 13.7.1.8.7 requires smoke alarms to be powered as required by *NFPA 72*; *NFPA 72* requires smoke alarms to be powered by the building's electrical system, which is achieved by using directly wired or plug-in-type smoke alarms. Alternatively, smoke alarms are permitted to be powered by a nonrechargeable, nonreplaceable battery capable of operating the device for 10 years under normal conditions, followed by 4 minutes of alarm, followed by 7 days of trouble alarm.

It is not the *Code's* intent to prohibit the interconnection of smoke alarms within individual apartments. Where an apartment unit requires more than one smoke alarm, interconnection will probably be required to meet the performance criterion for audibility detailed in 13.7.1.8.8.

13.7.2.17.6 Carbon Monoxide Alarms and Carbon Monoxide Detection Systems.

13.7.2.17.6.1 Carbon monoxide alarms or carbon monoxide detectors in accordance with 13.7.1.14 and 13.7.2.17.6 shall be provided in new apartment buildings where either of the following conditions exists:

(1) Dwelling units with communicating attached garages, unless otherwise exempted by 13.7.2.17.6.3
(2) Dwelling units containing a permanently installed fuel-burning appliance or fuel-burning fireplace

[***101:***30.3.4.6.1]

13.7.2.17.6.2 Where required by 13.7.2.17.6.1, carbon monoxide alarms or carbon monoxide detectors shall be installed in the following locations:

(1) Outside of each separate dwelling unit sleeping area in the immediate vicinity of the sleeping rooms
(2) On every occupiable level of a dwelling unit

[***101:***30.3.4.6.2]

Δ **13.7.2.17.6.3** Carbon monoxide alarms and carbon monoxide detectors as specified in 13.7.2.17.6.1(1) shall not be required in the following locations:

(1) In garages
(2) Within dwelling units with communicating attached garages that are open parking structures as defined by the building code
(3) Within dwelling units with communicating attached garages that are mechanically ventilated in accordance with the mechanical code

[***101:***30.3.4.6.3]

Δ **13.7.2.17.6.4*** Where fuel-burning appliances or fuel-burning fireplaces are installed outside dwelling units, carbon monoxide detectors shall be installed in accordance with the manufacturer's published instructions in the locations specified as follows:

(1) On the ceilings of rooms containing permanently installed fuel-burning appliances or fuel-burning fireplaces
(2) Centrally located position within occupiable spaces served by the first supply air register from a permanently installed, fuel-burning HVAC system
(3) Centrally located position within occupiable spaces adjacent to a communicating attached garage

[***101:***30.3.4.6.4]

N **A.13.7.2.17.6.4** Where fuel-burning appliances or fuel-burning fireplaces are located outside but attached to the dwelling unit, the area or room containing the fuel-burning appliance or fuel-burning fireplace could be considered part of the attached dwelling unit(s). In this application, either carbon monoxide alarms or carbon monoxide detectors are permitted to be installed in the attached dwelling unit(s) in accordance with 30.3.4.4. [***101:***A.30.3.4.6.4]

N **13.7.2.17.6.5** Where carbon monoxide detectors are installed in accordance with 13.7.2.17.6.4(1), the alarm signal shall be automatically transmitted to an approved on-site location or to an off-premises location in accordance with NFPA 720. [***101:***30.3.4.6.5]

The provisions of 13.7.2.17.6 mandate the installation of CO detectors or CO alarms in new apartment buildings where there is a potential for accidental CO poisoning from a vehicle in an attached, communicating garage or from fuel-burning appliances, such as a gas-fired or an oil-fired furnace or a fuel-burning fireplace. The reference to 13.7.1.14 in 13.7.2.17.6.1 requires compliance with NFPA 720. NFPA 720, which is modeled after *NFPA 72*, contains the detailed installation requirements for CO alarms, including those for power supply. Like smoke alarms, where more than one CO alarm is required in an apartment, they must be interconnected so that when one activates, all CO alarms in the apartment sound their alarms.

The provision of 13.7.2.17.6.5, which is new to the 2018 edition of the *Code*, requires CO detectors in rooms containing fuel-fired heating equipment, which are not normally occupied, to transmit their alarms to a location in the building approved by the AHJ or to an off-site location, such as an alarm monitoring company. This provision is intended to ensure that responsible building personnel will be promptly notified of a dangerous accumulation of CO in a space in which a local alarm might sound unheard for an extended period of time.

Although not mandated in existing apartment buildings, the installation of CO alarms is recommended if there is a potential for CO poisoning. It is important to note that the typical service life of a CO alarm varies from about 5 to 10 years. CO alarms must be replaced by the date indicated on the device to ensure proper operation. See the commentary following 13.7.1.14 for additional details.

13.7.2.18 Existing Apartment Buildings.

13.7.2.18.1 General.

13.7.2.18.1.1 Existing apartment buildings four or more stories in height or with more than 11 dwelling units, other than those meeting the requirements of 13.7.2.18.1.2, shall be provided with a fire alarm system in accordance with Section 13.7, except as modified by 13.7.2.18.1.2 through 13.7.2.18.5. [***101:***31.3.4.1.1]

13.7.2.18.1.2 A fire alarm system shall not be required where each dwelling unit is separated from other contiguous dwelling units by fire barriers *(see Section 12.7)* having a minimum ½-hour fire resistance rating, and where each dwelling unit has either its own independent exit or its own independent stairway or ramp discharging at the finished ground level. [***101:***31.3.4.1.2]

The intent of 13.7.2.18.1.2 is to exempt townhouse-type apartment buildings from the requirement for a fire alarm system, because, during a fire, each apartment unit retains safe egress routes for longer than is typical of apartment buildings with interior exit access corridors. The safe egress route helps to ensure that any delay in occupant notification resulting from the absence of an alarm system can be tolerated without undue risk.

See the commentary following 13.7.2.17.1.2.

13.7.2.18.2 Initiation.

13.7.2.18.2.1 Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7, unless the building complies with 13.7.2.18.2.2. [***101:***31.3.4.2.1]

13.7.2.18.2.2 Initiation of the required fire alarm system by manual means shall not be required in buildings four or fewer stories in height, containing not more than 16 dwelling units, and protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 13.7.2.18. [***101:***31.3.4.2.2]

13.7.2.18.2.3 In buildings using Option 2 as defined by NFPA *101*, the required fire alarm system shall be initiated by the automatic fire detection system in addition to the manual initiation means of 13.7.2.18.2.1. [***101:***31.3.4.2.3]

13.7.2.18.2.4 In buildings using Option 3 as defined by NFPA *101*, the required fire alarm system shall be initiated upon operation of the automatic sprinkler system in addition to the manual initiation means of 13.7.2.18.2.1. [***101:***31.3.4.2.4]

13.7.2.18.2.5 In buildings using Option 4 as defined by NFPA *101*, the required fire alarm system shall be initiated upon operation of the automatic sprinkler system in addition to the manual initiation means of 13.7.2.18.2.1. [*101:*31.3.4.2.5]

13.7.2.18.3 Notification.

13.7.2.18.3.1 Occupant notification shall be provided automatically in accordance with Section 13.7, and all of the following shall also apply:

(1) Visible signals shall be installed in units designed for the hearing impaired.
(2) Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted.
(3) Existing approved presignal systems shall be permitted in accordance with 13.7.1.9.3.

[*101:*31.3.4.3.1]

13.7.2.18.3.2 An annunciator panel, whose location shall be approved by the AHJ, connected with the required fire alarm system shall be provided, unless the building meets the requirements of 13.7.2.18.3.3 or 13.7.2.18.3.4. [*101:*31.3.4.3.2]

13.7.2.18.3.3 Annunciation shall not be required in buildings two or fewer stories in height and having not more than 50 rooms. [*101:*31.3.4.3.3]

13.7.2.18.3.4 Annunciation shall not be required in buildings four or fewer stories in height containing not more than 16 dwelling units and protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 13.3.2.18. [*101:*31.3.4.3.4]

13.7.2.18.3.5 Emergency forces notification shall be accomplished in accordance with 13.7.1.10. [*101:*31.3.4.3.5]

If a fire alarm system is required in an apartment building, then it must provide notification to the fire department using one of the four methods described in 13.7.1.10.2 (i.e., auxiliary fire alarm system, central station fire alarm system, proprietary supervising station fire alarm system, or remote supervising station fire alarm system). This requirement, which first appeared in the 2003 edition of the *Code*, applies to both new and existing apartment buildings.

Note that 13.7.1.10.3 recognizes that some existing fire alarm systems are not readily adaptable to provide automatic fire department notification. In such cases, the AHJ can approve an alternative plan to ensure a prompt fire department response. With the proliferation of personal cellular phones in recent years, the AHJ might consider approving the installation of signs located at the manual fire alarm boxes that read "Local Alarm Only — In Case of Fire, Call 911," or similar wording, in lieu of requiring automatic notification. In all cases, where a supervised automatic sprinkler system is required by the *Code*, a sprinkler waterflow condition must automatically provide alarm notification to the fire department (see 13.3.1.8.2).

13.7.2.18.4 Detection.

13.7.2.18.4.1* In buildings using Option 2 as defined by NFPA *101*, a complete automatic fire detection system in accordance with 9.6.2.9 of NFPA *101* and 13.7.2.18.4.2 shall be required. [*101:*31.3.4.4.1]

A.13.7.2.18.4.1 It is intended that a building compliant with Option 2[, as defined in Chapter 31 of NFPA *101*,] function as described in the paragraph that follows. [*101:*A.31.3.4.4.1]

Occupants within a living unit become aware of a fire emergency, either through personal awareness or through being alerted by the smoke alarm(s) installed within the living unit. Other building occupants are alerted to the fire emergency by the building fire alarm system that is initiated by manual fire alarm boxes adjacent to the exits, heat detection within the living unit where the fire emergency exists, smoke detection in the common areas outside the living unit, or a combination thereof. The installation of system heat detectors versus smoke detectors within the living unit is intended to eliminate nuisance-type alarms and reduce occupant complacency from frequent false alarms. The installation of smoke detection within the living unit should only be contemplated after a careful analysis of the goals and with the approval of the AHJ. [*101:*A.31.3.4.4.1]

13.7.2.18.4.2 Automatic fire detection devices shall be installed as follows:

(1) Smoke detectors shall be installed in all common areas and work spaces outside the living unit, such as exit stairs, egress corridors, lobbies, storage rooms, equipment rooms, and other tenantless spaces in environments that are suitable for proper smoke detector operation.
(2) Heat detectors shall be located within each room of the living unit.

[*101:*31.3.4.4.2]

13.7.2.18.5 Smoke Alarms.

13.7.2.18.5.1* In buildings other than those equipped throughout with an existing, complete automatic smoke detection system, smoke alarms shall be installed in accordance with 13.7.1.8, as modified by 13.7.2.18.5.2, outside every sleeping area in the immediate vicinity of the bedrooms and on all levels of the dwelling unit, including basements. [*101:*31.3.4.5.1]

Δ **A.13.7.2.18.5.1** NFPA *101* provides adequate, balanced fire protection and takes into consideration the passive and active systems required in a given occupancy. The level of protection prescribed by *NFPA 72* which includes smoke alarms in all sleeping rooms, without exception, does not necessarily take into consideration the complete protection package mandated by NFPA *101*. [*101:*A.31.3.4.5.1]

13.7.2.18.5.2 Smoke alarms required by 13.7.2.18.5.1 shall not be required to be provided with a secondary (standby) power source. [*101:*31.3.4.5.2]

13.7.2.18.5.3 In buildings other than those equipped throughout with an existing, complete automatic smoke detection system or a complete, supervised automatic sprinkler system in accordance with 13.3.2.18, smoke alarms shall be installed in every sleeping area in accordance with 13.7.1.8, as modified by 13.7.2.18.5.4. [*101:*31.3.4.5.3]

13.7.2.18.5.4 Smoke alarms required by 13.7.2.18.5.3 shall be permitted to be battery powered. [***101:***31.3.4.5.4]

NFPA *101* provides four options that specify the varying degrees to which an existing apartment building is protected by fire detection or suppression systems. Life safety requirements are predicated on the option with which the existing building complies. The four options prescribed by NFPA *101* are as follows:

Option 1: No automatic sprinkler or fire detection system
Option 2: Complete fire detection system
Option 3: Partial automatic sprinkler system
Option 4: Complete automatic sprinkler system

Existing apartment buildings using Option 2 are protected throughout by a fire detection system (see 13.7.2.18.4.1). The increased travel distance permitted in an Option 2 apartment building (see 31.2.6.1 and 31.2.6.2 of NFPA *101*) is based on early occupant notification of fire. Therefore, the detectors must initiate the alarm system in addition to the initiation provided by manual fire alarm boxes.

Sprinkler systems protect the corridors of existing apartment buildings using Option 3 (see 13.3.2.18.5). The activation of the sprinkler system must initiate the alarm system in addition to the initiation provided by manual fire alarm boxes.

Existing apartment buildings using Option 4 are protected throughout by automatic sprinkler systems (see 13.3.2.18.6). The activation of the sprinkler system must initiate the alarm system in addition to the initiation provided by manual fire alarm boxes.

In existing apartment buildings using Option 2, a total automatic fire detection system is required and must be interconnected with the building fire alarm system in accordance with 13.7.2.18.2.3. This system is required in addition to the smoke alarms required by 13.7.2.18.5. Note that 13.7.2.18.4 does not require the fire detection system to consist solely of smoke detectors but, instead, permits the use of heat or smoke detectors or a combination of the two. Heat detectors are permitted by 13.7.2.18.4 within apartments, because they are used as part of a system that is separate from the smoke alarms addressed in 13.7.2.18.5. The smoke alarms will alert occupants within an apartment of a fire originating within that unit. When an occupant leaves the apartment, the door closes and latches behind the occupant, and the occupant pulls a manual fire alarm box. If the occupant fails to sound the alarm manually and the fire continues to develop in the apartment, the heat detectors will initiate the building fire alarm system prior to the fire becoming a threat to other apartment units. Fire detection systems have proved very effective where used. In addition, because the system is required to be tied into the building fire alarm system, the use of heat detectors instead of system smoke detectors eliminates nuisance alarms that might be caused by cooking or smoking.

The smoke alarm(s) required by 13.7.2.18.5 should be located in the hall area(s) that provides access to rooms used for sleeping. In multilevel apartment units, the smoke alarm covering the upper level should normally be located at the top of the stairs. The smoke alarm(s) should be mounted on the ceiling or on the wall; *NFPA 72* provides detailed smoke alarm placement requirements. Smoke alarms should be remotely located from cooking areas. Where unusual factors such as room configuration, air movement, or stagnant air pockets must be considered, the AHJ and the designer should determine the placement of the smoke alarms.

In existing apartment buildings, sleeping room smoke alarms are required where the building is not protected by a complete smoke detection or automatic sprinkler system. Because this retroactive requirement for smoke alarms in existing apartment building sleeping rooms would likely cause a hardship if they were required to be powered by the building electrical system, 13.7.2.18.5.4 permits the sleeping room smoke alarms to be powered only by replaceable batteries. The smoke alarms outside of the sleeping rooms must be powered as required by *NFPA 72.*

Note that 13.7.1.8.7 requires smoke alarms to be powered as required by *NFPA 72*. *NFPA 72* requires smoke alarms to be powered by the building's electrical system, which is achieved by using directly wired or plug-in-type smoke alarms. Alternatively, smoke alarms are permitted to be powered by a nonrechargeable, nonreplaceable battery capable of operating the device for 10 years under normal conditions, followed by 4 minutes of alarm, followed by 7 days of trouble condition.

It is not the *Code*'s intent to prohibit the interconnection of smoke alarms within individual apartments. Where an apartment unit requires more than one smoke alarm, interconnection will probably be required to meet the performance criterion for audibility detailed in 13.7.1.8.8.

13.7.2.19 New, Small (Not More Than 16 Residents) Residential Board and Care Occupancies.

N **13.7.2.19.1 General.** A fire alarm system shall be provided in accordance with Section 13.7. [***101:***32.2.3.4.1]

N **13.7.2.19.2 Initiation.** Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7.1(1). [***101:***32.2.3.4.2]

13.7.2.19.3 General. A manual fire alarm system shall be provided in accordance with Section 13.7. [***101:***32.2.3.4.1]

13.7.2.19.4 Occupant Notification. Occupant notification shall be provided automatically, without delay, in accordance with 13.7.1.9. [***101:***32.2.3.4.2]

13.7.2.19.5 Smoke Alarms.

13.7.2.19.5.1 Approved smoke alarms shall be provided in accordance with 13.7.1.8. [***101:***32.2.3.4.5.1]

13.7.2.19.5.2 Smoke alarms shall be installed on all levels, including basements but excluding crawl spaces and unfinished attics. [***101:***32.2.3.4.5.2]

13.7.2.19.5.3 Additional smoke alarms shall be installed in all living areas, as defined in 3.3.21.5 of NFPA *101*. [***101:***32.2.3.4.5.3]

13.7.2.19.5.4 Each sleeping room shall be provided with an approved smoke alarm in accordance with 13.7.1.8. [***101:***32.2.3.4.5.4]

In both new and existing small board and care facilities, a means of manually initiating the fire alarm system is required. However, 13.7.2.21.1 contains two options for existing facilities. The use of a system of interconnected multiple-station smoke alarms is permitted by 13.7.2.21.1.1 to meet the fire alarm requirement by providing one manual fire alarm box that is integrated with the smoke alarms on each floor. In addition, 13.7.2.21.1.2 recognizes that, in a small existing building, a sophisticated fire alarm system that employs components listed for use in fire alarm systems might not be necessary. The requirements can be satisfied by the installation of alternative means of notifying the occupants, such as electric bells activated by a clearly identified switch on each floor where approved by the AHJ.

The requirement of 13.7.2.19.5.1 does not mandate a system of smoke detectors in a small facility. If the building is small enough, single-station smoke alarms might meet the criterion of audibility in all sleeping areas. However, if the building is of significant size or consists of multiple levels, interconnected multiple-station smoke alarms will probably be needed. Additional smoke alarms are required in living rooms and day rooms.

Prior to the 2003 edition of the *Code*, several provisions permitted the omission of smoke alarms from small board and care facilities. However, given the wider acceptance of unprotected vertical openings permitted by 32.2.3.1 of NFPA *101*, the smoke alarm exemptions are no longer permitted for new facilities. Several conditions for exempting smoke alarms from existing small board and care facilities, however, are provided. To exempt the requirement for common space smoke alarms, as permitted by 13.7.2.21.4.6 and 13.7.2.21.4.7, the entire building must be protected with an automatic sprinkler system using quick-response or residential sprinklers in accordance with 13.3.2.22.2, and the bedrooms must be provided with smoke alarms. If the existing smoke alarms in the bedrooms are powered solely by batteries, they do not need to be replaced with electrically powered smoke alarms if the AHJ judges that the facility has an adequate testing, maintenance, and battery replacement program.

13.7.2.20 New, Large (More than 16 Residents) Residential Board and Care Occupancies.

13.7.2.20.1 General. A fire alarm system shall be provided in accordance with Section 13.7. [***101:***32.3.3.4.1]
