13.7.2.20.2 Initiation. The required fire alarm system shall be initiated by each of the following:

(1) Manual means in accordance with 13.7.1.7
(2) Manual fire alarm box located at a convenient central control point under continuous supervision of responsible employees
(3) Required automatic sprinkler system
(4) Required detection system

[***101:***32.3.3.4.2]

13.7.2.20.3 Annunciator Panel. An annunciator panel, connected to the fire alarm system, shall be provided at a location readily accessible from the primary point of entry for emergency response personnel. [***101:***32.3.3.4.3]

13.7.2.20.4 Occupant Notification. Occupant notification shall be provided automatically, without delay, in accordance with 13.7.1.9. [***101:***32.3.3.4.4]

13.7.2.20.5 High-Rise Buildings. High-rise buildings shall be provided with an approved emergency voice communication/alarm system in accordance with 13.7.2.29.2. [***101:***32.3.3.4.5]

13.7.2.20.6* Emergency Forces Notification. Emergency forces notification shall meet the following requirements:

(1) Emergency forces notification shall be accomplished in accordance with 13.7.1.10.
(2) Smoke detection devices or smoke detection systems shall be permitted to initiate a positive alarm sequence in accordance with 13.7.1.9.4 for not more than 120 seconds.

[***101:***32.3.3.4.6]

A.13.7.2.20.6 Positive alarm sequence applies only to emergency forces notification. Occupant notification is required to occur immediately upon activation of the detection device or system. [***101:***A.32.3.3.4.6]

13.7.2.20.7 Smoke Alarms. Approved smoke alarms shall be installed in accordance with 13.7.1.8 inside every sleeping room, outside every sleeping area in the immediate vicinity of the bedrooms, and on all levels within a resident unit. [***101:***32.3.3.4.7]

13.7.2.20.8 Smoke Detection Systems.

13.7.2.20.8.1 Corridors and spaces open to the corridors, other than those meeting the requirement of 13.7.2.20.8.3, shall be provided with smoke detectors that comply with *NFPA 72* and are arranged to initiate an alarm that is audible in all sleeping areas. [***101:***32.3.3.4.8.1]

13.7.2.20.8.2 Reserved.

13.7.2.20.8.3 Smoke detection systems shall not be required in unenclosed corridors, passageways, balconies, colonnades, or other arrangements with one or more sides along the long dimension fully or extensively open to the exterior at all times. [***101:***32.3.3.4.8.3]

In addition to the normal distribution of manual fire alarm boxes (see 13.7.1.7), 13.7.2.20.2 and 13.7.2.22.2 require certain locations, such as that of the telephone operator, to be equipped with a manual fire alarm box. The intent is that a manual fire alarm box is to be available at the location where a report of an emergency phoned in by residents or staff would be received.

Sleeping room smoke alarms are exempt from activating the building fire alarm system. The detection devices installed in the sleeping rooms are usually single-station or multiple-station smoke alarms and are not part of a required automatic detection system. Therefore, such smoke alarms are intended to notify the occupants of the room of a smoke condition. The provision of 13.7.2.22.2(4) emphasizes this intent. The *Code*, in fact, prohibits sleeping room smoke alarms from activating the fire alarm system, as stated in 13.7.1.8.9, to prevent numerous nuisance alarms, which could pose a particular problem in large board and care facilities. Because the purpose of the sleeping room smoke alarms is to warn the occupants of an individual room, notification of the management and other occupants is the occupants' responsibility. Therefore, manual alarm initiation should be emphasized in the required training for residents. See 20.5.2.2 for resident training requirements.

The location of audible alarm notification devices in residential board and care facilities affects their audibility. In most new construction, corridor walls are of such sound-insulating character that a sounding device would be needed in each room to meet the performance criterion for alarm audibility throughout the building. If sounding devices are installed only in the corridor, they might have to operate at dangerous sound levels to awaken residents in their rooms.

New large board and care facilities must be provided with means to automatically notify the fire department of an alarm condition (see 13.7.1.10) per 13.7.2.20.6. In existing facilities, automatic emergency forces notification is not required by 13.7.2.22.6 unless a new system is installed or the existing system is replaced; at a minimum, however, means must be provided for staff to call the fire department. If a telephone is provided, the telephone must be equipped for direct outside dialing without going through a switchboard; the telephone is not permitted to be a pay phone.

The purpose of placing smoke alarms in each sleeping room, as required by 13.7.2.20.7 and 13.7.2.22.7, is to alert the occupants of a room to the presence of smoke within that room. The alarms are not permitted to be connected to the building fire alarm system, as previously discussed. When an occupant leaves a room, the door automatically closes behind the occupant, and the occupant is expected to pull a manual fire alarm box. If the occupant fails to sound the alarm manually, compensation is provided by corridor smoke detectors or by automatic sprinklers. See 13.7.2.20.8.1, 13.7.2.22.8.1, 13.3.2.21.1, and 13.3.2.22.1.

In existing board and care facilities, 13.7.2.22.7.2 applies only to existing battery-powered alarms — not to newly installed alarms in existing facilities. Battery-powered alarms are permitted only if they already exist and the facility can document that they are properly maintained and tested to ensure their reliability.

The provision of 13.7.2.22.7.3 recognizes that the installation of corridor smoke detection systems, rather than sleeping room smoke alarms, was a *Code* requirement in earlier editions. Note that the installation of a new corridor smoke detection system does not waive the need for single-station smoke alarms in each room. However, if an existing facility already has a corridor smoke detection system, single-station smoke alarms in bedrooms are not required.

New large board and care facilities must be provided with a corridor smoke detection system in accordance with 13.7.2.20.8.1. In existing facilities, 13.7.2.22.8 requires a system of smoke detectors in the corridors and living areas where the facilities are not fully sprinklered. Note that 13.7.2.22.8.2 does not exempt the requirement of 13.7.2.22.7 for the provision of smoke alarms in each sleeping room even when automatic sprinklers are installed. The *Code* is not equating sprinklers with smoke detectors but establishes that a fully sprinklered existing building is an adequate alternative to smoke detection in common spaces. If the facility uses exterior access corridors in the motel style, smoke detection is not required in the exterior corridors in accordance with 13.7.2.20.8.3 and 13.7.2.22.8.3.

N **13.7.2.20.9 Carbon Monoxide Alarms and Carbon Monoxide Detection Systems.**

N **13.7.2.20.9.1** Carbon monoxide alarms or carbon monoxide detectors in accordance with 13.7.1.14 and 13.7.2.20.9 shall be provided in new large board and care facilities where either of the following conditions exists:

(1) Where large board and care facilities have communicating attached garages, unless otherwise exempted by 13.7.2.20.9.3
(2) Where sleeping rooms or sleeping room suites contain fuel-burning appliances or fuel-burning fireplaces

[***101:***32.3.3.4.9.1]

N **13.7.2.20.9.2** Where required by 13.7.20.9.1, carbon monoxide alarms or carbon monoxide detectors shall be installed in the following locations:

(1) Outside each separate sleeping room area in the immediate vicinity of the sleeping rooms
(2) Within sleeping rooms containing fuel-burning appliances or fuel-burning fireplaces
(3) On every occupiable level of a sleeping room and sleeping room suite
(4) Centrally located within occupiable spaces adjacent to a communicating attached garage, unless otherwise exempted by 13.7.2.20.9.3

[***101:***32.3.3.4.9.2]

N **13.7.2.20.9.3** Carbon monoxide alarms and carbon monoxide detectors as specified in 13.7.2.20.9.1(1) shall not be required in the following locations:

(1) In garages
(2) Within facilities with communicating attached garages that are open parking structures as defined by the building code
(3) Within facilities with communicating attached garages that are mechanically ventilated in accordance with the mechanical code

[***101:***32.3.3.4.9.3]

N **13.7.2.20.9.4** Where fuel-burning appliances or fuel-burning fireplaces are installed outside sleeping rooms, carbon monoxide alarms or carbon monoxide detectors shall be installed in the locations specified as follows:

(1) Within rooms containing fuel-burning appliances or fuel-burning fireplaces
(2) Centrally located within occupiable spaces served by the first supply air register from a fuel-burning HVAC system

[***101:***32.3.3.4.9.4]

The requirements of 13.7.2.20.9, which are new to the 2018 edition of the *Code*, mandate the installation of CO detection equipment in new, large residential board and care facilities where there is a potential for accidental CO poisoning from a vehicle in an attached, communicating garage or from fuel-burning appliances, such as a gas-fired or an oil-fired furnace or a fuel-burning fireplace. The reference to 13.7.1.14 in 13.7.2.20.9.1 requires compliance with NFPA 720. NFPA 720, which is modeled after *NFPA 72*, contains the detailed installation requirements for CO alarms, including those for power supply.

Although not mandated in existing board and care facilities, the installation of CO alarms is recommended if there is a potential for CO poisoning. It is important to note that the typical service life of a CO alarm varies from about 5 to 10 years. CO alarms must be replaced by the date indicated on the device to ensure proper operation. See the commentary following 13.7.1.14 for additional details.

13.7.2.21 Existing, Small (Not More Than 16 Residents) Residential Board and Care Occupancies.

See the commentary following 13.7.2.19.5.4.

13.7.2.21.1 Fire Alarm Systems. A manual fire alarm system shall be provided in accordance with Section 13.7, unless the provisions of 13.7.2.21.3.1 or 13.7.2.21.3.2 are met. [***101:***33.2.3.4.1]

13.7.2.21.1.1 A fire alarm system shall not be required where interconnected smoke alarms complying with 13.7.2.21.5, and not less than one manual fire alarm box per floor arranged to continuously sound the smoke detector alarms, are provided. [***101:***33.2.3.4.1.1]

13.7.2.21.1.2 Other manually activated continuously sounding alarms acceptable to the AHJ shall be permitted in lieu of a fire alarm system. [***101:***33.2.3.4.1.2]

N **13.7.2.21.2 Initiation.** Initiation of the required fire alarm system shall be by manual means in accordance with 13.7.1.7.1(1). [***101:***33.2.3.4.2]

13.7.2.21.3 Occupant Notification. Occupant notification shall be in accordance with 13.7.1.9. [***101:***33.2.3.4.4]

13.7.2.21.4* Smoke Alarms.

Δ **A.13.7.2.21.5** Most often, smoke alarms sounding an alarm at 85 dBA or greater, installed outside the bedroom area, will meet the intent of this requirement. Smoke alarms remotely located from the bedroom might not be loud enough to awaken the average person. In such cases, it is recommended that smoke alarms be interconnected so that the activation of any smoke alarm will cause all smoke alarms to activate. [***101:***A.33.2.3.4.3]

NFPA *101* provides adequate, balanced fire protection and takes into consideration the passive and active systems required in a given occupancy. The level of protection prescribed by *NFPA 72* which includes smoke alarms in all sleeping rooms, without exception, does not necessarily take into consideration the complete protection package prescribed by NFPA *101*. [***101:***A.33.2.3.4.3]

13.7.2.21.4.1 Approved smoke alarms shall be provided in accordance with 13.7.1.8, unless otherwise indicated in 13.7.2.21.5.6 and 13.7.2.21.5.7. [***101:***33.2.3.4.4]

13.7.2.21.4.2 Smoke alarms shall be installed on all levels, including basements but excluding crawl spaces and unfinished attics. [***101:***33.2.3.4.3.2]

13.7.2.21.4.3 Additional smoke alarms shall be installed for living rooms, dens, day rooms, and similar spaces. [***101:***33.2.3.4.3.3]

13.7.2.21.4.4 Reserved.

13.7.2.21.4.5 Smoke alarms shall be powered from the building electrical system and, when activated, shall initiate an alarm that is audible in all sleeping areas. [***101:***33.2.3.4.3.5]

13.7.2.21.4.6 Smoke alarms in accordance with 13.7.2.21.5.1 shall not be required where buildings are protected throughout by an approved automatic sprinkler system, in accordance with 13.3.2.22.2, that uses quick-response or residential sprinklers, and are protected with approved smoke alarms installed in each sleeping room, in accordance with 13.7.1.8, that are powered by the building electrical system. [***101:***33.2.3.4.3.6]

13.7.2.21.4.7 Smoke alarms in accordance with 13.7.2.21.5.1 shall not be required where buildings are protected throughout by an approved automatic sprinkler system, in accordance with 13.3.2.22.2, that uses quick-response or residential sprinklers, with existing battery-powered smoke alarms in each sleeping room, and where, in the opinion of the AHJ, the facility has demonstrated that testing, maintenance, and a battery replacement program ensure the reliability of power to the smoke alarms. [***101:***33.2.3.4.3.7]

13.7.2.22 Existing, Large (More Than 16 Residents) Residential Board and Care Occupancies.

See the commentary following 13.7.2.20.8.3.

Δ **13.7.2.22.1 General.** A fire alarm system in accordance with Section 13.7 shall be provided, unless all of the following conditions are met:

(1) The facility has an evacuation capability of prompt or slow.
(2) Each sleeping room has exterior exit access in accordance with 14.10.3.
(3) The building does not exceed three stories in height.

[***101:***33.3.3.4.1]

13.7.2.22.2 Initiation. The required fire alarm system shall be initiated by each of the following means:

(1) Manual means in accordance with 13.7.1.7, unless there are other effective means (such as a complete automatic sprinkler or detection system) for notification of fire as required
(2) Manual fire alarm box located at a convenient central control point under continuous supervision of responsible employees
(3) Automatic sprinkler system, other than that not required by another section of this *Code*
(4) Required detection system, other than sleeping room smoke alarms

[***101:***33.3.3.4.2]

13.7.2.22.3 Reserved.

13.7.2.22.4 Occupant Notification. Occupant notification shall be provided automatically, without delay, by internal audible alarm in accordance with 13.7.1.9. [***101:***33.3.3.4.4]

13.7.2.22.5 Reserved.

13.7.2.22.6 Emergency Forces Notification.

13.7.2.22.6.1* Where the existing fire alarm system does not provide for automatic emergency forces notification in accordance with 13.7.1.10, provisions shall be made for the immediate notification of the public fire department by either telephone or other means, or, where there is no public fire department, notification shall be made to the private fire brigade. [***101:***33.3.3.4.6.1]

A.13.7.2.22.6.1 See A.13.7.2.16.3.6. [***101:***A.33.3.3.4.6.1]

13.7.2.22.6.2 Where a new fire alarm system is installed, or the existing fire alarm system is replaced, emergency forces notification shall be provided in accordance with 13.7.1.10. [***101:***33.3.3.4.6.2]

13.7.2.22.7 Smoke Alarms. Smoke alarms shall be provided in accordance with 13.7.2.22.7.1, 13.7.2.22.7.2, or 13.7.2.22.7.3. [***101:***33.3.3.4.7]

13.7.2.22.7.1 Each sleeping room shall be provided with an approved smoke alarm in accordance with 13.7.1.8 that is powered from the building electrical system. [***101:***33.3.3.4.7.1]

13.7.2.22.7.2 Existing battery-powered smoke alarms, rather than building electrical service–powered smoke alarms, shall be accepted where, in the opinion of the AHJ, the facility has demonstrated that testing, maintenance, and battery replacement programs ensure the reliability of power to the smoke alarms. [***101:***33.3.3.4.7.2]

13.7.2.22.7.3 Sleeping room smoke alarms shall not be required in facilities having an existing corridor smoke detection system that complies with Section 13.7 and is connected to the building fire alarm system. [***101:***33.3.3.4.7.3]

13.7.2.22.8 Smoke Detection Systems.

13.7.2.22.8.1 All living areas, as defined in 3.3.21.5 of NFPA *101*, and all corridors shall be provided with smoke detectors that comply with *NFPA 72* and are arranged to initiate an alarm that is audible in all sleeping areas, as modified by 13.7.2.22.8.2 and 13.7.2.22.8.3. [***101:***33.3.3.4.8.1]

13.7.2.22.8.2 Smoke detection systems shall not be required in living areas of buildings having a prompt or slow evacuation capability protected throughout by an approved automatic sprinkler system installed in accordance with 13.7.2.22.1. [***101:***33.3.3.4.8.2]

13.7.2.22.8.3 Smoke detection systems shall not be required in unenclosed corridors, passageways, balconies, colonnades, or other arrangements with one or more sides along the long dimension fully or extensively open to the exterior at all times. [***101:***33.3.3.4.8.3]

13.7.2.23 New Mercantile Occupancies.

13.7.2.23.1 General. New Class A mercantile occupancies shall be provided with a fire alarm system in accordance with Section 13.7. [***101:***36.3.4.1]

Δ **13.7.2.23.2 Initiation.** Initiation of the required fire alarm system shall be by any one of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1)
(2) Approved automatic fire detection system in accordance with 13.7.1.7.1(2) that provides protection throughout the building, and the provision of 13.7.1.7.6 shall apply.
(3) Approved automatic sprinkler system in accordance with 13.7.1.7.1(3) that provides protection throughout the building, and the provision of 13.7.1.7.6 shall apply.

[***101:***36.3.4.2]

13.7.2.23.3 Notification.

13.7.2.23.3.1 Occupant Notification. During all times that the mercantile occupancy is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

(1) It shall activate an alarm in accordance with 13.7.1.9 throughout the mercantile occupancy.
(2) Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted.

[***101:***36.3.4.3.1]

13.7.2.23.3.2 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying both of the following:

(1) Fire department in accordance with 13.7.1.10
(2) Local emergency organization, if provided

[***101:***36.3.4.3.2]

Neither Class B nor Class C mercantile occupancies are required to have a fire alarm system.

Because all new Class A stores and most existing Class A stores must be sprinklered based on gross floor area (see 13.3.2.23.1 and 13.3.2.24.1), it is logical that the sprinkler system waterflow method described in 13.7.2.23.2(3) and 13.7.2.24.2(3) will be used most commonly to activate the fire alarm system. The requirement for manual fire alarm boxes is waived if the sprinkler waterflow activates the fire alarm system. Eliminating the manual fire alarm boxes and satisfying the initiation requirements by means of waterflow through the sprinkler system may reduce the number of nuisance alarms. However, in accordance with 13.7.1.7.6, at least one manual fire alarm box must be provided at a location acceptable to the AHJ.

If a fire alarm system is required, emergency forces notification must also be provided, as specified by 13.7.2.23.3.2 and 13.7.2.24.3.2. Several different methods of automatically notifying the fire department are permitted by 13.7.1.10.

13.7.2.24 Existing Mercantile Occupancies.

13.7.2.24.1 General. Existing Class A mercantile occupancies shall be provided with a fire alarm system in accordance with Section 13.7. [***101:***37.3.4.1]

Δ **13.7.2.24.2 Initiation.** Initiation of the required fire alarm system shall be by one of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1)
(2) Approved automatic fire detection system in accordance with 13.7.1.7.1(2) that provides protection throughout the building, and the provision of 13.7.1.7.6 shall apply.
(3) Approved automatic sprinkler system in accordance with 13.7.1.7.1(3) that provides protection throughout the building, and the provision of 13.7.1.7.6 shall apply.

[***101:***37.3.4.2]

13.7.2.24.3 Notification.

13.7.2.24.3.1 Occupant Notification. During all times that the mercantile occupancy is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

(1) It shall activate an alarm in accordance with 13.7.1.9 throughout the mercantile occupancy, and both of the following also shall apply:
   (a) Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted.
   (b) A presignal system in accordance with 13.7.1.9.3 shall be permitted.
(2) Occupant notification shall be made via a voice communication or public address system in accordance with 13.7.1.9.9.2

[***101:***37.3.4.3.1]

13.7.2.24.3.2 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying both of the following:

(1) Fire department in accordance with 13.7.1.10
(2) Local emergency organization, if provided

[***101:***37.3.4.3.2]

See the commentary following 13.7.2.23.3.2(2).

13.7.2.25 New Business Occupancies.

Δ **13.7.2.25.1 General.** A fire alarm system in accordance with Section 13.7 shall be provided in all business occupancies where any one of the following conditions exists:

(1) The building is three or more stories in height.
(2) The occupancy is subject to 50 or more occupants above or below the level of exit discharge.
(3) The occupancy is subject to 300 or more total occupants.

[***101:***38.3.4.1]

Δ **13.7.2.25.2 Initiation.** Initiation of the required fire alarm system shall be by any one of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1)
(2) Approved automatic fire detection system in accordance with 13.7.1.7.1(2) that provides protection throughout the building and the provision of 13.7.1.7.6 shall apply.
(3) Approved automatic sprinkler system in accordance with 13.7.1.7.1(3) that provides protection throughout the building and the provision of 13.7.1.7.6 shall apply.

[***101:***38.3.4.2]

13.7.2.25.3 Occupant Notification. During all times that the building is occupied *(see 7.2.1.1.3 of NFPA 101)*, the required fire alarm system, once initiated, shall perform one of the following functions:

(1) It shall activate a general alarm in accordance with 13.7.1.9
(2) A positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted.

[***101:***38.3.4.3]

13.7.2.25.4 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying both of the following:

(1) Fire department in accordance with 13.7.1.10
(2) Approved local emergency organization, if provided

[***101:***38.3.4.4]

A fire alarm system is required in a business occupancy under the same conditions as those under which emergency lighting is required (see 38/39.2.9.1 of NFPA *101*). If any one of the three conditions of 13.7.2.25.1 or 13.7.2.26.1 exists, a fire alarm system must be provided.

A required fire alarm system must have initiation means per 13.7.2.25.2 or 13.7.2.26.2, but the requirement for manual fire alarm boxes is waived if the system is initiated by either an automatic fire detection system providing protection throughout the building or an automatic sprinkler system providing protection throughout the building. This waiver does not exempt the fire alarm system but only the manual fire alarm boxes. Note that 13.7.1.7.6 requires at least one manual fire alarm box to be provided at a location acceptable to the AHJ.

When the required fire alarm system is initiated by one of the means specified in 13.7.2.25.2 or 13.7.2.26.2, the system must automatically sound a general alarm throughout the building. In existing business occupancies, if a continuously attended location is provided (as is often the case in high-rise or other large office buildings), the alarm is permitted to sound at that location only, with the appropriate emergency action initiated at that location by use of a voice communication or public address system (see 13.7.1.9.9.2). See 13.7.2.25.3 and 13.7.2.26.3 for details on occupant notification requirements.

Presignal systems are permitted in existing business occupancies only where such systems already exist [see 13.7.2.26.3(1)(b)]; where presignal systems are used, the fire department must be notified automatically, without delay, in case of a delay in notifying, or failure to notify, the building occupants. The superior fail-safe system — positive alarm sequence — is permitted for both new and existing business occupancies. See 13.7.1.9.3, 13.7.1.9.4, and *NFPA 72* for details on presignal and positive alarm sequence systems.

The provision of 13.7.2.25.4 requires automatic emergency forces notification in accordance with 13.7.1.10 for all new business occupancies that are required to be provided with a fire alarm system and for all existing business occupancies when an existing, required fire alarm system is replaced.

N **13.7.2.25.5 Risk Analysis for Mass Notification.**

N **13.7.2.25.5.1** Business occupancies requiring a fire alarm system in accordance with 13.7.2.25.5.1 shall conduct a risk analysis to determine the need for a mass notification system in accordance with 13.7.1.15. [***101:***38.3.4.5.1]

N **13.7.2.25.5.2*** A risk analysis to determine the need for a mass notification system in accordance with Section 13.7.1.15 shall be conducted for buildings containing a classroom where the building is owned, rented, leased, or operated by a college or university. [***101:***38.3.4.5.2]

N **A.13.7.2.25.5.2** It is not the intent of this section to require a new risk analysis where an existing risk analysis addresses the issues or arrangements associated with a new building. [***101:***A.38.3.4.5.2]

Section 13.7.1.15 is new to the 2018 edition of the *Code*. By reference to these new provisions, new business occupancies that include spaces used for college/university classrooms require a risk analysis to be conducted in accordance with Chapter 24 of *NFPA 72* to determine if an MNS is necessary. Paragraph 13.7.2.25.5.1 requires a risk analysis for those business occupancies containing a classroom where the building containing the classroom is owned, rented, leased, or operated by a college or university. This language is intended to apply to classroom buildings on college and university campuses that fall under the business occupancy classification. Those buildings with larger classrooms (50 or more occupants) that are classified as assembly occupancies would need to apply the provisions appropriate to that occupancy. Recent events on college campuses over the past decade have demonstrated a need for better communication of emergencies in college and university settings. Paragraph 13.7.2.25.5.1 clarifies that a new risk analysis is not always required where an existing risk analysis addresses the issues presented when a new building was added. See the commentary associated with 13.7.1.15 for more information.

13.7.2.26 Existing Business Occupancies.

13.7.2.26.1 General. A fire alarm system in accordance with Section 13.7 shall be provided in all existing business occupancies where any one of the following conditions exists:

(1) The building is three or more stories in height.
(2) The occupancy is subject to 100 or more occupants above or below the level of exit discharge.
(3) The occupancy is subject to 1000 or more total occupants.

[***101:***39.3.4.1]

Δ **13.7.2.26.2 Initiation.** Initiation of the required fire alarm system shall be by one of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1)
(2) Approved automatic fire detection system in accordance with 13.7.1.7.1(2) that provides protection throughout the building and the provision of 13.7.1.7.6 shall apply.
(3) Approved automatic sprinkler system in accordance with 13.7.1.7.1(3) that provides protection throughout the building and the provision of 13.7.1.7.6 shall apply.

[***101:***39.3.4.2]

13.7.2.26.3 Occupant Notification. During all times that the building is occupied *(see 7.2.1.1.3 of NFPA 101)*, the required fire alarm system, once initiated, shall perform one of the following functions:

(1) It shall activate a general alarm in accordance with 13.7.1.9, and both of the following also shall apply:
    (a) Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted.
    (b) A presignal system in accordance with 13.7.1.9.3 shall be permitted.
(2) Occupant notification shall be permitted to be made via a voice communication or public address system in accordance with 13.7.1.9.9.2.

[***101:***39.3.4.3]

13.7.2.26.4 Emergency Forces Notification. Emergency forces notification shall be accomplished in accordance with 13.7.1.10 when the existing fire alarm system is replaced. [***101:***39.3.4.4]

13.7.2.27 New and Existing Industrial Occupancies.

13.7.2.27.1 General. A fire alarm system shall be required in accordance with Section 13.7 for new and existing industrial occupancies, unless the total occupant load of the building is under 100 persons and unless, of these, fewer than 25 persons are above or below the level of exit discharge. [***101:***40.3.4.1]

Δ **13.7.2.27.2 Initiation.** Initiation of the required fire alarm system shall be by any of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1)
(2) Approved automatic fire detection system in accordance with 13.7.1.7.1(2) throughout the building, plus a minimum of one manual fire alarm box in accordance with 13.7.1.7.6
(3) Approved, supervised automatic sprinkler system in accordance with 13.7.1.7.1(3) throughout the building, plus a minimum of one manual fire alarm box in accordance with 13.7.1.7.6

[***101:***40.3.4.2]

13.7.2.27.3 Notification.

13.7.2.27.3.1 The required fire alarm system shall meet one of the following criteria:

(1) It shall provide occupant notification in accordance with 13.7.1.9.
(2) It shall sound an audible and visible signal in a constantly attended location for the purposes of initiating emergency action.

[***101:***40.3.4.3.1]

13.7.2.27.3.2 Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***40.3.4.3.2]

13.7.2.27.3.3 Existing presignal systems in accordance with 13.7.1.9.3 shall be permitted. [***101:***40.3.4.3.3]

13.7.2.27.3.4 In high hazard industrial occupancies, as described in 40.1.2.1.3 of NFPA *101*, the required fire alarm system shall automatically initiate an occupant evacuation alarm signal in accordance with 13.7.1.9. [***101:***40.3.4.3.4]

Note that 13.7.2.27 applies to both new and existing industrial occupancies.

The requirements of 13.7.2.27.3.1 and 13.7.2.27.3.4 specify two separate and distinct provisions for audible alarms activated by the fire alarm system required by 13.7.2.27.1. In low and ordinary hazard industrial occupancies, the system is permitted to activate an evacuation alarm or to sound an alarm at a constantly attended location for the purpose of initiating emergency action (see 13.7.2.27.3.1). This provision permits an interface between the alarm system and the plant's emergency organization. The alarm system is permitted to be controlled from a central security console or a similar location. The key feature is that the location from which the alarm sounds must be constantly staffed. This requirement is not intended to mandate the installation of supervisory service, such as that connected to a central station, but the location must be fully attended at all times when the building is occupied.

In high hazard occupancies, the alarm must be arranged to automatically provide evacuation signals (see 13.7.2.27.3.4), because the safety of the occupants of such areas depends on their immediate notification of a fire.

Note that 13.7.2.27.3.3 recognizes existing presignal systems but not new presignal systems. If an automatic form of delay is desired for an existing alarm system that does not already have a presignal feature, or for a new alarm system, the more reliable system feature known as *positive alarm sequence* is permitted by 13.7.2.27.3.2. The positive alarm sequence option might be applied to the high hazard industrial occupancies addressed in 13.7.2.27.3.4 for which an automatic form of occupant notification is needed. Also, positive alarm sequence might be used in industrial occupancies, other than those that are high hazard, where the provisions of 13.7.2.27.3.1(1) are used instead of those of 13.7.2.27.3.1(2).

13.7.2.28 New and Existing Storage Occupancies.

13.7.2.28.1 General. A fire alarm system shall be required in accordance with Section 13.7 for new and existing storage occupancies, except as modified by 13.7.2.28.1.1, 13.7.2.28.1.2, and 13.7.2.28.1.3. [***101:***42.3.4.1]

13.7.2.28.1.1 Storage occupancies limited to low hazard contents shall not be required to have a fire alarm system. [***101:***42.3.4.1.1]

13.7.2.28.1.2 Storage occupancies with ordinary or high hazard contents not exceeding an aggregate floor area of 100,000 ft^2 (9300 m^2) shall not be required to have a fire alarm system. [101:42.3.4.1.2]

13.7.2.28.1.3 Storage occupancies protected throughout by an approved automatic sprinkler system in accordance with Section 13.3 shall not be required to have a fire alarm system. [***101:***42.3.4.1.3]

Δ **13.7.2.28.2 Initiation.** Initiation of the required fire alarm system shall be by any of the following means:

(1) Manual means in accordance with 13.7.1.7.1(1)
(2) Approved automatic fire detection system in accordance with 13.7.1.7.1(2) throughout the building, plus a minimum of one manual fire alarm box in accordance with 13.7.1.7.6
(3) Approved, supervised automatic sprinkler system in accordance with 13.7.1.7.1(3) throughout the building, plus a minimum of one manual fire alarm box in accordance with 13.7.1.7.6

[***101:***42.3.4.2]

13.7.2.28.3 Notification.

13.7.2.28.3.1 The required fire alarm system shall meet one of the following criteria:

(1) It shall provide occupant notification in accordance with 13.7.1.9.
(2) It shall sound an audible and visible signal in a constantly attended location for the purposes of initiating emergency action.

[***101:***42.3.4.3.1]

13.7.2.28.3.2 Positive alarm sequence in accordance with 13.7.1.9.4 shall be permitted. [***101:***42.3.4.3.2]

13.7.2.28.3.3 Existing presignal systems in accordance with 13.7.1.9.3 shall be permitted. [***101:***42.3.4.3.3]

13.7.2.28.3.4 In high hazard storage occupancies, the required fire alarm system shall automatically initiate an occupant evacuation alarm signal in accordance with 13.7.1.9. [***101:***42.3.4.3.4]

Storage placement limits visibility in buildings with large floor areas. As a result, personnel who work in storage areas might be unaware of the occurrence of fire for a long period. If fire spreads, which is highly possible in an unprotected storage building, means of egress could be blocked. An alarm system provides a means of alerting all occupants to the presence of fire and allows for timely egress.

The requirements of 13.7.2.28.3.1 and 13.7.2.28.3.4 specify two separate and distinct provisions for audible alarms activated by the fire alarm system required by 13.7.2.28.1. In low and ordinary hazard storage occupancies (see 13.7.2.28.3.1), the system is permitted to activate an evacuation alarm or sound an alarm in a constantly attended location for the purpose of initiating emergency action. This provision permits an interface between the alarm system and the building's emergency organization. The alarm system is permitted to be controlled from a central security console or a similar location. The key feature is that the location from which the alarm sounds must be constantly staffed. This requirement is not intended to mandate the installation of supervisory service, such as connection to a central station, but the location must be fully attended at all times when the building is occupied.

In high hazard storage occupancies (see 13.7.2.28.3.4), the alarm must be arranged to provide evacuation signals, because the safety of the occupants of such areas depends on their immediate notification of a fire.

13.7.2.29 Special Structures and High-Rise Buildings.

13.7.2.29.1 Detection, Alarm, and Communications Systems. Towers, as defined in 3.3.281 of NFPA *101*, designed for occupancy by not more than three persons shall be exempt from requirements for detection, alarm, and communications systems. [***101:***11.3.3.4]

13.7.2.29.2 New High-Rise Buildings.

13.7.2.29.2.1* A fire alarm system using an approved emergency voice/alarm communication system shall be installed in accordance with Section 13.7 and NFPA *101*. [***101:***11.8.4.1]

A.13.7.2.29.2.1 The need for voice communication can be based on a decision regarding staged or partial evacuation versus total evacuation of all floors. The determination of need is a function of occupancy classification and building height. [***101:***A.11.8.4.1]

13.7.2.29.2.2 Two-way telephone service shall be in accordance with 13.7.2.29.2.2.1 and 13.7.2.29.2.2.2. [***101:***11.8.4.2]

13.7.2.29.2.2.1 Two-way telephone communication service shall be provided for fire department use. This system shall be in accordance with *NFPA 72*. The communications system shall operate between the emergency command center and every elevator car, every elevator lobby, and each floor level of exit stairs. [***101:***11.8.4.2.1]

13.7.2.29.2.2.2* The requirement of 13.7.2.29.2.2.1 shall not apply where the fire department radio system is approved as an equivalent system. [***101:***11.8.4.2.2]

Δ **A.13.7.2.29.2.2.2** Public safety radio enhancement systems provide for greater flexibility and safety for emergency responders during in-building operations. This provision serves to facilitate adoption of *Code* language prescribing design, installation, testing, and maintenance criteria for in-building public safety radio enhancement systems. AHJs are directed to Chapter 24 of *NFPA 72* for details.

13.7.3 Fire Alarm Systems.

13.7.3.1 General.

13.7.3.1.1 Equipment.

13.7.3.1.1.1 Equipment constructed and installed in conformity with this *Code* shall be listed for the purpose for which it is used. [**72:**10.3.1]

Just noting that a piece of equipment is listed is not sufficient. In accordance with the requirements of 13.7.3.1.1.1, equipment must be listed for the purpose for which it is used. The listing of equipment involves evaluation of the equipment to determine its suitability for a specific purpose. The evaluation is usually accomplished through the use of product testing standards developed to demonstrate that specific performance requirements have been met. Many of these performance requirements are based on specific requirements in *NFPA 72* and go far beyond requirements used only to demonstrate electrical safety.

While most equipment would be listed for fire alarm system use, some equipment may possess a different listing. As an example, equipment (such as routers and modems) that might be used with some transmission methods in the signal transmission path between a protected premises and a supervising station might be listed as general communications equipment (see 26.6.3.12 of *NFPA 72*).

Equipment listings generally contain information pertaining to the permitted use, required ambient conditions in the installed location, mounting orientation, voltage tolerances, compatibility, and so on. Equipment must be installed, tested, and maintained in conformance with the listing and the manufacturer's published instructions to meet the requirements of *NFPA 72*. Conformance with the listing and the manufacturer's instructions has been a longstanding requirement, originating in the requirements of *NFPA 70®*, *National Electrical Code®*, and reinforced in 13.7.3.1.1.2.

13.7.3.1.1.2 System components shall be installed, tested, inspected, and maintained in accordance with the manufacturer's published instructions and this *Code*. [**72:**10.3.2]

13.7.3.1.1.3* All devices and appliances that receive their power from the initiating device circuit or signaling line circuit of a control unit shall be listed for use with the control unit. [**72:**10.3.3]

A.13.7.3.1.1.3 This requirement does not apply to notification appliance circuits. [**72:**A.10.3.3]

Detection devices and notification appliances that receive their power directly from either an initiating device circuit (IDC) or a signaling line circuit (SLC) must be listed for that particular control unit. Listing with the specific control unit is not required for devices and appliances installed on notification appliance circuits (NACs).

The most common application where this is a concern is two-wire and addressable (addressable/analog) smoke detectors. A two-wire smoke detector obtains its power from the control unit initiating device circuit. Addressable devices and appliances on signaling line circuits communicate with the control unit using manufacturer-specific protocols. The listing organizations have developed specific requirements for this listing process and should be consulted if necessary to confirm the detector's or appliance's compatibility with a specific control unit.

Δ **13.7.3.1.1.4** All apparatus requiring rewinding or resetting to maintain normal operation shall be restored to normal after each abnormal condition and maintained in normal condition for operation. [**72:**10.3.4]

13.7.3.1.1.5 Equipment shall be designed so that it is capable of performing its intended functions under the following conditions:

(1)* At 85 percent and at 110 percent of the nameplate primary (main) and secondary (standby) input voltage(s)

A.13.7.3.1.1.5(1) The requirement of 13.7.3.1.1.5(1) does not preclude transfer to secondary supply at less than 85 percent of nominal primary voltage, provided the requirements of 10.6.7 of *NFPA 72* are met. [**72:**A.10.3.5(1)]

(2) At ambient temperatures of 0°C (32°F) and 49°C (120°F)
(3) At a relative humidity of 85 percent and an ambient temperature of 30°C (86°F)

[**72:**10.3.5]

Equipment might be listed for use outside these limits, or the space must be conditioned to meet these parameters. If the space must be artificially conditioned, standby power to operate that artificial conditioning should be considered to ensure that the conditioning continues during a power outage for at least as long as the standby power required for the alarm system.

13.7.3.2 Documentation.

13.7.3.2.1 Approval and Acceptance. The AHJ shall be notified prior to installation or alteration of equipment or wiring. [**72:**10.19.2]

13.7.3.2.2 Minimum Required Documentation.

Many AHJs require a permit for the installation or modification of a system prior to that work occurring. A wise practice is to contact the local AHJ to determine if a permit is needed and what the submittal requirements might entail. Additionally, there are many times when more than one AHJ will be interested in the work that will be occurring, and while nongovernmental authorities having jurisdiction might not issue a permit for proposed work, they could be in a position to approve or deny the proposed installation on behalf of the owner or the insurance carrier. Due diligence is always a vital key.

Δ **13.7.3.2.2.1** Where documentation is required by the authority having jurisdiction, the following list shall represent the minimum documentation required for new fire alarm systems, supervising station and shared communication equipment, and emergency communications systems, including new systems and additions or alterations to existing systems:

(1) Written narrative providing intent and system description
(2) Riser diagram
(3) Floor plan layout showing locations of all devices, control equipment, and supervising station and shared communications equipment with each sheet showing the following:
  (a) Point of compass (north arrow)
  (b) A graphic representation of the scale used
  (c) Room use identification
  (d) Building features that will affect the placement of initiating devices and notification appliances
(4) Sequence of operation in either an input/output matrix or narrative form
(5) Equipment technical data sheets
(6) Manufacturers' published instructions, including operation and maintenance instructions
(7) Battery capacity and de-rating calculations (where batteries are provided)
(8) Voltage drop calculations for notification appliance circuits
(9) Mounting height elevation for wall-mounted devices and appliances
(10) Where occupant notification is required, minimum sound pressure levels that must be produced by the audible notification appliances in applicable covered areas
(11) Pathway diagrams between the control unit and the supervising station and shared communications equipment
(12) Completed record of completion in accordance with 13.7.3.2.43.6 and 13.7.3.2.5.2
(13) For software-based systems, a copy of site-specific software, including specific instructions on how to obtain the means of system and software access (password)
(14) Record (as-built) drawings

Some of the documentation required by items (1) through (8) of 13.7.3.2.2.1 will typically need to be provided as part of the permit submittal process for a new system or the alteration of an existing system. Other documentation [items (9) through (12)] will be provided at the system's commission. Still other documentation [items (13) and (14)] will need to be made available as the system is used and maintained during its life.

Many AHJs require a permit for the installation or modification of a system prior to that work occurring. It is always wise to contact the local AHJ to determine if a permit is needed and what the submittal requirements may include. Additionally, more than one AHJ could be regulating the work that will be occurring, and while nongovernmental AHJs might not issue a permit for the proposed work, they could be in a position to approve or deny the proposed installation on behalf of the owner or the insurance carrier.

Due diligence is always vital. Meeting with the AHJ before the system design occurs can often save time and money, especially when it comes to the permit review process.

(15) Records, record retention, and record maintenance in accordance with Section 7.7 of *NFPA 72*
(16) Completed record of inspection and testing in accordance with 13.7.3.2.4.6 and 13.7.3.2.5.2

[**72:**7.2.1]

13.7.3.2.2.2 System design documents shall identify the name and contact information of the system designer. [**72:**7.2.2]

The requirement to identify the system designer on the system design documents encourages the designer to feel a sense of ownership toward the design. This identification, in turn, provides an additional incentive for the designer to meet the requirements of the *Code* and provides the AHJ with the name of the person responsible for the design who can respond to questions or comments.

Δ **13.7.3.2.2.3** All fire alarm drawings shall use symbols described in NFPA 170 or other symbols acceptable to the AHJ. [**72:**7.2.3]

The symbols used on fire alarm drawings should be standardized as described in NFPA 170, *Standard for Fire Safety and Emergency Symbols*, or as permitted by the AHJ. The use of NFPA 170 allows for consistent utilization of fire alarm equipment symbols within jurisdictions and simplifies symbol identification for the alarm industry in the designing of plans for submittal and approval.

13.7.3.2.3 Completion Documentation.

13.7.3.2.3.1 The requirements of 13.7.3.2.3 shall apply only where required by other governing laws, codes, or standards; by other parts of *NFPA 72*; or by project specifications or drawings. [**72:**7.5.1]

13.7.3.2.3.2 Before requesting final approval of the installation, if required by the AHJ, the installing contractor shall furnish a written statement stating that the system has been installed in accordance with approved plans and tested in accordance with the manufacturer's published instructions and the appropriate NFPA requirements. [**72:**7.5.2]

13.7.3.2.3.3 All systems including new systems and additions or alterations to existing systems shall include the following documentation, which shall be delivered to the owner or the owner's representative upon final acceptance of the system:

(1) An owner's manual and manufacturer's published instructions covering all system equipment

In addition to the owner's manual and the manufacturer's published instructions required to be delivered to the owner or the owner's representative by 13.7.3.2.3.3(1), it is advisable to include a copy of the edition of *NFPA 72* that was used to design the system. By having this document on file, the owner will be able to ascertain the inspection, testing, and servicing frequencies and requirements for the system and, for historical purposes, the prescriptive- and performance-based design requirements that were in effect when the system was installed.

(2) Record (as-built) drawings in accordance with 13.7.3.2.3.5
(3) A completed record of completion form in accordance with 13.7.3.2.3.6
(4) For software-based systems, record copy of the site-specific software in accordance with 13.7.3.2.3.7

[**72:**7.5.3]

A record copy of the site-specific software must be delivered to the owner or the owner's representative upon final acceptance of the system. Having a backup copy of the software will help facilitate reconfiguration of the system in situations where a catastrophic failure has occurred due to lightning or other causes. Refer to the definition of the term *site-specific software* in 3.3.269.2 of *NFPA 72*. The site-specific software is the system programming for its specific application and not the executive software or the source code used to develop the site-specific software.

13.7.3.2.3.4 For new emergency communications systems, an owner's manual shall be provided and shall contain the following documentation:

(1) Detailed narrative description of the system inputs, evacuation signaling, ancillary functions, annunciation, intended sequence of operations, expansion capability, application considerations, and limitations
(2) Written sequence of operation for the system including an operational input/output matrix
(3) Operator instructions for basic system operations, including alarm acknowledgment, system reset, interpretation of system output (LEDs, CRT display, and printout), operation of manual evacuation signaling and ancillary function controls, and change of printer paper
(4) Detailed description of routine maintenance and testing as required and recommended and as would be provided under a maintenance contract, including testing and maintenance instructions for each type of device installed, which includes the following:
    (a) Listing of the individual system components that require periodic testing and maintenance
    (b) Step-by-step instructions detailing the requisite testing and maintenance procedures, and the intervals at which those procedures shall be performed, for each type of device installed
    (c) Schedule that correlates the testing and maintenance procedures that are required by this section
(5) Service directory, including a list of names and telephone numbers of those who provide service for the system
(6) Product data sheets for all system equipment (SIG-ECS)

[**72:**7.5.4]

13.7.3.2.3.5 Record Drawings (As-Builts).

Δ **13.7.3.2.3.5.1** Record drawings shall consist of current updated shop drawings reflecting the actual installation of all system equipment, components, and wiring. [**72:**7.5.5.1]

Drawings turned over to the system owner should accurately reflect the installation that has occurred. As-built drawings provide the owner, the owner's representative, or the servicing technician with invaluable assistance when future repairs or changes need to be made. Coupled with the written sequence of operation, the as-built drawings also allow for the orderly and thorough testing of all system components during routine inspection and testing.

13.7.3.2.3.5.2 A sequence of operations in input/output matrix or narrative form shall be provided with the record drawings to reflect actual programming at the time of completion. [**72:**7.5.5.2]

An on-site copy of the sequence of operation enables those who work on or those who provide further designs to the existing system to have a full understanding of how the system is intended to work. As these systems become more complex and have more interactions with other building systems, the information provided in the sequence of operation document is critical.

13.7.3.2.3.5.3 Where necessary, revised calculations in accordance with 7.4.10 of *NFPA 72* shall be provided depicting any changes due to installation conditions. [**72:**7.5.5.3]

Deviations from the approved plans frequently occur during the installation of any system. In addition to the changes being noted of the as-built drawings and documented on the record of completion, changes affecting calculations need to be documented and verified to be correct. Changes can impact standby power and NACs, the loop resistance of a circuit, or the permitted number of devices on an SLC. At times, these changes could result in batteries being incapable of providing the necessary standby power or circuits being overloaded or overextended beyond acceptable limits or the manufacturer's published instructions.

13.7.3.2.3.5.4 Record drawings shall be turned over to the owner with a copy placed inside the documentation cabinet in accordance with Section 7.7 of *NFPA 72*. [**72:**7.5.5.4]

13.7.3.2.3.5.5 Record drawings shall include approval documentation resulting from variances, performance-based designs, risk analyses, and other system evaluations or variations. [**72:**7.5.5.5]

13.7.3.2.3.6 Record of Completion.

13.7.3.2.3.6.1 The record of completion shall be documented in accordance with 13.7.3.2.3.6 using either the record of completion forms, Figure 13.7.3.2.5.2(a) through Figure 13.7.3.2.5.2(f), or an alternative document that contains only the elements of Figure 13.7.3.2.5.2(a) through Figure 13.7.3.2.5.2(f) applicable to the installed system. [**72:**7.5.6.1]

13.7.3.2.3.6.2 The record of completion documentation shall be completed by the installing contractor and submitted to the enforcing authority and the owner at the conclusion of the job. The record of completion documentation shall be permitted to be part of the written statement required in 13.7.3.2.3.2 and part of the documents that support the requirements of 13.7.3.2.3.8. When more than one contractor has been responsible for the installation, each contractor shall complete the portions of the documentation for which that contractor has responsibility. [**72:**7.5.6.2]

13.7.3.2.3.6.3 The preparation of the record of completion documentation shall be the responsibility of the qualified and experienced person in accordance with 10.5.2 of *NFPA 72*. [**72:**7.5.6.3]

The system installer is responsible for the preparation of the record of completion form. It documents the name of the installer and the location of record drawings, owners' manuals, and test reports. The form also provides a confirming record of the acceptance test and gives details of the components and wiring of the system. A record of completion is required for all installed fire alarm and emergency communications systems.

Δ **13.7.3.2.3.6.4** The record of completion documentation shall be updated to reflect all system additions or modifications. [**72:**7.5.6.4]

13.7.3.2.3.6.5 The updated copy of the record of completion documents shall be maintained in a documentation cabinet in accordance with 7.7.2 of *NFPA 72*. [**72:**7.5.6.5]

13.7.3.2.3.6.6 Revisions.

Δ **13.7.3.2.3.6.6.1** All modifications made after the initial installation shall be recorded on a revised version of the original completion documents. [**72:**7.5.6.6.1]

13.7.3.2.3.6.6.2 The revised record of completion document shall include a revision date. [**72:**7.5.6.6.2]

13.7.3.2.3.6.6.3 Where the original or the latest overall system record of completion cannot be obtained, a new system record of completion shall be provided that documents the system configuration as discovered during the current project's scope of work. [**72:**7.5.6.6.3]

Documentation of revisions made to a system after the original installation has been completed is just as important as documentation of the original installation. Every change to the system must be documented so that designers, service personnel, and others will know exactly what is on the system and how the system is to function.

In cases where a record of completion does not exist, it is not required that one be completed retroactively for the entire system when revisions are made to portions of the system. This record of completion is only required to provide pertinent information based upon the revisions to the existing fire alarm system.

13.7.3.2.3.6.7 Electronic Record of Completion.

13.7.3.2.3.6.7.1 Where approved by the AHJ, the record of completion shall be permitted to be filed electronically instead of on paper. [**72:**7.5.6.7.1]

A record of completion that is filed electronically indicates that the individual or entity — the owner, equipment supplier, service company, or installer — has a copy of it in their media records. Refer to 7.7.2.6 of *NFPA 72* regarding storage and access to electronic documentation.

13.7.3.2.3.6.7.2 If filed electronically, the record of completion document shall be accessible with standard software and shall be backed up. [**72:**7.5.6.7.2]

13.7.3.2.3.7 Site-Specific Software.

N **13.7.3.2.3.7.1** For software-based systems, a copy of the site-specific software shall be provided to the system owner or owner's designated representative. [**72:**7.5.7.1]

N **13.7.3.2.3.7.1.1** The site-specific software documentation shall include both the user passcode and either the system programming password or specific instructions on how to obtain the programming password from the system manufacturer. [**72:**7.5.7.1.1]

N **13.7.3.2.3.7.1.2** The passwords provided shall enable currently certified qualified programming personnel to access, edit, modify, and add to the existing system site-specific software. [**72:**7.5.7.1.2]

N **13.7.3.2.3.7.2** A copy of the site-specific software shall be stored on-site in nonvolatile, nonerasable, nonrewritable memory. [**72:**7.5.7.2]

13.7.3.2.3.8 Verification of Compliant Installation.

N **13.7.3.2.3.8.1** Where required by the AHJ, compliance of the completed installation with the requirements of *NFPA 72* shall be certified by a qualified and impartial third-party organization acceptable to the AHJ. [**72:**7.5.8.1]

The AHJ is permitted to mandate that a third-party review and certify an installation for compliance with *NFPA 72*. A third-party is an independent entity that has the experience and knowledge to review and certify an installation for compliance with *NFPA 72*. This requirement applies to all systems and is not the same as the documentation required for central station alarm systems in 13.7.3.4.

13.7.3.2.3.8.2 Verification of compliant installation shall be performed according to testing requirements and procedures specified in 14.4.1 and 14.4.2 of *NFPA 72*. [**72:**7.5.8.2]

13.7.3.2.3.8.3 Verification shall ensure that:

(1) All components and functions are installed and operate per the approved plans and sequence of operation.
(2) All required system documentation is complete and is archived on site.
(3) For new supervising station systems, the verification shall also ascertain proper arrangement, transmission, and receipt of all signals required to be transmitted off-premises and shall meet the requirements of 14.4.1 and 14.4.2 of *NFPA 72*.
(4) For existing supervising station systems that are extended, modified, or reconfigured, the verification shall be required for the new work only, and reacceptance testing in accordance with Chapter 14 of *NFPA 72* shall be acceptable.
(5) Written confirmation has been provided that any required corrective actions have been completed

[**72:**7.5.8.3]

13.7.3.2.3.9 Documentation of central station service shall be in accordance with 26.3.4 of *NFPA 72*. [**72:**7.5.9]

13.7.3.2.3.10 Documentation of remote station service shall be in accordance with 26.5.2 of *NFPA 72*. [**72:**7.5.10]

13.7.3.2.4 Inspection, Testing, and Maintenance Documentation.

13.7.3.2.4.1 Test plan documentation shall be provided in accordance with 14.2.10 of *NFPA 72*. [**72:**7.6.1]

Subsection 14.2.10 of *NFPA 72* requires that a written test plan be created. This is particularly important when the fire alarm system interfaces with other functions, including those functions covered by Chapter 21 of *NFPA 72*. The test plan and the results of the testing that occurs are to be documented and kept with the system records.

It is important to ensure that other systems that interface with fire alarm systems as part of the fire alarm sequence of operation are properly tested as part of an integrated test plan under NFPA 4. It is also important that the interaction of the various systems being tested is properly documented and part of the documentation required in Chapter 7 of *NFPA 72*. This is especially important when system interfaces are complex.

The following is a list of some items that could be included in a test plan:

1. Information regarding the test, such as the intent of the test, established criteria of the design documents, applicable codes, and administrative procedures
2. Documentation that could include the following:
   a. Log books
   b. Daily reports
   c. Issuing nonconformance reports
   d. Clearing nonconformance reports
   e. Final report
   f. Information on what equipment is going to be reviewed and on the visual inspection of items that could include the following:
      i. Fire alarm devices
      ii. Smoke barriers
      iii. Ducts
      iv. Dampers
      v. Fans
      vi. Doors
      vii. Electrical systems
      viii. Interface relays
      ix. Other supervisory devices
3. Information on items, which could include the following, to be tested, how they are going to be tested, and in what mode (normal or abnormal conditions):
   a. Initiation devices
   b. Fans
   c. Duct leakage
   d. Air balancer

Having the interface documentation available for maintenance and future improvements is invaluable. If a building owner is contemplating a fire alarm upgrade and does not have the proper record documentation, finding out what the sequence of operation is for the smoke control system and how it interfaces with the fire alarm system can be difficult. Since the smoke control system relies on input from the fire alarm system, it is important to know how it works. What activates when there is a fire alarm condition? Proper record documentation on system interfaces can answer this type of question.

13.7.3.2.4.2 Acceptance testing documentation shall be provided in accordance with 14.6.1 of *NFPA 72*. [**72:**7.6.2]

13.7.3.2.4.3 Reacceptance test documentation shall be provided in accordance with 14.6.1 of *NFPA 72*. [**72:**7.6.3]

Δ **13.7.3.2.4.4** Periodic inspection and testing documentation shall be provided in accordance with 14.6.2 through 14.6.4 of *NFPA 72*. [**72:**7.6.4]

13.7.3.2.4.5 Impairment documentation shall be provided in accordance with Section 10.20 of *NFPA 72*. [**72:**7.6.5]

Δ **13.7.3.2.4.6 Record of Inspection and Testing.** The record of all inspections, testing, and maintenance as required by 14.6.2.4 of *NFPA 72* shall be documented using either the record of inspection and testing forms, Figure 13.7.3.2.5.2(g) through Figure 13.7.3.2.5.2(l), or an alternative record that includes all the applicable information shown in Figure 13.7.3.2.5.2(g) through Figure 13.7.3.2.5.2(l). [**72:**7.6.6]

13.7.3.2.5 Forms.

13.7.3.2.5.1 General.

13.7.3.2.5.1.1 The requirements of 13.7.3.2.5 shall apply only where required by other governing laws, codes, or standards; by other parts of this *Code*; or by project specifications or drawings. [**72:**7.8.1.1]

13.7.3.2.5.1.2 Where specific forms are required by other governing laws, codes, or standards; by other parts of *NFPA 72*; or by project specifications or drawings, form layouts and content that differ from those in 13.7.3.2.5 shall be permitted provided that the minimum required content is included. [**72:**7.8.1.2]

Δ **13.7.3.2.5.2 Forms for Documentation.** Forms for documentation shall be as follows:

(1) Unless otherwise permitted or required in 13.7.3.2.3.6, 13.7.3.2.4.6, or 13.7.3.2.5.1.2, 13.7.3.2.5.2(a) through Figure 13.7.3.2.5.2(l) shall be used to document the record of completion and record of inspection and testing.
(2) Unless otherwise permitted or required in Figure 13.7.3.2.5.2(g) through Figure 13.7.3.2.5.2(l) shall be used to document the record of inspection and testing.

[**72:**7.8.2]

Forms to satisfy the record keeping requirements of the *Code* have been developed for use. The use of forms other than those found in the *Code* is allowed so long as the required documented information is included in the other form.

13.7.3.3 Manually Actuated Alarm-Initiating Devices.

Many fire alarm systems are not equipped with automatic off-site capability for signal transmission to a supervising station. In those buildings where the fire alarm system is not equipped with automatic off-site signal transmission to a supervising station system, activation of the manual fire alarm box notifies only other occupants in the building of the presence of a fire. The manual fire alarm box does not notify the fire service. For such buildings, explicit instructions to the operator of the manual fire alarm box to also notify the fire department from outside the building are desirable and might be required by the local ordinance or code to be placed at each manual fire alarm box location.

Δ **13.7.3.3.1** Manually actuated alarm-initiating devices for initiating signals other than for fire alarm shall be permitted if the devices are differentiated from manual fire alarm boxes by a color other than red and labeling. [**72:**17.14.1]

The color red is reserved for manual initiating devices that initiate a fire signal. If manual initiating devices are used to initiate some other emergency signal (e.g., toxic release, radiological release, medical emergency, hazardous weather), they must be differentiated from each other and from the fire alarm boxes by both color and labeling. No color code is specified for manual emergency reporting–initiating devices.

13.7.3.3.2 Combination manual fire alarm boxes and guard's signaling stations shall be permitted. [**72:**17.14.2]

If the manual fire alarm box is incorporated into some other non-fire-related assembly (with the single exception of guards' tour supervisory stations), the probability of unwarranted operation is increased. This arrangement leads to false alarms and erodes the occupants' confidence in the system. Also, when manual fire alarms are combined with non-fire-related functions, the probability that a failure in the non-fire-related function will compromise the fire alarm system increases.

13.7.3.3.3 Manually actuated alarm-initiating devices shall be securely mounted. [**72:**17.14.3]

13.7.3.3.4 Manually actuated alarm-initiating devices shall be mounted on a background of contrasting color. [**72:**17.14.4]

13.7.3.3.5 The operable part of a manually actuated alarm-initiating device shall be not less than 42 in. (1.07 m) and not more than 48 in. (1.22 m) from the finished floor. [**72:**17.14.5]

The *Americans with Disabilities Act and Architectural Barriers Act Accessibility Guidelines* specifies a maximum unobstructed "side reach" and unobstructed "forward reach" of 48 in. (1.22 m). Refer to the specific details of the guidelines for what constitutes an obstructed versus unobstructed approach. Information concerning the policies of the Architectural and Transportation Barriers Compliance Board can be found at the website www.access-board.gov. See Exhibit 13.43 for an example of a manual fire alarm box.

13.7.3.3.6 Manually actuated alarm-initiating devices shall be permitted to be single action or double action. [**72:**17.14.6]

13.7.3.3.7* Listed protective covers shall be permitted to be installed over single- or double-action manually actuated alarm-initiating devices. [**72:**17.14.7]

A.13.7.3.3.7 Protective covers, also called pull station protectors can be installed over manually actuated alarm initiating devices to provide mechanical protection, environmental protection, and

 NFPA 72 (p. 2 of 2)

N ***FIGURE 13.7.3.2.5.2(l)*** *Continued* to reduce the likelihood of accidental or malicious activation. The protective covers must be listed to ensure that they do not hinder the operation of the pull stations and to ensure that they meet accessibility requirements for activation by persons with physical disabilities. The *Code* explicitly permits installing them over single- or double-action devices. When installed over a double-action device, the assembly effectively becomes a triple-action device. Some units include battery-operated audible warning signals that have been shown to deter malicious activations. To be effective, it is important that the regular staff or occupants be aware of the sound and investigate immediately in order to catch someone who might otherwise activate the device without cause or to ensure that the device is activated if there is a legitimate reason. [**72:**A.17.14.7]

Protective covers are permitted to be installed over manual fire alarm boxes to provide relief from unintentional or malicious alarms. These covers must be listed for such use. Some covers provide a local signal that sounds at the device when the cover is lifted. In locations where an audible signal is incorporated into a cover, users should be aware that the opening of the cover does not initiate a fire alarm signal and that the fire alarm box must still be actuated. See Exhibit 13.40 for an example of a manual fire alarm box protective cover.

13.7.3.3.8 Manual fire alarm boxes shall comply with 13.7.3.3.8.1 through 13.7.3.3.8.6. [**72:**17.14.8]

13.7.3.3.8.1 Manual fire alarm boxes shall be used only for fire alarm initiating purposes. [**72:**17.14.8.1].

If manual fire alarm boxes are used for some other purpose, for the actuation of a special extinguishing system, for example, then someone unfamiliar with the facility could actuate the wrong manual fire alarm box in response to a fire incident. Consequently, manual fire alarm boxes are permitted to be used only for initiation of a fire alarm signal. A manual alarm-initiating device other than a manual fire alarm initiation device must be used for those other purposes. This requirement limits the potential for occupant confusion during a fire.

When manual alarm-initiating devices are installed to initiate some other type of emergency response, such as for toxic release or spill, the manual alarm-initiating device should be obviously different from those used to report a fire to minimize the probability of confusion during an emergency. Refer to Chapter 24 of *NFPA 72* for guidance on manual initiation devices used for MNSs.

13.7.3.3.8.2 Manual fire alarm boxes shall be installed so that they are conspicuous, unobstructed, and accessible. [**72:**17.14.8.2]

The objective is to ensure that, as occupants leave the building, they can easily see manual fire alarm–initiating devices without searching. Each manual fire alarm box must be clearly identifiable from a distance. Decorative items or furnishings that are placed in front of or adjacent to manual fire alarm boxes can hinder a person from locating and operating the manual fire alarm box as that person proceeds to the means of egress. The AHJ determines if the manual fire alarm–initiating devices are sufficiently conspicuous, unobstructed, and accessible.

13.7.3.3.8.3* Unless installed in an environment that precludes the use of red paint or red plastic, manual fire alarm boxes shall be red in color. [**72:**17.14.8.3]

Δ **A.13.7.3.3.8.3** In environments where red paint or red plastic is not suitable, an alternative material, such as stainless steel, could be used as long as the box meets the requirements of 13.7.3.3.8.2. [**72:**A.17.14.8.3].

13.7.3.3.8.4 Manual fire alarm boxes shall be located within 5 ft (1.5 m) of each exit doorway on each floor. [**72:**17.14.8.4]

The purpose of locating the manual fire alarm box within 5 ft (1.5 m) of the exit doorway on each floor is to have the location consistent with the path of travel that occupants will use during an evacuation. As occupants approach the entry door into an exit stairway, a manual fire alarm box (if required) should be in close proximity to that entry door. Normally, the discharge doors of a stairway do not require a manual fire alarm box, because such doors might not be considered an exit entry door; review of the NFPA *101* or the relevant building code is recommended. Doors that serve as entry into an exit passageway or a horizontal exit or doors that provide direct access to the exterior from a grade floor are normally considered exit entry doors and require the manual fire alarm box to be within 5 ft (1.5 m) of the exit doorway, where manual fire alarm boxes are required by codes or ordinances.

13.7.3.3.8.5* Additional manual fire alarm boxes shall be provided so that the travel distance to the nearest manual fire alarm box will not exceed 200 ft (61 m), measured horizontally on the same floor. [**72:**17.14.8.5]

A.13.7.3.3.8.5 It is not the intent of 13.7.3.3.8.5 to require manual fire alarm boxes to be attached to movable partitions or to equipment, nor to require the installation of permanent structures for mounting purposes only. [**72:**A.17.14.8.5]

The criterion described in 13.7.3.3.8.5 is derived from the requirements established in NFPA *101*.

13.7.3.3.8.6 Manual fire alarm boxes shall be mounted on both sides of grouped openings over 40 ft (12.2 m) in width, and within 5 ft (1.5 m) of each side of the grouped opening. [**72:**17.14.8.6]

The objective of 13.7.3.3.8.6 is to provide a manual fire alarm box within easy reach in the normal exit path of the occupants. Where multi-leaf door sets are installed, the actual exitway can become wide enough that departing occupants might not notice the fire alarm box on the far side of a wide set of doors. Also, an occupant might have to cross the doors to activate the manual fire alarm box, which would delay departure. Consequently, when door sets attain 40 ft (12.2 m) in width, fire alarm boxes are required on both sides of the means of egress. The number and the location of the manual fire alarm boxes required for multi-leaf doors must be consistent where there are groups of exit doors.

13.7.3.3.9 When fire alarm systems are not monitored, an approved permanent sign shall be installed adjacent to each manual fire alarm box. The sign shall read as follows:

Local alarm only:

(1) Activate alarm

(2) Exit building

(3) Call fire department

13.7.3.4* Indication of Central Station Service. The prime contractor shall conspicuously indicate that the alarm system providing service at a protected premises complies with all the requirements of this *Code* through the use of a systematic follow-up program under the control of the organization that has listed the prime contractor. [**72:**26.3.4]

A.13.7.3.4 The terms *certificated* and *placarded*, which appeared in previous editions of *NFPA 72*, were considered by some to be too specific to two listing organizations and were replaced with more generic wording. The concept of providing documentation to indicate ongoing compliance of an installed system continues to be reflected by the current language. [**72:**A.26.3.4]

To help ensure the inherent higher level of protection that a central station fire alarm system provides, 13.7.3.4 requires the prime contractor to indicate that the entire fire alarm system meets the requirements of the *Code* through the use of a systematic follow-up program under the control of the organization that has listed the prime contractor.

This requirement does not intend that the organization providing the systematic follow-up service will actually inspect every central station fire alarm system. Nor does it mean that when the organization providing the systematic follow-up service does inspect a central station fire alarm system that such an organization will inspect every aspect of that system. However, by providing a systematic follow-up program under the control of the organization that has listed the prime contractor, the prime contractor makes provision for a potential additional level of oversight.

The requirement in 13.7.3.4 tends to promote and encourage installation, testing, and maintenance procedures that will help ensure the overall quality of the central station alarm system. Further, the conspicuous indication that the installation complies with all the requirements of the *Code* helps promote a much more determined effort to implement the requirements of the *Code* than might otherwise occur.

Listing organizations do not conduct reviews of fire alarm system plans as a part of the listing process. Nor do they conduct acceptance testing or commissioning of systems. These functions are conducted by other entities, such as the local fire authority or an insurance carrier for the protected premises.

The prime contractor must conspicuously post documentation issued by the organization that has listed the prime contractor within a stated distance of the main fire alarm system control unit.

By intent, the *Code* does not provide details of the process by which the listing organization provides follow-up service or issues the required documentation to the listed prime contractor. Rather, the *Code* leaves those details up to the procedures and practices of the listing organization.

13.7.3.4.1 Documentation indicating *Code* compliance of the alarm system shall be issued by the organization that has listed the prime contractor. [**72:**26.3.4.1]

Δ **13.7.3.4.2** The documentation shall include, at a minimum, the following information:

(1) Name of the prime contractor involved with the ongoing *Code* compliance of the central station service
(2)* Full description of the alarm system as installed

A.13.7.3.4.2(2) The record of completion *(see Chapter 10 of NFPA 72)* can be used to fulfill this requirement. [**72:**A.26.3.4.2(2)]

(3) Issue and expiration dates of the documentation
(4) Name, address, and contact information of the organization issuing the document
(5) Identification of the AHJ(s) for the central station service installation

[**72:**26.3.4.2]

13.7.3.4.3 The documentation shall be physically posted within 3 ft (1 m) of the control unit, and copies of the documentation shall be made available to the AHJ(s) upon request. [**72:**26.3.4.3]

13.7.3.4.4 A central repository of issued documentation, accessible to the AHJ, shall be maintained by the organization that has listed the prime contractor. [**72:**26.3.4.4]

13.7.3.4.5* Alarm system service that does not comply with all the requirements of Section 26.3 of *NFPA 72* shall not be designated as central station service. [**72:**26.3.4.5]

A.13.7.3.4.5 It is the prime contractor's responsibility to remove all compliance markings (certification markings or placards) when a service contract goes into effect that conflicts in any way with the requirements of 13.7.3.4. [**72:**A.26.3.4.5]

13.7.3.4.6* For the purpose of Section 26.3 of *NFPA 72*, the subscriber shall notify the prime contractor, in writing, of the identity of the AHJs. [**72:**26.3.4.6]

A.13.7.3.4.6 The prime contractor should be aware of statutes, public agency regulations, or certifications regarding alarm systems that might be binding on the subscriber. The prime contractor should identify for the subscriber which agencies could be an AHJ and, if possible, advise the subscriber of any requirements or approvals being mandated by these agencies. [**72:**A.26.3.4.6]

The subscriber has the responsibility for notifying the prime contractor of those private organizations that are being designated as an AHJ. The subscriber also has the responsibility to notify the prime contractor of changes in the AHJ, such as where there is a change in insurance companies. Although the responsibility is primarily the subscriber's, the prime contractor should also take responsibility for seeking out these private AHJs through the subscriber. The prime contractor is responsible for maintaining current records on the AHJ for each protected premises. [**72:**A.26.3.4.6]

The most prevalent public agency involved as an AHJ with regard to alarm systems is the local fire department or fire prevention bureau. These are normally city or county agencies with statutory authority, and their approval of alarm system installations might be required. At the state level, the fire marshal's office is most likely to serve as the public regulatory agency. [**72:**A.26.3.4.6]

The most prevalent private organizations involved as AHJs are insurance companies. Others include insurance rating bureaus, insurance brokers and agents, and private consultants. It is important to note that these organizations have no statutory authority and become AHJs only when designated by the subscriber. [**72:**A.26.3.4.6]

With both public and private concerns to satisfy, it is not uncommon to find multiple AHJs involved with a particular protected premises. It is necessary to identify all AHJs in order to obtain all the necessary approvals for a central station alarm system installation. [**72:**A.26.3.4.6]

The phrase "in writing" can include any form of correspondence that can be verified upon request, such as a letter, fax, email, or other means of documented transfer of information from one entity to another. [**72:**A.26.3.4.6]

The subscriber and the prime contractor must identify all the AHJs involved at the protected premises. Although this responsibility rests primarily with the subscriber, the subscriber would normally know only the private AHJs. From experience gained by working in a particular jurisdiction, the prime contractor would most often know any additional public AHJs. Thus, a joint effort most effectively resolves this important requirement.

13.7.3.4.7 The AHJ(s) identified in 13.7.3.4.2(5) shall be notified within 30 calendar days of the expiration or cancellation by the organization that has listed the prime contractor. [**72:**26.3.4.7]

13.7.3.4.8 The subscriber shall surrender expired or canceled documentation to the prime contractor within 30 days of the termination date. [**72:**26.3.4.8]

Over the life of a central station system, someone might make a change that results in the expiration or cancellation of contracted service. In turn, that expiration or cancellation would invalidate the designation "central station service." In such a case, the organization that has listed the prime contractor must notify the AHJ, as required in 13.7.3.4.7. Further, the subscriber must return the expired or canceled documentation to the prime contractor within 30 days of the termination date.

The AHJ should rigorously enforce this requirement, which ensures that only those systems meeting and maintaining all the *Code* requirements for central station service have this designation.

13.7.3.5 Automatic Fire Detection and Alarm Service.

13.7.3.5.1 Automatic fire detectors shall be located, maintained, and tested in accordance with *NFPA 72*.

13.7.4 Automatic Fire Detectors.

13.7.4.1 General Requirements.

13.7.4.1.1 The requirements of 13.7.4.1.1 through 13.7.4.1.5 shall apply to all initiating devices. [**72:**17.4.1]

As used in this *Code*, the term *initiating device* covers not only fire detection devices such as manual fire alarm boxes, heat detectors, smoke detectors, and radiant energy–sensing detectors, but also other devices that monitor conditions related to fire safety. These other devices include gas detectors, sprinkler system waterflow switches, pressure switches, valve tamper switches, building temperature monitoring devices, and any signaling switches used to monitor special extinguishing systems or activate suppression systems. The requirements in 13.7.4 apply to all monitoring devices that provide information in the form of binary, digital, or analog data transmitted to a fire alarm control unit (FACU).

13.7.4.1.2 Where subject to mechanical damage, an initiating device shall be protected. A mechanical guard used to protect a smoke, heat, or radiant energy–sensing detector shall be listed for use with the detector. [**72:**17.4.2]

Mechanical guards used to protect smoke detectors, heat detectors, and radiant energy–sensing detectors must be listed for that purpose. Because both smoke detectors and heat detectors rely on the ceiling jet to convey smoke and hot combustion product gases from the fire plume to the detector, any object that impedes that flow retards the detector's response. Similarly, any object that impedes the transmission of radiant energy to radiant energy–sensing detectors would have an adverse effect on the detector's response. The only means to be certain that the mechanical guard is not a material impediment to detector response is to require that a qualified testing laboratory test and list the guard for the specific make and model detector. The listing will indicate the reduction in spacing or sensitivity that will result from use of the guard. See Exhibit 13.44 for an example of a mechanical guard for a smoke detector.

Exhibit 13.44

Protective mechanical guard for a smoke detector.

13.7.4.1.3 Initiating devices shall be supported independently of their attachment to the circuit conductors. [**72:**17.4.3]

The copper used in the wiring conductors is not formulated to serve as a mechanical support. Copper fatigues over time if placed under a mechanical stress, resulting in increasing brittleness and electrical resistance. Ultimately, the fatigued conductor breaks or its resistance becomes too high to allow the circuit to function properly. In either case, the operation of the circuit is impaired, and a loss of life or property conceivably could result because of fire alarm system failure.

Initiating devices must always be mounted as shown in the manufacturer's installation instructions. The requirements for listing include a method for mounting that adequately supports the initiating device so that no undue mechanical stresses are applied to the circuit conductors. If the instructions show the use of an electrical device or outlet box, then installation of the device with a box is a requirement of the listing, and the specific type of box shown must be used. If not shown, the use of an electrical box is determined by field conditions and the requirements of *NFPA 70*.

13.7.4.1.4 Initiating devices shall be installed in a manner that provides accessibility for periodic inspection, testing, and maintenance. [**72:**17.4.4]

It is not permitted to install initiating devices where they cannot be inspected, tested, and maintained during the life of the system. If the initiating devices are inaccessible, the maintenance contractor will not be able to maintain them in accordance with Chapter 14 of *NFPA 72* and the devices cannot be expected to provide reliable service. The term *inaccessible* is not defined in the *Code*; however, Chapter 3 of *NFPA 72* has incorporated three definitions of the term *accessible* from *NFPA 70*. The definitions of *accessible (as applied to equipment)*, *accessible (as applied to wiring methods)*, and *accessible, readily (readily accessible)* provide the criteria to judge the acceptability of equipment, wiring, and device locations. Also see the definition of *accessible spaces (as applied to detection coverage in Chapter 17 [of NFPA 72])* in 3.3.4 of *NFPA 72*.

The intent is not to discourage the use of portable ladders to access detection devices; the use of portable ladders would typically be needed to service detectors on normal height and higher ceilings. Rather, the *Code* is concerned with extreme cases in which unusually tall extension ladders (such as would be required in atriums) would be needed to service the devices. In high ceiling space areas, the only method of readily accessing detectors would be by using proper equipment such as high lifts. If special equipment is necessary to install a detection device, the designer should ensure that the owner understands that this special equipment will be needed for future inspection, testing, and maintenance of that device. The accessibility of a detector or other initiating device will ultimately be reflected in the ability of service personnel to perform the required inspection, testing, and maintenance in accordance with Chapter 14 of *NFPA 72*.

13.7.4.1.5 Initiating devices shall be installed in all areas, compartments, or locations where required by other governing laws, codes, or standards. [**72:**17.4.5]

Paragraph 13.7.4.1.5 provides correlation between this *Code*, *NFPA 72*, and other codes and standards. Initiating devices must be used wherever required by another code or standard. Chapter 17 of *NFPA 72* answers the questions relative to how many devices are required and how they should be installed.

13.7.4.1.6 Duct Detector Installation.

13.7.4.1.6.1 Smoke detectors shall be installed, tested, and maintained in accordance with *NFPA 72*. [**90A:**6.4.4.1]

Δ **13.7.4.1.6.2** In addition to the requirements of 6.4.3 of NFPA 90A where an approved fire alarm system is installed in a building, the smoke detectors required by the provisions of Section 6.4 of NFPA 90A shall be connected to the fire alarm system in accordance with the requirements of *NFPA 72*. [**90A:**6.4.4.2]

13.7.4.1.6.2.1 Smoke detectors used solely for closing dampers or for heating, ventilating, and air-conditioning system shutdown shall not be required to activate the building evacuation alarm. [**90A:**6.4.4.2.1]

Δ **13.7.4.1.6.3** Where smoke detectors required by Section 6.4 of NFPA 90A are installed in a building not equipped with an approved fire alarm system as specified by 13.7.4.1.6.2, the following shall occur:

(1) Smoke detector activation required by Section 6.4 of NFPA 90A shall cause a visual and audible signal in a normally occupied area.
(2) Smoke detector trouble conditions shall be indicated visually or audibly in a normally occupied area and shall be identified as air duct detector trouble.

[**90A:**6.4.4.3]

13.7.4.1.6.4 Smoke detectors powered separately from the fire alarm system for the sole function of stopping fans shall not require standby power. [**90A:**6.4.4.4]

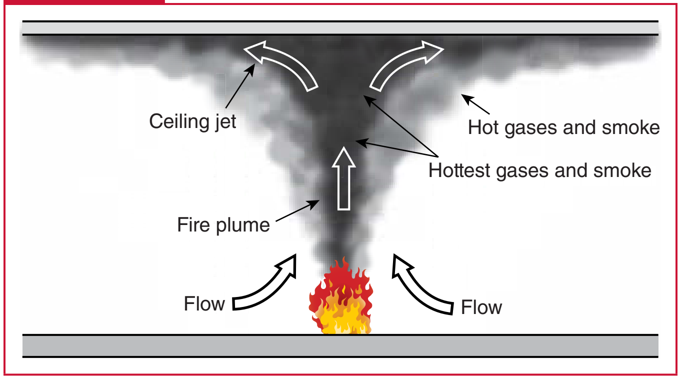
13.7.4.2 Requirements for Smoke and Heat Detectors.

13.7.4.2.1 Recessed Mounting. Unless tested and listed for recessed mounting, detectors shall not be recessed into the mounting surface. [**72:**17.5.1]

Both heat and smoke detectors rely on the flow of the ceiling jet to convey heat and smoke, respectively, to the detectors. Recessing detectors that are not tested and listed for recessed mounting would locate the detector out of the prevailing flow of the ceiling jet and, hence, would have an adverse effect on the detector's ability to perform as intended.

A heat detector must absorb heat from the hot gases of the ceiling jet, as shown in Exhibit 13.45, before it can respond. Approximately 92 percent to 98 percent of the heat that a heat detector receives is carried to the detector in the hot air and combustion product gases of the ceiling jet that are created by

Exhibit 13.45



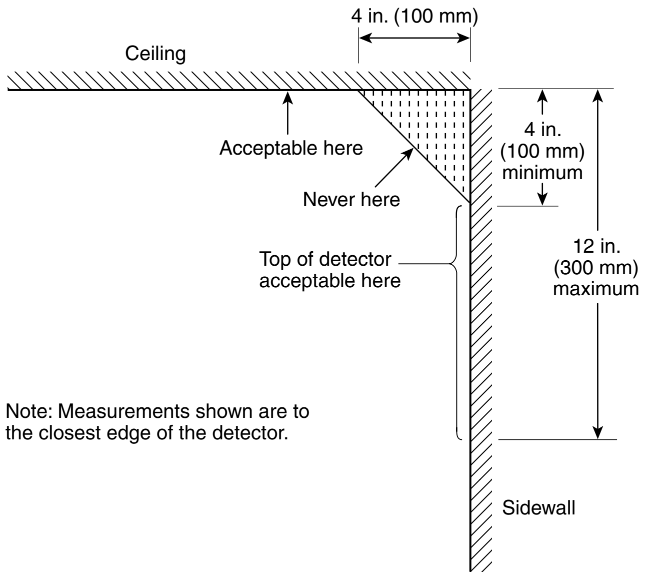
Ceiling jet formed by fire plume.

the fire. This process is called *convection* or *convective heat transfer*. Note that the velocity, temperature, and smoke concentration are not uniform across the thickness of the ceiling jet. At the surface of the ceiling, the ceiling jet moves more slowly due to frictional losses and is slightly cooler due to heat transfer to the ceiling. A heat detector that is recessed is removed from the flow of air; consequently, the quantity of heat it receives per unit of time is reduced. The heat detector's response slows, allowing the fire to grow larger before it is detected. A heat detector also receives a small percentage of radiated heat. If the detector is recessed, less of this radiated heat energy can strike the detector. Consequently, if heat detectors are installed recessed into the ceiling, contrary to the *Code*, the system will likely respond more slowly, if at all, than if the heat detectors are mounted as required by the *Code*.

The effect is the same with smoke detectors. Smoke detectors depend on air movement to convey smoke from the fire to the detector. Usually this air movement is the ceiling jet produced by the fire. Smoke detectors are typically mounted on the ceiling to take advantage of fire plume dynamics and the ceiling jet. However, because of frictional energy loss between the ceiling jet and the ceiling surface, a very thin layer of air immediately beneath the ceiling surface flows more slowly than the layer located a little beneath it. The force that pushes the smoke into the sensing chamber is a function of the ceiling jet velocity. If the velocity at the detector is low, smoke moves into the detector slowly. If a smoke detector is recessed, the more slowly moving air immediately beneath the ceiling surface is the only flow impinging upon the detector. Because a recessed detector is in a no-flow or low-flow location, relative to the ceiling jet, it will be very slow to respond — if it responds at all — compared with the same detector mounted on the ceiling surface.

13.7.4.3 Location.

13.7.4.3.1* Unless otherwise modified by 17.6.3.2.2, 17.6.3.3.2, or 17.6.3.7 of *NFPA 72*, spot-type heat-sensing fire detectors shall be located on the ceiling not less than 4 in. (100 mm) from the sidewall or on the sidewalls between 4 in. and 12 in. (100 mm and 300 mm) from the ceiling. [**72:**17.6.3.1.3.1]



Δ ***FIGURE A.13.7.4.3.1*** *Example of Proper Mounting for Heat Detectors. [**72:** Figure A.17.6.3.1.3.1]*

A.13.7.4.3.1 Figure A.13.7.4.3.1 illustrates the proper mounting placement for detectors. [**72:**A.17.6.3.1.3.1]

Paragraph 13.7.4.3.1 applies only to spot-type heat detectors. A ceiling surface is the upper surface of a space, regardless of height. The ceiling location derives the maximum benefit from the upward flow of the fire plume and the flow of the ceiling jet beneath the ceiling plane. As the ceiling jet approaches the wall, its velocity decreases. Lower ceiling jet velocities result in slower heat transfer to the detector and, therefore, a retarded response. Generally, it is best to keep detectors farther from the wall than the 4 in. (100 mm) minimum distance. In practice, this requirement is also appropriately applied where heat detectors are installed near to downward projecting obstructions such as beams.

The original research data used to support the existence of a "dead air space" where the walls meet the ceiling in a typical room was based on work performed in 1993 [Fire Protection Research Foundation, 1993]. Figure A.13.7.4.3.1 shows this potential dead air space extending 4 in. (100 mm) in from the wall and 4 in. (100 mm) down from the ceiling. More recent work related to smoke detection but not heat detection indicates that this dead air may not exist to the degree originally thought [Fire Protection Research Foundation Report, April 2006]. Since the research has yet to be extended to heat detectors, heat detectors are still excluded from being installed in those areas.

13.7.4.3.2 Unless otherwise modified by 17.6.3.2.2, 17.6.3.3.2, or 17.6.3.7 of *NFPA 72*, line-type heat detectors shall be located on the ceiling or on the sidewalls not more than 20 in. (510 mm) from the ceiling. [**72:**17.6.3.1.3.2]

Line-type heat detectors are generally considered to be equivalent to a row of spot-type detectors for the purposes of spacing and location. However, different manufacturers of line-type detectors have had their products listed with different mounting techniques. The location of line-type detectors must always be in conformance with the manufacturer's installation instructions. Keep in mind that attaching a line-type detector directly to, and in contact with, a structural building component that can absorb heat will retard the response of the detector — the building component will act as a heat sink and retard the increase in detector temperature as a function of time.

13.7.4.3.3* Spot-Type Smoke Detectors.

A.13.7.4.3.3 In high-ceiling areas, such as atriums, where spot-type smoke detectors are not accessible for periodic maintenance and testing, projected beam–type or air sampling–type detectors should be considered where access can be provided. [**72:**A.17.7.3.2]

The importance of accessibility and the maintenance of a smoke detection system cannot be overemphasized. The designer must exercise judgment and discretion to provide a system that can be maintained pursuant to the criteria established in Chapter 14 of *NFPA 72*. Paragraph A.13.7.4.3.3 clarifies 13.7.4.1.4, which requires that all initiating devices, including smoke detectors, be installed in such a manner that they can be effectively maintained.

Atriums and other areas with exceptionally high ceilings (such as auditoriums, gymnasiums, exhibit halls, storage facilities, and some manufacturing facilities) represent difficult situations for the use of spot-type smoke detection. Stratification, maintenance concerns, accessibility for testing, and smoke dissipation may warrant the use of other types of detection. Paragraph A.13.7.4.3.3 advises the designer to consider either air sampling–type or linear projected beam–type photoelectric light obscuration smoke detection as alternatives. However, note that the air-sampling ports of an air sampling–type detector are treated as individual spot-type detectors. Air sampling–type detectors rely on the plume and ceiling jet to carry smoke to the sampling ports. Consequently, where stratification is a concern, this type of detection (air-sampling detectors) might not represent an advantage over traditional spot-type detectors. Furthermore, when stratification is a concern, the beams of projected-beam smoke detection must be carefully located to ensure that the design fire will be detected. Annex B of *NFPA 72* provides additional information on how to predict the elevation of a stratification plane under known conditions.

13.7.4.3.3.1* Spot-type smoke detectors shall be located on the ceiling or, if on a sidewall, between the ceiling and 12 in. (300 mm) down from the ceiling to the top of the detector. [**72:**17.7.3.2.1]

A.13.7.4.3.3.1 Refer to Figure A.13.7.4.3.3.1 for an example of proper mounting for detectors. Sidewall detectors mounted closer to the ceiling will respond faster. [**72:**A.17.7.3.2.1]

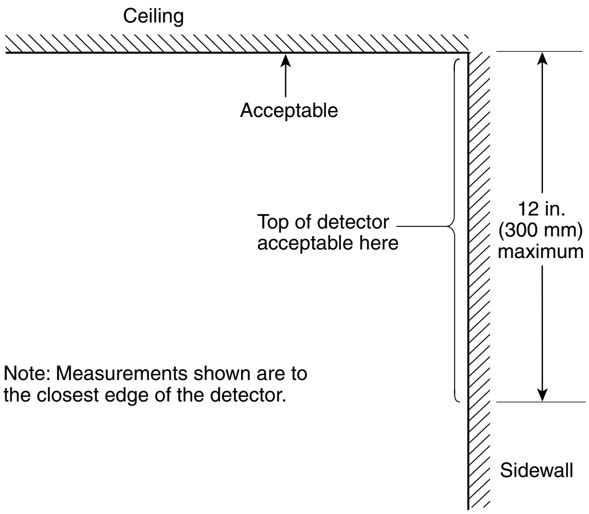


FIGURE A.13.7.4.3.3.1 *Example of Proper Mounting of Smoke Detectors. [**72:** Figure A.17.7.3.2.1]*

Prior to the 2013 edition of *NFPA 72*, ceiling-mounted smoke detectors were not permitted within 4 in. (100 mm) of a sidewall, and sidewall-mounted smoke detectors were not permitted within 4 in. (100 mm) of the ceiling. The concern was that smoke flow would be compromised in a dead-air space in the corner where the ceiling and the wall meet. Computational fluid dynamics simulations have shown smoke flowing into such corners for a range of room geometries and ceiling heights, thereby removing the dead-air space concern. [Note that the 4 in. (100 mm) prohibition still applies to heat detectors. See 13.7.4.3.1.]

The location requirement in 13.7.4.3.3.1 is valid for both a low-energy incipient fire and a high-energy-output fire that is immediately life threatening. Either the normally existing air currents or the fire plume and ceiling jet from the larger fire convey smoke to ceiling-mounted detectors. While the ceiling-wall corner is permitted to be used, it is not the most desirable location. For the detectors to be able to respond, they must be installed in the working air volume of the compartment. A prudent designer should avoid locating detectors in tight corner spaces that may preclude sufficient air flow and circulation of smoke into the detector entry points.

13.7.4.3.3.2* To minimize dust contamination, smoke detectors, where installed under raised floors, shall be mounted only in an orientation for which they have been listed. [**72:**17.7.3.2.2]

A.13.7.4.3.3.2 Figure A.13.7.4.3.3.2 illustrates under-floor mounting installations. [**72:**A.17.7.3.2.2]

The fast-moving air in a data center under-floor space has sufficient energy to suspend dust. As that air enters the detector, it slows down, and the suspended dust settles in the detector. The accumulation of dust within a smoke detector has an effect similar to that of smoke. In an ionization smoke detector, the dust impedes the

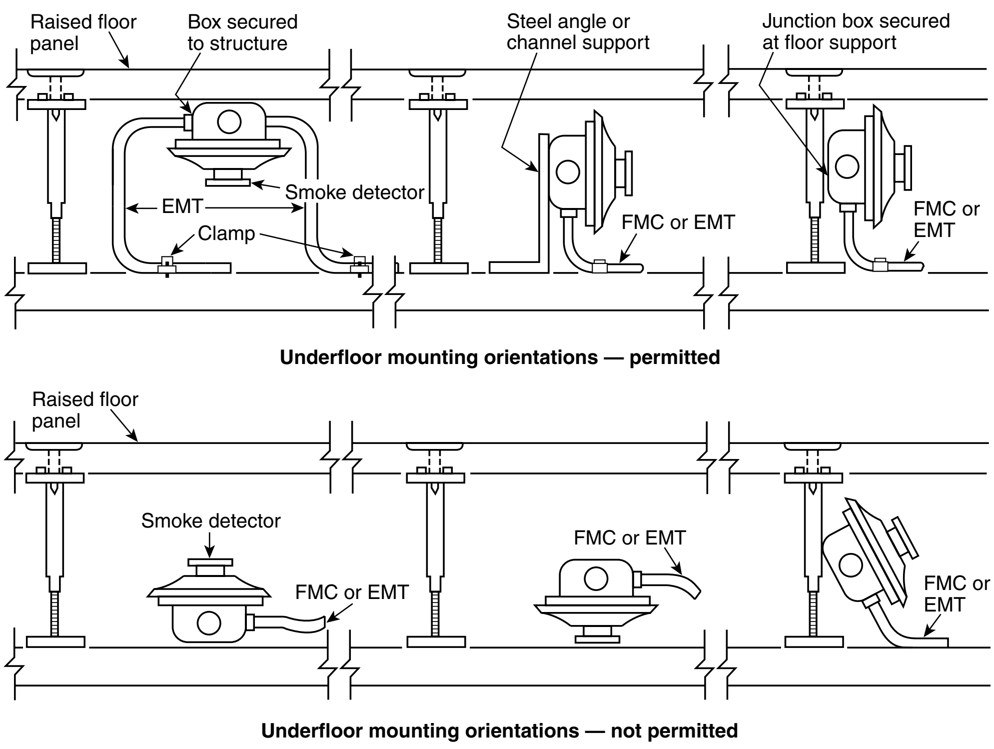

***FIGURE A.13.7.4.3.3.2** Mounting Installations Permitted (**top**) and Not Permitted (**bottom**). [**72:** Figure A.17.7.3.2.2]*

flow of current within the chamber. In a spot-type photoelectric detector, the dust increases the reflectance within the chamber. Thus, dust causes each type of detector to become more sensitive, increasing the likelihood of unwarranted alarms. The permitted orientations shown in Figure A.13.7.4.3.3.2 (top) minimize the probability of dust falling into the detector from the floor and also minimize the effect of air-conveyed dust on the detector.

Other concerns reinforce the benefits of positioning detectors as shown in Figure A.13.7.4.3.3.2 (top). The detector is placed in the upper half of the under-floor volume. Because the purpose of the under-floor space is to allow for the routing of cables between machines, the floor is usually covered with cable. This cable has the same effect on the flow of air in the under-floor volume that joists have on airflow in a room. The cables create turbulence and force the flow to be concentrated in the upper half of the under-floor volume. Placing the detector in the upper half of the under-floor volume improves the system's ability to respond to an early-stage fire.

Another reason for positioning detectors as shown in Figure A.13.7.4.3.2.2 (top) is that detectors mounted in the upper half of the under-floor volume are far less likely to be damaged as new cables are installed or old cables are rerouted through the under-floor space. Where water-cooled computers are in use, the detectors are less likely to become wet if the computer cooling system leaks. Also, when air is not flowing, the detectors will be in the best orientation for detection. Finally, Figure A.13.7.4.3.2.2 (top) shows the detectors in the orientation for which they have been tested and listed.

13.7.4.3.3.3 On smooth ceilings, spacing for spot-type smoke detectors shall be in accordance with 13.7.4.3.3.3.1 through 13.7.4.3.3.3.4. [**72:**17.7.3.2.3]

Δ **13.7.4.3.3.3.1*** In the absence of specific performance-based design criteria, one of the following requirements shall apply:

(1) The distance between smoke detectors shall not exceed a nominal spacing of 30 ft (9.1 m) and there shall be detectors within a distance of one-half the nominal spacing, measured at right angles from all walls or partitions extending upward to within the top 15 percent of the ceiling height.

(2)* All points on the ceiling shall have a detector within a distance equal to or less than 0.7 times the nominal 30 ft (9.1 m) spacing (0.7 *S*).

[**72:**17.7.3.2.3.1]

Δ **A.13.7.4.3.3.3.1** The 30 ft (9.1 m) spacing is a guide for prescriptive designs. The use of such a spacing is based upon customary practice in the fire alarm community. [**72:**A.17.7.3.2.3.1]

Where there are explicit performance objectives for the response of the smoke detection system, the performance-based design methods outlined in Annex B of *NFPA 72* should be used. [**72:**A.17.7.3.2.3.1]

For the purposes of this section, "nominal 30 ft (9.1 m)" should be determined to be 30 ft (9.1 m) ±5 percent [±18 in. (460 mm)]. [**72:**A.17.7.3.2.3.1]

According to the listing investigations performed on smoke detectors, no full-scale fire test establishes a listed spacing for smoke detectors. One reason is because a sufficiently explicit response criterion against which a smoke detector can be measured has not been established. However, experience has shown that installing smoke detectors using a nominal 30 ft (9.1 m) spacing criterion achieves the necessary life safety objectives. Where the owner and other relevant stakeholders have objectives other than life safety or are applying a performance-based design, a different spacing criterion might be appropriate. That criterion could be developed using the performance-based methods outlined in Annex B of *NFPA 72* or other acceptable methods. It is not intended that enforcement authorities measure smoke detector to–smoke detector spacings with critical precision. The nominal plus or minus 5 percent criterion set forth in 13.7.4.3.3.3.1 is intended to provide some latitude in enforcement. The development of a fire and the extension of smoke through a real space are highly variable. A difference in smoke detector spacing of as much as 2 or 3 ft (0.61 to 0.91 m) will have no material effect on the ultimate performance of the system.

Δ **A.13.7.4.3.3.3.1(2)** This is useful in calculating locations in corridors or irregular areas *[see 17.6.3.1.1 of NFPA 72 and Figure A.17.6.3.1.1(h) of NFPA 72]*. For irregularly shaped areas, the spacing between detectors can be greater than the selected spacing, provided the maximum spacing from a detector to the farthest point of a sidewall or corner within its zone of protection is not greater than 0.7 times the selected spacing (0.7*S*). [**72:**A.17.7.3.2.3.1(2)]

13.7.4.3.3.3.2 In all cases, the manufacturer's published instructions shall be followed. [**72:**17.7.3.2.3.2]

When a manufacturer, through its own testing and research program, publishes a specific spacing recommendation that is different from the 30 ft (9.1 m) spacing, that spacing recommendation becomes an enforceable part of this *Code*.

13.7.4.3.3.3.3 Other spacing shall be permitted to be used depending on ceiling height, different conditions, or response requirements. [**72:**17.7.3.2.3.3]

In the prescriptive design environment, a spacing other than 30 ft (9.1 m) can be used, provided that the justification for doing so is based on the fire dynamics, environment, compartment dimensions, and response objectives. The criteria imply, but do not explicitly require, a formal design process such as that required by 17.7.1.3 of *NFPA 72*. The designer should document the basis for selecting a spacing other than 30 ft (9.1 m), and that document should become a permanent part of the project file. Finally, the spacing selected will be subject to review and approval by the relevant AHJ.

13.7.4.3.3.3.4 For the detection of flaming fires, the guidelines in Annex B of *NFPA 72* shall be permitted to be used. [**72:**17.7.3.2.3.4]

Currently, no computational models are designed to develop predictions of smoke flow for nonflaming fires. Where the design objective is the detection of a smoldering fire, the designer should model ambient compartment air currents and the power commitment to them to determine to what extent they will dominate the flow of smoke.

Two analytical methods are provided in Annex B of *NFPA 72*. Because these methods rely on plume and ceiling jet dynamics, their use must be limited to scenarios involving flaming fires that produce a buoyant plume. For smoldering fire scenarios, other methods must be used until open flaming commences, after which the methods of Annex B of *NFPA 72* can be used.

Several available computer models (including FPETool, FastLite, and Hazard 1) predict smoke detector activation to the flaming fire scenario. However, it must be noted that these computer models use a temperature rise model, not optical density or mass density of smoke, to predict the activation of smoke detectors. Their credibility is limited by the validity of the temperature correlation plugged into the model for smoke detector response.

In this regard, the research paper *Fire Detection Modeling, State of the Art*, by Robert P. Schifiliti and William E. Pucci, analyzes the various ways the computer fire models predict smoke detector operation and points out the advantages and disadvantages of each method.

Fire Dynamics Simulator (FDS), a computational fluid dynamics model, has become popular for modeling the flow of smoke and fire plumes in rooms and buildings. However, this computer model is not simple to operate and requires considerable skill to generate reliable simulations. FDS tracks mass, velocity, and temperature. Users of the FDS model must, again, set numerical values for these parameters, which are then used to infer smoke detector activation.

13.7.4.3.3.4* For solid joist and beam construction, spacing for spot-type smoke detectors shall be in accordance with 13.7.4.3.3.4.1 through 13.7.4.3.3.4.5. [**72:**17.7.3.2.4]

A.13.7.4.3.3.4 Detectors are placed at reduced spacings at right angles to joists or beams in an attempt to ensure that detection time is equivalent to that which would be experienced on a flat ceiling. It takes longer for the combustion products (smoke or heat) to travel at right angles to beams or joists because of the phenomenon wherein a plume from a relatively hot fire with significant thermal lift tends to fill the pocket between each beam or joist before moving to the next beam or joist. [**72:**A.17.7.3.2.4]

Though it is true that this phenomenon might not be significant in a small smoldering fire where there is only enough thermal lift to cause stratification at the bottom of the joists, reduced spacing is still recommended to ensure that detection time is equivalent to that which would exist on a flat ceiling, even in the case of a hotter type of fire. [**72:**A.17.7.3.2.4]

13.7.4.3.3.4.1 Solid joists shall be considered equivalent to beams for smoke detector spacing guidelines. [**72:**17.7.3.2.4.1]

When the rules in 13.7.4.3.3.4 for the spacing of spot-type smoke detectors are applied, solid joists and solid beams are treated the same. At the fire sizes normally associated with the response of a smoke detection system, the ceiling jet velocities are relatively low and produce less turbulence at the beam and joist bottoms. Consequently, the effects of beams and joists on the ceiling jet flow are expected to be essentially the same.

13.7.4.3.3.4.2 For level ceilings, the following shall apply:

(1) For ceilings with beam depths of less than 10 percent of the ceiling height (0.1 *H*), smooth ceiling spacing shall be permitted. Spot-type smoke detectors shall be permitted to be located on ceilings or on the bottom of beams.

Because the thickness of the ceiling jet is generally taken to be equal to the upper 10 percent of the floor-to-ceiling height, beams and joists extending down a depth of less than this thickness are not expected to have a significant effect on the response time of the smoke detector, especially in view of the fact that the farthest a detector should be from the fire is 0.7 times the 30 ft (9.1 m) spacing. Consequently, the *Code* permits the designer to use smooth ceiling spacing where the beams and joists extend less than 10 percent of the floor-to-ceiling height down from the ceiling surface, regardless of the beam spacing. Detectors can be located on either the ceiling or the bottom of the beam. Also see 13.7.4.3.3.4.6 where applicable. Refer to Exhibit 13.46.

(2) For ceilings with beam depths equal to or greater than 10 percent of the ceiling height (0.1 *H*), the following shall apply:
   (a) Where beam spacing is equal to or greater than 40 percent of the ceiling height (0.4 *H*), spot-type detectors shall be located on the ceiling in each beam pocket.
   (b) Where beam spacing is less than 40 percent of the ceiling height (0.4 *H*), the following shall be permitted for spot detectors:
      (i) Smooth ceiling spacing in the direction parallel to the beams and at one-half smooth ceiling spacing in the direction perpendicular to the beams
      (ii) Location of detectors either on the ceiling or on the bottom of the beams

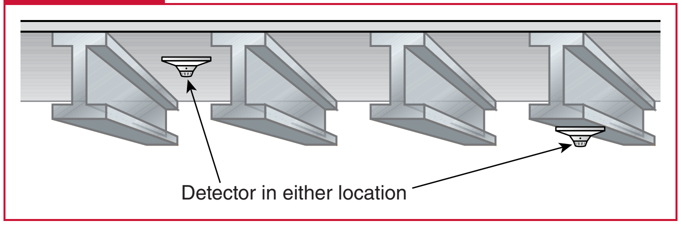
Where the beams extend down from a level ceiling more than 10 percent of the floor-to-ceiling height (0.1 *H*), they are expected to obstruct the ceiling jet flow. The obstruction of the ceiling jet delays the arrival of the smoke at the detector location. Furthermore, the speed with which smoke enters the sensing chamber of the detector is controlled by the speed of the ceiling jet past the detector. When ceiling jet flow is obstructed, it flows more slowly, increasing the smoke entry time once it arrives at the detector location.

Since it is generally accepted that the smoke plume from the fire will diverge at a nominal 22 degrees from the vertical axis, the plume will cover an area on the ceiling equal to 40 percent of the floor-to-ceiling height (0.4 *H*). Where the beam spacing exceeds 40 percent of the floor-to-ceiling height, the entire plume can be surrounded by beams. See Exhibit 13.47. If a smoke detector is not located in the bay created by the beams, the entire bay must fill with smoke before there is fill-and-spill propagation to an adjacent bay where a smoke detector might be located. This phenomenon will result in a delayed response. In the case where the beams are *both* equal to or more than 10 percent of the floor-to-ceiling height in depth *and* spaced equal to or more than 40 percent of the floor-to-ceiling height, a detector must be installed in each beam pocket.

Where the beams are greater than 10 percent of the floor-to-ceiling height and are spaced less than 40 percent of the floor-to-ceiling height, the plume will fill more than one bay, regardless of where the plume is located relative to the beams. The presence of the beams will retard the flow of the ceiling jet in the direction perpendicular to the beams and channel the flow in the direction parallel to the beams. See Exhibit 13.48.

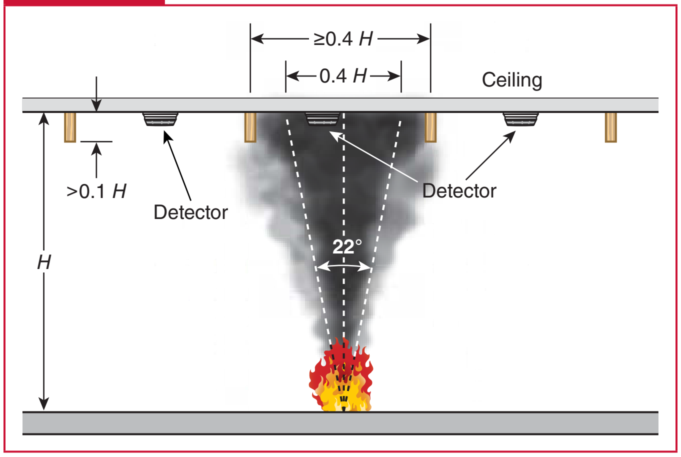
(3)* For beam pockets formed by intersecting beams, including waffle or pan-type ceilings, the following shall apply:
   (a) For beam depths less than 10 percent of the ceiling height (0.1 *H*), spacing shall be in accordance with 13.7.4.3.3.4.2(1).
   (b) For beam depths greater than or equal to 10 percent of the ceiling height (0.1 *H*), spacing shall be in accordance with 13.7.4.3.3.4.2(2)(2).

Exhibit 13.46



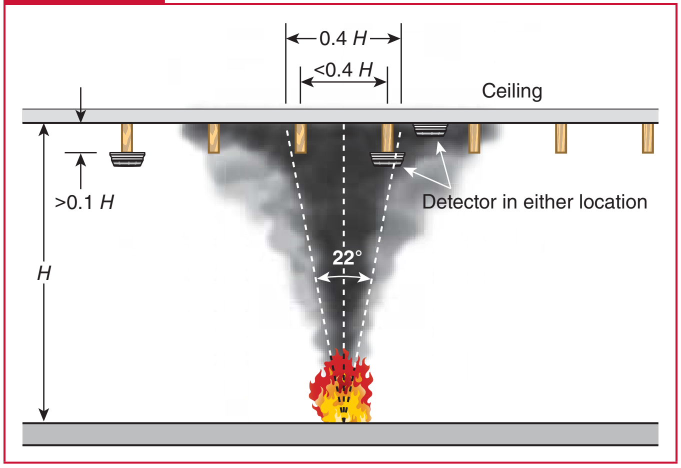
Smoke detector spacing with beams less than 0.1 H.

Exhibit 13.47



Smoke detector spacing with beam depths greater than 0.1 H and spaced more than 0.4 H.

Exhibit 13.48



Smoke detector spacing with beam depths greater than 0.1 H and spaced less than 0.4 H.

A.13.7.4.3.3.4.2(3) The geometry and reservoir effect is a significant factor that contributes to the development of velocity, temperature, and smoke obscuration conditions at smoke detectors located on the ceiling in beam pocket areas or at the bottom of beams as smoke collected in the reservoir volume spills into adjacent pockets. The waffle- or pan-type ceiling created by beams or solid joists, although retarding the initial flow of smoke, results in increased optical density, temperature rise, and gas velocities comparable to unconfined smooth ceilings. [**72:**A.17.7.3.2.4.2(3)]

For waffle- or pan-type ceilings with beams or solid joists, an alternative smoke detector grid arrangement (such as a shifted grid), with detectors located to take advantage of the channeling effect due to the reservoirs created by the beam pockets, will improve detector response and might allow greater spacing. See Figure A.13.7.4.3.3.4.2(3)(a) and Figure A.13.7.4.3.3.4.2(3)(b) for an example of shifted grids. The alternative smoke detector grid arrangement and spacing should be justified by an engineering analysis comparing the alternative smoke detector grid arrangement with the performance of smoke detectors on a level ceiling of equal height using 30 ft (9.1 m) smoke detector spacing. [**72:**A.17.7.3.2.4.2(3)]

Figure A.13.7.4.3.3.4.2(3)(a) illustrates the reservoir and channeling effect that results from the deep beam configuration. The strongest gas flows occur in a direction perpendicular to the beam opposite the fire location. The weaker flow occurs in a directional 45 degrees off the beam grid; however, the reservoir effect accounts for higher concentrations of smoke eventually flowing from the strong area reservoirs into the weak area reservoirs. [**72:**A.17.7.3.2.4.2(3)]

Figure A.13.7.4.3.3.4.2(3)(b) is a generic example illustrating how a smoke detection grid using 30 ft (9.1 m) spacing can be shifted to take advantage of the channeling and reservoir effect to optimize detection response. In the circle, the fire is split into four beam bays that must fill with smoke before appreciable flows occur into the next adjoining eight beam bays. This represents the worst case scenario for smoke to reach the detectors on the circle. The three other fire locations shown require the fire to initially fill only one or two bays before spilling to adjacent bays. [**72:**A.17.7.3.2.4.2(3)]

(4)* For corridors 15 ft (4.6 m) in width or less having ceiling beams or solid joists perpendicular to the corridor length, the following shall apply:
  (a) Smooth ceiling spacing shall be permitted.
  (b) Location of spot-type smoke detectors on ceilings, sidewalls, or the bottom of beams or solid joists

A.13.7.4.3.3.4.2(4) Corridor geometry is a significant factor that contributes to the development of velocity, temperature, and smoke obscuration conditions at smoke detectors located along a corridor. This is based on the fact that the ceiling jet is confined or constrained by the nearby walls without opportunity for entrainment of air. For corridors of approximately 15 ft (4.6 m) in width and for fires of

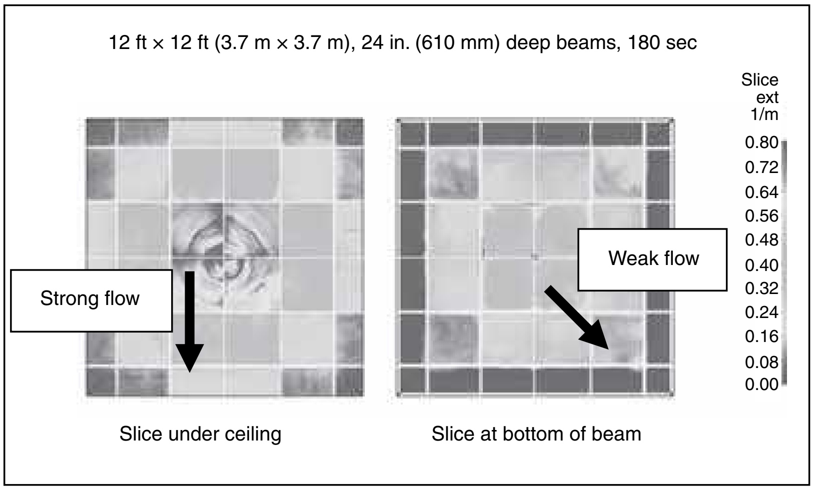


FIGURE A.13.7.4.3.3.4.2(3)(a) *Reservoir and Channeling Effect of Deep Beams. [72: Figure A.17.7.3.2.4.2(3)(a)]*

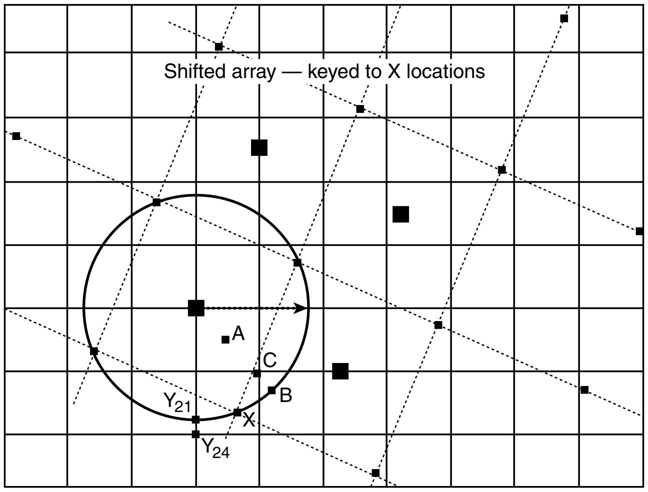

FIGURE A.13.7.4.3.3.4.2(3)(b) Shifted Smoke Detection Grid to Optimize Detection for Deep Beam Effects. [72: Figure A.17.7.3.2.4.2(3)(b)]

approximately 100 kW or greater, modeling has demonstrated that the performance of smoke detectors in corridors with beams has been shown to be comparable to spot smoke detector spacing on an unconfined smooth ceiling surface. [**72:**A.17.7.3.2.4.2(4)]

(5) For rooms of 900 ft² (84 m²) or less, the following shall be permitted:
   (a) Use of smooth ceiling spacing
   (b) Location of spot-type smoke detectors on ceilings or on the bottom of beams

[**72:**17.7.3.2.4.2]

Where smoke detectors are installed in a room of only 900 ft² (84 m²), the small floor constrains the ceiling jet such that even where ceiling beams are present, the fire can be detected sufficiently early to achieve the objective. Where other objectives demand more rapid response, performance-based design methods should be employed.

It is not the intent of 13.7.4.3.3.4.2(5) that the 900 ft² (84 m²) be applied to 5 ft (1.5 m) wide passageways 180 ft (54.9 m) in length, 10 ft (3.1 m) wide corridors 90 ft (27.4 m) in length, or other compartments where the fire hazard and risk are nominally equivalent to the rest of the normally occupied portion of the building. Item (a) requires the use of smooth spacing; see 13.7.4.3.3.3.1.

Δ **13.7.4.3.3.4.3*** For sloping ceilings with beams running parallel up slope, the following shall apply:

(1) Spot-type detector(s) shall be located on the ceiling within beam pocket(s).
(2) The ceiling height shall be taken as the average height over slope.
(3) Spacing shall be measured along a horizontal projection of the ceiling.
(4) Smooth ceiling spacing shall be permitted within beam pocket(s) parallel to the beams.
(5) For beam depths less than or equal to 10 percent of the ceiling height (0.1 *H*), spot-type detectors shall be located with smooth ceiling spacing perpendicular to the beams.
(6) For beam depths greater than 10 percent of the ceiling height (0.1 *H*), the following shall apply for spacing perpendicular to the beams:
   (a) For beam spacing greater than or equal to 40 percent of the ceiling height (0.4 *H*), spot-type detectors shall be located in each beam pocket.
   (b) For beam spacing less than 40 percent of the ceiling height (0.4 *H*), spot-type detectors shall not be required in every beam pocket but shall be spaced not greater than 50 percent of smooth ceiling spacing.

[**72:**17.7.3.2.4.3]

The term *sloping ceiling* is defined in *NFPA 72* as "a ceiling that has a slope of more than 1 in 8." A slope of 1 in 8 corresponds to a rise-over-run ratio of 0.125, or an angle of about 7.2 degrees. Any slope less than or equal to 1 in 8 is deemed to be equivalent to a level ceiling. Beams that are parallel to the slope are perpendicular to the ridge beam of the roof. (Beams that are perpendicular to the slope are parallel to the ridge beam.)

The concept behind these design requirements is analogous to those regarding heat detectors. When a buoyant plume from a flaming fire impinges on a sloped ceiling, it will progress rapidly upward toward the ridge beam. The buoyancy of the ceiling jet gases accelerates the ceiling jet up the slope. This acceleration provides for faster response by detectors that are up-slope from the fire. Computer-based computational fluid dynamics (CFD) modeling demonstrate that the beams are very effective in channeling the smoke in the beam channel up the slope to the peak of the roof. This rapid upward flow reduces the lateral flow parallel to the ridge beam.

A.13.7.4.3.3.4.3 A smoke detector should be placed within each beam channel. Computer modeling has shown that parallel beams (upslope) are very effective at channeling smoke, and smoke spillover is rarely detectable in adjacent parallel pockets. [**72:**A.17.7.3.2.4.3]

Δ **13.7.4.3.3.4.4*** For sloping ceilings with beams running perpendicular across slope, the following shall apply:

(1) Spot-type detector(s) shall be located at the bottom of the beams.
(2) The ceiling height shall be taken as the average height over slope.
(3) Spacing shall be measured along a horizontal projection of the ceiling.
(4) Smooth ceiling spacing shall be permitted within beam pocket(s).
(5) For beam depths less than or equal to 10 percent of the ceiling height (0.1 *H*), spot-type detectors shall be located with smooth ceiling spacing.

(6) For beam depths greater than 10 percent of the ceiling height (0.1 *H*), spot-type detectors shall not be required to be located closer than (0.4 *H*) and shall not exceed 50 percent of smooth ceiling spacing.

[**72:**17.7.3.2.4.4]

Beams that are perpendicular to the slope are parallel to the ridge beam. These beams form dams that prevent the smoke from flowing up the ceiling slope toward the ridge beam. When the smoke encounters a beam running across the slope, the ceiling jet will begin forming a smoke layer. Smoke will flow laterally as the depth of the smoke layer increases. Eventually, the smoke layer will become deep enough to spill over the beam and begin filling the next bay. This process is a much slower propagation than when the beams run up the slope. However, the damming effect of the beams will tend to channel smoke across the roof, parallel to the beams. The spacing adjustments in this section are the result of a detailed analysis of the computer-based CFD modeling research that was conducted to investigate this issue.

A.13.7.4.3.3.4.4 Irregular area spacing guidance for level beam ceilings can be used. Computer modeling has shown that spot-type detectors should be located on the bottom of perpendicular beams. [**72:**A.17.7.3.2.4.4]

Δ **13.7.4.3.3.4.5*** For sloped ceilings with beam pockets formed by intersecting beams, the following shall apply:

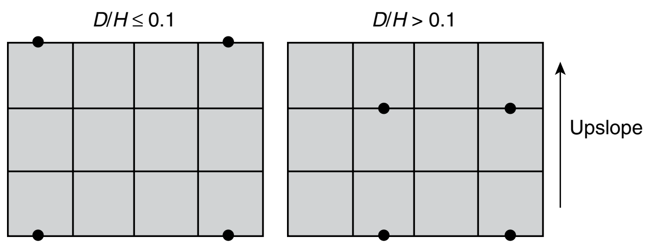
(1) Spot-type detector(s) shall be located at the bottom of the beams.
(2) The ceiling height shall be taken as the average height over slope.
(3) Spacing shall be measured along a horizontal projection of the ceiling.
(4) For beam depths less than or equal to 10 percent of the ceiling height (0.1 *H*), spot-type detectors shall be spaced with not more than three beams between detectors and shall not exceed smooth ceiling spacing.
(5) For beam depths greater than 10 percent of the ceiling height (0.1 *H*), spot-type detectors shall be spaced with not more than two beams between detectors, but shall not be required to be spaced closer than (0.4 *H*), and shall not exceed 50 percent of smooth ceiling spacing.

[**72:**17.7.3.2.4.5]

A.13.7.4.3.3.4.5 Computer modeling has shown that spot-type detectors should be located on the bottom of perpendicular beams and should be aligned with the center of pocket, as shown, in Figure A.13.7.4.3.3.4.5. [**72:**A.17.7.3.2.4.5]

13.7.4.3.3.4.6 For sloped ceilings with solid joists, the detectors shall be located on the bottom of the joist. [**72:**17.7.3.2.4.6]

The relatively small volume of the channel between joists results in smoke filling this volume quickly. Once the channel is filled, the smoke flows across the bottom of the joists. Locating smoke detectors at the bottom of the joist places them where the dominant flow of smoke is expected to occur. Paragraph 13.7.4.3.3.4.1 specifies that solid joists be treated as beams for smoke detector spacing guidelines. However, where the beams are actually joists, that is, greater than 4 in. (100 mm) in depth and on centers 3.0 ft (0.9 m) or less, the detectors must be placed on the bottoms of the joists. Keep in mind that bar joists or open web beams do not affect smoke flow unless the top plate exceeds 4 in. (100 mm) in depth.



Δ ***FIGURE A.13.7.4.3.3.4.5*** *Spot-Type Detector Spacing for Sloping Ceilings with Beam Pockets.* *[72: Figure A.17.7.3.2.4.5]*

13.7.4.3.4 Air Sampling–Type Smoke Detector.

The term *air sampling–type detector*, addressed in 13.7.4.3.4, is defined in 3.3.87.1. These detectors use one or more sampling tubes and draw a sample of air from the hazard area to the detector, where the presence of visible smoke or invisible combustion products is identified. These detectors include a number of cloud chamber–type smoke detectors and several varieties of high sensitivity, photoelectric-type smoke detectors. Air sampling–type smoke detectors consist of a sampling pipe network, an aspirating fan, and a highly sensitive centralized detector.

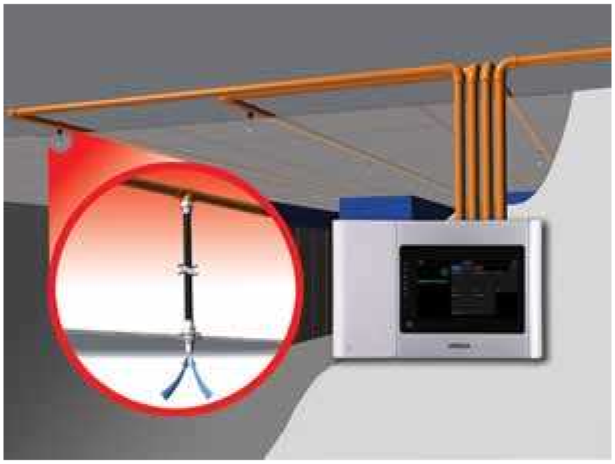
Air sampling–type detectors are used in a variety of applications where the designer is concerned with very early smoke detection and where increased sensitivity is needed to meet the owner's fire protection goals. Because of their sensitivity range flexibility, air-sampling detectors are often used in areas that house valuable equipment as well as conventional settings that do not require high sensitivity. See Exhibit 13.49 through Exhibit 13.52 for examples of air sampling–type smoke detectors.

13.7.4.3.4.1 Each sampling port of an air sampling–type smoke detector shall be treated as a spot-type detector for the purpose of location and spacing. [**72:**17.7.3.6.1]

The International Fire Detection Research Project showed that the sampling port does not produce the effect of drawing the smoke up to the sampling port from lower down in the compartment. Air sampling–type detectors used to protect rooms and other large compartments rely on either ambient air currents or the fire plume and ceiling jet as much as do spot-type smoke detectors.

13.7.4.3.4.2 Maximum air sample transport time from the farthest sampling port to the detector shall not exceed 120 seconds. [**72:**17.7.3.6.2]

Exhibit 13.49



Use of sampling tubes to convey smoke-laden air to the central detection unit of an air-sampling detector. (Courtesy of Xtralis, Inc., Norwell, MA)

The air transport time criterion places an effective limit on the design of the fan and the maximum distance from the detector to the farthest sampling port, as well as the size and layout of the sampling pipes. The manufacturer's listing and instructions provide the details on how the particular product must be used in order to comply with this limitation. Some air sampling–type smoke detectors have a means to detect changes in airflow, which provides some measure of monitoring the integrity of the piping network.

13.7.4.3.4.3* Sampling pipe networks shall be designed on the basis of, and shall be supported by, sound fluid dynamic principles to ensure required performance. [**72:**17.7.3.6.3]

A.13.7.4.3.4.3 A single-pipe network has a shorter transport time than a multiple-pipe network of similar length pipe; however, a multiple-pipe system provides a faster smoke transport time than a single-pipe system of the same total length. As the number of sampling holes in a pipe increases, the smoke transport time increases. Where practicable, pipe run lengths in a multiple-pipe system should be nearly equal, or the system should be otherwise pneumatically balanced. [**72:**A.17.7.3.6.3]

13.7.4.3.4.4 Sampling pipe network design details shall include calculations showing the flow characteristics of the pipe network and each sample port. [**72:**17.7.3.6.4]

The transport time is determined by flow calculations. Flow calculations provide the only way to be certain that sufficient pressure and flow volume are available at all the sampling ports and that the air sampling–type detector will provide detection over the entire area it is to cover.

Exhibit 13.51

Air sampling–type smoke detectors. (Courtesy of Xtralis, Inc., Norwell, MA)

Exhibit 13.52

Air sampling–type smoke detector with cover removed. (Courtesy of Fenwal Protection Systems, Ashland, MA)

13.7.4.3.4.5 Air-sampling detectors shall give a trouble signal if the airflow is outside the manufacturer's specified range. [**72:**17.7.3.6.5]

The detection of a flow rate outside the manufacturer's design range is indicative of a failure of the physical integrity of the sampling pipes. This requirement is analogous to the requirement for monitoring for integrity of the initiating device circuit wiring.

13.7.4.3.4.6* The sampling ports and in-line filter, if used, shall be kept clear in accordance with the manufacturer's published instructions. [**72:**17.7.3.6.6]

A.13.7.4.3.4.6 The air sampling–type detector system should be able to withstand dusty environments by air filtering, electronic discrimination of particle size, or other listed methods or combinations thereof. The detector should be capable of providing optimal time delays of alarm outputs to eliminate nuisance alarms due to transient smoke conditions. The detector should also provide facilities for the connection of monitoring equipment for the recording of background smoke level information necessary in setting alert and alarm levels and delays. [**72:**A.17.7.3.6.6]

Dust from the protected space can cause clogging of the sampling pipes as well as the sampling ports of those makes of detectors that employ a filter at the sampling port. Both clogging and filter loading can lead to reduced sampling flow from the affected portions of the sampling network.

13.7.4.3.4.7 Air-sampling network piping and fittings shall be airtight and permanently fixed. [**72:**17.7.3.6.7]

Although Article 760 of *NFPA 70* has detailed criteria for detection system wiring, no national consensus standards are published for sampling tube installation. Each manufacturer makes its own recommendations that establish the minimum compliance criteria for that product. The integrity of the sampling tube network is just as important to the air sampling–type detector as the integrity of the wiring is to the spot-type smoke detector. The installation methods used for air-sampling tubing should provide equivalent security and mechanical protection.

Δ **13.7.4.3.4.8** Sampling system piping shall be conspicuously identified as "SMOKE DETECTOR SAMPLING TUBE — DO NOT DISTURB," as follows:

(1) At changes in direction or branches of piping
(2) At each side of penetrations of walls, floors, or other barriers
(3) At intervals on piping that provide visibility within the space, but no greater than 20 ft (6.1 m)

[**72:**17.7.3.6.8]

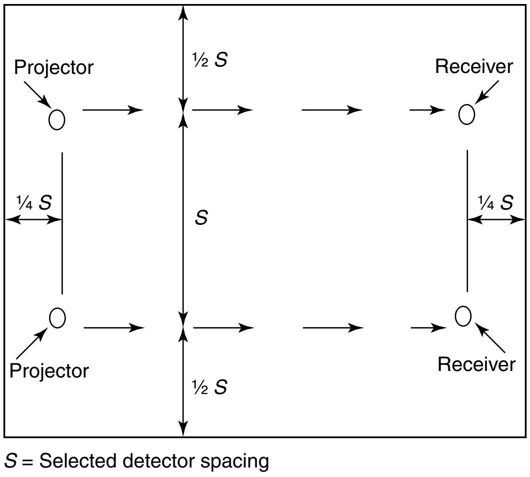
Numerous building systems are often installed in the above-ceiling space. If the sampling piping is damaged by some other trade at a later time, a break in the air-sampling detector piping could result in the detector sampling the above-ceiling air rather than the air beneath the ceiling plane, as intended. This potentiality necessitates that tubing be clearly marked in a manner that will endure for the lifetime of the unit.

13.7.4.3.5* Projected Beam–Type Smoke Detectors.

A.13.7.4.3.5 On smooth ceilings, a spacing of not more than 60 ft (18.3 m) between projected beams and not more than one-half that spacing between a projected beam and a sidewall (wall parallel to the beam travel) should be used as a guide. Other spacing should be determined based on ceiling height, airflow characteristics, and response requirements. [**72:**A.17.7.3.7]

In some cases, the light beam projector is mounted on one end wall, with the light beam receiver mounted on the opposite wall. However, it is also permitted to suspend the projector and receiver from the ceiling at a distance from the end walls not exceeding one-quarter the selected spacing (S). *(See Figure A.13.7.4.3.5.)* [**72:**A.17.7.3.7]

13.7.4.3.5.1 Projected beam–type smoke detectors shall be located in accordance with the manufacturer's published instructions. [**72:**17.7.3.7.1]



Δ ***FIGURE A.13.7.4.3.5*** *Maximum Distance at Which Ceiling-Suspended Light Projector and Receiver Can Be Positioned from End Wall Is One-Quarter Selected Spacing* ***(S)****.* *[**72:**Figure A.17.7.3.7]*

Each make and model of linear projected beam–type smoke detector has specific installation limitations as well as performance capabilities. Most notable of these limitations are the maximum and minimum beam lengths. The designer should make certain that the contemplated installation is consistent with the criteria established in the published installation instructions of the product the designer plans to use. It should be noted that the spacing criteria noted in Figure A.13.7.4.3.5 are general examples and that the actual spacing requirements will be dependent on the technology of the beam detector and the performance standards applied by the listing authority.

13.7.4.3.5.2 The effects of stratification shall be evaluated when locating the detectors. [**72:**17.7.3.7.2]

As with other types of smoke detection, the location selected for detectors must account for the effects of stratification. In high-ceiling areas where stratification is probable and a serious concern, detectors can be positioned at several levels. Alternatively, the methods in Annex B of *NFPA 72* can be used to calculate the plume divergence at the detector mounting height. The plume width at the detector mounting height can then be used as the spacing between adjacent beams in a performance-based design.

13.7.4.3.5.3 The beam length shall not exceed the maximum permitted by the equipment listing. [**72:**17.7.3.7.3]

Linear projected beam–type smoke detectors have limitations on both the minimum and maximum beam length over which they will operate properly. The minimum beam length limitation is established by the lowest smoke concentration that can be detected at that minimum beam length. The maximum beam length is determined by the maximum distance at which the detector can maintain its design stability, even when some normal light obscuration is present. The projected beam–type smoke detector must be able to identify a low concentration of smoke distributed along a substantial portion of the beam and a high concentration of smoke localized in a short segment of the beam. Each manufacturer obtains a listing from a qualified testing laboratory that sets the upper and lower limits on the beam length. Failure to observe these limits could result in an unstable detector or the failure to detect a fire consistent with the performance objectives.

13.7.4.3.5.4 If mirrors are used with projected beams, the mirrors shall be installed in accordance with the manufacturer's published instructions. [**72:**17.7.3.7.4]

Mirrors used with linear projected beam–type smoke detectors must also be listed for use with the detector.

13.7.4.3.5.5 A projected beam–type smoke detector shall be considered equivalent to a row of spot-type smoke detectors for level and sloping ceiling applications. [**72:**17.7.3.7.5]

Given the similarities between the installation and spacing concepts developed for line-type heat detectors and projected beam–type smoke detectors, the logic behind the design requirements remains consistent. When spacing strategies are being developed, a linear projected beam–type detector can be thought of as equivalent to a row of spot-type smoke detectors, much like how a line-type heat detector can be thought of as a row of spot-type heat detectors. The distance between the linear projected beams is analogous to the distance between rows of spot-type smoke detectors.

13.7.4.3.5.6 Projected beam–type detectors and mirrors shall be mounted on stable surfaces to prevent false or erratic operation due to movement. [**72:**17.7.3.7.6]

13.7.4.3.5.7 The beam shall be designed so that small angular movements of the light source or receiver do not prevent operation due to smoke and do not cause nuisance or unintentional alarms. [**72:**17.7.3.7.7]

Contrary to popular belief, buildings move under normal, everyday conditions. Portions of buildings vibrate due to traffic on nearby streets. Buildings sway due to wind or uneven thermal expansion; even the ebb and flow of the tides can cause ocean-front buildings to flex. Modern curtain wall/steel frame buildings are designed to flex. This movement, however, places a demand on fire alarm systems, especially fire alarm systems using projected-beam smoke detection. The detectors must be able to accommodate the natural or designed movement of the building. The manufacturers of projected beam–type detectors provide installation instructions that address the potential for this type of difficulty. Because of the physical instability of mounting surfaces and building movement, some manufacturers do not allow the use of mirrors. Often a limiting factor on beam length is the diameter of the projected beam and the receiver in relation to the expected flexure of the building.

13.7.4.3.5.8* The light path of projected beam–type detectors shall be kept clear of opaque obstacles at all times. [**72:**17.7.3.7.8]

A.13.7.4.3.5.8 Where the light path of a projected beam–type detector is abruptly interrupted or obscured, the unit should not initiate an alarm. It should give a trouble signal after verification of blockage. [**72:**A.17.7.3.7.8]

Projected beam–type detectors use obscuration algorithms in their software that can distinguish the progressive obscuration that occurs during a fire from the step-wise obscuration that usually indicates interference in the path of the beam by an opaque object. However, despite use of the most sophisticated software, Christmas decorations, party balloons, and hanging plants have been known to cause problems. Obstructions that can gradually grow and block a beam detector, such as trees in an atrium, should also be considered a potential problem.

13.7.4.3.6* Protection During Construction.

A.13.7.4.3.6 Construction debris, dust (especially gypsum dust and the fines resulting from the sanding of drywall joint compounds), and aerosols can affect the sensitivity of smoke detectors and, in some instances, cause deleterious effects to the detector, thereby significantly reducing the expected life of the detector. [**72:**A.17.7.1.11]

13.7.4.3.6.1 Where detectors are installed for signal initiation during construction, they shall be cleaned and verified to be operating in accordance with the listed sensitivity, or they shall be replaced prior to the final acceptance test of the system. [**72:**17.7.1.11.1]

Because renovation and construction activities include numerous fire ignition sources, smoke detection is often required in areas under construction. Where the AHJ requires early installation or detection during construction, detectors must be cleaned and measured for their normal operating sensitivity. Those detectors found outside their design sensitivity range must be cleaned and verified to be within their listed sensitivity or replaced.

13.7.4.3.6.2 Where detectors are installed but not operational during construction, they shall be protected from construction debris, dust, dirt, and damage in accordance with the manufacturer's recommendations and verified to be operating in accordance with the listed sensitivity, or they shall be replaced prior to the final acceptance test of the system. [**72:**17.7.1.11.2]

The requirement in 13.7.4.3.6.2 was introduced in the 2012 edition of the *Code* and should be considered as an alternative to the more restrictive provision 13.7.4.3.6.3. If detectors are installed before completion of construction cleanup, they must be protected in accordance with the manufacturer's instructions.

Many smoke detectors are shipped with a thin plastic cover over the sensing portion of the detector. It is widely assumed that these covers are suitable for protecting the detector from construction dust, dirt, and debris. In actuality, most of the covers supplied are merely for shipping and are not intended to be used in lieu of proper protection from construction debris.

Exhibit 13.53

Smoke detector with protective plastic cover. (Courtesy of Hochiki America Corp., Buena Park, CA)

Protective covers cannot be relied on to keep the detector entirely free of contaminants. Therefore, sensitivity measurement and cleaning of the detectors after all construction trades have finished their work will probably still be necessary. If covers are used, the contractor must also have a means of verifying that all of them have been removed when the construction trades have completed their work.

If the AHJ requires the covers to be removed at the end of each day, a good practice is to number the covers to ensure that all have been removed and then to replace them the next morning. Again, if the covers are removed during the construction process, it will be necessary to inspect the detectors closely, clean them when necessary, and test them to ensure that their sensitivity is within the listed and marked sensitivity range. See Exhibit 13.53 for an example of a smoke detector protective cover.

13.7.4.3.6.3 Where detection is not required during construction, detectors shall not be installed until after all other construction trades have completed cleanup. [**72:**17.7.1.11.3]

Many unwanted alarms are caused by smoke detectors installed too early in the construction process. Construction activities produce airborne dust that inevitably finds its way into detectors, contaminating them and making them prone to false alarms. Unless detection is required while the area is under construction, experience has shown that the best practice is to delay installation of smoke detectors until all construction cleanup has been completed.

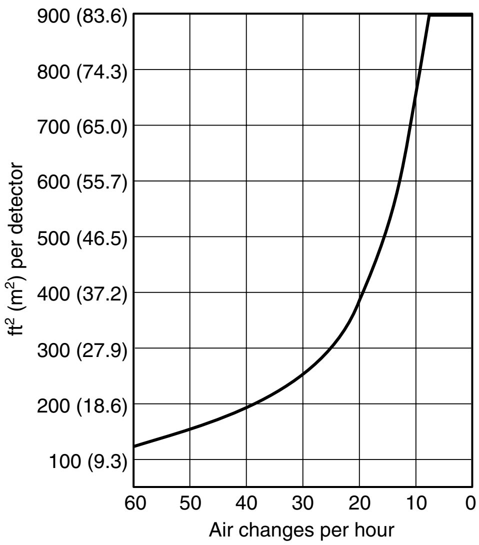
13.7.4.3.7 Ceiling Tiles and Ceiling Assemblies. Where automatic detectors are installed, ceilings necessary for the proper actuation of the fire protection device in accordance with *NFPA 72* shall be maintained.

13.7.4.3.8 High Air Movement Areas.

13.7.4.3.8.1 Location. Smoke detectors shall not be located directly in the airstream of supply registers. [**72:**17.7.6.3.2]

N *TABLE 13.7.4.3.8.2.2 Smoke Detector Spacing Based on Air Movement (Not to Be Used for Under-Floor or Above-Ceiling Spaces)*

Minutes per Air Change	Air Changes per Hour	Spacing per Detector ft²	Spacing per Detector m²
1	60	125	12
2	30	250	23
3	20	375	35
4	15	500	46
5	12	625	58
6	10	750	70
7	8.6	875	81
8	7.5	900	84
9	6.7	900	84
10	6	900	84



N *FIGURE 13.7.4.3.8.2.2 High Air Movement Areas (Not to Be Used for Under-Floor or Above-Ceiling Spaces). [**72:**Figure 17.7.6.3.3.2]*

13.7.4.3.8.2* Spacing.

A.13.7.4.3.8.2 Smoke detector spacing depends on the movement of air within the room. [**72:**A.17.7.6.3.3]

13.7.4.3.8.2.1 Smoke detector spacing shall be reduced where the airflow in a defined space exceeds 8 minutes per air change (total space volume) (equal to 7.5 air changes per hour). [**72:**17.7.6.3.3.1]

Δ **13.7.4.3.8.2.2** Where spacing must be adjusted for airflow, spot-type smoke detector spacing shall be adjusted in accordance with Table 13.7.4.3.8.2.2 or Figure 13.7.4.3.8.2.2 before making any other spacing adjustments required by this *Code*. [**72:**17.7.6.3.3.2]

N **13.7.4.3.8.2.3** Air-sampling or projected beam smoke detectors shall be installed in accordance with the manufacturer's published instructions. [**72:**17.7.6.3.3.3]

N **13.7.4.4 Inspection, Testing, and Maintenance.** The inspection, testing, and maintenance for fire alarm and fire detection systems shall be in accordance with *NFPA 72*.

13.7.4.5 Heat Detectors.

13.7.4.5.1 Fixed-Temperature, Rate-of-Rise, Rate-of-Compensation, Restorable Line, Spot Type (Excluding Pneumatic Tube Type). Heat test shall be performed with a listed and labeled heat source or in accordance with the manufacturer's published inspections. A test method for the installed equipment, shall be used that does not damage the nonrestorable fixed-temperature element of a combination rate-of-rise/fixed-temperature element detector. [**72:** Table 14.4.3.2, 17(d)1]

In previous editions of the *Code*, the heat source was required to be applied for "response within 1 minute." It is assumed that the 1-minute time requirement was introduced as an added level of protection to ensure that the test did not damage the thermal element or the detector housing. The requirement for response within 1 minute was removed from the 2010 edition of *NFPA 72*, because it was found that, in some instances, the 1-minute time frame was being incorrectly interpreted as a sensitivity test of the heat detectors.

There is no standardized, repeatable test method or test apparatus for all brands and all types of heat detectors. Neither the *Code* nor the test standards used by the listing organizations specify a particular response time in the field. The heat source and the test method specified in the manufacturer's published instructions should be used, and caution should be exercised to avoid damaging the detector or its components.

Extreme caution must be used in locations requiring hazardous (classified) electrical equipment (those containing flammable or explosive vapors or dusts) when heat detectors are being tested. In no case should open flames be used to test any type of heat detector. In most cases the use of hot water, a hair dryer, or similar safe means can be used to test a heat detector. For some types of rate-of-rise heat detectors, technicians might be able to actuate the detector by rubbing their hands together and then cupping both hands around the detector. This action is often all it takes to create the rate-of-temperature rise required to actuate the detector.

13.7.4.5.2 Fixed-Temperature, Nonrestorable Line Type. Heat test shall not be performed. Functionality shall be tested mechanically and electrically. Loop resistance shall be measured and recorded. Changes from acceptance test shall be investigated. [**72:** Table 14.4.3.2, 17(d)2]

The test required by 13.7.4.5.2 should be performed by shorting across the conductors at the end of the line to simulate actuation of the circuit or by using some other approved method identified in the manufacturer's published instructions for the device. Heat testing of a nonrestorable heat detector will actuate the detector, resulting in the need for replacement.

13.7.4.5.3 Nonrestorable (General). Heat tests shall not be performed. Functionality shall be tested mechanically and electrically. [**72:** Table 14.4.3.2, 17(d)4]

Testing can be conducted by operating contacts by hand, electrically shorted using a jumper, or other manufacturer-approved method. The purpose of the test is to ensure alarm response. Heat testing of a nonrestorable heat detector will actuate the detector, resulting in the need for replacement.

13.7.4.5.4 Restorable Line Type, Pneumatic Tube Only. Heat tests shall be performed (where test chambers are in circuit), with a listed and labeled heat source or in accordance with the manufacturer's published instructions of the detector or a test with pressure pump shall be conducted. [**72:**Table 14.4.2.2, 17(d)5]

Pneumatic tube–type heat detectors are often found actuating older deluge sprinkler systems or other special fire suppression systems.

13.7.4.6 Smoke Detectors.

Δ **13.7.4.6.1 In Other Than One- and Two-Family Dwellings, System Detectors.** Smoke detectors shall be tested in place to ensure smoke entry into the sensing chamber and an alarm response. Testing with smoke or listed and labeled product, acceptable to the manufacturer or in accordance with their published instructions, shall be permitted as acceptable test methods. Other methods listed in the manufacturer's published instructions that ensure smoke entry from the protected area, through the vents, into the sensing chamber shall be permitted. Any of the following tests shall be performed to ensure that each smoke detector is within its listed and marked sensitivity range:

(1) Calibrated test method
(2) Manufacturer's calibrated sensitivity test instrument
(3) Listed control equipment arranged for the purpose
(4) Smoke detector/control unit arrangement whereby the detector causes a signal at the control unit when its sensitivity is outside its listed sensitivity range
(5) Other calibrated sensitivity test method approved by the AHJ

[**72:**Table 14.4.3.2, 17(h)(1)]

13.7.4.6.2 Projected Beam Type. The detector shall be tested by introducing smoke, other aerosol, or an optical filter into the beam path. [**72:** Table 14.4.3.2, 17(g)6]

• **13.7.4.7*** In other than one- and two-family dwellings, sensitivity of smoke detectors shall be tested in accordance with 13.7.4.7.1 through 13.7.4.6. [**72:**14.4.4.3]

A.13.7.4.7 Detectors that cause unwanted alarms should be tested at their lower listed range (or at 0.5 percent obscuration if unmarked or unknown). Detectors that activate at less than this level should be replaced. [**72:**A.14.4.4.3]

13.7.4.7.1 Sensitivity shall be checked within 1 year after installation. [**72:**14.4.4.3.1]

13.7.4.7.2 Sensitivity shall be checked every alternate year thereafter unless otherwise permitted by compliance with 13.7.4.7.3. [**72:**14.4.4.3.2]

13.7.4.7.3 After the second required calibration test, if sensitivity tests indicate that the device has remained within its listed and marked sensitivity range (or 4 percent obscuration light gray smoke, if not marked), the length of time between calibration tests shall be permitted to be extended to a maximum of 5 years. [**72:**14.4.4.3.3]

After two tests in which sensitivity has remained stable, sensitivity testing may be extended to 5-year intervals in recognition of the apparent stability of the detector and the environment in which it is installed. Extending the sensitivity testing frequency requires maintaining detailed records of unwanted alarms, which may indicate that the detector has drifted outside the acceptable range of sensitivity. Such changes may warrant more frequent testing, cleaning of the detector, or replacement.

Exhibit 13.54 illustrates test equipment that can be used for smoke detector sensitivity testing.

Detectors found to be outside their listed and marked sensitivity range must be recalibrated and then retested or replaced in accordance with 13.7.4.7.4 and 13.7.4.7.5. Removal tools can assist maintenance personnel in removal of smoke detectors. See Exhibit 13.55 for an example of a removal tool.

Detectors manufactured prior to current standards did not require a sensitivity range to be marked on the product. These detectors typically have a sensitivity in the range of 0.5 percent to 4 percent per foot obscuration using light gray smoke. Sensitivities less than 0.5 percent obscuration per foot can lead to unwanted alarms. Sensitivities over 4 percent per foot can result

Exhibit 13.54

in detection delays. The manufacturer of the smoke detector can usually provide a recommended level of sensitivity for unmarked smoke detectors.

13.7.4.7.3.1 If the frequency is extended, records of nuisance alarms and subsequent trends of these alarms shall be maintained. [**72:**4.4.4.3.3.1]

13.7.4.7.3.2 In zones or in areas where nuisance alarms show any increase over the previous year, calibration tests shall be performed. [**72:**14.4.4.3.3.2]

13.7.4.7.4 Unless otherwise permitted by 13.7.4.7.5, smoke detectors found to have a sensitivity outside the listed and marked sensitivity range shall be cleaned and recalibrated or be replaced. [**72:**14.4.4.3.4]

13.7.4.7.5 Smoke detectors listed as field adjustable shall be permitted to either be adjusted within the listed and marked sensitivity range, cleaned, and recalibrated, or be replaced. [**72:**14.4.4.3.5]

13.7.4.7.6 The detector sensitivity shall not be tested or measured using any device that administers an unmeasured concentration of smoke or other aerosol into the detector or smoke alarm. [**72:**14.4.4.3.6]

Available means for sensitivity testing of smoke detectors include the use of manufacturers' calibrated test instruments, control equipment listed for the purpose, a smoke detector/control unit arrangement whereby the detector causes a signal at the control unit when its sensitivity is outside the listed range of sensitivity, or other calibrated sensitivity methods approved by the AHJ.

13.8 Other Fire Protection Systems

Where other fire protection systems are required to be installed by the provisions of this *Code*, or are installed with the approval of the AHJ as an alternative or equivalency, the design and installation of the system shall comply with the appropriate standards listed in Table 13.8. The system shall be tested and maintained in accordance with Section 10.4.

13.9 Non-Listed Fire Protection or Suppression Devices and Equipment

13.9.1 It shall be unlawful to market, sell, advertise, or distribute any device or equipment as suitable for fire protection or fire suppression purposes unless the device or equipment is listed for such purpose by a nationally recognized testing laboratory or as otherwise permitted by 13.9.2.

13.9.2 The requirements of 13.9.1 shall not apply where NFPA standards, other adopted standards, or the adopted code allow the use of non-listed fire protection or suppression equipment.

Means of Egress

14

Chapter 14 addresses *means of egress,* which is defined in 3.3.182 as "a continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge."

The term *exit* is defined by 3.3.105 as that portion of a means of egress that is separated from other building spaces by being enclosed within construction having the minimum degree of fire resistance specified by 14.3.1, with limited openings through the enclosing construction and protection of such openings. The exit might include door assemblies, stairs, ramps, smokeproof enclosures, exit passageways, and outside balconies. In each case, the exit components are required to conform to the *Code* specifications for fire protection, dimensions, and arrangement. In its simplest form, an exit is a doorway or a door opening directly to the exterior at grade. Such doorway or door opening provides the requisite protected way of travel to the exit discharge without the need for fire-rated, separating construction. An exit other than a door opening directly to the outside must provide a protected path of travel.

In the case of a stairway, the exit includes the door assembly into the stairway enclosure, the stair enclosure, the stairs and landings inside the enclosure, and the door assembly from the enclosure to the exterior or interior exit discharge.

The entrance to an exit enclosure is part of the exit and usually consists of a fire protection–rated door assembly that provides a protected entrance into a protected area. A fire door assembly, however, does not always signal an entrance to an exit. A door assembly or fire door assembly between a hotel room and a corridor or a fire door assembly across a corridor or lobby is part of exit access and not part of an exit, unless the corridor or lobby and all other openings into the corridor or lobby are separated and protected as required for an exit in accordance with 14.3.1, as might be accomplished using an exit passageway (see Section 14.7). Such protection is seldom provided for corridors, because, although it might be technically and monetarily feasible at the time the exit passageway is constructed, it would be difficult to maintain over the life of the building, as penetrations for communications cabling and other rehabilitation projects diminish the protection features.

Various building features — where properly arranged, located, or constructed — might constitute an exit. Examples include an exterior exit door assembly, an exit passageway, a horizontal exit, an exit stair, or an exit ramp.

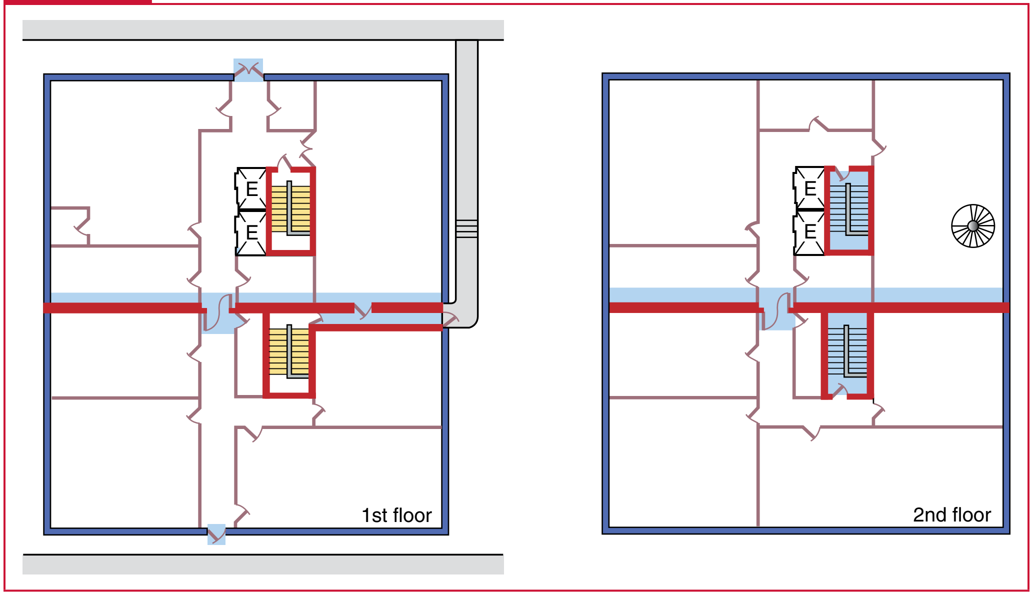
Several types of exits are shown in Exhibit 14.1 as shaded areas. On the second floor, exits include the following:

1. Two exit stairs enclosed by fire resistance–rated barriers, including a fire protection–rated, self-closing door assembly
2. Horizontal exit consisting of a fire resistance–rated barrier, including a pair of fire protection–rated, self-closing cross-corridor door assemblies that completely divide the floor into two fire compartments

On the first floor, exits include the following:

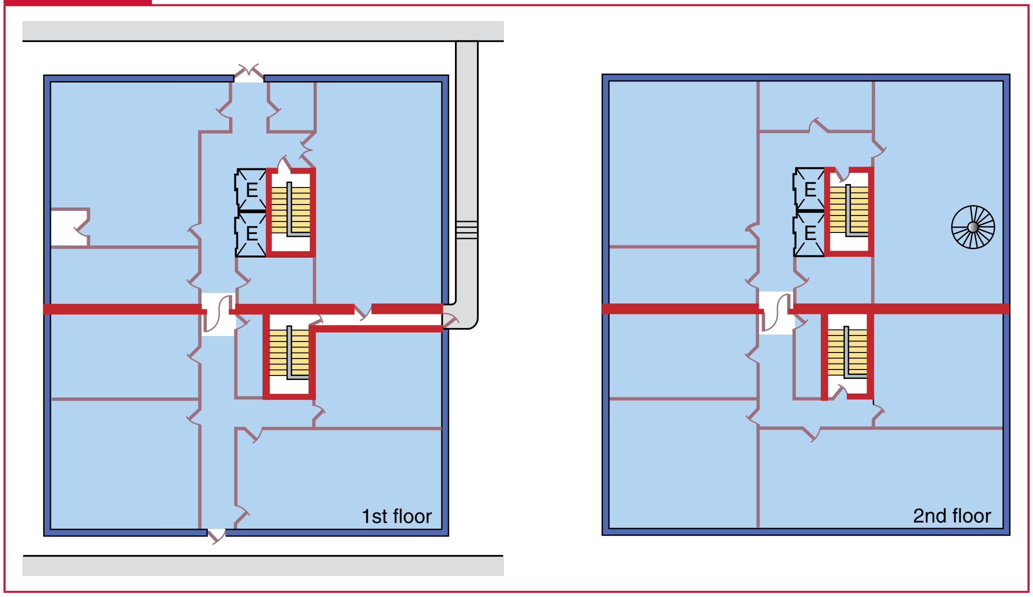
1. Two door assemblies from the corridor directly to the outside at grade level
2. Horizontal exit that is a vertical extension of and, therefore, similar to the horizontal exit located immediately above on the second floor
3. Exit passageway that connects one of the second-floor exit stair enclosures directly with the outside and is separated from the remainder of the first floor by fire resistance–rated barriers, including a fire protection–rated, self-closing door assembly from the room at the upper right corner

Exhibit 14.1



Various forms of exits.

Exhibit 14.2

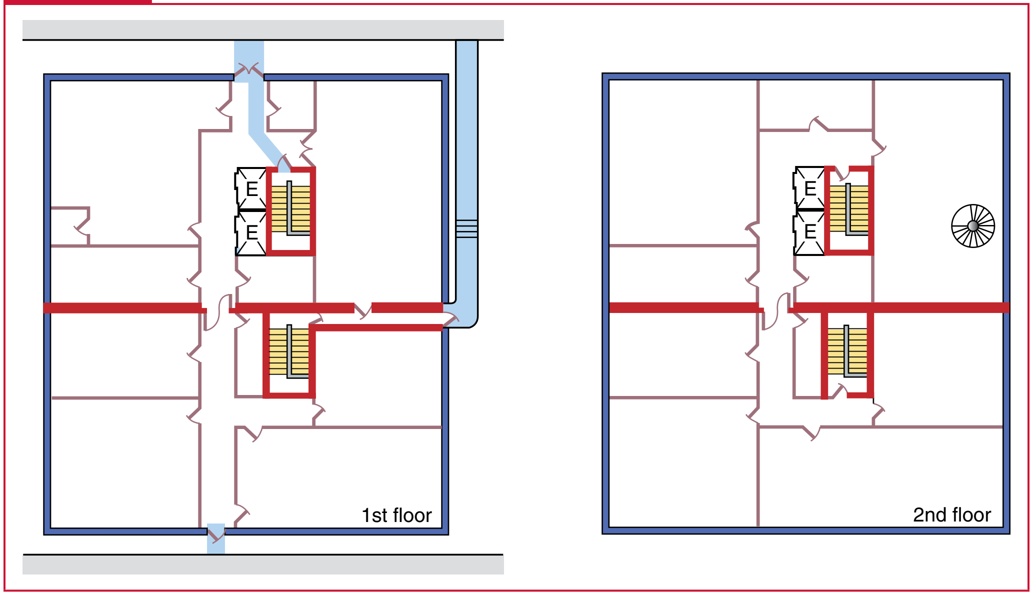


Spaces constituting exit access.

The exit access includes the rooms and building spaces that people occupy and the door assemblies, aisles, corridors, unenclosed stairs, and unenclosed ramps that are traversed to reach an exit. Spaces constituting exit access are shown in Exhibit 14.2 as shaded areas. All spaces occupied and traversed in reaching an exit are considered the exit access portion of the means of egress. The shading shown in Exhibit 14.2 indicates that exit access comprises more floor area than either of the other components of means of egress — the exit and the exit discharge.

The small closet in the room at the upper left corner of the first floor in Exhibit 14.2 is judged to be nonoccupiable and, therefore, is not part of the exit access. Similarly, if an HVAC shaft were running up through the building, it too would be considered nonoccupiable and not part of the exit access.

Exhibit 14.3



Spaces constituting exit discharge.

Note that the two elevators are shaded indicating that they are within the exit access. The elevators are not permitted to serve as components of the means of egress system. The building occupants must be provided with egress components and paths independent of the elevators. Yet, the travel across the elevator floor to the corridor is exit access for the building occupants who find themselves on the elevator at the time the fire emergency is called to their attention.

Because some exits do not discharge directly into a public way, the exit discharge is defined as providing building occupants with a path of travel from the termination of an exit to a public way. This path of travel might be inside the building, as permitted by 14.11.2, or outside. Where an exit opens onto an alley, a court, or a yard, a safe path of travel is required to be provided to a public way or some equivalent safe area. This portion of the means of egress is the exit discharge. (See also 14.11.1.)

Forms of exit discharge are shown in Exhibit 14.3 as shaded areas. Because occupants leave the building at the first floor only, no exit discharge occurs on the second floor. The first-floor exit discharge includes the following:

1. Exterior space beginning at the exit doors from the corridor and continuing to the public way (street)
2. Exterior walkway along the side of the building beginning at the door assembly from the exit passageway and continuing to the public way
3. Interior path of travel from the second-floor exit stair discharging through a portion of the first-floor corridor

A portion of the first floor through which an occupant of the second floor needs to travel is considered exit discharge, because the occupant reaches a required exit on the second floor (i.e., the enclosed exit stair) and then is forced to leave that protected area after traveling through the stair enclosure door opening on the first floor. However, an occupant of the first floor who travels across the same space, the space considered exit discharge for the person whose exit access travel began on the second floor, is considered to be within exit access and still en route to finding an exit, which occurs upon reaching the door opening to the outside. (See also 14.11.2.)

Δ 14.1 Application

Means of egress in new and existing buildings shall comply with this *Code* and NFPA *101*.

Δ 14.2 Exit Access Corridors

Corridors used as exit access and serving an area having an occupant load exceeding 30 shall be separated from other parts of the building by walls having not less than a 1-hour fire resistance rating in accordance with Section 12.7, unless otherwise permitted by one of the following:

(1) This requirement shall not apply to existing buildings, provided that the occupancy classification does not change.

(2) This requirement shall not apply where otherwise provided in Chapters 11 through 43 of NFPA *101*.

[***101:***7.1.3.1]

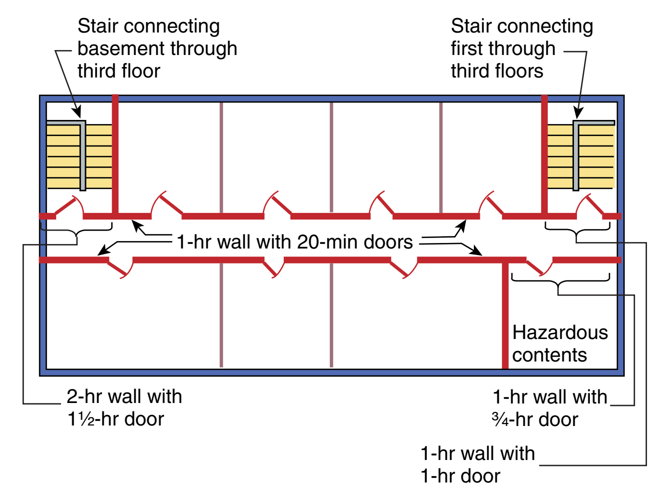
Section 14.2 requires protection via fire-rated corridor walls of exit access corridors serving more than 30 occupants. Note that the requirement for the corridor walls to be fire resistance rated, which is not a requirement for the floor/ceiling or roof/ceiling assemblies forming the top and bottom of the corridor compartment, provides separation only between the corridor and other spaces on the same floor. To provide the 1-hour separation between the corridor and the remainder of the floor, as required by Section 14.2, the fire barriers forming the corridor walls must extend above any ceiling membranes so as to be sealed tightly against the floor or roof above.

Item (1) of Section 14.2 exempts existing corridors from the requirement of Section 14.2, provided that the occupancy classification does not change. Therefore, if the occupancy classification of an existing building does change, the 1-hour corridor wall requirement applies, unless the specific occupancy involved has different requirements. Most of the occupancy chapters of NFPA *101*®, *Life Safety Code*®, establish new exit access corridor wall requirements that supersede the requirements of Section 14.2. Also, some of the occupancy chapters establish corridor wall requirements for existing buildings. Such provisions usually appear in subsection __.3.6 of NFPA *101*. For example, 14.3.6 of NFPA *101* addresses special requirements for corridor walls in new educational occupancies, and 15.3.6 of NFPA *101* addresses special requirements for corridor walls in existing educational occupancies. If no special requirements appear in an occupancy chapter of NFPA *101*, the provisions of Section 14.2 prevail.

Section 14.2 does not require corridors; however, it does require that, where corridors do exist and where they serve an area having an occupant load of more than 30 persons, they must be separated from other (i.e., noncorridor) spaces on that floor by corridor walls. Section 12.7 regulates the construction of the fire barrier forming the corridor walls and the opening protection. Wall segments that serve as both a corridor wall and part of an exit enclosure must meet the more stringent provisions required for the enclosure of exits. Similarly, wall segments that serve as both a corridor wall and enclosure protection of hazardous contents areas must meet the more stringent of the applicable provisions. In some cases, the provisions for corridor walls and those for hazardous area protection require a minimum 1-hour fire resistance rating. Yet, the minimum required fire protection rating of door assemblies in such walls might vary, with a minimum 45-minute rating required for the hazardous area protection and only a 20-minute rating for the corridor wall. Determining which set of requirements is more stringent involves comparing all related requirements, not only the fire resistance rating of the wall.

Exhibit 14.4 is an example of the protection of exit access corridors required by Section 14.2. Note the difference in the required protection for the corridor wall segments serving also as enclosure protection from the hazardous contents area (see Section 8.7 of NFPA *101*) and as part of the enclosure of an exit (see Section 14.3).

Exhibit 14.4



Protection of exit access corridors.

14.3 Exits

Δ **14.3.1** Where this *Code* requires an exit to be separated from other parts of the building, the separating construction shall meet the requirements of Section 8.2 of NFPA *101* and the following:

(1)* The separation shall have a minimum 1-hour fire resistance rating where the exit connects three or fewer stories.

Δ **A.14.3.1(1)** In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Annex O of NFPA 914. [***101:***A.7.1.3.2.1(1)]

(2) The separation specified in 14.3.1(1), other than an existing separation, shall be supported by construction having not less than a 1-hour fire resistance rating.

(3)* The separation shall have a minimum 2-hour fire resistance rating where the exit connects four or more stories, unless one of the following conditions exists:

   (a) In existing non-high-rise buildings, existing exit stair enclosures shall have a minimum 1-hour fire resistance rating.

   (b) In existing buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3, existing exit stair enclosures shall have a minimum 1-hour fire resistance rating.

   (c) The minimum 1-hour enclosures in accordance with 28.2.2.1.2, 29.2.2.1.2, 30.2.2.1.2, and 31.2.2.1.2 of NFPA *101* shall be permitted as an alternative to the requirement of 14.3.1(3).

A.14.3.1(3) In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Annex O of NFPA 914 and in the *SFPE Handbook of Fire Protection Engineering*. [***101:***A.7.1.3.2.1(3)]

(4) Reserved.

(5) The minimum 2-hour fire resistance–rated separation required by 14.3.1(3) shall be constructed of an assembly of noncombustible or limited-combustible materials and shall be supported by construction having a minimum 2-hour fire resistance rating, unless otherwise permitted by 14.3.1(7).

(6)* Structural elements, or portions thereof, that support exit components and either penetrate into a fire resistance–rated assembly or are installed within a fire resistance–rated wall assembly shall be protected, as a minimum to the fire resistance rating required by 14.3.1(1) or 14.3.1(3).

A.14.3.1(6) It is not the intent to require the structural elements supporting outside stairs, or structural elements that penetrate within exterior walls or any other wall not required to have a fire resistance rating, to be protected by fire resistance–rated construction. [***101:***A.7.1.3.2.1(6)]

(7) Fire-retardant-treated wood enclosed in noncombustible or limited-combustible materials shall be permitted in accordance with NFPA 220.

(8) Openings in the separation shall be protected by fire door assemblies equipped with door closers complying with 14.5.4.

(9)* Openings in exit enclosures shall be limited to door assemblies from normally occupied spaces and corridors and door assemblies for egress from the enclosure, unless one of the following conditions exists:

(a) Vestibules that separate normally unoccupied spaces from an exit enclosure shall be permitted provided the vestibule is separated from adjacent spaces by corridor walls and related opening protectives as required for the occupancy involved but not less than a smoke partition in accordance with Section 8.4 of NFPA *101*.

(b) In buildings of Type I or Type II construction as defined in NFPA 220 (*see 8.2.1.2 of* NFPA *101*), fire protection-rated door assemblies to normally unoccupied building service equipment support areas as addressed in Section 7.13 of NFPA *101* shall be permitted, provided the space is separated from the exit enclosure by fire barriers as required by 14.3.1(3).

(c) Openings in exit passageways in mall buildings as provided in Chapters 36 and 37 of NFPA *101* shall be permitted.

(d) In buildings of Type I or Type II construction, as defined in NFPA 220 (*see 8.2.1.2 of* NFPA *101*), existing fire protection–rated door assemblies to interstitial spaces shall be permitted, provided that such spaces meet all of the following criteria:

i. The space is used solely for distribution of pipes, ducts, and conduits.

ii. The space contains no storage.

iii. The space is separated from the exit enclosure in accordance with Section 12.7.

(e) Existing openings to mechanical equipment spaces protected by approved existing fire protection–rated door assemblies shall be permitted, provided that the following criteria are met:

i. The space is used solely for non-fuel-fired mechanical equipment.

ii. The space contains no storage of combustible materials.

iii. The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3 or the mechanical equipment space is provided with sprinkler protection in accordance with Section 13.3 and provided with complete smoke detection in accordance with Section 13.7.

A.14.3.1(9) Means of egress from the level of exit discharge is permitted to pass through an exit stair enclosure or exit passageway serving other floors. Doors for convenience purposes and unrelated to egress also are permitted to provide access to and from exit stair enclosures and exit passageways, provided that such doors are from corridors or normally occupied spaces. It is also the intent of this provision to prohibit exit enclosure windows, other than approved vision panels in doors, that are not mounted in an exterior wall. [***101:***A.7.1.3.2.1(9)]

(10) Penetrations into, and openings through, an exit enclosure assembly shall be limited to the following:

(a) Door assemblies permitted by 14.3.1(9)

(b)* Electrical conduit serving the exit enclosure

Δ **A.14.3.1(10)(b)** The intent of this provision is to prevent the exit enclosure from being used as a vertical chase for building services. Penetrations for electrical wiring are permitted where the wiring serves equipment permitted by the AHJ to be located within the exit enclosure. [***101:***A.7.1.3.2.1(10)(b)]

(c) Pathways for devices for security and communication systems serving the exit enclosure, where pathways are installed in metal conduit

(d)* Required exit door openings

N **A.14.3.1(10)(d)** This provision will allow security cameras, public address systems, emergency communication systems, telephone repeaters and similar life safety devices in the exit enclosure, and wiring and similar pathways for such devices, to penetrate the fire barrier serving the exit enclosure. It is the intent of this provision to prevent the exit enclosure from being used as a vertical chase for building services. [***101:***A.7.1.3.2.1(10)(d)]

(e) Ductwork and equipment necessary for independent stair pressurization

(f) Water or steam piping necessary for the heating or cooling of the exit enclosure

(g) Sprinkler piping
(h) Standpipes
(i) Existing penetrations
(j) Penetrations for fire alarm circuits, where the circuits are installed in metal conduit

(11) Penetrations or communicating openings shall be prohibited between adjacent exit enclosures.

(12) All penetrations in fire barriers separating the exit from other parts of the building shall be protected in accordance with 12.7.8.

(13) Membrane penetrations shall be permitted on the exit access side of the exit enclosure and shall be protected in accordance with 12.7.5.6.

[***101:***7.1.3.2.1]

Exits must provide protection from fire originating inside or outside the exit. Protection from fire originating within the enclosure is accomplished by prohibiting use of the enclosure for any purpose that could possibly interfere with the exit functioning as a protected path of travel (see 14.3.3) and by limiting the combustibility of interior wall, ceiling, and floor finish materials within exit enclosures (see 7.1.4 of NFPA *101*). Details on interior wall, ceiling, and floor finish are found in Section 12.5 and Chapter 20.

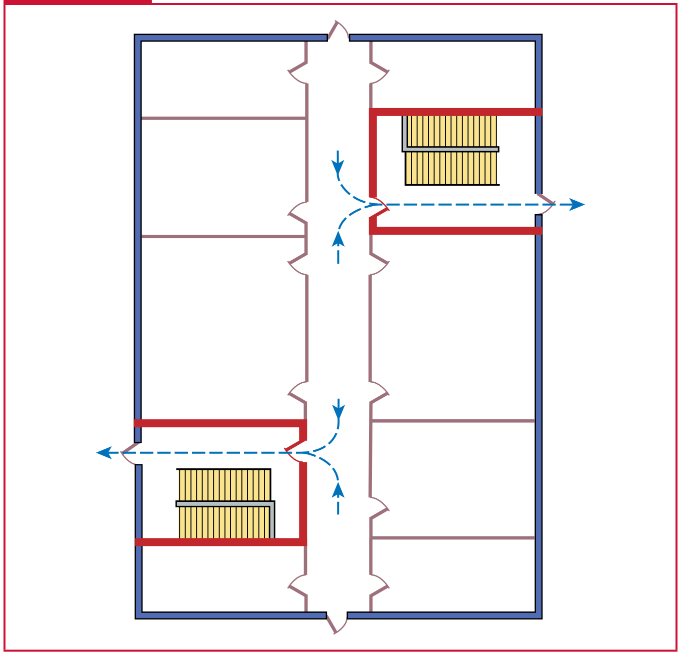
Protection from fire originating outside the exit enclosure is accomplished by providing separating construction having the required specified degree of fire resistance and by careful control of openings into the exit enclosure itself. The only openings permitted in the fire barriers between the exit and the building spaces are those for entering the exit from any normally occupied space or corridor and those for leaving the exit to reach the exit discharge. In other words, only openings provided for an occupant to enter and leave the exit enclosure are permitted.

Exhibit 14.5 depicts an egress arrangement on the ground floor of a building where occupants of that floor can enter the two exit stair enclosures, although such door assemblies are not required, because the door assemblies at the end of the corridor that discharge directly outside provide the required means of egress for the ground floor occupants. Earlier editions of the *Code* limited door assemblies into exit stair enclosures to those necessary for access to the enclosure. Some authorities having jurisdiction (AHJs) interpreted that limitation as prohibiting the convenience door assembly from the ground floor to the exit stair enclosure. The *Code* was revised to delete the concept of necessity for openings and states that openings in exit enclosures are limited to door assemblies from normally occupied spaces and corridors and door assemblies for egress from the enclosure. Thus, the arrangement depicted in Exhibit 14.5, with the convenience door assemblies into the stair enclosures on the ground floor, is permitted.

The required degree of fire resistance–rated separation for the exit enclosure depends on the number of stories or floor levels the exit connects, not the height of the building. It is possible to have stairs in a high-rise building connecting only three or fewer stories. In such a case, the enclosing construction is not required to be more than 1-hour fire resistance rated. See Exhibit 14.6. Where connecting four stories or more, exit stairs must be separated from other spaces within the building by 2-hour fire resistance–rated noncombustible, limited-combustible, or fire retardant–treated wood construction. Where the exit stairs connect three or fewer stories, the separation is permitted to be reduced to a minimum 1-hour rating. In accordance with 14.3.1(3)(a) and 14.3.1(3)(b), existing exit stair enclosures in existing non-high-rise buildings or in existing sprinklered buildings — regardless of height — are permitted a 1-hour fire resistance rating. As indicated by 14.3.1(3)(c), some occupancy chapters of NFPA *101* reduce the 2-hour fire resistance–rated construction requirement to 1 hour — even for new construction — if the building is protected throughout by an approved, supervised automatic sprinkler system. An example applicable to new hotels can be found in 28.2.2.1.2 of NFPA *101*.

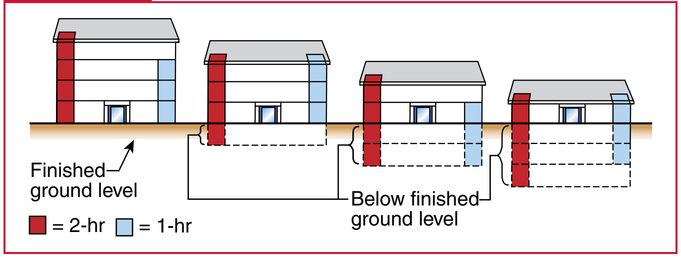
The door assemblies in walls of exit enclosures are to be 1-hour fire protection–rated door assemblies where used

Exhibit 14.5



Convenience door assemblies permitted from ground floor into exit enclosure.

Exhibit 14.6



Required separating construction for exit stairs.

in 1-hour fire resistance–rated enclosures and 1½-hour fire protection–rated door assemblies where used in 2-hour fire resistance–rated enclosures. See Table 12.7.6.2.2. Paragraph 12.7.6.2.3 modifies the provisions of Table 12.7.6.2.2 by permitting existing ¾-hour fire protection–rated door assemblies to continue in use in lieu of the minimum 1-hour fire protection rating required by the table.

The provision of 14.3.1(2) applies a requirement to 1-hour fire resistance–rated exit enclosure barriers similar to the requirement applied to 2-hour barriers by 14.3.1(5) for fire rating the supporting construction. The provisions of 14.3.1(5) and (7) work together to limit the combustibility of the minimum 2-hour fire resistance–rated separating construction required by 14.3.1(3).

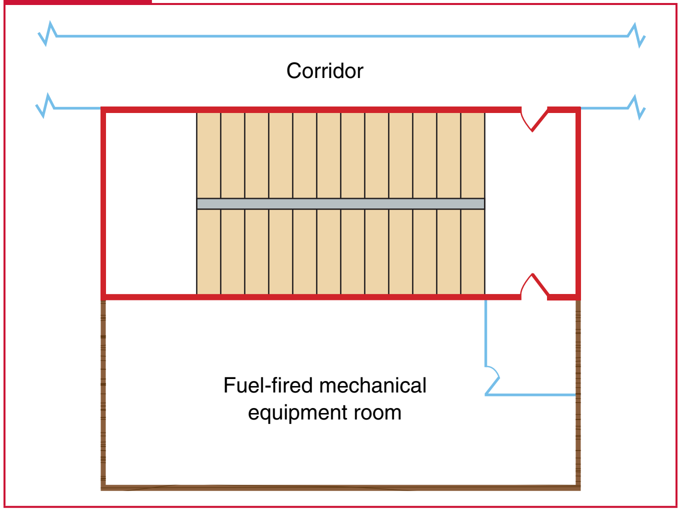
Additionally, such 2-hour separating construction must be supported by construction having a minimum 2-hour fire resistance rating. The effect of this requirement is that, in a building with floor/ceiling assemblies having less than a 2-hour fire resistance rating, the exit stair enclosure fire barrier walls are not permitted to be supported by the building floors. Rather, the exit stair enclosure needs to be a self-supporting shaft system.

The provision of 14.3.1(6) supplements the requirement of 14.3.1(5) to help ensure that structural elements that support exit stair components are protected to the same level as required for the exit enclosure. This provision prevents the early failure of exit enclosures and related egress elements. For example, a hanger rod supporting a stair landing must not be installed within a wall cavity, because the cavity and the outer wall membrane do not provide the required minimum fire resistance rating that the entire wall assembly provides (i.e., the fire resistance rating achieved by the combination of the outer wall membrane, the cavity, and the inner wall membrane). The text of A.14.3.1(6) clarifies that outside walls that are not required to be fire rated to complete the separation of the exit stair from the remainder of the floor are permitted to be penetrated by structural elements, such as the stair landing hanger rod referenced earlier in this paragraph.

The provision of 14.3.1(7) was revised for the 2018 edition of NFPA *101* to recognize that NFPA 220, *Standard on Types of Building Construction*, permits fire-retardant-treated wood (FRTW) for limited applications in all building construction types. It is not the intent for NFPA *101* to overrule the provisions of NFPA 220.

In accordance with 14.3.1(9), the only openings permitted in the exit enclosure are for door assemblies providing access into the enclosure from normally occupied spaces and corridors and for door assemblies providing egress from the enclosure into the exit discharge. These door assemblies are required to be self-closing fire door assemblies, as described in 14.5.4. No opening through the exit enclosure walls — including a door opening — is permitted from storage rooms, closets, boiler rooms, equipment spaces, utility rooms, electrical vaults, or similar spaces that are not normally occupied. Access panels to access building spaces cannot be installed in the walls or ceilings of exit enclosures, regardless of whether the access panels have a fire resistance rating.

Exhibit 14.7



Vestibule separating exit enclosure from normally unoccupied space.

The provision of 14.3.1(9)(a) recognizes the often practiced arrangement whereby a vestibule is created to prevent a normally unoccupied space from opening directly onto an exit enclosure. Exhibit 14.7 depicts a fuel-fired mechanical equipment room that is to be considered as a normally unoccupied space. The vestibule and the associated door that opens directly into the room comply with the corridor wall and door provisions of the applicable occupancy chapter of NFPA *101*. Where an occupancy chapter of NFPA *101* requires no corridor separation, as is the case with existing business occupancies per 39.3.6 of NFPA *101*, the vestibule barriers must be smoke partitions. The corridor is permitted to open directly onto the stair per 14.3.1(9). Similarly, normally occupied spaces are permitted to open directly onto the exit enclosure.

The provision of 14.3.1(9)(b) treats a normally unoccupied building service equipment support area (see Section 7.14 of NFPA *101*) as a normally occupied space but requires that the separation between such space and the exit enclosure be based on the provisions applicable to an exit enclosure that connects four or more stories. In other words, a minimum 2-hour fire resistance–rated separation is required unless one of the exemptions to 14.3.1(3) is met, in which case a minimum 1-hour fire resistance–rated separation is required.

Paragraph 14.3.1(9)(c) permits openings from normally unoccupied spaces within the exit enclosures created by exit passageways in mall structures, as detailed in Chapters 36 and 37 of NFPA *101*. By consulting the provisions of 36.4.4.9.2 and 37.4.4.9.2 of NFPA *101*, one finds that rooms housing building service equipment, service elevators, and janitor closets — spaces not normally occupied — are permitted to open directly onto mall structure exit passageways.

Paragraph 14.3.1(9)(d) recognizes that, in some existing buildings, it is safe to permit unoccupied rooms to open directly onto an exit stair enclosure. For example, in some existing hospitals, a common practice is to have interstitial spaces above the ceiling of each floor for purposes of running pipes, ducts, and conduits. The interstitial spaces appear much like separate floors. For example, in an elevation view of a four-story hospital, it would appear that there are eight stories. Patients would occupy every other floor, and the alternating floors created by the interstitial spaces would house the service pipes, ducts, and conduits. This arrangement is depicted in Exhibit 14.8. Access to the patient floors and to the interstitial space floors would be by means of fire protection–rated door assemblies from the stair enclosure. See 14.3.1(9)(d) for the other criteria necessary to permit the existing situation to be continued in use.

Paragraph 14.3.1(9)(e) has traditionally permitted existing openings, protected by fire protection-rated door assemblies, between an exit enclosure and a mechanical equipment space that has no combustible materials and no fuel-fired equipment, provided the building is protected throughout by automatic sprinklers. For the 2018 edition of NFPA *101*, an option to full-building sprinklering was added. The option recognizes sprinklering of just the mechanical equipment room provided the room has complete smoke detection.

Exit enclosure penetrations generally are prohibited for new construction. Penetrations for ductwork for pressurization of smokeproof enclosures might be permitted (see 7.2.3 of NFPA *101*), but penetration by other ductwork is prohibited. Penetrations are permitted by 14.3.1(10) for the following:

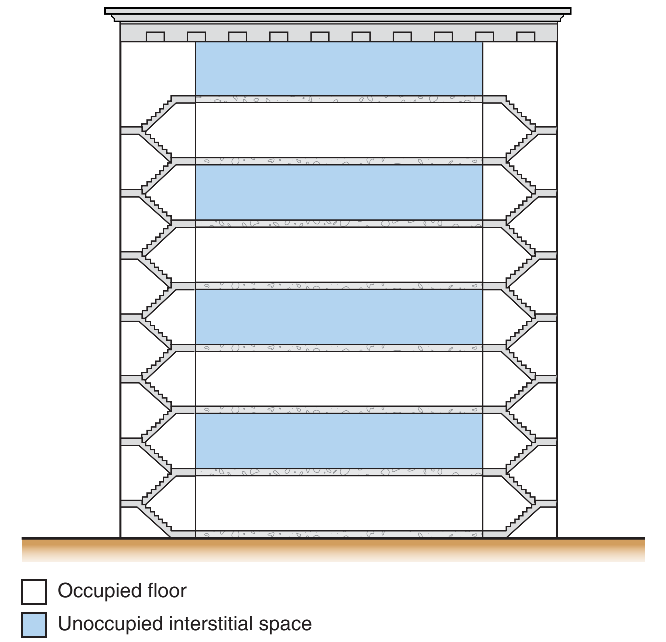
1. Water and steam piping necessary for the heating and cooling of the exit enclosure
2. Electrical conduit serving the exit enclosure
3. Fire alarm system circuit wiring installed in metallic conduit and serving the building
4. Standpipe and sprinkler piping serving the building
5. Security and communication system wiring serving the exit enclosure and installed in metal conduit (new to the 2018 edition of NFPA *101*; see, for example, the stairway video monitoring provisions of 11.8.8 of NFPA *101*)

The NFPA *101* Technical Committee on Means of Egress carefully compiled the list of penetrations permitted by 14.3.1(10) to create a complete list rather than a partial list of examples. Given that fire alarm system circuit wiring installed in metallic conduit is permitted, some designers and contractors have attempted to justify placing control panels within the exit enclosure. It was not the committee's intent to permit fire alarm system controls and associated components, other than circuit wiring in metallic conduit, to be installed within the exit enclosure.

Exhibit 14.9 shows fire protection and alarm system features installed within an exit enclosure. The equipment is connected to equipment outside the enclosure via penetrations of the enclosing fire barriers. Some of the penetrations are specifically permitted by 14.3.1(10), and others might fall into the category of existing penetrations protected in accordance with 12.7.5 as permitted by 14.3.1(10)(h). Other items, such as the fire alarm system cabinets, should not be within the exit enclosure.

The provision of 14.3.1(13) recognizes that the purpose of 14.3.1 is to limit through-penetrations into an exit enclosure but not to prohibit membrane penetrations on the outside of

Exhibit 14.8



Unoccupied interstitial spaces with openings to exit stair enclosure.

Exhibit 14.9

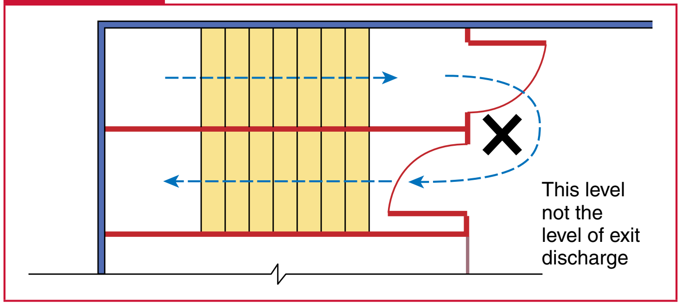
Fire protection and alarm equipment within, and penetrating the barrier walls of, an exit enclosure. (Courtesy of Jake Pauls) the exit enclosure. The new provision allows for membrane penetrations such as those for the installation of fire alarm system manual fire alarm boxes next to the door into the stair enclosure. In prior editions of the *Code,* such membrane penetrations on the outside of the exit enclosure were not addressed, since they were not specifically permitted by 14.3.1(10).

14.3.2 An exit enclosure shall provide a continuous protected path of travel to an exit discharge. [***101:***7.1.3.2.2]

Subsection 14.3.2 emphasizes that exit enclosures and the protection they afford the occupants must be continuous. It is a fundamental premise that, once an occupant has been provided the level of protection afforded by an exit, that level of protection must be maintained to the exit discharge.

Subsection 14.3.2 prohibits an exit stair or exit ramp arrangement that requires a person to leave the exit enclosure, become exposed to conditions on a floor, and then re-enter the exit enclosure to continue moving to the exit discharge. Exhibit 14.10 shows an unacceptable arrangement. The discontinuity of leaving the stair enclosure and then re-entering the stair enclosure to continue moving to the level of exit discharge creates too great a potential for exposing occupants to danger and blocking their egress route.

Exhibit 14.10



Unacceptable arrangement for enclosing a stair serving as a required exit.

14.3.3* An exit enclosure shall not be used for any purpose that has the potential to interfere with its use as an exit and, if so designated, as an area of refuge. *(See also 14.6.3.)* [***101:***7.1.3.2.3]

A.14.3.3 This provision prohibits the use of exit enclosures for storage or for installation of equipment not necessary for safety. Occupancy is prohibited other than for egress, refuge, and access. The intent is that the exit enclosure essentially be "sterile" with respect to fire safety hazards. [***101:***A.7.1.3.2.3]

Subsection 14.3.3 prohibits the use of an exit enclosure for any purpose that could potentially interfere with its use as an exit or as an area of refuge. For example, use of an enclosed exit stair to house vending machines, copying machines, or storage or to run electrical distribution wires and cables to areas of the building is prohibited. Standpipes and emergency lighting that are part of the life safety features are permitted only if their arrangement does not interfere with the passage of people. This limitation covers more than mechanical obstruction of the egress path; it includes any use that could interfere with the use of the exit. See also 14.4.1 and 14.6.3.

Exhibit 14.11 shows rolled carpet on a stair landing within an exit enclosure. The presence of the carpeting violates the requirement of 14.3.3 in two ways:

1. The carpet encroaches on the required egress width.
2. If the combustible carpet were to burn, the resultant heat and smoke would prevent the exit enclosure from serving its intended use.

The prohibitions of 14.3.3 also apply to exit passageways, because they also are exit enclosures.

Exhibit 14.11

Rolled carpet stored in an exit enclosure. (Courtesy of Jake Pauls)

14.4 Means of Egress Reliability

14.4.1* Maintenance. Means of egress shall be continuously maintained free of all obstructions or impediments to full instant use in the case of fire or other emergency. [***101:***7.1.10.1]

A.14.4.1 A proper means of egress allows unobstructed travel at all times. Any type of barrier including, but not limited to, the accumulations of snow and ice in those climates subject to such accumulations is an impediment to free movement in the means of egress. Another example of an obstruction or impediment to full instant use of means of egress is any security device or system that emits any medium that could obscure a means of egress. It is, however, recognized that obstructions occur on a short-duration basis. In these instances, awareness training should be provided to ensure that blockages are kept to a minimum and procedures are established for the control and monitoring of the area affected. [***101:***A.7.1.10.1]

The provision in 14.4.1 emphasizes the importance of keeping the egress system usable at all times. In the case of a

Class A mercantile occupancy, for example, the minimum 60 in. (1525 mm) exit access aisle width required by 36.2.5.6 and 37.2.5.6 of NFPA *101* must not, subsequent to receipt of the store's occupancy permit, be filled with mid-aisle displays that reduce the aisle width. Similarly, in a business occupancy with a new exit stair of the minimum 44 in. (1120 mm) width required by Table 7.2.2.2.1.2(B) of NFPA *101*, the stair width must not be reduced by the introduction of a mechanized chairlift that is installed, for example, to comply with legislation mandating accessibility for persons with mobility impairments. [For additional guidance on the installation of stair descent devices, see A.7.2.12.2.3 of NFPA *101*.] In an apartment building complex, the required width of the outside exit discharge sidewalk that runs along the side of the building must not be reduced by the presence of a trash dumpster on either a temporary or a permanent basis.

An egress path that was *Code* compliant when constructed might have its egress reliability compromised by human action. Exhibit 14.12 shows a stair with flaring tread width near its base. Graspable handrails were installed along the stair flight, but the placement of potted plants prevents the stair user from accessing a handrail while traveling on the lowest three treads.

Exhibit 14.12

Potted plants prevent access to required handrails. (Courtesy of Jake Pauls)

14.4.2 Furnishings and Decorations in Means of Egress.

Paragraphs 14.4.2.1 through 14.4.2.3 provide guidance for the interior decoration and maintenance of buildings that serve, for example, as restaurants and theaters, where mirrored wall surfaces and excessive decoration can camouflage and, in some cases, obstruct exits. For such occupancies, care must be taken to ensure that the required, standard, well-marked exit access that leads to an unobstructed exit is not obscured in the pursuit of period or style authenticity. For example, a restaurant that is heavily decorated with red wall coverings might use green exit signs to help meet the requirements of these paragraphs, despite the fact that Section 14.14 does not specify exit sign color.

14.4.2.1 No furnishings, decorations, or other objects shall obstruct exits or their access thereto, egress therefrom, or visibility thereof. [***101:***7.1.10.2.1]

14.4.2.2 No obstruction by railings, barriers, or gates shall divide the means of egress into sections appurtenant to individual rooms, apartments, or other occupied spaces. Where the AHJ finds the required path of travel to be obstructed by furniture or other movable objects, the authority shall be permitted to require that such objects be secured out of the way or shall be permitted to require that railings or other permanent barriers be installed to protect the path of travel against encroachment. [***101:***7.1.10.2.2]

Paragraph 14.4.2.2 relates to the arrangement of furniture, as well as to the arrangement of railings, gates, or barriers found in lobbies, foyers, waiting spaces, or staging areas of businesses, hospitals, health care clinics, hotels, and apartments. Because these large spaces are often subdivided by furniture (e.g., chairs, tables, and plants) or by railings and gates, furnishings must be prevented from blocking access to exits.

Paragraph 14.4.2.2 recommends fastening furnishings so that they are clear of access to exits or placing railings around furnishings to ensure that they are held within a fixed area and cannot be easily moved or rearranged. The *Code* recognizes the problem created by storage that is placed within the exit access aisles of storage rooms in mercantile occupancies, which is a violation of *Code* requirements. Both Chapters 36 and 37 of NFPA *101* require an unobstructed egress path to be maintained as a specific condition for permitting egress to pass through storerooms.

14.4.2.3 Mirrors shall not be placed on exit door leaves. Mirrors shall not be placed in or adjacent to any exit in such a manner as to confuse the direction of egress. [***101:***7.1.10.2.3]

14.4.2.4 Every door opening and every principal entrance that is required to serve as an exit shall be designed and constructed so that the path of egress travel is obvious and direct. Windows that, because of their physical configuration or design and the materials used in their construction, have the potential to be mistaken for door openings shall be made inaccessible to the occupants by barriers or railings. [***101:***7.2.1.1.2]

The purpose of the barriers or railings required by 14.4.2.4 is to prevent an occupant from walking through a window. Such barriers are not required to comply with the requirements of 7.2.2.4 of NFPA *101* applicable to guards. For example, intermediate rails or balusters spaced to meet the 4 in. (100 mm) diameter sphere requirement of 7.2.2.4.6.3 of NFPA *101* are not needed. A simple barrier rail, without ornamental grille-like fill or closely spaced

Exhibit 14.13

Circular decals that call attention to glass door in corridor egress path.

balusters, will adequately warn occupants to avoid walking into a glass wall or large windowpane.

Exhibit 14.13 shows a clear glass cross-corridor door in a hotel guest floor corridor. The circular decals on the door and glass sidelight call attention to the door positioned across the corridor egress path.

14.4.3 Impediments to Egress. Any device or alarm installed to restrict the improper use of a means of egress, and any device or system installed to monitor or record use of a means of egress, shall be designed and installed so that it cannot, even in case of failure, impede or prevent emergency use of such means of egress unless otherwise provided in 14.5.3 and Chapters 18, 19, 22, and 23 of NFPA *101*. [***101:***7.1.9]

14.5 Door Openings

Doors serve multiple purposes that relate to the comfort and safety of building occupants and provide protection from the following:

1. Weather, drafts, noise, and disturbance from adjoining areas
2. Trespass by unauthorized persons
3. Fire and smoke, with which this *Code* is concerned

14.5.1 Swing and Force to Open.

Δ **14.5.1.1* Swinging-Type Door Assembly Requirement.** Any door assembly in a means of egress shall be of the side-hinged or pivoted-swinging type, and shall be installed to be capable of swinging from any position to the full required width of the opening in which it is installed, unless otherwise specified as follows:

(1) Door assemblies in dwelling units, as provided in Chapter 24 of NFPA *101*, shall be permitted.
(2) Door assemblies in residential board and care occupancies, as provided in Chapters 32 and 33 of NFPA *101*, shall be permitted.
(3) Where permitted in Chapters 11 through 43 of NFPA *101*, horizontal-sliding or vertical-rolling security grilles or door assemblies that are part of the required means of egress shall be permitted, provided that all of the following criteria are met:
   (a) Such grilles or door assemblies shall remain secured in the fully open position during the period of occupancy by the general public.
   (b) On or adjacent to the grille or door opening, there shall be a readily visible, durable sign in letters not less than 1 in. (25 mm) high on a contrasting background that reads as follows: THIS DOOR TO REMAIN OPEN WHEN THE SPACE IS OCCUPIED.
   (c) Door leaves or grilles shall not be brought to the closed position when the space is occupied.
   (d) Door leaves or grilles shall be operable from within the space without the use of any special knowledge or effort.
   (e) Where two or more means of egress are required, not more than half of the means of egress shall be equipped with horizontal-sliding or vertical-rolling grilles or door assemblies.
(4) Horizontal-sliding door assemblies shall be permitted under any of the following conditions:
   (a) Horizontal-sliding door assemblies in detention and correctional occupancies, as provided in Chapters 22 and 23 of NFPA *101*, shall be permitted.
   (b) Special purpose horizontally sliding accordion or folding door assemblies complying with 7.2.1.14 of NFPA *101* shall be permitted.
   (c) Unless prohibited by Chapters 11 through 43 of NFPA *101*, horizontal-sliding door assemblies serving a room or area with an occupant load of fewer than 10 shall be permitted, provided that all of the following criteria are met:
      i. The area served by the door assembly has no high hazard contents.
      ii. The door assembly is readily operable from either side without special knowledge or effort.
      iii. The force required to operate the door assembly in the direction of door leaf travel is not more than 30 lbf (133 N) to set the door leaf in motion and is not more than 15 lbf (67 N) to close the door assembly or open it to the minimum required width.
      iv. The door assembly complies with any required fire protection rating, and, where rated, is self-closing or automatic-closing by means of smoke detection in accordance with 14.5.4 and is installed in accordance with NFPA 80.
      v. Corridor door assemblies required to be self-latching shall have a latch or other mechanism that ensures

that the door leaf will not rebound into a partially open position if forcefully closed.

(d) Where private garages, business areas, industrial areas, and storage areas with an occupant load not exceeding 10 contain only low or ordinary hazard contents, door openings to such areas and private garages shall be permitted to be horizontal-sliding door assemblies.

(5) Where private garages, business areas, industrial areas, and storage areas with an occupant load not exceeding 10 contain only low or ordinary hazard contents, door openings to such areas and private garages shall be permitted to be vertical-rolling door assemblies.
(6) Revolving door assemblies complying with 7.2.1.10 of NFPA *101* shall be permitted.
(7) Existing fusible link–operated horizontal-sliding or vertical-rolling fire door assemblies shall be permitted to be used as provided in Chapters 39, 40, and 42 of NFPA *101*.

[***101:***7.2.1.4.1]

Paragraph 14.5.1.1 requires that door assemblies within the means of egress be of the side-hinged or pivoted-swinging type. A pivoted-swinging door does not have hinges connecting the hinge stile edge of the door to the side of the door frame. Instead, pins inserted into the top and bottom of the door leaf, a short distance from the hinge stile edge, create the pivot point on which the door leaf swings. Side-hinged and pivoted-swinging types of door assemblies are the types most familiar to the general public, and their operation is readily understood.

Furthermore, 14.5.1.1 requires that the door leaf be capable of swinging to the full required width of the opening. The required width is determined by two width considerations. The first consideration involves the width required for egress capacity purposes. The second consideration involves the minimum clear width required, regardless of occupant load served. The required width is the larger of the two widths.

Items (1) and (2) of 14.5.1.1 recognize that some occupancy chapters in NFPA *101* provide exemptions to the requirement that door assemblies be of the side-hinged or pivoted-swinging type. Chapters 24, 32, and 33 of NFPA *101*, which apply to one- and two-family dwellings and residential board and care occupancies, do not require that door leaves be of the swinging type. These exemptions recognize the smaller numbers of persons using door assemblies within dwellings and the familiarity those occupants have with the operation of other door assembly types, such as sliding door assemblies.

Item (3) of 14.5.1.1 permits horizontal-sliding or vertical-rolling security grilles or door assemblies to be used in lieu of side-hinged- or pivoted-swinging-type door assemblies, provided that the exemption is specifically permitted by the applicable occupancy chapter in NFPA *101*. This exemption permits the type of security door assemblies and grilles normally found in mall structures.

Note that there is a difference between 14.5.1.1(3)(a) and 7.2.1.4.1(3)(c). Paragraph 14.5.1.1(3)(a) requires that the door assembly be fully open when the public occupies the space, while 14.5.1.1(3)(c) states that the grille or door leaf cannot be closed when the space is occupied. This allows the common practice of leaving the grille or door leaf partially closed at closing time and at other times when restricting entry to the general public is desired.

As referenced in 14.5.1.1(4)(a), detention and correctional occupancies permit certain sliding door assemblies, because swinging door leaves can become readily accessible weapons for use by residents against staff.

Paragraph 14.5.1.1(4)(b) recognizes the use of a special-purpose horizontally sliding accordion or folding door assembly under detailed conditions. One of the characteristic features of this door assembly is its operability in the direction of door leaf travel when a specified force is applied in the direction of occupant travel. See also 14.5.10.

Paragraph 14.5.1.1(4)(c) was new to the 2009 edition of NFPA *101* and expanded a provision that applied only to horizontal-sliding door assemblies in health care occupancies. The provision recognizes horizontal-sliding door assemblies serving fewer than 10 persons in any occupancy, unless an occupancy chapter specifically prohibits use of the provision. See the detailed criteria in 14.5.1.1(4)(c)i through 14.5.1.1(4)(c)v.

Paragraphs 14.5.1.1(4)(d) and 14.5.1.1(5) recognize that many private garages, small businesses, and industrial and storage buildings typically have only vertical-rolling or horizontal-sliding door assemblies and no side-hinged door assemblies. Provided that the maximum 10-person occupant load is not exceeded and there are no high hazard contents, such door assemblies are permitted to substitute for side-hinged or pivoted-swinging door assemblies.

Paragraph 14.5.1.1(6) cross-references the provisions of 14.5.6, which apply to revolving door assemblies. If 14.5.1.1(6) did not exist, it might be assumed, incorrectly, that revolving door assemblies violate the requirement for door assemblies to be side-hinged or pivoted-swinging.

Paragraph 14.5.1.1(7) recognizes the few occupancies in NFPA *101* that permit existing fusible link–operated sliding door assemblies to be positioned within the exit access of existing business, industrial, and storage occupancies if additional criteria are met. These provisions help to ensure that the door leaf is open when conditions in the door opening's vicinity are tenable for occupant movement and that it is closed once it is no longer safe for persons to seek egress via that exit access path.

A.14.5.1.1 Where doors are subject to two-way traffic, or where their opening can interfere with pedestrian traffic, an appropriately located vision panel can reduce the chance of accidents. [***101:***A.7.2.1.4.1]

Swinging doors in horizontal- or vertical-rolling partitions complying with the following should be permitted in a means of egress where the following criteria are met:

(1) The door or doors comply with 14.5.1.
(2) The partition in which the doors are mounted complies with the applicable fire protection rating and closes upon smoke

detection or power failure at a speed not exceeding 9 in./s (230 mm/s) and not less than 6 in./s (150 mm/s).

(3) The doors mounted in the partition are self-closing or automatic-closing in accordance with 14.5.4.1.

[***101:***A.7.2.1.4.1]

14.5.1.2* Door Leaf Swing Direction. Door leaves required to be of the side-hinged or pivoted-swinging type shall swing in the direction of egress travel under any of the following conditions:

(1) Where serving a room or area with an occupant load of 50 or more, except under any of the following conditions:
  (a) Door leaves in horizontal exits shall not be required to swing in the direction of egress travel where permitted by 7.2.4.3.8.1 or 7.2.4.3.8.2 of NFPA *101*.
  (b) Door leaves in smoke barriers shall not be required to swing in the direction of egress travel in existing health care occupancies, as provided in Chapter 19 of NFPA *101*.

(2) Where the door assembly is used in an exit enclosure, unless the door opening serves an individual living unit that opens directly into an exit enclosure

(3) Where the door opening serves a high hazard contents area

[***101:***7.2.1.4.2]

The provisions regulating the direction of door leaf swing appear in 14.5.1.2 of this *Code* and 7.2.4.3.8(1) of NFPA *101*.

Item (1) of 14.5.1.2 requires all door leaves serving in the means of egress from a room or area with an occupant load of 50 or more persons to swing in the direction of egress travel. For example, if the occupant load of a room with two exit access door assemblies is 80 persons, the door leaves of both door assemblies are required to swing in the direction of egress travel. The 50-person criterion is not related to the number of persons expected to use a given door opening but, rather, to the total occupant load of the room. Therefore, it would be incorrect in the case of this 80-person example to claim that 40 persons will move to each of the two door openings, that the 40-person number is fewer than the 50-person threshold, and that neither door leaf needs to swing in the direction of egress travel. The fact that the total occupant load of the room is more than 50 persons is a sufficient condition to require the exit access door leaves to swing in the direction of egress travel.

Item (2) of 14.5.1.2 requires a door leaf used in an exit enclosure to swing in the direction of egress travel. An example of a door leaf used in an exit enclosure is the door leaf in the opening between an exit access corridor and an enclosed exit stair. The main entrance and exit door leaf from an office building lobby to the outside is not a door leaf used in an exit enclosure, although it is an exit door. Door leaf swing direction for such a door would be regulated by the 50-person criterion of 14.5.1.2(1).

Item (3) of 14.5.1.2 requires a door leaf serving a high hazard contents area to swing in the direction of egress travel. Persons leaving high hazard contents spaces under fire or similar emergency must not be impeded, as would occur if they had to stop and pull a door toward them before egressing the space.

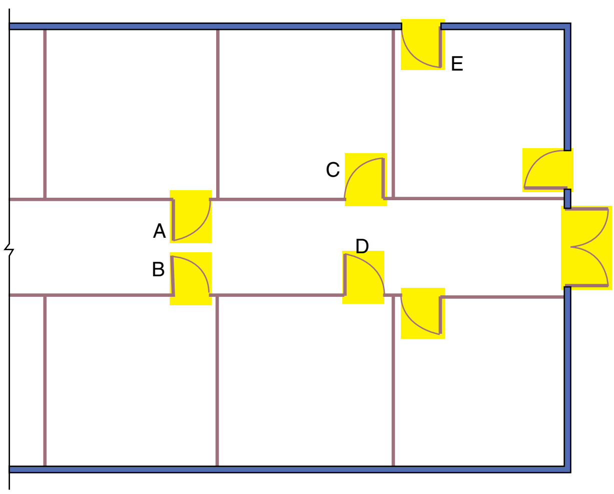
In NFPA *101*, 7.2.4.3.8(1) requires a swinging fire door assembly used in a horizontal exit to swing in the direction of egress travel.

If none of the requirements of 14.5.1.2(1) through (3) or 7.2.4.3.8(1) of NFPA *101* applies, a door leaf is permitted to swing against the direction of egress travel.

Ideally, all door leaves in a means of egress would swing in the direction of egress travel. However, because of operational concerns, there are cases where door leaf swing in the direction of egress travel is not desirable. For example, a classroom door leaf that swings into a corridor serving as an exit access for several classrooms might open against another door leaf or against the flow of people and possibly restrict the width available as corridor exit access. The *Code* recognizes this danger and permits the classroom/corridor door leaf from a room with an occupant load of fewer than 50 persons to swing against the direction of egress travel. This provision limits the number of people using a door opening whose door leaf swings against egress travel to that which is safe. The *Code* also recognizes similar constraints with regard to an exterior exit door assembly; although such a door assembly is considered an exit but not within an exit enclosure, the *Code* does not require that it swing in the direction of egress travel, unless it serves 50 or more occupants.

Exhibit 14.14 illustrates considerations involved in evaluating door leaf swing direction as addressed in 14.5.1.2. Door assembly C is permitted to swing back into the room if the room has an occupant load of fewer than 50 persons and does not have high hazard contents [see 14.5.1.2(1) and (3)]. Door assembly D must swing in the direction of egress travel if the room has an occupant load of 50 or more [see 14.5.1.2(1)]. Door assembly E, although it is an exit door assembly, is not used in an exit enclosure [see 14.5.1.2(2)], so its door leaf is permitted to swing back into the room if the occupant load is fewer than

Exhibit 14.14



Door leaf swing direction considerations.

50 and the room does not have high hazard contents. Door assemblies A and B are related to the encroachment-related provisions of 14.5.1.3. They open into the corridor directly opposite each other. Although this does not violate any *Code* provision, it is preferable that door leaves do not swing in a direction that blocks the use of the corridor when both are open.

Paragraph 14.5.1.2(1)(a) recognizes that the provisions of 7.2.4.3.8.1 of NFPA *101* exempt door leaves in horizontal exits from having to swing in the direction of egress travel in accordance with specific allowances and conditions for existing health care occupancies and existing detention and correctional occupancies. For these occupancies, staff is expected to be able to control occupant movement at horizontal exit door assemblies to prevent a crowd from pushing against a door leaf that is arranged to open only by swinging back toward the occupants. See 7.2.4.3.8.1 of NFPA *101*. Also see 7.2.4.3.8.2 of NFPA *101* for an exemption with applicability to any occupancy that recognizes the impracticality of replacing an existing horizontal exit door leaf with a pair of door leaves where the corridor does not have sufficient width to accommodate the pair.

Paragraph 14.5.1.2(1)(b) exempts smoke barrier door assemblies from having to swing in the direction of egress travel in existing health care occupancies. Such door assemblies usually span the width of a corridor. Because existing health care occupancies are permitted to have corridors as narrow as 48 in. (1220 mm), it might be impractical to install a pair of door leaves swinging in opposite directions. The single door leaf recognized by the exception swings in the correct direction for occupants on one side and swings against the direction of egress travel for occupants on the other side. Because staff directs the egress or relocation movement necessary during an emergency, the direction of door leaf swing problem is alleviated.

The exemption offered by 14.5.1.2(2) addresses the common design in apartment buildings in which door assemblies from the exit enclosure into apartment units normally swing into the apartment units. This design is common in a three-story, single-exit garden apartment. The swing of the door leaf in this arrangement is not a significant concern. The exemption also addresses another situation common to hotels where guest room door assemblies frequently open directly into an exit enclosure created to enclose a formerly open stair. Because it is often necessary to use part of the corridor to create a stair landing for the newly enclosed exit stair, the exemption offers some relief without compromising safety.

Per 14.5.1.2(3), door leaves to high hazard contents areas must swing in the direction of egress travel. A conflict sometimes arises between this requirement and the desire of those responsible for explosion control, who prefer that door leaves to areas subject to explosion be required to swing inward to impede spreading the effects of a blast to adjacent rooms and spaces. In new construction, this conflict can usually be resolved if the high hazard contents area can be located along an outside wall of the main building; the required egress door assemblies then open directly to the outside, which is desirable for life safety. This arrangement is also favorable for explosion relief, because it easily allows the door leaves to swing outward. In existing situations or where the hazardous area must be located internal to a building and away from exterior walls, the conflict is not easily resolved. The AHJ needs to work with the building owner, the insurer, and other involved parties to determine how best to reduce the explosion hazard while adequately providing needed life safety to those who work in the hazardous area. See also Section 7.11 of NFPA *101*.

N **A.14.5.1.2** See 7.4.2.1.2 and 7.4.2.2.2 of NFPA *101* for door swing direction requirements for working space about electrical equipment.

14.5.1.3 Door Leaf Encroachment.

14.5.1.3.1* During its swing, any door leaf in a means of egress shall leave not less than one-half of the required width of an aisle, a corridor, a passageway, or a landing unobstructed, unless both of the following conditions are met:

(1) The door opening provides access to a stair in an existing building.
(2) The door opening meets the requirement of 14.5.1.3.2.

[***101:***7.2.1.4.3.1]

Door leaves capable of swinging a full 180 degrees, so that they rest nearly flat against the wall in which the door opening is installed, have a greater utility than door leaves capable of swinging only 90 degrees. The 180-degree swinging door leaf can be fully opened into a corridor without significant intrusion on corridor width. The 90-degree swinging door leaf, however, might have to open into an unusually wide corridor, be set into an alcove, or otherwise be recessed so as not to exceed the maximum encroachment permitted by 14.5.1.3.1.

Note that 14.5.1.3.1 requires that, during its swing, a door leaf must leave unobstructed at least one-half the required width of a corridor. Note that this requirement is concerned with the required corridor width, which is not necessarily the same as the actual width. For example, in a corridor that is required to be 44 in. (1120 mm) wide but that is voluntarily constructed to be 56 in. (1420 mm) wide, a 34 in. (865 mm) wide door leaf — a door leaf that provides the minimum 32 in. (810 mm) clear width required by 7.2.1.2.3 of NFPA *101* — would swing to encroach on 34 in. (865 mm) of the corridor width. Although this encroachment is more than one-half the *actual* corridor width, it does leave one-half the *required* corridor width [22 in. (560 mm)] unobstructed. Such an arrangement meets the requirement of 14.5.1.3.1.

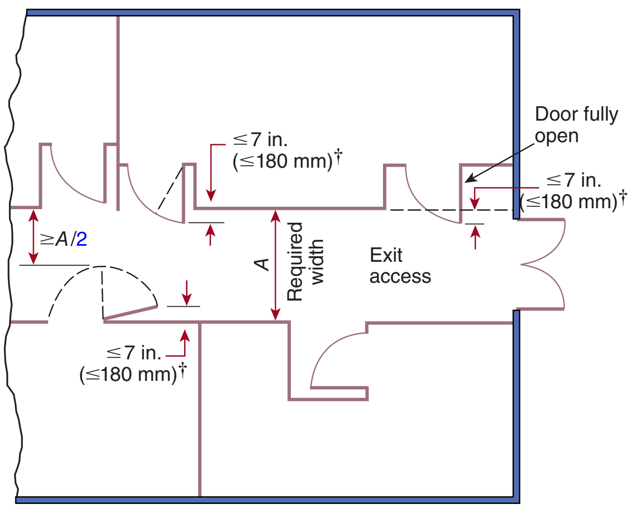
Door leaves that swing within a recessed pocket of the corridor, so as not to protrude into the required corridor width, provide the best arrangement for clear passage through an exit access corridor. Exhibit 14.15 shows a school classroom door swinging into a recessed pocket in the corridor. Door leaves that swing 180 degrees so that they come to rest against a wall and do not extend into more than 7 in. (180 mm) of required corridor width provide an acceptable arrangement. A door leaf that

Exhibit 14.15

Classroom door swinging into recessed pocket in corridor.

swings 90 degrees so that it comes to rest in the path of travel is considered not to encroach excessively on the exit access corridor width if not more than 7 in. (180 mm) of the required width of the corridor remains obstructed. Additionally, any door leaf swinging into the corridor must leave at least one-half the required corridor width unobstructed during its entire swing. See Exhibit 14.16.

Exhibit 14.16



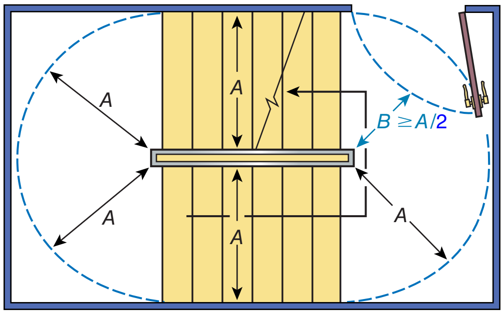
†Unless door leaf is self-closing

Door leaf swing into a corridor.

Door leaves of door assemblies serving as an entrance into an enclosed stair must not unduly block the stair landing or the stairs. Ideally, the door leaf should not reduce the required width either during its swing or while at rest. However, the *Code* does permit encroachment on the stair landing, as shown in Exhibit 14.17. For most stairs, Table 7.2.2.2.1.2(B) of NFPA *101* requires a 44 in. (1120 mm) clear width. In cases such as these, the $B \geq A/2$ rule shown in Exhibit 14.17 requires that the clearance between the leading edge of the opening door leaf and the stair newel post be at least 22 in. (560 mm). However, where the total occupant load of all floors served by the stair is fewer than 50 persons, 7.2.2.2.1.2(A) of NFPA *101* permits a 36 in. (915 mm) wide stair; in this case, the $B \geq A/2$ rule requires that the clearance between the leading edge of the opening door leaf and stair newel post be at least 18 in. (455 mm).

An acceptable arrangement for a door leaf opening onto a stair landing in an existing building is shown in Exhibit 14.18. In lieu of a $B \geq A/2$ rule, existing stairs are not required to maintain a specified clearance between the leading edge of the opening door leaf and the stair newel post.

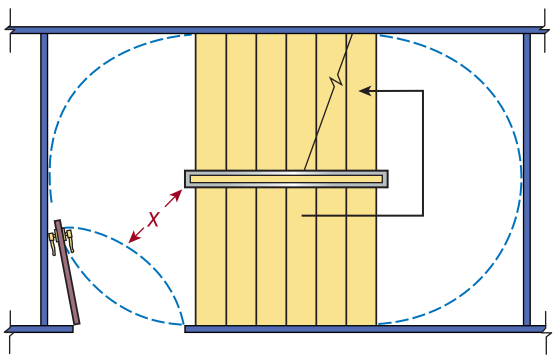
Exhibit 14.17



A — Required width
B — ≥*A*/2

Minimum required unobstructed clearance with door leaf encroaching on landing in new buildings.

Exhibit 14.18



X — No required minimum

Encroachment during door leaf swing not limited in existing buildings.

A.14.5.1.3.1 The requirements of 14.5.1.3 are not intended to apply to the swing of cross-corridor doors, such as smoke barrier doors and horizontal exits. Neither are the requirements intended to apply to doors from rooms that are typically unoccupied such as janitor's closets, electrical closets or telecommunications closets. [***101:***A.7.2.1.4.3.1]

14.5.1.3.2 When fully open, any door leaf in a means of egress shall not project more than 7 in. (180 mm) into the required width of an aisle, a corridor, a passageway, or a landing, unless the door leaf is equipped with an approved self-closing device and is not required by the provisions of 14.5.1.2 to swing in the direction of egress travel. [***101:***7.2.1.4.3.2]

14.5.1.3.3 Surface-mounted latch release hardware on the door leaf shall be exempt from being included in the maximum 7 in. (180 mm) projection requirement of 14.5.1.3.2, provided that both of the following criteria are met:

(1) The hardware is mounted to the side of the door leaf that faces the aisle, corridor, passageway, or landing when the door leaf is in the open position.
(2) The hardware is mounted not less than 34 in. (865 mm), and not more than 48 in. (1220 mm), above the floor.

[***101:***7.2.1.4.3.3]

The provision of 14.5.1.3.3 specifies that latch release hardware that is surface mounted to the side of the door leaf that faces the aisle, corridor, passageway, or landing when the door leaf is in the open position is exempted from inclusion in the maximum 7 in. (180 mm) projection specified in 14.5.1.3.1, provided that such hardware is mounted 34 in. to 48 in. (865 mm to 1220 mm) above the floor. The hardware on the back side of the door leaf is counted in the maximum 7 in. (180 mm) projection, but the hardware on the side of the door leaf that faces the landing is not. The provision is consistent with the door-opening clear width encroachment criteria of 7.2.1.2.1.1(5) of NFPA *101*. This provision helps to alleviate the problem where the AHJ cites the door leaf encroachment as excessive because of the latch release hardware that protrudes into the egress path. Wheelchair users are able to travel past the door without being encumbered, as the hardware must be at least 34 in. (865 mm) off the floor.

14.5.1.4 Screen Door Assemblies and Storm Door Assemblies. Screen door assemblies and storm door assemblies used in a means of egress shall be subject to the requirements for direction of swing that are applicable to other door assemblies used in a means of egress. [***101:***7.2.1.4.4]

14.5.1.5 Door Leaf Operating Forces.

Δ **14.5.1.5.1** The forces required to fully open any door leaf manually in a means of egress shall not exceed 15 lbf (67 N) to release the latch, 30 lbf (133 N) to set the leaf in motion, and 15 lbf (67 N) to open the leaf to the minimum required width, unless otherwise specified as follows:

(1) The opening forces for interior side-hinged or pivoted-swinging door leaves without closers shall not exceed 5 lbf (22 N).
(2) The opening forces for existing door leaves in existing buildings shall not exceed 50 lbf (222 N) applied to the latch stile.
(3) The opening forces for horizontal-sliding door leaves in detention and correctional occupancies shall be as provided in Chapters 22 and 23 of NFPA *101*.
(4) The opening forces for power-operated door leaves shall be as provided in 7.2.1.9 of NFPA *101*.

[***101:***7.2.1.4.5.1]

14.5.1.5.2 The forces specified in 14.5.1.5 shall be applied to the latch stile. [***101:***7.2.1.4.5.2]

The *Code* recognizes that several movements are necessary to move a door leaf from its closed to its fully open position. Paragraph 14.5.1.5.1 identifies each of those movements and limits the force needed to accomplish each. The force required to unlatch the door assembly is limited to 15 lbf (67 N); the force necessary to start the door leaf in motion or to overcome its inertia is limited to not more than 30 lbf (133 N); and the force necessary to move the door leaf to its required open position is limited to not more than 15 lbf (67 N).

Care must be taken to ensure that the 30 lbf (133 N) needed to overcome the inertia of a door leaf in a means of egress is not exceeded for door assemblies opening into pressurized stairs. The pressure necessary to protect the stair often might be such that 30 lbf (133 N) is insufficient to open the door leaf. The use of barometric relief dampers or other pressure-regulating methods might be required. See NFPA 92, *Standard for Smoke Control Systems*.

A person with severe mobility impairment, such as someone who uses a wheelchair, might find it difficult or impossible to exert even the 15 lbf (67 N) specified by 14.5.1.5.1. Specification of a lower operating force for self-closing door assemblies might adversely affect the door assembly closer's ability to perform its intended function of returning an open door leaf to the fully closed and latched position. For interior side-hinged or pivoted-swinging door assemblies without closers, no conflict exists between the needs of a closer and those of a person with physical disabilities. Therefore, 14.5.1.5.1(1) specifies that such door assemblies be operable when not more than 5 lbf (22 N) is applied at the latch stile.

Circumstances such as wet floors, smooth-soled shoes, and light body weight can render many people incapable of exerting 50 lbf (222 N) horizontally. Therefore, the maximum 50 lbf (222 N) operating requirement of earlier editions of the *Code* remains applicable only to existing door assemblies via the provisions of 14.5.1.5.1(2).

Items (3) and (4) of 14.5.1.5.1 address special situations where the operating force requirements of 14.5.1.5 cannot be applied. For horizontal-sliding door assemblies in detention and correctional occupancies, see 22.2.11.1.6 and 23.2.11.1.6 of NFPA *101*. For requirements specific to power-operated door assemblies, see 7.2.1.9 of NFPA *101*.

Paragraph 14.5.1.5.2 clarifies that the forces specified in 14.5.1.5.1 are to be applied to the latch stile.

14.5.2 Locks, Latches, and Alarm Devices.

An increase in thefts, muggings, and similar crimes has led to the practice of providing extra security on door assemblies within the means of egress. Such a practice, particularly where door assemblies to exit stairs and exit discharges are involved, is an open invitation to tragedy in the event of fire or other emergency. The provisions of 14.5.2 are aimed at preventing locked door assemblies in means of egress or any other unnecessary interference with the orderly movement of people through door openings in the event of fire. The *Code* has attempted to accomplish this objective while maintaining features that are essential to security within the building.

The requirement that door assemblies be easily openable from the egress side is consistent with the concept that all components in the means of egress must be under the control of the occupants. This requirement prohibits the use of key locks or hard-to-use devices, such as door handles or latches covered with glass that has to be broken. Where panic hardware or fire exit hardware is used, no device that might interfere with its operation can be used; however, this does not prevent the use of alarm connections that indicate that the door assembly is in use.

Requirements for door assemblies leading to exits also apply to door assemblies that open to roofs where, for example, exit stairs from a high-rise portion of the building discharge to the roof of the low-rise portion of the building and to exit discharge door assemblies leading to the street or other public way.

14.5.2.1 Door leaves shall be arranged to be opened readily from the egress side whenever the building is occupied. [***101:***7.2.1.5.1]

14.5.2.2* The requirement of 14.5.2.1 shall not apply to door leaves of listed fire door assemblies after exposure to elevated temperature in accordance with the listing, based on laboratory fire test procedures. [***101:***7.2.1.5.2]

A.14.5.2.2 Some fire door assemblies are listed for use with fire pins or fusible links that render the door leaf release inoperative upon exposure to elevated temperature during a fire. The door leaf release mechanism is made inoperative where conditions in the vicinity of the door opening become untenable for human occupancy, and such door opening no longer provides a viable egress path. [***101:***A.7.2.1.5.2]

14.5.2.3 Locks, if provided, shall not require the use of a key, a tool, or special knowledge or effort for operation from the egress side. [***101:***7.2.1.5.3]

Paragraph 14.5.2.1 establishes the principle that, when a building is occupied, door assemblies must be able to be opened easily from the side from which egress is to be made.

The provision of 14.5.2.2 is explained in A.14.5.2.2.

Paragraph 14.5.2.3 prohibits the installation of locks that require the use of a key, a tool, or special knowledge or effort to open the door leaf from the egress side. Door assemblies are generally permitted to be locked from the non-egress side, to prevent unauthorized entry into a building. However, door assemblies from an exit stair enclosure to the building floors might have to provide for re-entry as detailed in 14.5.2.8.

See the commentary following 14.5.2.6, which explains the concept whereby a door assembly with a magnetic lock, with building access via a card reader, can be considered a normal door assembly in compliance with 14.5.2.1, 14.5.2.3, and 14.5.2.10 if the door leaf has a latch release, like a lever handle with an integral switch that releases the lock to allow free egress by building occupants.

14.5.2.4 The requirements of 14.5.2.1 and 14.5.2.3 shall not apply where otherwise provided in Chapters 18 through 23 of NFPA *101*. [***101:***7.2.1.5.4]

Paragraph 14.5.2.4 cross-references the provisions applicable to health care occupancies and detention and correctional occupancies where door assemblies locked against egress by building occupants are permitted under specific conditions. For examples, see 18.1.1.1.7, 18.2.2.2.2, 18.2.2.2.4, and 18.2.2.2.5 of NFPA *101* and similar provisions in Chapter 19 of NFPA *101*. Also see 22.2.11.1 and 22.2.11.1.7 through 22.2.11.1.10 of NFPA *101* and similar provisions in Chapter 23 of NFPA *101*.

14.5.2.5 Key-Operated Locks.

Δ **14.5.2.5.1*** Exterior door assemblies shall be permitted to have key-operated locks from the egress side, provided that all of the following criteria are met:

(1) This alternative is permitted in Chapters 11 through 43 of NFPA *101* for the specific occupancy.
(2) A readily visible, durable sign in letters not less than 1 in. (25 mm) high on a contrasting background that reads as follows is located on or adjacent to the door leaf: THIS DOOR TO REMAIN UNLOCKED WHEN THE BUILDING IS OCCUPIED
(3) The locking device is of a type that is readily distinguishable as locked.
(4) A key is immediately available to any occupant inside the building when it is locked.

[***101:***7.2.1.5.5.1]

A.14.5.2.5.1 Where the entrance consists of an exterior vestibule, the locking arrangement should be permitted on the egress side of either the interior or exterior door of the vestibule. [***101:***A.7.2.1.5.5.1]

14.5.2.5.2 The alternative provisions of 14.5.2.5.1 shall be permitted to be revoked by the AHJ for cause. [***101:***7.2.1.5.5.2]

The provisions of 14.5.2.5.1 address key-operated locks that must meet four conditions — one of which is that the appropriate occupancy chapter of NFPA *101* must specifically permit use of the alternative. Compliance with 14.5.2.5.1(3), which requires that the locking device be of a type readily distinguishable as locked, is to be judged by the AHJ. Locks specifically designed to meet this requirement often have an indicating window mechanism that displays the word *open* when the device is in the unlocked position and the word *locked* when the device is in the locked position.

In permitting up to 10 persons in a locked building (i.e., an unoccupied building, as addressed in 7.2.1.1.3 of NFPA *101*), the *Code* does not dismiss such occupants as unimportant. The *Code* recognizes that there are instances in which a building must be occupied by security personnel or by janitorial crews when it is locked. Such persons are generally familiar with the premises, and the *Code* requires that they have keys available for egress when necessary.

The occupancies in the list that follows permit the use of the key-operated lock addressed by 14.5.2.5. Additional restrictions that might be imposed by the applicable occupancy chapter of NFPA *101* are contained in the paragraphs referenced within parentheses in the list. For example, in new assembly occupancies, use of a key-operated lock is restricted to the main exit of a building with an occupant load of not more than 500 persons. In addition, the main exit of the assembly occupancy is required to consist of a single door leaf or single pair of door leaves, and any latch on the door leaf or leaves is required to be released by panic hardware.

The occupancies permitting the use of the key-operated lock addressed in 14.5.2.5 are as follows:

1. Assembly occupancies (12.2.2.2.4 and 13.2.2.2.4 of NFPA *101*)
2. Mercantile occupancies (36.2.2.2.2 and 37.2.2.2.2 of NFPA *101*)
3. Business occupancies (38.2.2.2.3 and 39.2.2.2.3 of NFPA *101*)

Exhibit 14.19 shows the sign for an assembly occupancy required by 14.5.2.5.1(2).

Exhibit 14.19

Sign over door subject to locking in an assembly occupancy.

Δ **14.5.2.6 Door Hardware Release of Electrically Locked Egress Door Assemblies.** Door assemblies in the means of egress shall be permitted to be equipped with approved electrical locking systems released by the operation of door hardware provided that all of the following conditions are met:

(1) The hardware for egress-side occupant release of the electrical lock is affixed to the door leaf.
(2) The hardware has an obvious method of operation that is readily operated in the direction of egress under all lighting conditions.
(3) The hardware is capable of being operated with one hand in the direction of egress.
(4) Operation of the hardware directly interrupts the power supply to the electric lock and unlocks the door assembly in the direction of egress.
(5) Loss of power to the listed releasing hardware automatically electrically unlocks the door assembly in the direction of egress.
(6) Hardware for new installations is listed in accordance with ANSI/UL 294.

[***101:***7.2.1.5.6]

The provisions of 14.5.2.6 address door hardware release of electrically locked egress doors as a normal door assembly and not as a special locking arrangement. Note that the provisions are positioned within 14.5.2, related to traditional locks and latches, and not within 14.5.3, which addresses specialized, nontraditional locking arrangements like delayed-egress electrical locking systems and sensor-release of electrical locking systems.

The door assemblies addressed by 14.5.2.6 typically take the form of a door leaf that is held locked to its frame via an electromagnet. Some AHJs, in enforcing the provisions of earlier editions of the *Code*, often required any door assembly with an electromagnetic lock to comply with one of the sets of provisions of 14.5.3 for special locking arrangements, regardless of how the lock was operated. The text of 14.5.2.6 has the effect of equating the electrically controlled lock to a traditional, mechanically latched or locked door.

The criteria detailed in 14.5.2.6(1) through (6) ensure that the electrically controlled egress door assembly meets the requirements of 14.5.2.1, 14.5.2.3, and 14.5.2.10, as well as additional safeguards imposed, because the lock is electrically controlled. See also the third sentence of A.14.5.2.10.

14.5.2.7 Where permitted in Chapters 11 through 43 of NFPA *101*, key operation shall be permitted, provided that the key cannot be removed when the door leaf is locked from the side from which egress is to be made. [***101:***7.2.1.5.7]

Paragraph 14.5.2.7 permits what is known as *captive key* hardware, which is permitted in lodging or rooming houses via the provisions of 26.2.3.6 of NFPA *101*. The captive key lock has the potential for misuse and must be used carefully. The design of the lock is such that an occupant could unlock the door assembly from the inside, thus freeing the key; move through the door opening, taking the key to the outside; lock the door assembly from the outside; and leave the property — potentially leaving others locked in the building. Thus, this lock is permitted with limited use within the occupancy chapters of NFPA *101*.

Δ **14.5.2.8*** Every door assembly in a stair enclosure serving more than four stories, unless permitted by 14.5.2.8.2, shall meet one of the following conditions:

(1) Re-entry from the stair enclosure to the interior of the building shall be provided.
(2) An automatic release that is actuated with the initiation of the building fire alarm system shall be provided to unlock all stair enclosure door assemblies to allow re-entry.
(3) Selected re-entry shall be provided in accordance with 14.5.2.8.1.

[***101:***7.2.1.5.8]

A.14.5.2.8 It is intended that the re-entry provisions apply only to enclosed exit stairs, not to outside stairs. This arrangement makes it possible to leave the stairway at such floor if the fire renders the lower part of the stair unusable during egress or if the occupants seek refuge on another floor. [***101:***A.7.2.1.5.8]

Every door assembly in a stair enclosure serving more than four stories in a new building or nonsprinklered high-rise existing building [see 14.5.2.8.2(1) and (2)] must be arranged to permit re-entry into the building. However, the *Code* recognizes the need for varying degrees of security and does specify some equivalent alternatives. Stairway door assemblies are permitted to be locked to the stairwell side if arranged to unlock automatically upon initiation of the fire alarm system. Selected re-entry is addressed in the commentary associated with 14.5.2.8.1.

Δ **14.5.2.8.1** Door assemblies on stair enclosures shall be permitted to be equipped with hardware that prevents re-entry into the interior of the building, provided that the following criteria are met:

(1) There shall be not less than two levels where it is possible to leave the stair enclosure to access another exit.
(2) There shall be not more than four stories intervening between stories where it is possible to leave the stair enclosure to access another exit.
(3) Re-entry shall be possible on the top story or next-to-top story served by the stair enclosure, and such story shall allow access to another exit.
(4) Door assemblies allowing re-entry shall be identified as such on the stair side of the door leaf.
(5) Door assemblies not allowing re-entry shall be provided with a sign on the stair side indicating the location of the nearest door opening, in each direction of travel, that allows re-entry or exit.

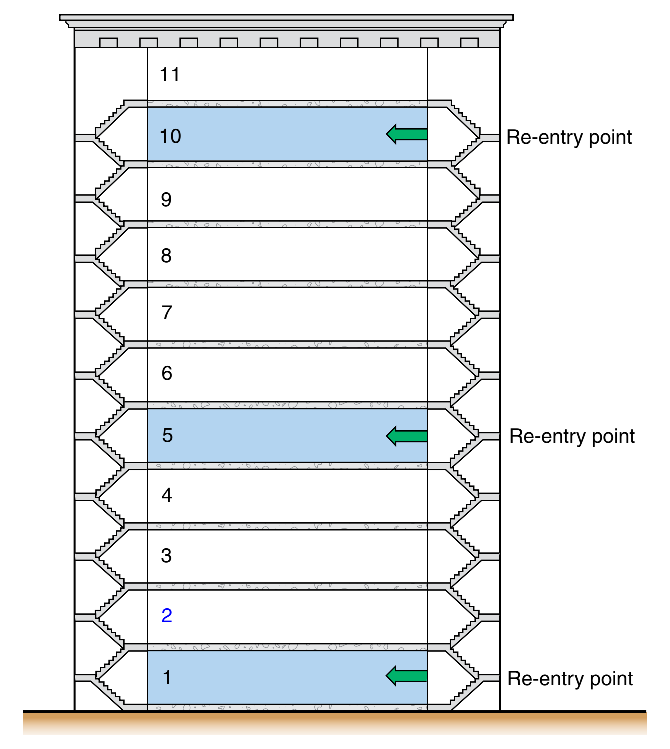
[***101:***7.2.1.5.8.1]

Paragraph 14.5.2.8.1 permits some stair enclosure door assemblies, regardless of occupancy, to be locked to prevent re-entry on selected floors. In such instances, at least two levels with unlocked door assemblies must provide a way out of the stairway, one of which must be the top floor or the next-to-top floor; the other is usually the door assembly at the level of exit discharge. Because the *Code* prohibits more than four floors between floors that provide a way out of the stairway, stair enclosures serving more than six or seven stories must have more than two unlocked re-entry points. This arrangement provides flexibility in buildings that, perhaps for security reasons, need to prevent re-entry on certain floors, while at the same time ensuring that a person can re-enter the building without having to travel up or down too many flights of stairs. See Exhibit 14.20. Any door assembly providing a way out of the stair enclosure must be identified as such on the stairwell side.

Δ **14.5.2.8.2** The requirements of 14.5.2.8, except as provided in 14.5.2.8.3, shall not apply to the following:

(1) Existing installations in buildings that are not high-rise buildings as permitted in Chapters 11 through 43 of NFPA *101*.

Exhibit 14.20



Stairway selected re-entry option.

(2) Existing installations in high-rise buildings as permitted in Chapters 11 through 43 of NFPA *101* where the occupancy is within a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.
(3) Existing approved stairwell re-entry installations as permitted by Chapters 11 through 43 of NFPA *101*.
(4) Stair enclosures serving a building permitted to have a single exit in accordance with Chapters 11 through 43 of NFPA *101*.
(5) Stair enclosures in health care occupancies where otherwise provided in Chapter 18 of NFPA *101*.
(6) Stair enclosures in detention and correctional occupancies where otherwise provided in Chapter 22 of NFPA *101*.

[***101:***7.2.1.5.8.2]

14.5.2.8.3 When the provisions of 14.5.2.8.2 are used, signage on the stair door leaves shall be required as follows;

(1) Door assemblies allowing re-entry shall be identified as such on the stair side of the door leaf.
(2) Door assemblies not allowing re-entry shall be provided with a sign on the stair side indicating the location of the nearest door opening, in each direction of travel, that allows re-entry or exit.

[***101:***7.2.1.5.8.3]

The provisions of 14.5.2.8.2(1) and (2) work together as follows:

1. Existing stair installations in a non-high-rise building are permitted to be exempted by the applicable occupancy chapter of NFPA *101*.

2. Existing stair installations in a high-rise building are permitted to be exempted by the applicable occupancy chapter of NFPA *101* only if the building is fully sprinklered.
3. Where the existing high-rise building is not sprinklered, re-entry in accordance with 14.5.2.8 is required.

Where an existing stairwell re-entry installation does not meet all the criteria of 14.5.2.8, the provision of 14.5.2.8.2(3) establishes that the existing installation can be continued in use if approved. The term *approved* means acceptable to the AHJ, and its definition appears in 3.2.1.

Paragraph 14.5.2.8.2(4) recognizes that re-entry in buildings permitted to have a single exit is not necessary. In most single-exit buildings, the door assemblies from the stairway open directly into the occupant space. Most of the single-exit buildings recognized by the occupancy chapters of NFPA *101* are not more than four stories in height and are exempt from the stairwell re-entry provisions via the base paragraph of 14.5.2.8.

The provisions of 14.5.2.8.2(5) and (6) specify, for correlation with the occupancy chapters of NFPA *101*, that health care occupancies and detention and correctional occupancies are exempt from the stair enclosure re-entry provisions. The exemption is based on the level of protection provided via a defend-in-place approach that minimizes the need for vertical evacuation by stairs or, where such movement is needed, relies heavily on staff with access to keys to direct the evacuation or relocation.

The provisions of 14.5.2.8.3 require signage in each exit stair enclosure serving more than four stories and not providing re-entry in accordance with the criteria of 14.5.2.8(1), (2), or (3). The signage must be installed on the stair side of each door leaf. The provisions of 14.5.2.8.3 are illustrated by the following example: An existing business occupancy building is six stories in height above grade plane. Egress from all floors above floor 1 is provided by two remote exit stair enclosures that are accessed by a corridor on each floor. On floors 2 through 6, all door leaves from the corridor to the exit stair enclosures are locked from the stairwell side to prevent re-entry as permitted by 39.2.2.2.5(1) of NFPA *101* and 14.5.2.8.2(1). On floor 1, the door from the corridor to each stair enclosure is left unlocked to permit re-entry onto the floor. In accordance with 14.5.2.8.3(2), the exit stair enclosure door leaves on floors 2 through 6 must be provided with signage, on the stair side, indicating that re-entry is provided at floor 1.

14.5.2.9 If a stair enclosure allows access to the roof of the building, the door assembly to the roof either shall be kept locked or shall allow re-entry from the roof. [***101:***7.2.1.5.9]

Paragraph 14.5.2.9 was written to prevent building occupants from being trapped on a roof by a locked door assembly that does not permit re-entry into the building. If security concerns, for example, dictate that rooftop door assemblies are to be locked against entry from the outside, then the door assemblies also need to be locked from the inside to prevent unauthorized building occupants from going to the roof and becoming trapped. Note that there is no requirement that stair enclosure door assemblies provide rooftop access. Heroic helicopter rescues from rooftops of burning buildings are Hollywood movie illusions that seldom happen in real life.

14.5.2.10* A latch or other fastening device on a door leaf shall be provided with a releasing device that has an obvious method of operation and that is readily operated under all lighting conditions. [***101:***7.2.1.5.10]

A.14.5.2.10 Examples of devices that might be arranged to release latches include knobs, levers, and bars. This requirement is permitted to be satisfied by the use of conventional types of hardware, whereby the door is released by turning a lever, knob, or handle or by pushing against a bar, but not by unfamiliar methods of operation such as a blow to break glass. It is also within the intent of this requirement that switches integral to traditional doorknobs, lever handles, or bars, and that interrupt the power supply to an electromagnetic lock, be permitted, provided that they are affixed to the door leaf. The operating devices should be capable of being operated with one hand and should not require tight grasping, tight pinching, or twisting of the wrist to operate. [***101:***A.7.2.1.5.10]

Paragraph 14.5.2.10 requires that, where a latch or other similar device is provided, the method of operation of its releasing device must be obvious, even in the dark. The intention of this requirement is that the method of release be one that is familiar to the average person. Generally, a two-step release, such as a knob and an independent slide bolt, is not permitted. In most occupancies, it is important that a single action unlatch the door assembly. See the commentary following 14.5.2.10.7 for an explanation of night latches permitted as a device in addition to the main latch/lock on residential occupancy dwelling unit door assemblies.

See the commentary following 14.5.2.6, which explains the concept whereby a door assembly with an electrically controlled lock can be considered a normal door assembly in compliance with 14.5.2.1, 14.5.2.3, and 14.5.2.10 if the door assembly includes an arrangement where the locked door leaf is provided with a latch release, like a lever handle with an integral switch that releases the lock to allow free egress by building occupants. See 14.5.2.6(1) through (6), which details these criteria.

14.5.2.10.1 The releasing mechanism for any latch shall be located as follows:

(1) Not less than 34 in. (865 mm) above the finished floor for other than existing installations
(2) Not more than 48 in. (1220 mm) above the finished floor

[***101:***7.2.1.5.10.1]

14.5.2.10.2 The releasing mechanism shall open the door leaf with not more than one releasing operation, unless otherwise specified in 14.5.2.10.3 and 14.5.2.10.4 or 14.5.2.10.6. [***101:***7.2.1.5.10.2]

14.5.2.10.3* Egress door assemblies from individual living units and guest rooms of residential occupancies shall be permitted to be provided with devices, including automatic latching devices, that require not more than one additional releasing operation, provided that such device is operable from the inside without the use of a key or tool and is mounted at a height not exceeding 48 in. (1220 mm) above the finished floor. [***101:***7.2.1.5.10.3]

A.14.5.2.10.3 Examples of devices that, when used with a latch, can be arranged to require not more than one additional releasing operation include night latches, dead bolts, and security chains. [***101:***A.7.2.1.5.10.3]

14.5.2.10.4 Existing security devices permitted by 14.5.2.10.3 shall be permitted to have two additional releasing operations. [***101:***7.2.1.5.10.4]

14.5.2.10.5 Existing security devices permitted by 14.5.2.10.3, other than automatic latching devices, shall be located not more than 60 in. (1525 mm) above the finished floor. [***101:***7.2.1.5.10.5]

14.5.2.10.6 Two releasing operations shall be permitted for existing hardware on a door leaf serving an area having an occupant load not exceeding three, provided that releasing does not require simultaneous operations. [***101:***7.2.1.5.10.6]

N **14.5.2.10.7** Where permitted by Chapters 11 through 43 of NFPA *101*, two releasing operations shall be permitted for doors secured against unwanted entry. [***101:***7.2.1.5.10.7]

Paragraph 14.5.2.10.1 specifies that new latch release mechanisms be located at least 34 in. (865 mm) above the floor, and that both new and existing latch release mechanisms be not more than 48 in. (1220 mm) above the floor, so that the latch release is located in a position that is neither too low nor too high to be reached by persons in wheelchairs. The maximum mounting height for the latch release also helps to ensure that children can reach the latch.

Paragraphs 14.5.2.10.3 and 14.5.2.10.4 provide an exemption to the requirement for a single releasing mechanism. The exemption recognizes the use, in residential living units and hotel guest rooms, of one additional device requiring release in new construction and two additional devices requiring release in existing installations. The exemption permits an existing condition to continue where a hotel room door assembly, for example, has hardware arranged such that one operation releases the security chain or bar (i.e., night latch), another operation releases the dead bolt (usually via a thumb turn-type knob), and a third operation releases the door latch (usually by turning the doorknob or operating the door lever). However, in new installations, if a night latch or security device is installed, one operation would release the security device and a second operation, such as turning the doorknob or operating the door lever, would have to release both the dead bolt and normal door latch. Hardware that releases both the dead bolt and the normal door latch by turning the door lever is called a *hotel latch set* and is shown in Exhibit 14.21.

Exhibit 14.21

Hotel latch set.

The *Code* prohibits supplemental automatic latching security devices from being located more than 48 in. (1220 mm) above the floor, even in existing buildings (see 14.5.2.10.3). This prohibition is intended to prevent children and wheelchair users from being trapped in a space when an automatic latching device that is located above a person's reach engages, locking the door assembly. Existing security devices that must be physically engaged are permitted in locations not more than 60 in. (1525 mm) above the floor (see 14.5.2.10.5), based on the assumption that the person engaging such a device is present to disengage it when needed.

Paragraph 14.5.2.10.6 offers a leniency to existing situations where two releasing operations are required to release the door latch. The allowance expands the use of a practice formerly permitted only in residential occupancies but controls such situations by restricting the door to serving an area with an occupant load not exceeding three persons. The provision would permit a night chain to be dropped, followed by the turning of a door knob. It does not permit simultaneous operations such as sliding a bolt and then turning a release lever while holding the bolt in its new position.

The provision of 7.2.1.5.10.7 is new for the 2018 edition of NFPA *101*. It recognizes, for example, the new allowance of 15.2.2.2.4 in NFPA *101* for existing educational occupancy buildings to secure classroom doors against unwanted entry provided that classroom occupants can release the locking mechanism to open the door leaf with not more than two releasing operations. New educational occupancy buildings are permitted by 14.2.2.2.4 in NFPA *101* to lock classroom doors against unwanted entry but must be able to release the lock and open the door leaf with not more than one releasing operation as required by 14.5.2.10.2 of this *Code*.

Δ **14.5.2.11** Where pairs of door leaves are required in a means of egress, one of the following criteria shall be met:

(1) Each leaf of the pair shall be provided with a releasing device that does not depend on the release of one leaf before the other.
(2) Approved automatic flush bolts shall be used and arranged such that both of the following criteria are met:
 (a) The door leaf equipped with the automatic flush bolts shall have no doorknob or surface-mounted hardware on the egress side of the door.
 (b) Unlatching of any leaf shall not require more than one operation.

[***101:***7.2.1.5.11]

The requirement of 14.5.2.11(1) for independent releasing hardware applies only to pairs of door leaves in a common door opening where both door leaves are required for means of egress. If a second leaf is provided for a reason other than required egress, that leaf can have a releasing mechanism that requires the egress leaf to be released first. However, in such a case, the leaf not used for egress must be arranged so it is not mistaken for the egress door leaf.

Paragraph 14.5.2.11(2) permits a pair of door leaves — both a part of the required means of egress — to be placed within a common frame, whereby one leaf has no visible releasing hardware but has approved automatic flush bolts that release that leaf when the other leaf, which has visible hardware, is released. Therefore, the user is directed to the leaf with releasing hardware and disengages the latch on that leaf, and the other leaf automatically unlatches to allow its use if pushed in the direction of door leaf travel.

14.5.2.12* Devices shall not be installed in connection with any door assembly on which panic hardware or fire exit hardware is required where such devices prevent or are intended to prevent the free use of the leaf for purposes of egress, unless otherwise provided in 14.5.3. [***101:***7.2.1.5.12]

A.14.5.2.12 Examples of devices prohibited by this requirement include locks, padlocks, hasps, bars, chains, or combinations thereof. [***101:***A.7.2.1.5.12]

It is not the intent of 14.5.2.12 to require panic hardware or fire exit hardware; that requirement is specified by the various occupancy chapters of NFPA *101*. Rather, 14.5.2.12 requires that, where panic hardware or fire exit hardware is installed, no device or arrangement is to interfere with its intended function. The intended function is the release of the latch when pressure — such as that exerted by persons pushing up against the door leaf — is applied to the bar or pad extending across the majority of the door leaf width [see 14.5.3.4.1(1)].

14.5.3* Special Locking Arrangements.

A.14.5.3 None of the special locking arrangements addressed in 14.5.3 are intended to allow *credentialed egress, request to exit*, or similar provisions, where an occupant cannot leave the building without swiping a card through a reader. Where such an arrangement is desired to keep track of occupants, the swiping of cards needs to be procedural but not necessary for releasing the door lock or latch. Free egress needs to be available at all times. Another option to free egress is the use of a delayed-egress electrically locking system. [***101:***A.7.2.1.6]

The special locking arrangements described in 14.5.3 include delayed-egress electrical locking systems, sensor-release of electrical locking systems, and elevator lobby exit access door assemblies locking. Each of these terms has a specific, but limited, meaning for purposes of applying the *Code*. For example, a building operator installs a magnetic lock on an outside door assembly and provides a card reader outside the building that releases the door assembly lock, so that only authorized persons are allowed entry to the building. Further, a lever handle is mounted on the inside surface of the door leaf and has an integral switch that releases the magnetic lock whenever a building occupant operates the lever. The building operator refers to this system as a sensor-release of electrical locking system, but it is not the sensor-release of electrical locking system addressed in 14.5.3.2, and it is not subject to those requirements. Rather, the door assembly locking system described is an electrically controlled egress door assembly subject to the provisions of 14.5.2.6. Such door assemblies in accordance with 14.5.2.6 comply with 14.5.2.1, 14.5.2.3, and 14.5.2.10 so as not to be considered special locking arrangements. The concept is further explained by the third sentence of A.14.5.2.10.

14.5.3.1 Delayed-Egress Electrical Locking Systems.

Δ **14.5.3.1.1** Approved, delayed-egress electrical locking systems shall be permitted to be installed on door assemblies serving low and ordinary hazard contents in buildings protected throughout by an approved, supervised automatic fire detection system in accordance with Section 13.7 or an approved, supervised automatic sprinkler system in accordance with Section 13.3, and where permitted in Chapters 11 through 43 of NFPA *101*, provided that the following criteria are met:

(1) The delay of the delayed-egress electrical locking system shall deactivate allowing unobstructed egress upon actuation of one of the following:
 (a) Approved, supervised automatic sprinkler system in accordance with Section 13.3
 (b) Not more than one heat detector of an approved, supervised automatic fire detection system in accordance with Section 13.7
 (c) Not more than two smoke detectors of an approved, supervised automatic fire detection system in accordance with Section 13.7
(2) The delay of the delayed-egress electrical locking system shall deactivate allowing unobstructed egress upon loss of power controlling the lock or locking mechanism.
(3)* An irreversible process shall release the electrical lock in the direction of egress within 15 seconds, or 30 seconds where approved by the AHJ, upon application of a force to the release

device required in 14.5.2.10 under all of the following conditions:

(a) The force shall not be required to exceed 15 lbf (67 N).
(b) The force shall not be required to be continuously applied for more than 3 seconds.
(c) The initiation of the release process shall activate an audible signal in the vicinity of the door opening.
(d) Once the electrical lock has been released by the application of force to the releasing device, rearming the delay electronics shall be by manual means only.

A.14.5.3.1.1(3) It is not the intent to require a direct physical or electrical connection between the door release device and the lock. It is the intent to allow door movement initiated by operating the door release device required in 14.5.2.10 as one option to initiate the irreversible process. [***101:***A.7.2.1.6.1.1(3)]

Several factors need to be considered in approving an increase in delay time from 15 seconds to 30 seconds. Some of those factors include occupancy, occupant density, ceiling height, fire hazards present, fire protection features provided, and the location of the delayed-egress locks. An example of a location where the increase on delay time might not be approved is at an exit stair discharge door. [***101:***A.7.2.1.6.1.1(3)]

(4)* A readily visible, durable sign that conforms to the visual characters requirements of ICC/ANSI A117.1 shall be located on the door leaf adjacent to the release device in the direction of egress, and shall read as follows:

(a) PUSH UNTIL ALARM SOUNDS, DOOR CAN BE OPENED IN 15 SECONDS, for doors that swing in the direction of egress travel
(b) PULL UNTIL ALARM SOUNDS, DOOR CAN BE OPENED IN 15 SECONDS, for doors that swing against the direction of egress travel

A.14.5.3.1.1(4) In the event that the AHJ has permitted increased operation time, the sign should reflect the appropriate time. [***101:***A.7.2.1.6.1.1(4)]

(5) The egress side of doors equipped with delayed-egress electrical locking system shall be provided with emergency lighting in accordance with Section 7.9 of NFPA *101*.
(6) Hardware for new installations shall be listed in accordance with ANSI/UL 294, *Standard for Access Control System Units*.

[***101:***7.2.1.6.1.1]

•

Delayed-egress locking systems prevent a door leaf from being opened for 15 seconds or 30 seconds under either nonemergency conditions or those encountered very early in a fire or similar emergency. Delayed-egress locking systems are to be used only where specifically permitted by the appropriate occupancy chapter of NFPA *101*. Their use is further limited to buildings protected throughout by either an approved, supervised automatic fire detection system or an approved, supervised automatic sprinkler system.

Item (1) of 14.5.3.1.1 requires that the locking devices unlock upon activation of the corresponding detection or sprinkler system. The required detection system provides early warning; the alternately required sprinkler system provides early control of the fire — with each system performing to the degree necessary to make tolerable the delay experienced in waiting for the door leaf to be unlocked.

Item (2) of 14.5.3.1.1 provides a fail-safe feature where, upon loss of the electrical power that controls the lock, immediate unlocking from the egress side occurs. Note that, where the door leaf is unlocked, it is not required to be unlatched. Building occupants might need to operate the actuating bar or push pad to release the latch before opening the door, and the door might remain locked from the non-egress side. See the sixth paragraph of this commentary.

Item (3) of 14.5.3.1.1 requires that, once the release device is manually activated, the door leaf must unlock within 15 seconds or, with specific permission of the AHJ, within 30 seconds. This action must be irreversible and cannot require the user to maintain pressure on the release device for more than 3 seconds. To provide occupants attempting egress with cues to indicate that the system is functioning, a signal is sounded in the vicinity of the door opening. Additionally, the signage required by 14.5.3.1.1(4) provides useful, reassuring information.

After the door leaf is unlatched and physically opened (i.e., swung on its hinges away from the door frame), it is permitted to be relocked by manual means only. Relocking generally involves returning the door leaf to its closed and latched position and then resetting the system to engage the lock. Relatching is not prohibited, provided that the releasing mechanism (i.e., the push pad or actuating bar), when operated, unlatches the door leaf without any delay.

Note that the unlocking required by 14.5.3.1.1(1), (2), and (3) need not automatically open the door leaf. Rather, the door leaf is permitted to remain latched. The unlocking allows the user to open the door leaf immediately by operating the releasing mechanism on the door leaf. Security is not sacrificed. Of course, any exterior exit door assembly is permitted to be locked against building entry at any time. Also see the third paragraph of this commentary.

The positioning of the provision of 14.5.3.1.1(5) reinforces the emergency lighting requirements of 14.13.1.1(4). It is helpful to the user to see the requirement repeated as part of the provisions for delayed-egress electrical locking systems.

The provision of 14.5.3.1.1(6) is new for the 2018 edition of NFPA *101*. It requires new delayed-egress electrical locking systems hardware to comply with a listing laboratory test standard specifically developed for such hardware, namely, ANSI/UL 294, *Standard for Access Control System Units*.

Exhibit 14.22 shows delayed-egress electrical locking systems hardware and the sign required by 14.5.3.1.1(4).

The occupancies in the list that follows are permitted by NFPA *101* to use delayed-egress electrical locking systems in accordance with 14.5.3.1. Additional restrictions that might be imposed by the occupancy chapter of NFPA *101* are contained in the paragraphs referenced within parentheses in the list. For example, lodging or rooming houses, hotels and dormitories,

Exhibit 14.22

Delayed-egress electrical locking system hardware.

and apartment buildings permit delayed-egress electrical locking systems if all the conditions of 14.5.3.1 are met.

The occupancies permitting delayed-egress electrical locking systems are as follows:

1. Assembly occupancies (12.2.2.2.5 and 13.2.2.2.5 of NFPA *101*)
2. Educational occupancies (14.2.2.2.3.1 and 15.2.2.2.3.1 of NFPA *101*)
3. Day-care occupancies (16.2.2.2.3.1 and 17.2.2.2.3.1 of NFPA *101*)
4. Health care occupancies [18.2.2.2.4(2) and 19.2.2.2.4(2) of NFPA *101*]
5. Ambulatory health care occupancies (20.2.2.2.6 and 21.2.2.2.6 of NFPA *101*)
6. Lodging or rooming houses (26.2.3.5.2 of NFPA *101*)
7. Hotels and dormitories (28.2.2.2.2.2 and 29.2.2.2.2.2 of NFPA *101*)
8. Apartment buildings (30.2.2.2.2.2 and 31.2.2.2.2.2 of NFPA *101*)
9. Residential board and care occupancies [32.2.2.5.5.1, 32.3.2.2.2(4), 33.2.2.5.5.1, and 33.3.2.2.2(4) of NFPA *101*]
10. Mercantile occupancies (36.2.2.2.5 and 37.2.2.2.5 of NFPA *101*)
11. Business occupancies (38.2.2.2.6 and 39.2.2.2.6 of NFPA *101*)
12. Industrial occupancies (40.2.2.2.2 of NFPA *101*)
13. Storage occupancies (42.2.2.2.2 and 42.8.2.2.2.2 of NFPA *101*)

14.5.3.1.2 The provisions of 14.5.3.2 for sensor-release of electrical locking systems shall not apply to door assemblies with delayed-egress electrical locking systems. [***101:***7.2.1.6.1.2]

Paragraph 14.5.3.1.2 serves mainly as a reminder that delayed-egress electrical locking systems and sensor-release of electrical locking systems are two different features that are not to be intermixed. In the case of delayed-egress electrical locking systems, the releasing mechanism is mounted on the door leaf, and the system delays occupants from initially opening the door leaf. Sensor-release of electrical locking systems involve a door assembly that is not provided with an occupant-activated releasing mechanism on the door leaf and, therefore, relies on a motion detector to sense the approaching occupant, with the door leaf unlocking as the occupant reaches the door leaf.

Δ **14.5.3.2 Sensor-Release of Electrical Locking Systems.** Where permitted in Chapters 11 through 43 of NFPA *101*, door assemblies in the means of egress shall be permitted to be equipped with sensor-release electrical locking system hardware provided that all of the following criteria are met:

(1) A sensor shall be provided on the egress side, arranged to electrically unlock the door leaf in the direction of egress upon detection of an approaching occupant.
(2) Door leaves shall automatically electrically unlock in the direction of egress upon loss of power to the sensor or to the part of the locking system that electrically locks the door leaves.
(3) Door locks shall be arranged to electrically unlock in the direction of egress from a manual release device complying with all of the following criteria:
    (a) The manual release device shall be located on the egress side, 40 in. to 48 in. (1015 mm to 1220 mm) vertically above the floor, and within 60 in. (1525 mm) of the secured door openings.
    (b) The requirement of 14.5.3.2(3)(a) to locate the manual release device within 60 in. (1525 mm) of the secured door opening shall not apply to previously approved existing installations.
    (c) The manual release device shall be readily accessible and clearly identified by a sign that reads as follows: PUSH TO EXIT.
    (d) When operated, the manual release device shall result in direct interruption of power to the electrical lock — independent of the locking system electronics — and the lock shall remain unlocked for not less than 30 seconds.
(4) Activation of the building fire-protective signaling system, if provided, shall automatically electrically unlock the door leaves in the direction of egress, and the door leaves shall remain electrically unlocked until the fire-protective signaling system has been manually reset.
(5) The activation of manual fire alarm boxes that activate the building fire-protective signaling system specified in 14.5.3.2(4) shall not be required to unlock the door leaves.
(6) Activation of the building automatic sprinkler or fire detection system, if provided, shall automatically electrically unlock the door leaves in the direction of egress, and the door leaves shall remain electrically unlocked until the fire-protective signaling system has been manually reset.

(7) The egress side of sensor-release electrically locked egress doors, other than existing sensor-release electrically locked egress doors, shall be provided with emergency lighting in accordance with Section 14.13.

(8) Hardware for new installations shall be listed in accordance with ANSI/UL 294.

[***101:***7.2.1.6.2]

The sensor-release of electrical locking systems addressed by 14.5.3.2 are intended to be locked against access from the outside the building and require a magnetic card or similar instrument for authorized entry. However, such door assemblies must be arranged for free egress use whenever the building is occupied. The *Code* addresses these door assemblies under the subject of special locking arrangements because such door assemblies generally do not have the leaf-mounted manual latch/lock release typically installed on egress door assemblies. The absence of the door leaf–mounted manual latch/lock release prevents a person on the outside from inserting a wire hanger or other tool between the gaps at the door leaf edges to reach the release. Use of sensor-release of electrical locking systems requires specific occupancy chapter permission from NFPA *101*.

See the commentary following 14.5.3, which explains the concept whereby a door assembly with a magnetic lock, with building access via a card reader, can be considered a normal door assembly in accordance with 14.5.2.6 if the door leaf has a lever handle with an integral switch that releases the lock to allow free egress by building occupants.

Paragraph 14.5.3.2(1) provides for the door leaf to unlock when a sensor detects an occupant approaching the door opening. This method is the normal primary means of releasing the lock to allow occupants to leave the building. If the sensor and the release system fail, the requirements of 14.5.3.2(3) through (5) provide a backup system consisting of a manual lock release mounted at a usable height in the immediate vicinity of the door opening. The *Code* permits the manual release to be installed as much as 60 in. (1525 mm) from the secured door assembly, recognizing that the glass sidelights featured on many of these door assemblies are an impractical place to install a manual release device.

Additionally, 14.5.3.2(2) requires a fail-safe feature to unlock the door leaf, in the direction of egress travel, immediately upon loss of the electrical power that controls the lock.

Items (1) through (3) of 14.5.3.2 work together to help ensure that the door opening is usable at all times, before and during a fire emergency. Items (4) and (6) of 14.5.3.2 provide added assurance that the door opening is usable under fire emergency conditions. If the building has a fire alarm system, initiation of that system (by devices other than manual fire alarm boxes) must unlock the door leaf. If the building has either a fire detection system or a sprinkler system, activation of such system must unlock the door leaf.

Item (5) of 14.5.3.2 clarifies that, if the building fire alarm system is initiated by a manual fire alarm box (formerly called a pull station), the door assembly is not required to unlock. This provision prevents an occupant who is intent on circumventing the security provided by such a door assembly from pulling the manual fire alarm box lever, which would initiate the alarm system and unlock the door assembly. Such an alarm initiation would readily defeat the purpose of the sensor-release of electrical locking systems provisions, which were developed to address security needs. The life safety features of the provisions of 14.5.3.2 are sufficient so as not to require an alarm initiation via a manual fire alarm box to unlock the door assembly.

The positioning of the provision of 14.5.3.2(7) reinforces the emergency lighting requirements of 14.13.1.1(6). It is helpful to the user to see the requirement repeated as part of the provisions for sensor-release of electrical locking systems.

The provision of 14.5.3.2(8) is new for the 2018 edition of NFPA *101*. It requires new sensor-release of electrical locking system hardware to comply with a listing laboratory test standard specifically developed for such hardware, namely, ANSI/UL 294.

Exhibit 14.23 shows a glass door that spans a hotel guest floor corridor. The door is held locked by an electromagnet and requires either a magnetic card that is inserted and read or a code that is entered into the key pad to unlock the door. The door is not required for egress of the occupants of the guest rooms in that portion of the corridor. Exhibit 14.24 shows the same door from the other side. The door serves as egress for the occupants of the guest rooms in that portion of the corridor. The door is equipped with access-controlled hardware. The motion sensor mounted at the ceiling unlocks the door upon occupant proximity. The "push to exit" button mounted on the wall serves as a backup if the motion sensor fails.

Exhibit 14.23

Non-egress side of sensor-release of electrical locking system door assembly.

Exhibit 14.24

Egress side of sensor-release of electrical locking system door assembly.

Provided that the applicable occupancy chapter of NFPA *101* permits sensor-release of electrical locking systems, and such occupancy chapter does not add an additional requirement limiting their location, the provisions of 14.5.3.2 are meant to permit sensor-release of electrical locking systems to be installed and used anywhere in the egress path; in addition, multiple such devices are permitted along any egress path. Unlike the delayed-egress electrical locking system, there is no waiting period before the door leaf is usable, other than having to push a release button in the fairly uncommon situation in which the electronics controlling the sensor-release of electrical locking systems hardware (such as the motion detector) fail.

Δ **14.5.3.3 Elevator Lobby Exit Access Door Assemblies Locking.** Where permitted in Chapters 11 through 43 of NFPA *101*, door assemblies separating the elevator lobby from the exit access required by 14.9.1.6.1 shall be permitted to be electrically locked, provided that all the following criteria are met:

(1) The electrical locking hardware is listed in accordance with ANSI/UL 294, *Standard for Access Control System Units*.
(2) The building is protected throughout by a fire alarm system in accordance with Section 13.7.
(3) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.
(4) Waterflow in the sprinkler system required by 14.5.3.3(3) is arranged to initiate the building fire alarm system.
(5) The elevator lobby is protected by an approved, supervised smoke detection system in accordance with Section 13.7.
(6) Detection of smoke by the detection system required by 14.5.3.3(5) is arranged to initiate the building fire alarm system and notify building occupants.
(7) Initiation of the building fire alarm system by other than manual fire alarm boxes unlocks the electrical locks on the elevator lobby door assembly.
(8) Loss of power to the elevator lobby electrical lock system unlocks the electrical locks on the elevator lobby door assemblies.
(9) Once unlocked, the elevator lobby door assemblies remain electrically unlocked until the building fire alarm system has been manually reset.
(10) Where the elevator lobby door assemblies remain mechanically latched after being electrically unlocked, latch-releasing hardware in accordance with 14.5.2.10 is affixed to the door leaves.
(11) A two-way communication system is provided for communication between the elevator lobby and a central control point that is constantly staffed.
(12) The central control point staff required by 14.5.3.3(11) is capable, trained, and authorized to provide emergency assistance.
(13) The provisions of 14.5.3.1 for delayed-egress electrical locking systems are not applied to the elevator lobby door assemblies.
(14)* The provisions of 14.5.3.2 for sensor-release of electrical locking systems are not applied to the elevator lobby door assemblies.

[***101:***7.2.1.6.3]

A.14.5.3.3(14) It is not the intent to prohibit elevator lobby doors from being equipped with card access systems for gaining access, for example, to tenant spaces. It is the sensor-release of electrical locking systems described in 14.5.3.2 that is prohibited from being installed on the same door as the lock addressed by 14.5.3.3. [***101:***A.7.2.1.6.3(14)]

The provisions of 14.5.3.3 provide the technical details supporting the exemption offered by 14.9.1.6.3 to the requirements of 14.9.1.6.1 and 14.9.1.6.2 for unencumbered access to at least one exit from each elevator landing and lobby.

The provisions of 14.5.3.3 for the locking of elevator lobby access door assemblies are permitted to be used only where the applicable occupancy chapter of NFPA *101* specifically permits their use. Many of the occupancy chapters of NFPA *101* were revised concurrently with the development of 14.5.3.3 to permit its use.

Where the provisions of 14.5.3.3 are used, all the criteria detailed in 14.5.3.3(1) through (14) must be met. When the criteria of all 14 items are met, the locked door between the elevator lobby or landing and the exit should present a minimal, but tolerable, obstruction to speedy egress. The criteria blend a host of provisions for fire detection and alarm systems, sprinkler systems, occupant and staff two-way communication systems, and automatic lock release systems.

In earlier editions of the *Code*, 15 numbered criteria had to be met in order to lock elevator lobby exit access door assemblies. For the 2012 edition, the criterion prohibiting the elevator lobby electronic lock system from being supplied with emergency or standby electrical power was deleted. Such prohibition defeated necessary building security and could no longer be justified, provided that all the other criteria were met.

14.5.3.4* Panic Hardware and Fire Exit Hardware.

N **A.14.5.3.4** See 14.9.2.1.2 and 14.9.2.2.2 for door unlatching requirements for working space about electrical equipment. [***101:***A.7.2.1.7]

Δ **14.5.3.4.1** Where a side-hinged or pivoted-swinging door assembly is required to be equipped with panic or fire exit hardware, such hardware shall meet all of the following criteria:

(1) It shall consist of a cross bar or a push pad, with the length of the actuating portion of the cross bar or push pad not less than one-half of the width of the door leaf.
(2) It shall be mounted as follows:
   (a) New installations shall be not less than 34 in. (865 mm), and not more than 48 in. (1220 mm), above the floor.
   (b) Existing installations shall be not less than 30 in. (760 mm), and not more than 48 in. (1220 mm), above the floor.
(3) It shall be constructed so that a horizontal force not to exceed 15 lbf (66 N) actuates the cross bar or push pad and latches.

[***101:***7.2.1.7.1]

Panic hardware and fire exit hardware are required to be instantly and easily released. New panic hardware and fire exit hardware installations are to be located 34 in. to 48 in. (865 mm to 1220 mm) above the floor [for existing installations, 30 in. to 48 in. (760 mm to 1220 mm)]. The actuating member or bar is required to extend at least one-half the width of the door leaf, to create a target width sufficient to ensure that it will be engaged by the bodies of occupants pushing up against the door leaf. Such hardware, where mounted to a door leaf surface, might reduce the usable, clear width of a door opening. Provided that the hardware is installed at least 34 in. (865 mm) above the floor, the provisions of 7.2.1.2.1.1(5) of NFPA *101* permit a 4 in. (100 mm) encroachment on clear width without forcing a reduction in reported clear width. Installed below 34 in. (865 mm), the panic hardware or fire exit hardware might create a reduction in clear width sufficient to obstruct wheelchair passage through the opening associated with a 34 in. (865 mm) width door leaf. Where panic hardware is installed below 34 in. (865 mm), such as at the 30 in. (760 mm) height permitted for existing hardware by 14.5.3.4.1(2)(b), the clear width measurement is reduced by the amount of the panic hardware encroachment.

The maximum force that the panic hardware or fire exit hardware actuating bar or member can require for operation is 15 lbf (66 N). Note that this is the force needed to release the latching device only. The force needed to open the door leaf itself is governed by 14.5.1.5.

14.5.3.4.2* Only approved fire exit hardware shall be used on fire protection–rated door assemblies. New panic hardware and new fire exit hardware shall comply with ANSI/UL 305 and ANSI/BHMA A156.3. [***101:***7.2.1.7.2]

It is not the intent of 14.5.3.4.2 to require the use of panic hardware or fire exit hardware. Only approved hardware is to be used, which means such hardware must be acceptable to the AHJ, which generally relies on laboratory listing of the hardware. Where such hardware is used on a fire-rated door assembly, it must be that special form of panic hardware termed *fire exit hardware*, which ensures that it has been tested for use on fire-rated door assemblies (with the AHJ generally making approval conditional on the device being listed). Additionally, new panic hardware and new fire exit hardware must comply with recognized industry standards.

A.14.5.3.4.2 The presence of fire exit hardware on a door does not imply the door is required to be a fire protection-rated door. [***101:***A.7.2.1.7.2]

14.5.3.4.3 Required panic hardware and fire exit hardware, in other than detention and correctional occupancies as otherwise provided in Chapters 22 and 23 of NFPA *101*, shall not be equipped with any locking device, set screw, or other arrangement that prevents the release of the latch when pressure is applied to the releasing device. [***101:***7.2.1.7.3]

14.5.3.4.5 Devices that hold the latch in the retracted position shall be prohibited on fire exit hardware, unless such devices are listed and approved for such a purpose. [***101:***7.2.1.7.4]

It is the intent of the *Code* to permit the use of the delayed-egress electrical locking systems described by 14.5.3.1.1 where panic hardware is required if the applicable occupancy chapter specifically permits use of delayed-egress electrical locking systems. In those cases, the actuating member or bar, which 14.5.3.4.1(1) requires to extend across at least half the door leaf width, serves as the device that initiates the irreversible process that results in the door leaf unlocking within the 15 seconds or 30 seconds specified.

Panic hardware, which is prohibited from being used on fire-rated door assemblies, often features the ability to "dog" the bar in the down position, so as to hold the door leaf latch in the retracted position. This latch-retracting feature is not available on fire exit hardware, because it would violate the listing of the rated fire door assembly. Rated door assemblies must self-latch upon being brought to the closed position by the required closing device. A latch helps to keep the door leaf closed under the pressures generated by a fire.

14.5.4 Self-Closing Devices.

14.5.4.1* A door leaf normally required to be kept closed shall not be secured in the open position at any time and shall be self-closing or automatic-closing in accordance with 14.5.4.2, unless otherwise permitted by 14.5.4.3. [***101:***7.2.1.8.1]

A.14.5.4.1 Examples of doors designed to normally be kept closed include those to a stair enclosure or horizontal exit. [***101:***A.7.2.1.8.1]

Δ **14.5.4.2** In any building of low or ordinary hazard contents, as defined in 3.3.147.2 and 3.3.147.3, or where approved by the AHJ, door leaves shall be permitted to be automatic-closing, provided that all of the following criteria are met:

(1) Upon release of the hold-open mechanism, the leaf becomes self-closing.
(2) The release device is designed so that the leaf instantly releases manually and, upon release, becomes self-closing, or the leaf can be readily closed.
(3) The automatic releasing mechanism or medium is activated by the operation of approved smoke detectors installed in accordance with the requirements for smoke detectors for door leaf release service in *NFPA 72*.
(4) Upon loss of power to the hold-open device, the hold-open mechanism is released and the door leaf becomes self-closing.
(5) The release by means of smoke detection of one door leaf in a stair enclosure results in closing all door leaves serving that stair.

[***101:***7.2.1.8.2]

14.5.4.3 The elevator car doors and the associated hoistway enclosure doors at the floor level designated for recall in accordance with the requirements of 11.3.1 shall be permitted to remain open during Phase I Emergency Recall Operation. [***101:***7.2.1.8.3]

N **14.5.4.4 Delayed Action Closers.** Doors required to be self-closing and not required to be automatic closing shall be permitted to be equipped with delayed action closers. [***101:***7.2.1.8.4]

Fire door assemblies in a means of egress route should be kept in the closed position, particularly those serving as entrances to a stair enclosure or positioned in a horizontal exit; however, it is in these two locations that door assemblies so often are held open by some type of door-leaf stopping chock to aid in the free flow of normal traffic. This practice establishes conditions conducive to the rapid spread of fire, smoke, and heat to other sections of the building — the very situation that the stringent compartmentation requirements for the exit enclosure intend to prevent.

Exhibit 14.25 shows a door that is required to be self-closing and is equipped with a self-closer where the purpose of the self-closer is defeated by the use of a chair to hold the door in its open position in violation of the requirement of 14.5.4.1.

Recognizing that tampering with the self-closing feature might occur — and in an effort to encourage the use of effective positive measures, rather than ineffective prohibitions that often go ignored — the *Code* presents criteria for holding door leaves in the open position. The *Code* permits door leaves to be held open in buildings that house low or ordinary hazard contents or where the AHJ gives approval.

The provisions of 14.5.4.2 permit door leaves to be held open by an automatic releasing device. The triggering of the automatic release is done through the operation of smoke detectors installed in accordance with the requirements for smoke detectors for door release service as specified in *NFPA 72®, National Fire Alarm and Signaling Code®*. Fusible links are not an acceptable trigger in this system, because untenable smoke conditions could easily render an exit enclosure or adjoining fire compartment unusable long before the temperature in the vicinity of the door opening has risen enough to operate the fusible link.

Additionally, loss of power to the device providing the hold-open feature must cause immediate automatic release. A manual method of release is also required. The manual method might involve tugging on the door leaf to cause its release. Therefore, magnetic devices with significant holding forces that are not easily overcome by a deliberate tug on the door leaf cannot be used. Once the hold-open device is released, the self-closing device installed on the door leaf swings the door leaf to its closed position. On a fire protection–rated door assembly, the required door latch then engages.

Exhibit 14.26 depicts an automatic-closing door in the closed position and shows the door-mounted receptor plate and wall-mounted magnetic hold-open device near floor level. Exhibit 14.27 shows the same door in the open position, with the door receptor plate contacting the wall-mounted magnetic hold-open device.

The door leaves held open in accordance with the provisions of 14.5.4.2 can be arranged to close simultaneously throughout the building or only in the affected zones. Zoning is generally better, because it permits door assemblies in areas unaffected by the emergency to remain open to accommodate normal use. If protecting a room, that room might be considered a zone. If protecting a stair enclosure, the entire stair enclosure is considered a zone, and the signal to close one door leaf in the enclosing walls must close all door leaves in that stair enclosure.

Exhibit 14.25

Self-closing door held open by chair. (Courtesy of Jake Pauls)

Exhibit 14.26

Automatic-closing door in closed position.

Exhibit 14.27

Automatic-closing door in open position.

With the exception of certain hazardous areas where flash fires or explosions could occur, the use of automatic closers in accordance with these provisions is permitted. Use of automatic-closing equipment should be encouraged to prevent door leaves from being secured open by other means. Wedges, for example, need to be removed manually before the self-closer installed on the door leaf can move the door leaf to its closed position.

Paragraph 14.5.4.3 helps to coordinate the door leaf closing requirements of 7.2.1.8 of NFPA *101* with the provisions of 11.3.1 for elevator recall. The fire fighters' emergency operations requirements for elevators, as specified in 11.3.1 and detailed in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, mandate that an elevator — once recalled — is to remain at the designated recall floor with the elevator shaft and elevator car door leaves held in the open position. The open door leaves allow responding fire service personnel to ensure the elevator has been recalled. Paragraph 14.5.4.3 legitimizes a feature that would otherwise be prohibited by 14.5.4.1.

The provision of 14.5.4.4 is new to the 2018 edition of NFPA *101*. The text recognizes the use of delayed action closers for doors that are required to be self-closing but not required to be automatic closing. Delayed action closers might be effectively used in nursing home cross-corridor door openings in a smoke barrier, to provide additional time for a resident who moves slowly to travel through the door opening. See 7.2.4.3.11 of NFPA *101* for an example of a code requirement that does not offer the option of using self-closing door assemblies (and therefore does not permit the use of delayed action closers) but mandates the use of automatic-closing door assemblies for horizontal exit, cross-corridor locations because cross-corridor door assemblies are so commonly wedged open in violation of requirements.

N **14.5.5* Powered Door Leaf Operation.**

N **A.14.5.5** Special-purpose horizontally sliding accordion or folding door assemblies installed in accordance with 7.2.1.14 of NFPA *101* should not be considered powered doors subject to the provisions of 14.5.5. Powered doors are divided into two categories — power assisted and power operated. Power-assisted doors that conform to ANSI/BHMA A156.19, *Power Assist and Low Energy Power Operated Doors*, use limited power to operate the door. They require fewer safeguards as compared to full power–operated doors. These door operators are for swinging doors only. Power-operated doors that conform to ANSI/BHMA A156.10, *Power Operated Pedestrian Doors*, require more power to operate the door and require additional safeguards to provide protection against personal injury. Power-operated doors can be swinging, sliding, or folding doors. [***101:***A.7.2.1.9]

N **14.5.5.1* General.** Where means of egress door leaves are operated by power upon the approach of a person or are provided with power-assisted manual operation, the design shall be such that, in the event of power failure, the leaves open manually to allow egress travel or close when necessary to safeguard the means of egress. [***101:***7.2.1.9.1]

N **A.14.5.5.1** An example of the type of door addressed by 14.5.5.1 is one actuated by a motion-sensing device upon the approach of a person. [***101:***A.7.2.1.9.1]

N **14.5.5.1.1** New power-operated swinging doors, power-operated sliding doors, and power-operated folding doors shall comply with ANSI/BHMA A156.10, *Power Operated Pedestrian Doors*. [***101:***7.2.1.9.1.1]

N **14.5.5.1.2** New power-assisted swinging doors and low-energy power-operated swinging doors shall comply with ANSI/BHMA

A156.19, *Power Assist and Low Energy Power Operated Doors*. [***101:***7.2.1.9.1.2]

N **14.5.5.1.3** New low-energy power-operated sliding doors and low-energy power-operated folding doors shall comply with ANSI/BHMA A156.38, *Low Energy Power Operated Sliding and Folding Doors*. [***101:***7.2.1.9.1.3]

N **14.5.5.1.4** The forces required to manually open the door leaves specified in 14.5.5.1 shall not exceed those required in 14.5.1.5, except that the force required to set the leaf in motion shall not exceed 50 lbf (222 N). [***101:***7.2.1.9.1.4]

N **14.5.5.1.5** The door assembly shall be designed and installed so that, when a force is applied to the door leaf on the side from which egress is made, it shall be capable of swinging from any position to provide full use of the required width of the opening in which it is installed. *(See 14.5.1.)* [***101:***7.2.1.9.1.5]

N **14.5.5.1.6** A readily visible, durable sign in letters not less than 1 in. (25 mm) high on a contrasting background that reads as follows shall be located on the egress side of each door opening:

IN EMERGENCY, PUSH TO OPEN

[***101:***7.2.1.9.1.6]

N **14.5.5.1.7** Sliding, power-operated door assemblies in an exit access serving an occupant load of fewer than 50 that manually open in the direction of door leaf travel, with forces not exceeding those required in 14.5.1.5, shall not be required to have the swing-out feature required by 14.5.5.1.5. The required sign shall be in letters not less than 1 in. (25 mm) high on a contrasting background and shall read as follows:

IN EMERGENCY, SLIDE TO OPEN

[***101:***7.2.1.9.1.7]

N **14.5.5.1.8*** In the emergency breakout mode, a door leaf located within a two-leaf opening shall be exempt from the minimum 32 in. (810 mm) single-leaf requirement of 7.2.1.2.3.2(1) of NFPA *101*, provided that the clear width of the single leaf is not less than 30 in. (760 mm). [***101:***7.2.1.9.1.8]

N **A.14.5.5.1.8** Although a single power-operated door leaf located within a two-leaf opening might alone not provide more than 30 in. (760 mm) of clear width in the emergency breakout mode, where both leaves are broken out to become side hinged, the required egress width is permitted to be provided by the width of the entire opening. [***101:***A.7.2.1.9.1.8]

N **14.5.5.1.9** For a biparting sliding door assembly in the emergency breakout mode, a door leaf located within a multiple-leaf opening shall be exempt from the minimum 32 in. (810 mm) single-leaf requirement of 7.2.1.2.3.2(1) of NFPA *101* if a clear opening of not less than 32 in. (810 mm) is provided by all leafs broken out. [***101:***7.2.1.9.1.9]

N **14.5.5.1.10** Door assemblies complying with 14.5.10 shall be permitted to be used. [***101:***7.2.1.9.1.10]

N **14.5.5.1.11** The requirements of 14.5.5.1.1 through 14.5.5.1.10 shall not apply in detention and correctional occupancies where otherwise provided in Chapters 22 and 23. [***101:***7.2.1.9.1.11]

N **14.5.5.2 Self-Closing or Self-Latching Door Leaf Operation.** Where door leaves are required to be self-closing or self-latching and are operated by power upon the approach of a person, or are provided with power-assisted manual operation, they shall be permitted in the means of egress where they meet the following criteria:

(1) The door leaves can be opened manually in accordance with 14.5.5.1.1 to allow egress travel in the event of power failure.
(2) New door leaves remain in the closed position, unless actuated or opened manually.
(3) When actuated, new door leaves remain open for not more than 30 seconds.
(4) Door leaves held open for any period of time close — and the power-assist mechanism ceases to function — upon operation of approved smoke detectors installed in such a way as to detect smoke on either side of the door opening in accordance with the provisions of *NFPA 72*.
(5) Door leaves required to be self-latching are either self-latching or become self-latching upon operation of approved smoke detectors per 14.5.5.2(4).
(6) New power-assisted swinging door assemblies comply with BHMA/ANSI A156.19, *Power Assist and Low Energy Power Operated Doors*.

[***101:***7.2.1.9.2]

N 14.5.6 Revolving Door Assemblies.

N **14.5.6.1** Revolving door assemblies, whether used or not used in the means of egress, shall comply with all of the following:

(1) New revolving doors shall comply with ANSI/BHMA A156.27, *Power and Manual Operated Revolving Doors*, and shall be installed in accordance with the manufacturer's installation instructions.
(2) Revolving door wings shall be capable of book-fold or breakout for egress in accordance with BHMA A156.27, unless they are existing revolving doors approved by the authority having jurisdiction.
(3) When revolving door wings are collapsed into the book-fold position, the parallel egress paths formed shall provide an aggregate width of 36 in. (915 mm), unless they are approved existing revolving door assemblies.
(4) Revolving door assemblies shall not be used within 10 ft (3050 mm) of the foot or the top of stairs or escalators.
(5) A dispersal area acceptable to the authority having jurisdiction shall be located between stairs or escalators and the revolving door assembly.
(6) The revolutions per minute (rpm) of door wings shall not exceed the following:
    (a) The values in Table 14.5.6.1 for existing revolving doors.
    (b) The values in BHMA A156.27 for new revolving doors.
(7) Each revolving door assembly shall have a conforming side-hinged swinging door assembly in the same wall as the revolving door within 10 ft (3050 mm) of the revolving door, unless one of the following conditions applies:
    (a) Revolving door assemblies shall be permitted without adjacent swinging door assemblies, as required by 14.5.6.1(6),

TABLE 14.5.6.1 Existing Revolving Door Assembly Maximum Speed

Inside Diameter		Power-Driven Speed Control (rpm)	Manual Speed Control (rpm)
ft/in.	mm		
6 ft 6 in.	1980	11	12
7 ft	2135	10	11
7 ft 6 in.	2285	9	11
8 ft	2440	9	10
8 ft 6 in.	2590	8	9
9 ft	2745	8	9
9 ft 6 in.	2895	7	8
10 ft	3050	7	8

[***101:***Table 7.2.1.10.1]

in street floor elevator lobbies, provided that no stairways or door openings from other parts of the building discharge through the lobby and the lobby has no occupancy other than as a means of travel between the elevators and street.

(b) The requirement of 14.5.6.1(6) shall not apply to existing revolving door assemblies where the number of revolving door assemblies does not exceed the number of swinging door assemblies within 20 ft (6100 mm) of the revolving door assembly.

[***101:***7.2.1.10.1]

N **14.5.6.2** Where permitted in Chapters 11 through 43 of NFPA *101*, revolving door assemblies shall be permitted as a component in a means of egress, provided that all of the following criteria are met:

(1) Revolving door openings shall not be given credit for more than 50 percent of the required egress capacity.
(2) Each revolving door opening shall not be credited with more than a 50-person capacity or, if of not less than a 9 ft (2745 mm) diameter, a revolving door assembly shall be permitted egress capacity based on the clear opening width provided when collapsed into a book-fold position.
(3) Revolving door wings shall be capable of being collapsed into a book-fold position when a force not exceeding 130 lbf (580 N) is applied to the wings within 3 in. (75 mm) of the outer edge.

[***101:***7.2.1.10.2]

N **14.5.6.3** Revolving door assemblies not used as a component of a means of egress shall have a collapsing force not exceeding 180 lbf (800 N) applied at a point 3 in. (75 mm) from the outer edge of the outer wing stile and 40 in. (1015 mm) above the floor. [***101:***7.2.1.10.3]

N **14.5.6.4** The requirement of 14.5.6.3 shall not apply to revolving door assemblies, provided that the collapsing force is reduced to a force not to exceed 130 lbf (580 N) under all of the following conditions:

(1) Power failure, or removal of power to the device holding the wings in position
(2) Actuation of the automatic sprinkler system, where such a system is provided
(3) Actuation of a smoke detection system that is installed to provide coverage in all areas within the building that are within 75 ft (23 m) of the revolving door assemblies
(4) Actuation of a clearly identified manual control switch in an approved location that reduces the holding force to a force not to exceed 130 lbf (580 N)

[***101:***7.2.1.10.4]

N 14.5.7 Turnstiles and Similar Devices.

N **14.5.7.1** Turnstiles or similar devices that restrict travel to one direction or are used to collect fares or admission charges shall not be placed so as to obstruct any required means of egress, unless otherwise specified in 14.5.7.1.1, 14.5.7.1.2 and 14.5.7.1.3. [***101:***7.2.1.11.1]

N **14.5.7.1.1** Approved turnstiles not exceeding 39 in. (990 mm) in height that turn freely in the direction of egress travel shall be permitted where revolving door assemblies are permitted in Chapters 11 through 43 of NFPA *101*. [***101:***7.2.1.11.1.1]

N **14.5.7.1.2** Where turnstiles are approved by the authority having jurisdiction and permitted in Chapters 11 through 43, each turnstile shall be credited for a capacity of 50 persons, provided that such turnstiles meet all of the following criteria:

(1) They freewheel in the egress direction when primary power is lost, and freewheel in the direction of egress travel upon manual release by an employee assigned in the area.
(2) They are not given credit for more than 50 percent of the required egress width.
(3) They are not in excess of 39 in. (990 mm) in height and have a clear width of not less than 16½ in. (420 mm).

[***101:***7.2.1.11.1.2]

N **14.5.7.1.3*** Security access turnstiles that impede travel in the direction of egress utilizing a physical barrier shall be permitted to be considered as a component of the means of egress, where permitted in Chapters 11 through 43 of NFPA *101*, provided that all the following criteria are met:

(1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 14.8.
(2) Each security access turnstile lane configuration has a minimum clear passage width of 22 in. (560 mm).
(3) Any security access turnstile lane configuration providing a clear passage width of less than 32 in. (810 mm) shall be given an egress capacity of 50 persons.
(4) Any security access turnstile lane configuration providing a clear passage width of 32 in. (810 mm) or more shall be given an egress capacity as calculated in accordance with Section 14.5.6.
(5) Each secured physical barrier shall automatically retract or swing to an unobstructed open position in the direction of egress, under each of the following conditions:
    (a) Upon loss of power to the turnstile or any part of the access control system that secures the physical barrier
    (b) Upon actuation of a readily accessible and clearly identified manual release device that results in direct interruption of power to each secured physical barrier, remains in the

open position for not less than 30 seconds, and is positioned at one of the following locations:
   i. The manual release device is located on the egress side of each security access turnstile lane.
   ii. The manual release device is located at an approved location where it can be actuated by an employee assigned to the area.

(c) Upon actuation of the building fire-protective signaling system, if provided, and for which the following apply:
   i. The physical barrier remains in the open position until the fire-protective signaling system is manually reset.
   ii. The actuation of manual fire alarm boxes that actuate the building fire-protective signaling system is not required to meet the requirements specified in 14.5.7.1.3(5)(c)(i).

(d) Upon actuation of the building automatic sprinkler or fire detection system, and for which the physical barrier remains in the open position until the fire-protective signaling system is manually reset

[***101:***7.2.1.11.1.3]

Security access turnstiles limit entry to those with proper credentials, such as cards placed in proximity to an electronic reader. The security access turnstiles prevent unauthorized entry but are arranged to provide free egress under the conditions specified in 14.5.7.1.3(5).

N **A.14.5.7.1.3** Security access turnstiles are designed to control security access into and out of buildings. Security access turnstiles might utilize physical barriers consisting of arms, wings, gates, or panels. The subject physical barriers come in various heights and function by retracting or opening in the direction of travel. [***101:***A.7.2.1.11.1.3]

N **14.5.7.2** Turnstiles exceeding 39 in. (990 mm) in height shall meet the requirements for revolving door assemblies in 14.5.6 or the requirements of 14.5.7.1.3 for security access turnstiles. [***101:***7.2.1.11.2]

N **14.5.7.3** Turnstiles located in, or furnishing access to, required exits shall provide not less than 16½ in. (420 mm) clear width at and below a height of 39 in. (990 mm) and at least 22 in. (560 mm) clear width at heights above 39 in. (990 mm). [***101:***7.2.1.11.3]

N **14.5.8 Door Openings in Folding Partitions.** Where permanently mounted folding or movable partitions divide a room into smaller spaces, a swinging door leaf or open doorway shall be provided as an exit access from each such space, unless otherwise specified in 14.5.8.1 and 14.5.8.2. [***101:***7.2.1.12]

N **14.5.8.1** A door leaf or opening in the folding partition shall not be required, provided that all of the following criteria are met:

(1) The subdivided space is not used by more than 20 persons at any time.
(2) The use of the space is under adult supervision.
(3) The partitions are arranged so that they do not extend across any aisle or corridor used as an exit access to the required exits from the story.
(4) The partitions conform to the interior finish and other requirements of this *Code*.
(5) The partitions are of an approved type, have a simple method of release, and are capable of being opened quickly and easily by experienced persons in case of emergency.

[***101:***7.2.1.12.1]

N **14.5.8.2** Where a subdivided space is provided with not less than two means of egress, the swinging door leaf in the folding partition specified in 14.5.8 shall not be required, and one such means of egress shall be permitted to be equipped with a horizontal-sliding door assembly complying with 14.5.10. [***101:***7.2.1.12.2]

N **14.5.9 Balanced Door Assemblies.** If panic hardware is installed on balanced door leaves, the panic hardware shall be of the push-pad type, and the pad shall not extend more than approximately one-half the width of the door leaf, measured from the latch stile. *[See 14.5.3.4.1(1).]* [***101:***7.2.1.13]

N **14.5.10 Special-Purpose Horizontally Sliding Accordion or Folding Door Assemblies.** Special-purpose horizontally sliding accordion or folding door assemblies shall be permitted in means of egress, provided that all of the following criteria are met:

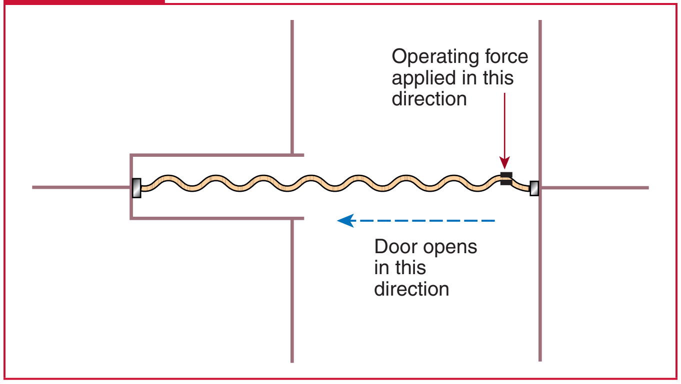
(1) The door leaf is readily operable from either side without special knowledge or effort.
(2) The force that, when applied to the operating device in the direction of egress, is required to operate the door leaf is not more than 15 lbf (67 N).
(3) The force required to operate the door leaf in the direction of travel is not more than 30 lbf (133 N) to set the leaf in motion and is not more than 15 lbf (67 N) to close the leaf or open it to the minimum required width.
(4) The door leaf is operable using a force of not more than 50 lbf (222 N) when a force of 250 lbf (1100 N) is applied perpendicularly to the leaf adjacent to the operating device, unless the door opening is an existing special-purpose horizontally sliding accordion or folding exit access door assembly serving an area with an occupant load of fewer than 50.
(5) The door assembly complies with the fire protection rating, if required, and, where rated, is self-closing or automatic-closing by means of smoke detection in accordance with 14.5.4 and is installed in accordance with NFPA 80.

[***101:***7.2.1.14]

The special type of horizontally sliding door assembly addressed by 14.5.10 — the special-purpose horizontally sliding accordion or folding door assembly — is different from a traditional horizontally sliding door assembly. When force is applied to the door actuator in the direction of egress travel, the door leaf must slide to the side to allow passage. This concept is illustrated in Exhibit 14.28.

It is important that sliding door assemblies, other than those addressed by 14.5.1.1(4)(c), (4)(d), or (5), be evaluated for compliance with all the requirements of 14.5.10. Traditional sliding door assemblies do not comply with these requirements; an example of a type of door assembly that does comply is shown in Exhibit 14.29.

Exhibit 14.28



Horizontally sliding door assembly operation.

Exhibit 14.29

Special-purpose horizontally sliding accordion door assembly addressed by 14.5.10. (Photo courtesy of Won-Door Corp.)

N **14.5.11 Inspection of Door Openings.**

N **14.5.11.1*** Where required by Chapters 11 through 43 of NFPA *101*, the following door assemblies shall be inspected and tested not less than annually in accordance with 14.5.11.2 through 14.5.11.7:

(1) Door leaves equipped with panic hardware or fire exit hardware in accordance with 14.5.3.4
(2) Door assemblies in exit enclosures
(3) Door hardware-release of electrically locked egress door assemblies
(4) Door assemblies with special locking arrangements subject to 14.5.3.3

[***101:***7.2.1.15.1]

N **A.14.5.11.1** Door assemblies within the required means of egress (e.g., door assemblies that discharge from exit enclosures) require a higher level of care and maintenance throughout the life of their installations to ensure they perform as intended by the *Code*. Annual inspection and functional testing of these door assemblies is necessary to verify that they are maintained in proper working condition. Panic hardware and fire exit hardware devices are specifically required to be used in assembly and educational occupancies. However, door leaves that are equipped with panic hardware or fire exit hardware, in areas not specifically required by the *Code* (e.g., stairwell entry doors and double-egress cross-corridor door assemblies not serving an assembly occupancy), should be subject to annual inspection and functional testing to ensure that the operating hardware functions correctly in accordance with 14.5.3.4, since the presence of panic hardware and fire exit hardware implies it is required by the *Code*. [***101:***A.7.2.1.15.1]

Additionally, door assemblies that are door hardware-release of electrically locked egress door assemblies in accordance with 14.5.2.5 and door assemblies that are equipped with special locking arrangements in accordance with 14.5.3.3 are outfitted with electrified hardware and access control devices that are susceptible to wear and abuse. Consequently, these door assemblies need to be inspected and tested on an annual basis, regardless of the occupant load being served. [***101:***A.7.2.1.15.1]

In cases where the authority having jurisdiction determines there is a distinct hazard to building occupant safety, the inspection requirements of 7.2.1.15 should be applied to other exit access, exit, and exit discharge door assemblies. [***101:***A.7.2.1.15.1]

N **14.5.11.2*** The inspection and testing interval for fire-rated and nonrated door assemblies shall be permitted to exceed 12 months under a written performance-based program. [***101:***7.2.1.15.2]

N **A.14.5.11.2** See NFPA 80, Annex J, for information pertaining to performance-based inspection, testing, and maintenance of door assemblies. [***101:***A.7.2.1.15.2]

N **14.5.11.2.1** Goals established under a performance-based program shall provide assurance that the door assembly will perform its intended function. [***101:***7.2.1.15.2.1]

N **14.5.11.2.2** Technical justification for inspection, testing, and maintenance intervals shall be documented. [***101:***7.2.1.15.2.2]

N **14.5.11.2.3** The performance-based option shall include historical data. [***101:***7.2.1.15.2.3]

The introductory requirements of 14.5.11.1 set the inspection and testing interval as once per year. Paragraph 14.5.11.2 provides an exemption so that the inspection interval can exceed 12 months. The text of A.14.5.11.2 advises that helpful information on a written performance-based program can be found in NFPA 80, *Standard for Fire Doors and Other Opening Protectives.* NFPA 80 addresses the performance-based option for extending the inspection and testing interval. The concept of a performance-based inspection and testing frequency program is to establish the type and frequency of inspection needed to demonstrate that the door assemblies are operational. The goal is to balance the inspection frequency with proven reliability of the door assemblies; thus, the performance-based option is required to include historical data acceptable to the AHJ. The goal of a performance-based inspection program is also to adjust test and inspection frequencies commensurate with historical, documented equipment performance and desired reliability. Program attributes that should be considered in the adjustment of test and inspection frequencies include maintenance programs, usage frequencies, history of repairs, building condition, and consequence of failure of the door assemblies.

N **14.5.11.3** A written record of the inspections and testing shall be signed and kept for inspection by the authority having jurisdiction. [***101:***7.2.1.15.3]

The required written record of the inspection and testing must be signed, preferably by the individual who performed the inspection and testing.

N **14.5.11.4** Functional testing of door assemblies shall be performed by individuals who can demonstrate knowledge and understanding of the operating components of the type of door being subjected to testing. [***101:***7.2.1.15.4]

The functional testing of door assemblies is not required to be performed by a licensed or certified individual. Rather, the person performing the functional testing must be able to demonstrate knowledge and understanding of the operating components of the type of door assemblies required to be inspected at the facility.

N **14.5.11.5** Door assemblies shall be visually inspected from both sides of the opening to assess the overall condition of the assembly. [***101:***7.2.1.15.5]

The overall condition of the door assembly can be visually evaluated only if inspected from both sides of the door opening. Some features are evident from only the pull side of the door opening, because the stops in the frame prevent viewing the feature; other features, like the door closer, are evident only from the push side of the door opening.

N **14.5.11.6** As a minimum, the following items shall be verified:

(1) Floor space on both sides of the openings is clear of obstructions, and door leaves open fully and close freely.
(2) Forces required to set door leaves in motion and move to the fully open position do not exceed the requirements in 14.5.1.5.
(3) Latching and locking devices comply with 14.5.2.
(4) Releasing hardware devices are installed in accordance with 14.5.2.10.1.
(5) Door leaves of paired openings are installed in accordance with 14.5.2.11.
(6) Door closers are adjusted properly to control the closing speed of door leaves in accordance with accessibility requirements.
(7) Projection of door leaves into the path of egress does not exceed the encroachment permitted by 14.5.1.3.
(8) Powered door openings operate in accordance with 14.5.5.
(9) Signage required by 14.5.1.1(3), 14.5.2.5, 14.5.3, and 14.5.5 is intact and legible.
(10) Door openings with special locking arrangements function in accordance with 14.5.3.
(11) Security devices that impede egress are not installed on openings, as required by 14.5.2.12.
(12) Where required by 7.2.2.5.5.7 of NFPA *101*, door hardware marking is present and intact.
(13) Emergency lighting on sensor-release of electrical locking systems and doors equipped with delayed-egress electrical locking systems is present in accordance with Section 14.13. [***101:***7.2.1.15.6]

The criteria required to be verified in 14.5.11.6(1) through (13) were developed to evaluate post-installation operating performance where the installation was made to comply with door assembly criteria of 7.2.1 of NFPA *101*. Fire-rated door assemblies must also meet additional criteria as detailed in Section 5.2 of NFPA 80, as required by 12.7.6.3.1.

N **14.5.11.7*** Door openings not in proper operating condition shall be repaired or replaced without delay. [***101:***7.2.1.15.7]

N **A.14.5.11.7** Performing corrective action work on door assemblies frequently requires ordering replacement components that might take time to produce, ship, and install. Consideration of the time it takes to procure and install components should be included in the timeline for restoring the door assemblies to normal working condition. [***101:***A.7.2.1.15.7]

The purpose of the inspection and testing program is to identify problems with door assemblies. Paragraph 14.5.11.7 completes the process by requiring that problems be corrected without delay. The correction of the problem is part of the overall inspection and testing program and needs to be documented in the written record required by 14.5.11.3.

14.6 Enclosure and Protection of Stairs

14.6.1 Enclosures.

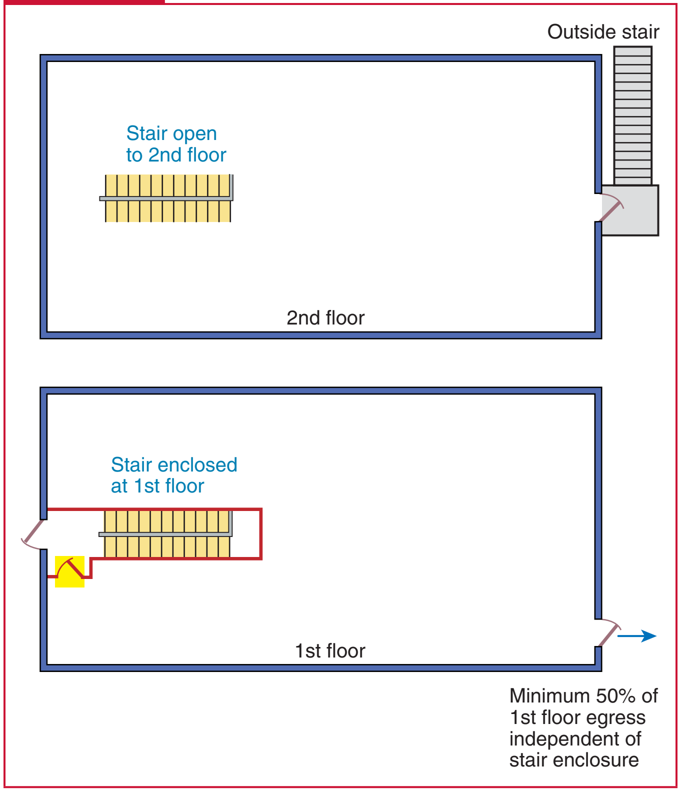
14.6.1.1 All inside stairs serving as an exit or exit component shall be enclosed in accordance with Section 14.3. [***101:***7.2.2.5.1.1]

14.6.1.2 Inside stairs, other than those serving as an exit or exit component, shall be protected in accordance with Section 8.6 of NFPA *101*. [***101:***7.2.2.5.1.2]

14.6.1.3 In existing buildings, where a two-story exit enclosure connects the story of exit discharge with an adjacent story, the exit shall be permitted to be enclosed only on the story of exit discharge, provided that not less than 50 percent of the number and capacity of exits on the story of exit discharge are independent of such enclosures. [***101:***7.2.2.5.1.3]

Paragraphs 14.6.1.1 and 14.6.1.2 emphasize that enclosure protection for stairs depends on whether they serve within an exit or involve a vertical opening between floors. Stairs that are not used as exits but that involve vertical openings are not subject to the requirements of Section 14.3; they must be protected in accordance with Section 8.6 of NFPA *101*. Many interior stairs serve as exits and are vertical openings; they must, therefore, meet the requirements of Section 14.3 for exits as well as those of Section 8.6 of NFPA *101*. Compliance with Section 8.6 of NFPA *101* does not ensure compliance with Section 14.3. Stairs

Exhibit 14.30



Partial enclosure of existing stair.

that are neither within an exit nor part of vertical openings, such as stairs to a platform or stage, or those running between two different floor levels on the same story do not have to comply with either Section 14.3 or Section 8.6 of NFPA *101*.

The provisions of 14.6.1.3 recognize existing two-story stairs that, rather than being fully enclosed by a fire-rated shaft at both the top and bottom, are separated only from the level of exit discharge. Because such stairs are open to another floor, they might compromise the use of the stair enclosure for egress purposes by occupants of the level of exit discharge. The *Code* requires that at least half the egress for the level of exit discharge be independent of the stair enclosure. This requirement limits the effect of occupants who are forced to travel into an enclosure that is smoke-filled due to a fire on another floor that is open to the stair. In Exhibit 14.30, the existing stair connecting the first and second floors, although separated from the first floor, is open to the second floor. This arrangement is permitted because a minimum of 50 percent of the first floor egress can be satisfied independently from use of the stair enclosure via the door assembly that opens directly to the outside at grade level at the right of the exhibit.

14.6.2* Exposures.

A.14.6.2 The purpose of this provision is to protect the exterior wall of a stairway from fires in other portions of the building. If the exterior wall of the stair is flush with the building exterior wall, the fire would need to travel around 180 degrees in order to impact the stair. This has not been a problem in existing buildings, so no protection is required. However, if the angle of exposure is less than 180 degrees, protection of either the stair wall or building wall is required. [***101:***A.7.2.2.5.2]

Figure A.14.6.2(a), Figure A.14.6.2(b), and Figure A.14.6.2(c) illustrate the requirement, assuming nonrated glass on the exterior wall of the stair is used. [***101:***A.7.2.2.5.2]

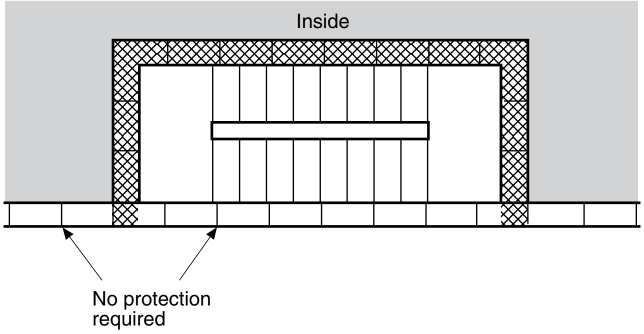


FIGURE A.14.6.2(a) *Stairway with Nonrated Exterior Wall in Same Plane as Building Exterior Wall. [**101:**Figure A.7.2.2.5.2(a)]*

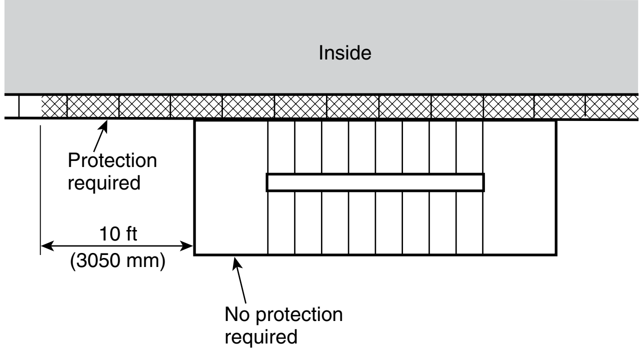

FIGURE A.14.6.2(b) *Stairway with Unprotected Exterior Perimeter Protruding Past Building Exterior Wall. [**101:**Figure A.7.2.2.5.2(b)]*

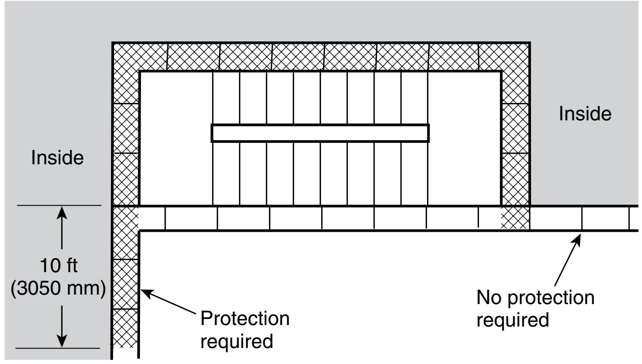

FIGURE A.14.6.2(c) *Stairway with Nonrated Exterior Wall Exposed by Adjacent Exterior Wall of Building. [**101:**Figure A.7.2.2.5.2(c)]*

14.6.2.1 Where nonrated walls or unprotected openings enclose the exterior of a stairway, other than an existing stairway, and the walls or openings are exposed by other parts of the building at an angle of less than 180 degrees, the building enclosure walls within 10 ft (3050 mm) horizontally of the nonrated wall or unprotected opening shall be constructed as required for stairway enclosures, including opening protectives. [***101:***7.2.2.5.2.1]

14.6.2.2 Construction shall extend vertically from the finished ground level to a point 10 ft (3050 mm) above the topmost landing of the stairs or to the roofline, whichever is lower. [***101:***7.2.2.5.2.2]

14.6.2.3 The fire resistance rating of the separation extending 10 ft (3050 mm) from the stairs shall not be required to exceed 1 hour where openings have a minimum ¾-hour fire protection rating. [***101:***7.2.2.5.2.3]

14.6.3* Usable Space. Enclosed, usable spaces, within exit enclosures shall be prohibited, including under stairs, unless otherwise permitted by 14.6.3.2. [***101:***7.2.2.5.3]

A.14.6.3 An example of a use with the potential to interfere with egress is storage. [***101:***A.7.2.2.5.3]

14.6.3.1 Open space within the exit enclosure shall not be used for any purpose that has the potential to interfere with egress. [***101:***7.2.2.5.3.1]

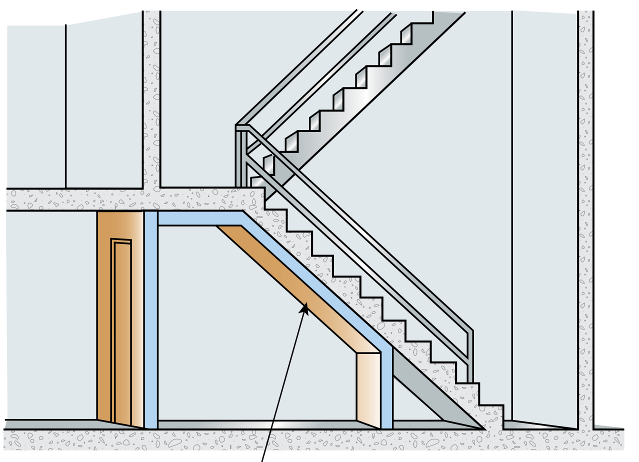
Δ **14.6.3.2** Enclosed, usable space shall be permitted under stairs, provided that both of the following criteria are met:

(1) The space shall be separated from the stair enclosure by the same fire resistance as the exit enclosure.
(2) Entrance to the enclosed, usable space shall not be from within the stair enclosure. *(See also 14.3.3.)*

[***101:***7.2.2.5.3.2]

Paragraphs 14.6.3 and 14.6.3.1 state that, within an exit enclosure, no enclosed, usable space is permitted, nor is any open space permitted to be used for any purpose that could interfere with the use of the exit enclosure. Per 14.6.3.2, an enclosed, usable space under a stair is permitted to be considered outside the exit enclosure, provided that (1) the walls and soffits of the enclosed space meet the same protection requirements as the stair enclosure, thereby separating the space from the exit enclosure; and (2) the door assembly to the space does not open into the exit enclosure. The provision of 14.6.3.2 is depicted in Exhibit 14.31. Note that fire resistance–rated construction isolates the space beneath the last run of stair so that the space is no longer within the exit enclosure. Note also that a door assembly that is outside the exit enclosure is used to enter the space, since a door communicating between the space and the exit enclosure would violate the provisions of 14.3.1(9).

Exhibit 14.31



Enclosed, usable space under flight of stairs.

14.7* Exit Passageways

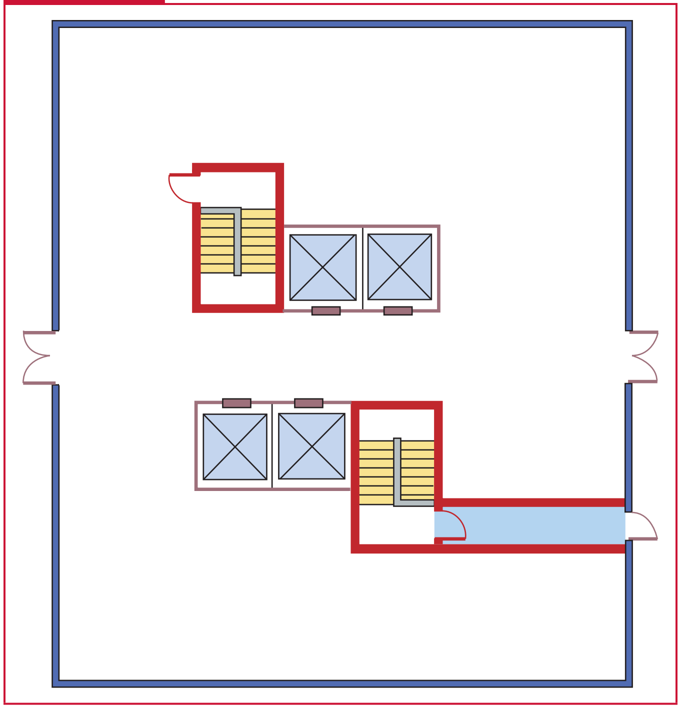
A.14.7 An exit passageway serves as a horizontal means of exit travel that is protected from fire in a manner similar to an enclosed interior exit stair. Where it is desired to offset exit stairs in a multistory building, an exit passageway can be used to preserve the continuity of the protected exit by connecting the bottom of one stair to the top of the stair that continues to the street floor. Probably the most important use of an exit passageway is to satisfy the requirement that at least 50 percent of the exit stairs discharge directly outside from multistory buildings *(see 7.7.2 of* NFPA *101)*. Thus, if it is impractical to locate the stair on an exterior wall, an exit passageway can be connected to the bottom of the stair to convey the occupants safely to an outside exit door. In buildings of extremely large area, such as shopping mall concourse and some factories, the exit passageway can be used to advantage where the travel distance to reach an exit would otherwise be excessive. [***101:***A.7.2.6]

The word *exit*, used in the term *exit passageway*, helps to distinguish between an exit passageway and an ordinary passageway or corridor that serves as exit access. An exit passageway is an exit; it provides a path of travel offering the same level of protection and safety that is required of an enclosed exit stair. An exit passageway is a versatile feature, because it can be used to extend an exit, or, as is done in many cases, it can be used to bring an exit closer to where the occupants are located.

In Exhibit 14.32, an exit passageway is used to continue the exit to the outside from one of the two enclosed interior exit stairs. This arrangement might be used to help comply with the requirements of 14.11.2, which mandate that at least one-half the egress capacity and at least one-half the number of exits must discharge directly to the outside at interior discharge levels.

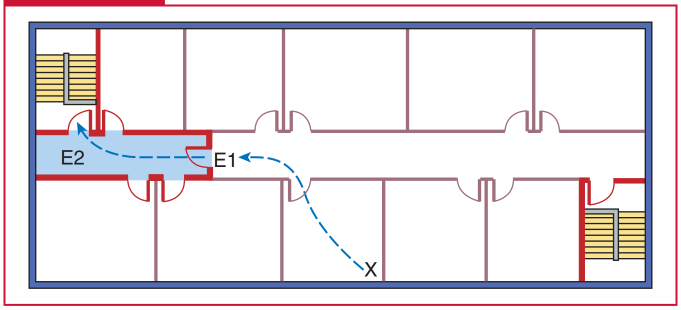
Extending the exit stair's required enclosure to include a portion of the corridor creates an exit passageway that brings the exit closer to the occupants, as is demonstrated in Exhibit 14.33. Travel distance measurement ends at entrance E1 to the exit passageway. The distance from X to E2 exceeds the allowed travel distance. The distance from X to E1 is within the allowed travel

Exhibit 14.32



Exit passageway used to connect exit stair with exterior of building.

Exhibit 14.33

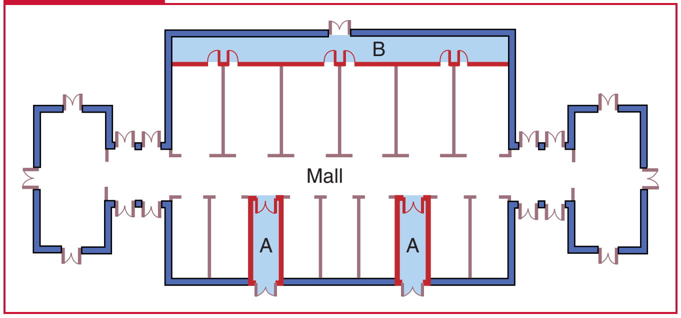


Exit passageway used to keep travel distance from becoming excessive.

distance. Extension of an exit stair's enclosure is often used where travel distance to the exit enclosure would otherwise be in excess of *Code* allowance. Because it is an exit, an exit passageway qualifies as the point at which travel distance measurement ends in accordance with Section 7.6 of NFPA *101*.

In Exhibit 14.34, the two exit passageways marked A bring exits within allowable travel distances for the occupants in a mall structure (similar to the exit passageway illustrated in Exhibit 14.33). The exit passageway marked B allows occupants of multiple stores in the mall structure to enter the exit directly from the rear of each store. This arrangement is often used to limit, for security purposes, the number of door assemblies that open directly to the outside.

Exhibit 14.34



Exit passageways used for multiple purposes in mall structure.

14.7.1* General. Exit passageways used as exit components shall conform to the general requirements of Section 7.1 of NFPA *101* and to the special requirements of Section 14.7. [***101:***7.2.6.1]

A.14.7.1 Examples of building elements that might be arranged as exit passageways include hallways, corridors, passages, tunnels, underfloor passageways, or overhead passageways. [***101:***A.7.2.6.1]

Δ **14.7.2 Enclosure.** An exit passageway shall be separated from other parts of the building as specified in Section 14.3, and the following alternatives shall be permitted:

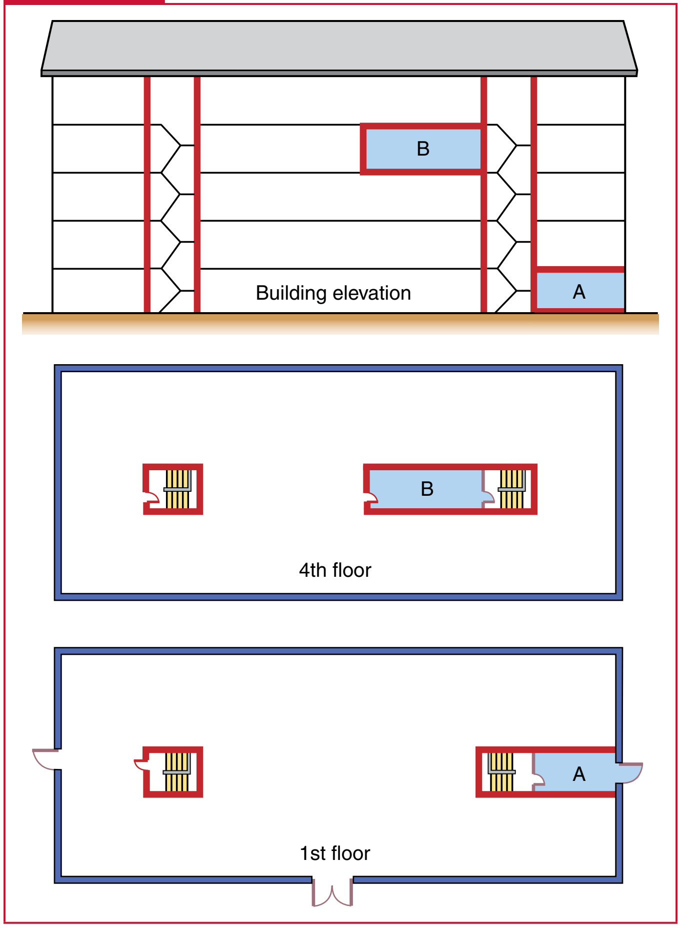
(1) Fire windows in accordance with 12.7.6 shall be permitted to be installed in the separation in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.
(2) Existing fixed wired glass panels in steel sash shall be permitted to be continued in use in the separation in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.

[***101:***7.2.6.2]

14.7.3 Stair Discharge. An exit passageway that serves as a discharge from a stair enclosure shall have not less than the same fire resistance rating and opening protective fire protection rating as those required for the stair enclosure. [***101:***7.2.6.3]

Paragraph 14.7.2 requires exit passageways to have walls with the hourly fire resistance ratings and door assemblies with the fire protection ratings required of exit stair enclosures, as detailed in 14.3.1(1) or (2) and 12.7.6.2.2. The requirement also limits door openings into, and penetrations through, the exit enclosure created by the exit passageway, as detailed in 14.3.1(9) and (10). In Exhibit 14.35, new exit passageway A on the first floor — the level of exit discharge — opens at one end to a five-story exit stair enclosure and, at the other end, to a door assembly to the outside. This exit passageway also serves as a horizontal continuation of, and discharge for, the stair enclosure. In serving as a discharge for the exit stair, the exit passageway must provide the same degree of protection required of the stair enclosure. Given that the exit stair must be enclosed by 2-hour fire resistance–rated construction because it is new and serves four or more stories, the exit passageway must also be enclosed

Exhibit 14.35



Exit passageways with fire resistance–rated enclosures and fire protection–rated door assemblies.

by 2-hour fire resistance–rated construction. This protection is addressed in 14.7.3.

In Exhibit 14.35, exit passageway A and the 5-story exit stair enclosure that it serves each have a 2-hour fire resistance rating as discussed in the preceding paragraph. The door shown between the exit stair enclosure and the exit passageway is not required. In other words, the exit passageway is permitted to be open to the exit stair enclosure. If the exit stair enclosure and exit passageway are open to each other, the exit passageway is not permitted to have fire windows as the exit stair enclosure is not permitted to have fire windows [see 14.3.1(9)]. If they are separated from each other as shown in Exhibit 14.35, the exit passageway is permitted to have fire windows in accordance with 14.7.2(1) if the building is sprinklered.

In Exhibit 14.35, exit passageway B, on the fourth floor, is used to provide the safety of an exit to occupants traveling to the exit stair enclosure. This exit passageway might have been built to meet the travel distance limitation. If a fire-rated wall and door assembly separate exit passageway B from the new 2-hour exit stair enclosure, the required rating of exit passageway B is only 1 hour, because the exit passageway serves only the occupants of the fourth floor. A similar 1-hour fire resistance–rated enclosure requirement applies, for example, to an exit passageway serving a single story of a shopping mall structure. Contrast this configuration with exit passageway A on the first floor, which potentially serves occupants of the second through fifth floors and must provide a continuation of the 2-hour separation required of the new stair enclosure.

For the same reasons that the exit stair enclosure cannot have door assemblies opening directly onto it from normally unoccupied spaces, a storage room, for example, is prohibited from opening directly onto exit passageways A and B and the exit stair enclosures. Penetrations through the enclosing walls are limited to those necessary for the functioning of life safety systems, such as lighting powered by electrical cables that enter the exit enclosure via properly sealed conduit penetrations. Ductwork for climate control is prohibited from penetrating enclosing walls. Thus, the exit passageways and the exit stair enclosures must receive their heating and cooling by systems independent of those serving the remainder of the building. Ductwork serving other parts of the floor must be routed around the outside of, not through, the exit passageway enclosures.

14.7.4 Width.

Δ **14.7.4.1** The width of an exit passageway shall be sized to accommodate the aggregate required capacity of all exits that discharge through it, unless one of the following conditions applies:

(1)* Where an exit passageway serves occupants of the level of exit discharge as well as other stories, the capacity shall not be required to be aggregated.

A.14.7.4.1(1) Where an exit passageway serves occupants on the level of exit discharge as well as other floors, it should not be required that the occupant loads be added, thus increasing the width of the exit passageway. The situation is the same as that in which occupants from the level of exit discharge join occupants from upper floors for a few feet of horizontal travel through a stair enclosure. [***101:***A.7.2.6.4.1(1)]

(2) As provided in Chapters 36 and 37 of NFPA *101*, an exit passageway in a mall structure shall be permitted to accommodate occupant loads independently from the mall concourse and the tenant spaces. *(See 36.2.2.7.2 and 37.2.2.7.2 of* NFPA *101.)* [***101:***7.2.6.4.1]

14.7.4.2 In new construction, the minimum width of any exit passageway into which an exit stair discharges, or that serves as a horizontal transfer within an exit stair system, shall meet the following criteria:

(1) The minimum width of the exit passageway shall be not less than two-thirds of the width of the exit stair.
(2) Where stairs are credited with egress capacity in accordance with 14.8.3.2, the exit passageway width shall be sized to accommodate the same capacity as the stair, with such capacity determined by use of the capacity factors in Table 14.8.3.1.

[***101:***7.2.6.4.2]

14.8 Capacity of Means of Egress

14.8.1 Occupant Load.

14.8.1.1 Sufficient Capacity.

Δ **14.8.1.1.1** The total capacity of the means of egress for any story, balcony, tier, or other occupied space shall be sufficient for the occupant load thereof unless one of the following conditions exists:

(1) The authority having jurisdiction shall be permitted to establish the occupant load as the number of persons for which existing means of egress is adequate, provided that measures are established to prevent occupancy by a greater number of persons.
(2) The egress capacity shall have been previously approved as being adequate.

[***101:***7.3.1.1.1]

It is a basic concept of the *Code* that the means of egress system be sized to accommodate all people occupying a building. Sizing is accomplished via a *Code*-specified method of matching the occupant load of a floor with the calculated egress capacity of the egress components serving the floor. The sizing criteria do not ensure that all occupants can leave immediately, but they do provide for sufficient quick movement without unacceptable queuing; that is, occupants might have to wait in line to pass through an exit stair enclosure door assembly to begin moving down the stairs, especially where occupants of upper floors who have already entered the stair enclosure are simultaneously using the stairs for egress travel in the downward direction.

The geometry of a building, its occupancy and related occupant load, and the travel distance to exits dictate, in large measure, the location of exits, the number of exits, and the capacity (i.e., width) of exits and access thereto. As a consequence, the exits themselves influence the plan and layout of the entire means of egress system. The number of people that the means of egress system can accommodate is determined not solely by the capacity of the exits but also by the number of persons each component within the exit access and exit discharge can accommodate. Very wide corridors that lead to very wide exit stair enclosure door assemblies that, in turn, lead to much narrower stairs provide a system comparable to average-width corridors that lead to average-width exit stair enclosure door assemblies that, in turn, lead to average-width stairs. A means of egress system is only as good as its most constricting component.

The number of people or occupant load for which the means of egress system must provide egress capacity is calculated or otherwise determined. The occupant load is to reflect the maximum number of people anticipated to occupy the building rooms or spaces at any given time and under all probable situations. The occupant load must not be based only on normal occupancy.

The provision of 14.8.1.1 was revised for the 2018 edition of NFPA *101* to provide two exemptions to the requirement that the means of egress be sized to handle the occupant load.

1. The provision of 14.8.1.1.1(1) offers relief in the case where the existing egress system is not large enough to accommodate the calculated occupant load; the AHJ establishes and approves a reduced occupant load equal to the number of occupants the current egress system can accommodate; and the building operator establishes and follows procedures that ensure that the number of occupants does not exceed the approved number.
2. The provision of 14.8.1.1.1(2) permits an egress system that was *previously approved* to be continued in use so as not to require that it be increased in size to accommodate the calculated occupant load. The provision recognizes the case where a building is constructed under a building code that permits the use of reduced capacity factors based on the building being sprinklered. The egress width for components providing level travel — like doors — is calculated using 0.15 in./person (3.8 mm/person) and not the 0.2 in./person (5 mm/person) of Table 14.8.3.1; the egress width for stairways is calculated using 0.2 in./person (5 mm/person) and not the 0.3 in./person (7.6 mm/person) of Table 14.8.3.1. Where the doors provide 32 in. (810 mm) of clear width and the associated stair provides 44 in. (1120 mm), the route's egress capacity is calculated to be 220 persons, not the 146 derived from use of Table 14.8.3.1. The egress system was approved at time of construction. The new provision of 14.8.1.1.1(1) permits the previously approved, existing means of egress system to be evaluated using the previously approved method.

14.8.1.1.2 For other than existing means of egress, where more than one means of egress is required, the means of egress shall be of such width and capacity that the loss of any one means of egress leaves available not less than 50 percent of the required capacity. [***101:***7.3.1.1.2]

The provision of 14.8.1.1.2 has the effect of requiring that new egress systems employing two means of egress be balanced in size, so that each egress route accommodates at least half the occupant load of the floor. It also has the effect of requiring that new egress systems employing more than two means of egress be sized so that no one egress route is credited with accommodating more than half the occupant load of the floor. The requirement is aimed at preventing a situation where the loss of any one egress route reduces the remaining egress capacity to less than half that needed to accommodate the occupant load of the floor. Application of the provision of 14.8.1.1.2 is demonstrated in the examples that follow.

Example 1

The occupant load of a floor in a new building is 350 persons. Two means of egress are provided. Egress route 1 is of sufficient width to accommodate 200 persons, and egress route 2 accommodates 150. The two egress routes, together, exactly accommodate the 350-person occupant load of the floor. If a fire or similar emergency were to render egress route 1 unusable, the performance-based criterion of 14.8.1.1.2 would not be met, because less than half the required egress capacity remains usable [i.e., 150 < 350/2]. The designer chooses to resize both egress routes so that each accommodates 175 persons. Following the redesign, the arrangement is again evaluated against the criterion of 14.8.1.1.2. The loss of any one of the two egress routes leaves available not less than 50 percent of the required egress capacity of the floor as required by 14.8.1.1.2.

Example 2

The occupant load of a floor in a new building is 350 persons. Two means of egress are provided. Egress route 1 is of sufficient width to accommodate 200 persons, and egress route 2 accommodates 175 persons. The two egress routes, together, accommodate 375 persons, which is 25 persons more than are required to be accommodated for the 350-person occupant load of the floor. If a fire or similar emergency were to render egress route 1 unusable, the performance-based criterion of 14.8.1.1.2 would be met, as at least half the required egress capacity (i.e., 350/2 = 175) remains usable as required by 14.8.1.1.2.

Example 3

The occupant load of a floor in a new building is 640 persons. Three means of egress are provided in accordance with 14.9.1.2. Egress route 1 is of sufficient width to accommodate 340 persons, and egress route 2 and egress route 3 each accommodate 150 persons. The three egress routes, together, exactly accommodate the 640-person occupant load of the floor. If a fire or similar emergency were to render egress route 1 unusable, the performance-based criterion of 14.8.1.1.2 would not be met, because less than half the required egress capacity remains usable via the combination of egress route 2 and egress route 3 [i.e., 150 + 150 = 300; 300 < 640/2]. The designer chooses to resize all three egress routes so that egress route 1 accommodates 320 persons and egress route 2 and egress route 3 each accommodate 160 persons. Following the redesign, the arrangement is again evaluated against the criterion of 14.8.1.1.2. The loss of egress route 1 leaves available not less than 50 percent of the required egress capacity of the floor as required by 14.8.1.1.2.

Δ **14.8.1.2* Occupant Load Factor.** The occupant load in any building or portion thereof shall be not less than the number of persons determined by dividing the floor area assigned to that use by the occupant load factor for that use as specified in Table 14.8.1.2, Figure 14.8.1.2(a), and Figure 14.8.1.2(b). Where both gross and net area figures are given for the same occupancy, calculations shall be made by applying the gross area figure to the gross area of the portion of the building devoted to the use for which the gross area figure is specified and by applying the net area figure to the net area of the portion of the building devoted to the use for which the net area figure is specified. [***101:***7.3.1.2]

A.14.8.1.2 The normal occupant load is not necessarily a suitable criterion, because the greatest hazard can occur when an unusually large crowd is present, which is a condition often difficult for AHJs to control by regulatory measures. The principle of this *Code* is to provide means of egress for the maximum probable number of occupants, rather than to attempt to limit occupants to a number commensurate with available means of egress. However, limits of occupancy are specified in certain special cases for other reasons. [***101:***A.7.3.1.2]

Suggested occupant load factors for components of large airport terminal buildings are given in Table A.14.8.1.2. However, the AHJ might elect to use different occupant load factors, provided that egress requirements are satisfied. [***101:***A.7.3.1.2]

The figure used in determining the occupancy load for mall shopping centers of varying sizes was arrived at empirically by surveying over 270 mall shopping centers, by studying mercantile occupancy parking requirements, and by observing the number of occupants per vehicle during peak seasons. [***101:***A.7.3.1.2]

NA: Not applicable. The occupant load is the maximum probable number of occupants present at any time.

[a]All factors are expressed in gross area unless marked "net."

[b]For the purpose of determining occupant load in mercantile occupancies where, due to differences in the finished ground level of streets on different sides, two or more floors directly accessible from streets (not including alleys or similar back streets) exist, each such floor is permitted to be considered a street floor. The occupant load factor is one person for each 40 ft^2 (3.7 m^2) of gross floor area of sales space.

[c]For the purpose of determining occupant load in mercantile occupancies with no street floor, as defined in 3.3.234, but with access directly from the street by stairs or escalators, the floor at the point of entrance to the mercantile occupancy is considered the street floor.

[d]For any food court or other assembly use areas located in the mall concourse that are not included as a portion of the gross leasable area of the mall structure, the occupant load is calculated based on the occupant load factor for that use as specified in Table 14.8.1.2. The remaining mall concourse area is not required to be assigned an occupant load.

[e]The portions of the mall concourse that are considered a pedestrian way and not used as gross leasable area are not required to be assessed an occupant load based on Table 14.8.1.2. However, means of egress from a mall pedestrian way are required to be provided for an occupant load determined by dividing the gross leasable area of the mall structure (not including anchor stores) by the appropriate lowest whole number occupant load factor from Figure 14.8.1.2(a) or Figure 14.8.1.2(b).

Each individual tenant space is required to have means of egress to the outside or to the mall concourse based on occupant loads calculated by using the appropriate occupant load factor from Table 14.8.1.2.

Each individual anchor store is required to have means of egress independent of the mall concourse.

[f]See A.14.8.1.2.

[***101:***Table 7.3.1.2]

TABLE A.14.8.1.2 Airport Terminal Occupant Load Factors

Airport Terminal Area	ft² (gross)	m² (gross)
Concourse	100	9.3
Waiting areas	15	1.4
Baggage claim	20	1.9
Baggage handling	300	27.9

[***101:*** Table A.7.3.1.2]

These studies show that, with an increase in shopping center size, there is a decrease in the number of occupants per square foot of gross leasable area. [***101:***A.7.3.1.2]

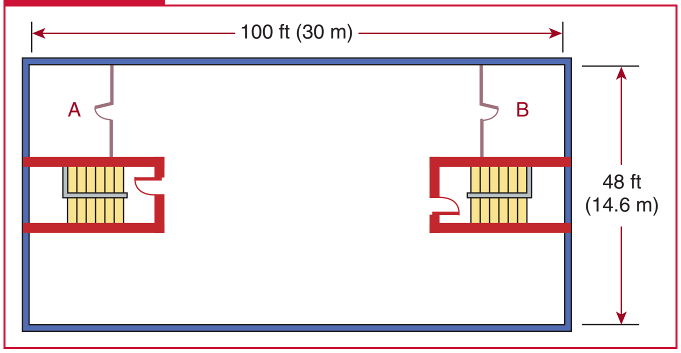
This phenomenon is explained when one considers that, above a certain shopping center gross leasable area [approximately 600,000 ft² (56,000 m²)], there exists a multiplicity of the same types of stores. The purpose of duplicate types of stores is to increase the choices available to a customer for any given type of merchandise. Therefore, when shopping center size increases, the occupant load increases as well, but at a declining rate. In using Table A.14.8.1.2, the occupant load factor is applied only to the gross leasable area that uses the mall concourse as a means of egress. [***101:***A.7.3.1.2]

The value for concentrated business use is intended to address business use spaces with a higher density of occupants than would normally be expected in a general business occupancy. Where furnishings and floor layouts are arranged to maximize the number of occupants in the space, the value for concentrated business use should be applied. Examples of concentrated business use areas are call centers, trading floors, and data processing centers. [***101:***A.7.3.1.2]

Occupant load is determined by the nature of the use of a building or space and the amount of space available for that use. Since different generic uses are characterized by different occupant densities, Table 14.8.1.2 has established occupant load factors for each use. The first column of the table is deliberately headed "use" rather than "occupancy," because the use of an area might differ from its occupancy classification. For example, a meeting room for fewer than 50 people in an office building is not an assembly occupancy; it is part of the larger business occupancy [see 6.1.14.1.3(2)], but its occupant load is based on an assembly use. The same concept applies to a classroom in a university, which, although classified as a business occupancy, has an occupant load based on educational use (for traditional classroom style) or assembly use (for lecture style with theater-type seating).

The occupant load factor, as a density factor, assumes the presence of at least one person for each specified unit of area. Note that some values are for net area, while others are based on gross area. The gross area figure applies to the building as a whole (the area within the confining perimeter walls of the building, including areas that are occupied by shafts and other elements that people do not occupy but excluding vertical openings complying with the communicating space provisions of 8.6.6 of NFPA *101* and the atrium provisions of 8.6.7 of NFPA *101*); the net area figure applies to actual occupied spaces, such as classroom spaces, and does not include the corridors, the area occupied by walls, or other unoccupied areas.

Exhibit 14.36



Floor area for occupant load considerations.

Cases of mixed use might exist where, for example, an assembly use space having an occupant load based on net floor area might be located in a building that is primarily a business occupancy, a classification for which the occupant load is based on gross area. In such instances, the net area calculations should be performed for those specific areas that use occupant load factors based on net area; the remaining floor area can then be used to calculate the occupant load for the uses employing gross floor area. This is illustrated in Exhibit 14.36.

In Exhibit 14.36, the majority of the 4800 ft² (446 m²) gross floor area [i.e., 100 ft × 48 ft (30 m × 14.6 m)] is used for business purposes and is occupied by desks, chairs, file cabinets, office machines, and associated office personnel. Rooms A and B are conference rooms with tables and chairs used on a regular basis, primarily by company personnel from other floors in the building. These rooms can be expected to be occupied simultaneously with the remainder of the floor. Each conference room provides 320 ft² (30 m²) of net usable area. Because neither conference room can accommodate 50 or more persons, an assembly occupancy is not created. Rather, the floor is a business occupancy with some incidental assembly use [again, see 6.1.14.1.3(2)].

Because occupant load is calculated based on use of the space (not occupancy classification), the occupant load of the floor shown in Exhibit 14.36 is calculated using occupant load factors for both an assembly use, which is based on net area, and a business use, which is based on gross area. The occupant load of the assembly use spaces (conference rooms A and B) is calculated first. Using Table 14.8.1.2, a net area factor of 15 ft² (1.4 m²) per person for assembly, "less concentrated use," is chosen. (Note that the concept of "less concentrated use" refers to the possible concentration of occupants where, because of the presence of tables and chairs, there are fewer occupants than would be possible without the tables and chairs, which is an example of "concentrated use.") The two conference rooms must be assumed to have a combined occupant load of at least 43 persons, according to the following calculation:

$$\frac{640 \text{ ft}^2}{15 \text{ ft}^2 \text{ per person}} = 43 \text{ persons}$$

$$\frac{60 \text{ m}^2}{1.4 \text{ m}^2 \text{ per person}} = 43 \text{ persons}$$

Next, the occupant load of the remainder of the floor must be calculated. The use is business, so a gross area factor of 100 ft² (9.3 m²) per person is chosen per Table 14.8.1.2. Because the net area usable as conference rooms has already been assigned an occupant load, that area can be subtracted from the gross floor area, and the remaining business use area is then assigned an occupant load as follows:

$$\left(\begin{array}{c}4800 \text{ ft}^2\\ \text{gross area}\end{array}\right) - \left(\begin{array}{c}640 \text{ ft}^2\\ \text{net assembly}\\ \text{use area}\end{array}\right) = 4160 \text{ ft}^2$$

$$\left(\begin{array}{c}446 \text{ m}^2\\ \text{gross area}\end{array}\right) - \left(\begin{array}{c}60 \text{ m}^2\\ \text{net assembly}\\ \text{use area}\end{array}\right) = 386 \text{ m}^2$$

$$\frac{4160 \text{ ft}^2 \text{ gross business use area}}{100 \text{ ft}^2 \text{ per person}} = 42 \text{ persons}$$

$$\left[\frac{386 \text{ m}^2 \text{ gross business use area}}{9.3 \text{ m}^3 \text{ per person}}\right] = 42 \text{ persons}$$

Adding together the assembly use occupant load (43) and the business use occupant load (42) results in a minimum occupant load of 85 persons for the floor. See the paragraph that follows for an explanation of conditions under which the occupant load might be a number greater than that calculated using the floor area and occupant load factor calculation. In any case, the occupant load is not permitted to be a number smaller than that calculated, even where the building operator plans to limit the number of occupants.

Egress capacity must be provided for at least the occupant load (expressed in number of persons) determined by dividing each area of the space by the appropriate occupant load factor. This calculated occupant load must serve as the minimum starting point for egress sizing, regardless of whether the building operator claims that the occupant load will never reach the occupant load determined by calculation. However, if the building operator plans to have more occupants present than the number determined by calculation using occupant load factors, the means of egress system must be sized to accommodate that larger number of occupants. In return for providing the larger egress system, the building operator is permitted to claim the larger number of persons as the occupant load. This concept is further explained in the commentary following 14.8.1.3.2.

Table 14.8.1.2 provides an occupant load factor for ambulatory health care use. The entry was changed for the 2015 edition of the *Code* from 100 ft² (9.3 m²) to 150 ft² (13.9 m²). The change reflects the technical committee's judgment that ambulatory health care use spaces are not as densely populated as previously assumed. A calculation of occupant load using a factor of 150 ft² (13.9 m²) per person instead of the traditional 100 ft² (9.3 m²) per person results in an occupant load that is two-thirds that specified by previous editions of the *Code* for a given area.

Note that the occupant load for storage use classified as a storage occupancy (e.g., a warehouse) is determined not by calculation but through negotiation between the designer or owner and the AHJ, based on actual use and population (see 42.1.7 of NFPA *101*). Table 14.8.1.2 does not have an occupant load factor for storage use in a storage occupancy. However, Table 14.8.1.2 provides occupant load factors for storage use in occupancies other than a storage occupancy (e.g., a central storage room in a hospital or a stock room in a department store) to allow occupant load to be aggregated via calculations for each use area on a building floor.

14.8.1.3 Occupant Load Increases.

14.8.1.3.1 The occupant load in any building or portion thereof shall be permitted to be increased from the occupant load established for the given use in accordance with 14.8.1.2 where all other requirements of this *Code* are also met, based on such increased occupant load. [***101:***7.3.1.3.1]

14.8.1.3.2 The AHJ shall be permitted to require an approved aisle, seating, or fixed equipment diagram to substantiate any increase in occupant load and shall be permitted to require that such a diagram be posted in an approved location. [***101:***7.3.1.3.2]

The *Code*'s intent for other than assembly occupancies is not to restrict the occupant load of a building based on the floor area of the building. Nor is the *Code* specifying the minimum area needed by each occupant for efficient or sanitary use of the space. An occupant load is established for use in sizing the means of egress system and in determining thresholds at which additional provisions, such as mandatory sprinklers, become applicable. If *Code* provisions can be met for a larger number of persons than the calculation determines, the larger number of occupants is permitted to be present and be considered as the occupant load, provided that the AHJ is satisfied that the egress system (including corridors, aisles, stairs, and other means of egress components) can accommodate the larger occupant load. For assembly occupancies, the increase in occupant load above the calculated number is restricted by 12.1.7 and 13.1.7 of NFPA *101*, based on maximum density criteria. Density is addressed in the last paragraph of this commentary.

As an example of increasing the occupant load above the calculated number, a factory of 20,000 ft² (1860 m²) gross area would be assigned an occupant load of 200 persons if the typical 100 ft² (9.3 m²) per person occupant load factor were used. However, the occupant load would be permitted to be increased (e.g., to 300 persons to accommodate the occupant load of an electronic components manufacturing facility where personnel work side by side on assembly lines) if all *Code* provisions dependent on numbers of persons were met for the increased load.

Assembly occupancies have special but similar provisions for increasing occupant load. Densities greater than one person for each 5 ft² (0.46 m²) are prohibited, because movement speeds are reduced to a crawl where the density exceeds one person for each 3 ft² (0.28 m²) of floor area. This density approaches the jam point at which movement stops.

14.8.1.4 Exits Serving More than One Story. Where an exit serves more than one story, only the occupant load of each story considered individually shall be used in computing the required capacity of the exit at that story, provided that the required egress capacity of the exit is not decreased in the direction of egress travel. [***101:***7.3.1.4]

Paragraph 14.8.1.4 provides that, once a maximum required egress capacity is determined, such required capacity must be maintained — in the direction of egress travel — for the remainder of the egress system.

Required stair width is determined by the required egress capacity of each floor the stair serves, considered independently. It is not necessary to accumulate occupant loads from floor to floor to determine stair width. Each story or floor level is considered separately when calculating the occupant load to be served by the means of egress from that floor. The size or width of the stair need only accommodate the portion of the floor's occupant load assigned to that stair. However, in a multistory building, the floor requiring the greatest egress capacity dictates the minimum stair width from that floor to the level of exit discharge in the direction of egress travel. It is not permissible to reduce such stair width along the remainder of the stair runs encountered in traveling to the level of exit discharge; that is, stairs encountered in the direction of egress travel. Exits serving floors above the floor of greatest egress capacity are permitted to use egress components sized to handle the largest demand created by any floor served by that section of stair run.

Exhibit 14.37 illustrates the intent of 14.8.1.4. It is not necessary to accumulate required egress capacity from floor to floor; no decrease in egress capacity is permitted in the direction of egress travel.

14.8.1.5 Capacity from a Point of Convergence. Where means of egress from a story above and a story below converge at an intermediate story, the capacity of the means of egress from the point of convergence shall be not less than the sum of the required capacity of the two means of egress. [***101:***7.3.1.5]

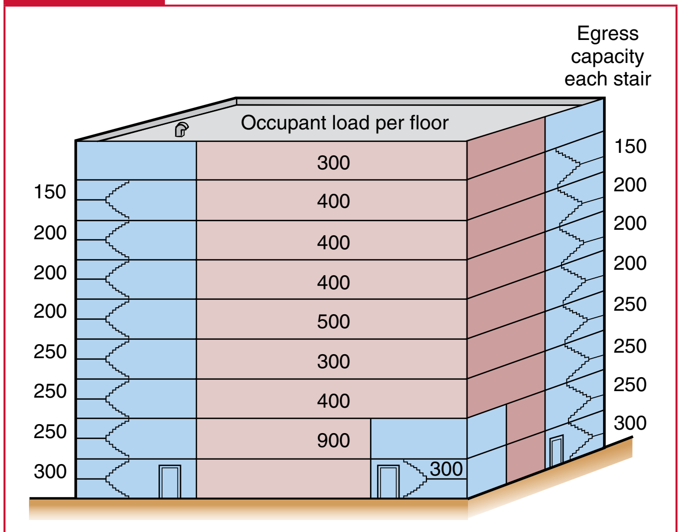
Exhibit 14.38 illustrates the intent of 14.8.1.5. Convergence from floors above and below requires the accumulation of required egress capacity. Paragraph 14.8.1.5 mandates that the *required* capacity, not the actual or provided capacity, must be aggregated at the point of convergence. Note that occupants of the second floor move down the stairs and converge with occupants of the basement, who are traveling up the stairs. From the merge point (i.e., the ground level stair landing) to the public way, the egress path must accommodate the 300-person combined occupant load represented as the sum of those persons moving downward and upward on the stair.

The occupants of the first floor (X) experience level travel through the stair enclosure. They are not considered to have merged from above or below, and egress capacity for the first-floor occupants is not added to that of the second floor and basement.

14.8.1.6 Egress Capacity from Balconies and Mezzanines. Where any required egress capacity from a balcony or mezzanine passes through the room below, that required capacity shall be added to the required egress capacity of the room in which it is located. [***101:***7.3.1.6]

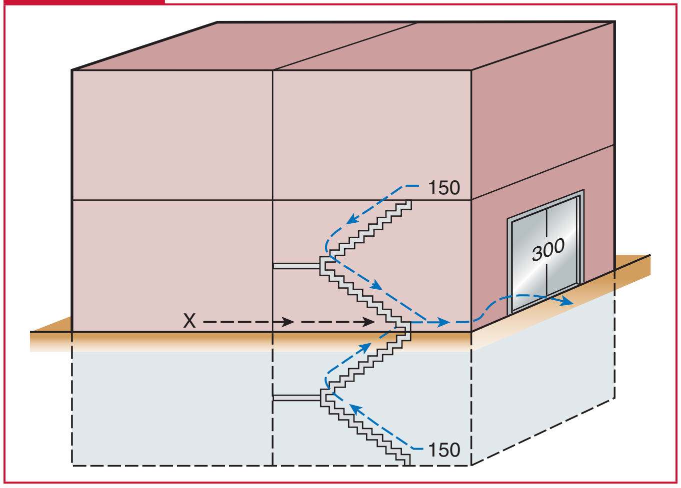
Mezzanines and balconies are considered as part of the room in which they are located. Occupants of mezzanines and balconies experience the effects of a fire in the room to which such spaces are open as readily as do the occupants of those spaces. Thus,

Exhibit 14.37



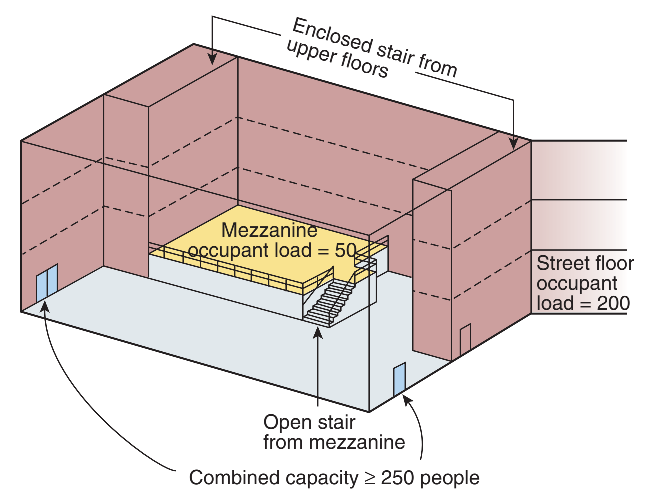
Capacity of exit stairs serving multiple floors.

Exhibit 14.38



Capacity of egress system from point on stairs where occupants from floors above and below converge.

Exhibit 14.39



Required capacity of main floor with mezzanine egress through that floor.

mezzanines and balconies must have their occupant load added to that of the room or space in which they are located if their egress passes through that room or space.

An example is depicted in Exhibit 14.39. There is no direct access to the enclosed exit stair from the mezzanine; therefore, egress from the mezzanine is down the open stair and through the main floor. Thus, the street floor egress capacity must accommodate the occupant load of the street floor and that of the mezzanine. If the main floor has an occupant load of 200 persons and the mezzanine has an occupant load of 50 persons, the egress capacity for the main floor must accommodate at least 250 persons.

14.8.2 Measurement of Means of Egress.

14.8.2.1 The width of means of egress shall be measured in the clear at the narrowest point of the egress component under consideration, unless otherwise provided in 14.8.2.2 or 14.8.2.3. [***101:***7.3.2.1]

14.8.2.2 Projections within the means of egress of not more than 4½ in. (114 mm) on each side shall be permitted at a height of 38 in. (965 mm) and below. In the case of stair and landing handrails forming part of a guard, in accordance with 7.2.2.4.4.3 of NFPA *101*, such projections shall be permitted at a height of 42 in. (1065 mm) and below. [***101:***7.3.2.2]

14.8.2.3 In health care and ambulatory health care occupancies, projections shall be permitted in corridors in accordance with Chapters 18 through 21 of NFPA *101*. [***101:***7.3.2.3]

Paragraph 14.8.2.2 permits maximum 4½ in. (114 mm) projections at each side of an egress component for purposes of determining width for use in egress capacity calculations, provided that such projections occur at a height of not more than 38 in. (965 mm), which is the maximum mounting height for handrails. Note that such encroachments are not limited to items such as handrails that are required by the *Code*. The encroachment might be the result of wainscoting applied to the lower portion of a wall, or it might be caused by the metal stringers to which metal pan stair treads and risers are welded.

A 4½ in. (114 mm) encroachment is permitted by 14.8.2.2 along stairs, corridors, passageways, and other components of the means of egress (other than door openings) for purposes of calculating egress capacity. The egress capacity of door openings is regulated by 7.2.1.2.2.1 of NFPA *101*, which substitutes a maximum 3½ in. (90 mm) projection at each side of the door opening in place of the 4½ in. (114 mm) projection permitted by 14.8.2.2. Figure A.7.2.1.2.2(b) of NFPA *101* depicts the allowable encroachment at each side of a door opening.

Exhibit 14.40 shows handrails along the right wall of the corridor in a medical office building. The handrails are permitted to encroach as much as 4½ in. (114 mm) into the corridor width in accordance with 14.8.2.2. Note that the cross-corridor door leaf (not the door opening) is provided with a handrail that serves as a corridor wall handrail when the door is held in its full open position.

For purposes of determining whether a door opening provides the minimum required width (such as that needed for a person in a wheelchair to pass through a door opening), see 7.2.1.2.1.1, Figure A.7.2.1.2.1(a), and Figure A.7.2.1.2.1(b) of NFPA *101*. Similarly, the minimum 48 in. (1220 mm) clear width

Exhibit 14.40

Permitted handrail encroachment on required corridor width. (Courtesy of Jake Pauls) between handrails, as required by 7.2.12.2.3 of NFPA *101* for stairs serving areas of refuge, does not allow for encroachments, based on the need to provide sufficient clear width to carry a person in a wheelchair on the stair.

Projections at or below 38 in. (965 mm) (i.e., handrail height) and not exceeding 4½ in. (114 mm) do not adversely restrict the effective egress width of stairs or corridors, because the human body is normally widest at shoulder level. Also, the body sway associated with walking, particularly on stairs, is greater at shoulder height than it is at waist height. Other projections, however, might constitute obstructions and cause impediments to the free flow of pedestrian travel. The *Code*, therefore, bases the measurements of widths of means of egress used for egress capacity calculation purposes on the clear, net, usable, unobstructed width. Only those projections specified are permitted to encroach on the required width without having to subtract the encroaching space from the overall width before performing the egress width calculation.

Paragraph 14.8.2.3 serves as a reminder that the provisions of 14.8.2 are modified to permit encroachments in health care and ambulatory health care occupancy corridors where the corridor width is at least 6 ft (1830 mm) — a width greater than the 36 in. (915 mm) minimum established for egress components by 14.8.3.4.1. See, for example, 19.2.3.4(2) of NFPA *101*.

14.8.3 Egress Capacity.

Δ **14.8.3.1** Egress capacity for approved components of means of egress shall be based on the capacity factors shown in Table 14.8.3.1, unless otherwise provided in 14.8.3.2. [***101:***7.3.3.1]

A significant change in egress capacity calculations was introduced in the 1988 edition of NFPA *101*. The unit of exit width formerly used as a measure of egress capacity was replaced by a system of smaller increments of egress width and capacity. The newer method of using smaller increments (approximating a linear formula) provides increased egress capacity.

The differences between the *stairways* and the *level components/ramps* capacity factors specified in Table 14.8.3.1 arise from the following:

Δ ***TABLE 14.8.3.1*** *Capacity Factors*

Area	Stairways (width/person) in.	Stairways (width/person) mm	Level Components and Ramps (width/person) in.	Level Components and Ramps (width/person) mm
Board and care	0.4	10	0.2	5
Health care, sprinklered	0.3	7.6	0.2	5
Health care, nonsprinklered	0.6	15	0.5	13
High hazard contents	0.7	18	0.4	10
All others	0.3	7.6	0.2	5

[***101:***Table 7.3.3.1]

1. Stairs entail a totally different type of movement, by both individuals and crowds, than do level and ramped components.
2. For stairs, there are differences in biomechanics, as well as a difficulty in the ability to see (or otherwise detect) the next stepping surface in order to avoid misstepping and suffering a fall and resulting injury. Exhibit 14.41 shows stair users looking for the next stepping surface.
3. The approximate ratio of 3 to 2, relating the required widths for vertical travel on stairs and level travel on floors, is based on previous ratios and on empirical observations.

The greater range of width requirements for different occupancies reflects the following two factors:

1. The need for a much more rapid egress time in the case of high hazard occupancies
2. The slower movement and greater need for assistance from others during evacuations in nonsprinklered health care and related institutional and semi-institutional occupancies

In summary, given the designer's knowledge of the occupancy, the occupant load of the floor level, and the type of egress component, the required minimum width for each component can be determined by simple multiplication (i.e., multiply the occupant load by the appropriate width-per-person factor found in Table 14.8.3.1 to obtain the minimum width of the component under consideration). If the width of the component under consideration is known, divide that width by the appropriate width-per-person factor to obtain the number of

Exhibit 14.41

Stair users looking for next stepping surface. (Courtesy of Jake Pauls) persons the component can accommodate over the entire evacuation. These calculated minimum widths are then considered along with other *Code* requirements, including minimum widths based on other factors, to design a system in which performance will be closely matched from one part of the system to another.

14.8.3.2* For stairways wider than 44 in. (1120 mm) and subject to the 0.3 in. (7.6 mm) width per person capacity factor, the capacity shall be permitted to be increased using the following equation:

$$C = 146.7 + \left(\frac{Wn - 44}{0.218}\right) \qquad \textbf{[14.8.3.2]}$$

where:

C = capacity, in persons, rounded to the nearest integer

Wn = nominal width of the stair as permitted by 14.8.3.2 (in.) [***101:***7.3.3.2]

Δ **A.14.8.3.2** The effective capacity of stairways has been shown by research to be proportional to the effective width of the stairway, which is the nominal width minus 12 in. (305 mm). This phenomenon, and the supporting research, were described in the chapter, "Movement of People," in the first, second, and third editions of the *SFPE Handbook of Fire Protection Engineering* and was also addressed in Appendix D of the 1985 edition of NFPA *101*, among several other publications. In 1988, this appendix was moved to form Chapter 2 of the 1988 edition of NFPA 101M, *Alternative Approaches to Life Safety*. (This document was later designated as NFPA 101A and this chapter remained in the document through the 1998 edition.) In essence, the effective width phenomenon recognizes that there is an edge or boundary effect at the sides of a circulation path. It has been best examined in relation to stairway width, where the edge effect was estimated to be 6 in. (150 mm) on each side, but a similar phenomenon occurs with other paths, such as corridors and doors, although quantitative estimates of their edge effect are not as well established as they have been for stairways, at least those stairways studied in Canada during the late 1960s through the 1970s in office building evacuation drills and in crowd movement in a variety of buildings with assembly occupancy. [***101:***A.7.3.3.2]

More recent studies have not been performed to determine how the edge effect might be changing (or has changed) with demographic changes to larger, heavier occupants moving more slowly, and thus swaying laterally, to maintain balance when walking. The impact of such demographic changes, which are significant and influential for evacuation flow and speed of movement on stairs, for example, has the effect of increasing the time of evacuation in a way that affects all stair widths, but will be most pronounced for nominal widths less than 56 in. (1422 mm). [***101:***A.7.3.3.2]

Without taking into account occupant demographic changes in the last few decades that affect evacuation performance, especially on stairs, the formula for enhanced capacity of stairways wider than 44 in. (1120 mm) assumes that any portion of the nominal width greater than 44 in. (1120 mm) is as effective proportionally as the effective width of a nominal 44 in. (1120 mm) stair, that is, 32 in. (810 mm). Thus, the denominator (0.218) in the equation is simply the effective width of 32 in. (810 mm) divided by the capacity of 147 persons that is credited, by the 0.3 in. (7.6 mm) capacity factor in Table A.14.8.3.2, to the corresponding nominal width, 44 in. (1120 mm). [***101:***A.7.3.3.2]

The resulting permitted stairway capacities, based on occupant load of single stories (in accordance with 7.3.1.4 of NFPA *101*), for several stairway widths are shown in Table A.14.8.3.2. [***101:***A.7.3.3.2]

TABLE A.14.8.3.2 *Stairway Capacities*

Permitted Capacity (no. of persons)	Nominal Width in.	Nominal Width mm	Clear Width Between Handrails[a] in.	Clear Width Between Handrails[a] mm	Effective Width in.	Effective Width mm
120[b]	36	915	28	710	24	610
147	44	1120	36	915	32	810
202	56	1420	48	1220	44	1120
257	68	1725	60	1525[c]	56	1420

[a]A reasonable handrail incursion of only 4 in. (100 mm), into the nominal width, is assumed on each side of the stair, although 7.3.3.2 of NFPA *101* permits a maximum incursion of 4½ in. (114 mm) on each side.

[b]Other *Code* sections limit the occupant load for such stairs more severely, (e.g., 50 persons in 7.2.2.2.1.2 of NFPA *101*). Such lower limits are partly justified by the relatively small effective width of such stairs, which, if taken into account by Table 7.3.3.1 of NFPA *101*, would result in a correspondingly low effective capacity of only 110 persons (24 divided by 0.218), or a more realistic capacity factor of 0.327, applicable to nominal width.

[c]A clear width of 60 in. (1525 mm) is the maximum permitted by the handrail reachability criteria of 7.2.2.4.1.2 of NFPA *101*. Although some prior editions of the *Code* permitted wider portions of stairs [up to 88 in. (2240 mm), between handrails], such wider portions are less effective for reasonably safe crowd flow and generally should not be used for major crowd movement. To achieve the maximum possible, reasonably safe egress capacity for such stairs, retrofit of an intermediate — not necessarily central — handrail is recommended; for example, with an intermediate handrail located 36 in. (915 mm) from the closest side handrail. In this case, the effective capacity would be 358 persons for the formerly permitted, now retrofitted, stair. This is based on a retrofitted, effective width of about 78 in. (1980 mm) [subtracting 2 in. (51 mm) from each usable side of a handrail and assuming a 2 in. (51 mm) wide, retrofitted intermediate handrail]. [***101:***A.7.3.3.2]

The enhanced capacity provision of 14.8.3.2 permits stairs that are wider than 44 in. (1120 mm) for which the 0.3 in. (7.6 mm) per person capacity factor from the last row (i.e., the entry for "all others") of Table 14.8.3.1 is applied to be credited with more capacity than results from the standard calculation performed by dividing the clear width of the stair by the 0.3 in. (7.6 mm) per person capacity factor. The rationale for the enhanced capacity allowance is detailed in this commentary to A.14.8.3.2.

The equation in 14.8.3.2 is presented only in inch-pound units. Where SI units are used, the equation for calculating capacity, C, is as follows:

$$C = 146.7 + \left[\frac{Wn - 1120}{5.45}\right]$$

where the nominal stair width, Wn, is expressed in mm.

An example of use of the enhanced capacity permitted by 14.8.3.2 follows. A 56 in. (1420 mm) stair has encroachments at handrail height and below that do not exceed the 4½ in. (114 mm) permitted at each side by 14.8.2.2. The stair exceeds the 44 in. (1120 mm) width specified in 14.8.3.2 and is in a business occupancy, so as to be subject to the 0.3 in. (7.6 mm) per person capacity factor from the last row of Table 14.8.3.1. The traditional capacity calculation involves taking the 56 in. (1420 mm) clear width and dividing it by 0.3 in. (7.6 mm) per person, which results in a traditional capacity of 187 persons. The nominal width of the stair, for purposes of performing the enhanced capacity calculation permitted by 14.8.3.2, is the full 56 in. (1420 mm) clear width, and the calculation is performed as follows:

$$\text{Enhanced capacity, } C = 146.7 + \left[\frac{(56\text{ in.} - 44\text{ in.})}{0.218}\right]$$

$$C = 146.7 + \frac{12}{0.218}$$

$$C = 146.7 + 55$$

$$C = 202$$

In SI units:

$$\text{Enhanced capacity, } C = 146.7 + \left[\frac{(1420\text{ mm} - 1120\text{ mm})}{5.45}\right]$$

$$C = 146.7 + \frac{300}{5.45}$$

$$C = 146.7 + 55$$

$$C = 202$$

Note that 7.2.2.4.1.2(2)(b) of NFPA *101* prohibits the enhanced capacity option of 14.8.3.2 from being applied to existing stairs where portions of the stair are more than 30 in. (760 mm) from a handrail even though the provision of 7.2.2.4.1.2(2)(a) of NFPA *101* would otherwise permit 44 in. (1120 mm). In other words, an existing stair is held to the same intermediate handrail criterion as new stairs, as found in 7.2.2.4.1.2(1) of NFPA *101*, if the existing stair is to make use of the increased capacity offered by the equation in 14.8.3.2.

14.8.3.3 The required capacity of a corridor shall be the occupant load that utilizes the corridor for exit access divided by the required number of exits to which the corridor connects, but the corridor capacity shall be not less than the required capacity of the exit to which the corridor leads. [***101:***7.3.3.3]

14.8.3.4 Minimum Width.

Δ **14.8.3.4.1** The width of any means of egress, unless otherwise provided in 14.8.3.4.1.1 through 14.8.3.4.1.3, shall be as follows:

(1) Not less than that required for a given egress component in this chapter or Chapter 7 or Chapters 11 through 43 of NFPA *101*
(2) Not less than 36 in. (915 mm) where another part of this chapter and Chapters 11 through 43 of NFPA *101* do not specify a minimum width.

[***101:***7.3.4.1]

Δ **14.8.3.4.1.1*** The width of exit access serving not more than six people, and having a length not exceeding 50 ft (15 m) shall meet both of the following criteria:

(1) The width shall be not less than 18 in. (455 mm), at and below a height of 38 in. (965 mm), and not less than 28 in. (710 mm) above a height of 38 in. (965 mm).
(2) A width of not less than 36 in. (915 mm) for new exit access, and not less than 28 in. (710 mm) for existing exit access, shall be capable of being provided without moving permanent walls.

[***101:***7.3.4.1.1]

A.14.8.3.4.1.1 The criteria of 14.8.3.4.1.1, as initially written, were intended to provide for minimum widths for small spaces such as individual offices. The intent is that these reductions in required width apply to spaces formed by furniture and movable walls so that accommodations can easily be made for mobility-impaired individuals. One side of a path could be a fixed wall, provided that the other side is movable. This does not exempt the door widths or widths of fixed-wall corridors, regardless of the number of people or length. The allowance for reduction in width has been expanded to include all exit accesses serving not more than six people where the travel length along the reduced-width path does not exceed 50 ft (15 m), regardless of occupancy or use of the space. [***101:***A.7.3.4.1.1]

Figure A.14.8.3.4.1.1(a) and Figure A.14.8.3.4.1.1(b) present selected anthropometric data for adults. The male and female figures depicted in the figures are average, 50th percentile, in size. Some dimensions apply to very large, 97.5 percentile, adults (noted as 97.5 P). [***101:***A.7.3.4.1.1]

14.8.3.4.1.2 In existing buildings, the width of exit access shall be permitted to be not less than 28 in. (710 mm). [***101:***7.3.4.1.2]

Δ **14.8.3.4.1.3** The requirement of 14.8.3.4.1 shall not apply to the following:

(1) Doors as otherwise provided for in 7.2.1.2 of NFPA *101*
(2) Aisles and aisle accessways in assembly occupancies as otherwise provided in Chapters 12 and 13 of NFPA *101*
(3) Industrial equipment access as otherwise provided in 40.2.5.2 of NFPA *101*

[***101:***7.3.4.1.3]

14.8.3.4.2 Where a single exit access leads to an exit, its capacity in terms of width shall be not less than the required capacity of the exit to which it leads. [***101:***7.3.4.2]

14.8.3.4.3 Where more than one exit access leads to an exit, each shall have a width adequate for the number of persons it accommodates. [***101:***7.3.4.3]

14.9 Number of Means of Egress

14.9.1 General.

Δ **14.9.1.1** The number of means of egress from any balcony, mezzanine, story, or portion thereof shall be not less than two, except under one of the following conditions:

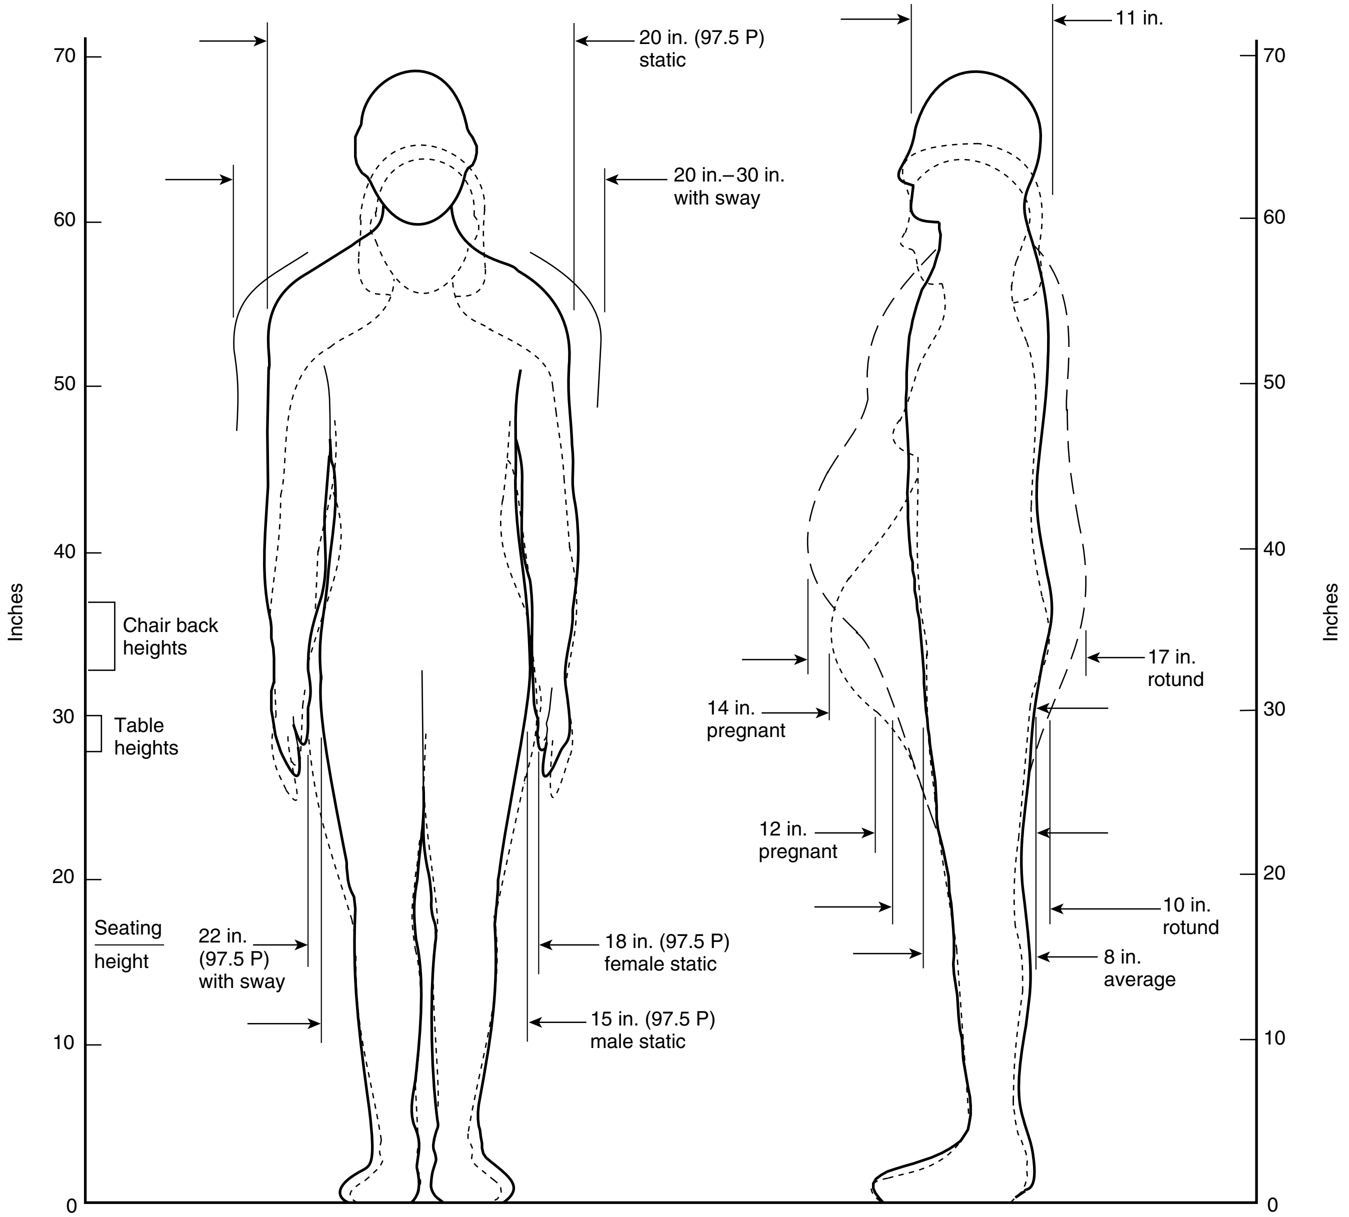


FIGURE A.14.8.3.4.1.1(a) *Anthropometric Data (in in.) for Adults; Males and Females of Average, 50th Percentile, Size; Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults. [**101:**Figure A.7.3.4.1.1(a)]*

(1) A single means of egress shall be permitted where permitted in Chapters 11 through 43 of NFPA *101*.

(2) A single means of egress shall be permitted for a mezzanine or balcony where the common path of travel limitations of Chapters 11 through 43 of NFPA *101* are met.

[***101:***7.4.1.1]

Most of the occupancy chapters of NFPA *101* provide redundancy with respect to the number of means of egress by requiring at least two means of egress. Some occupancies identify specific arrangements under which only a single means of egress is required. Where large numbers of occupants are to be present on any floor or portion of a floor in new construction, more than two means of egress must be provided as required by 14.9.1.2.

Mezzanines are required to have the same number of means of egress as any story of the building, unless an occupant can reach either the single exit or a point (at or past the bottom of a single open stair) where access to two exits becomes available within the allowable common path of travel permitted for the applicable occupancy.

Exhibit 14.42 illustrates the mezzanine provisions of 14.9.1.1 and 14.9.1.1(2), which are not intended to override the provisions for openness of mezzanines imposed by 8.6.10.3 of NFPA *101*. In

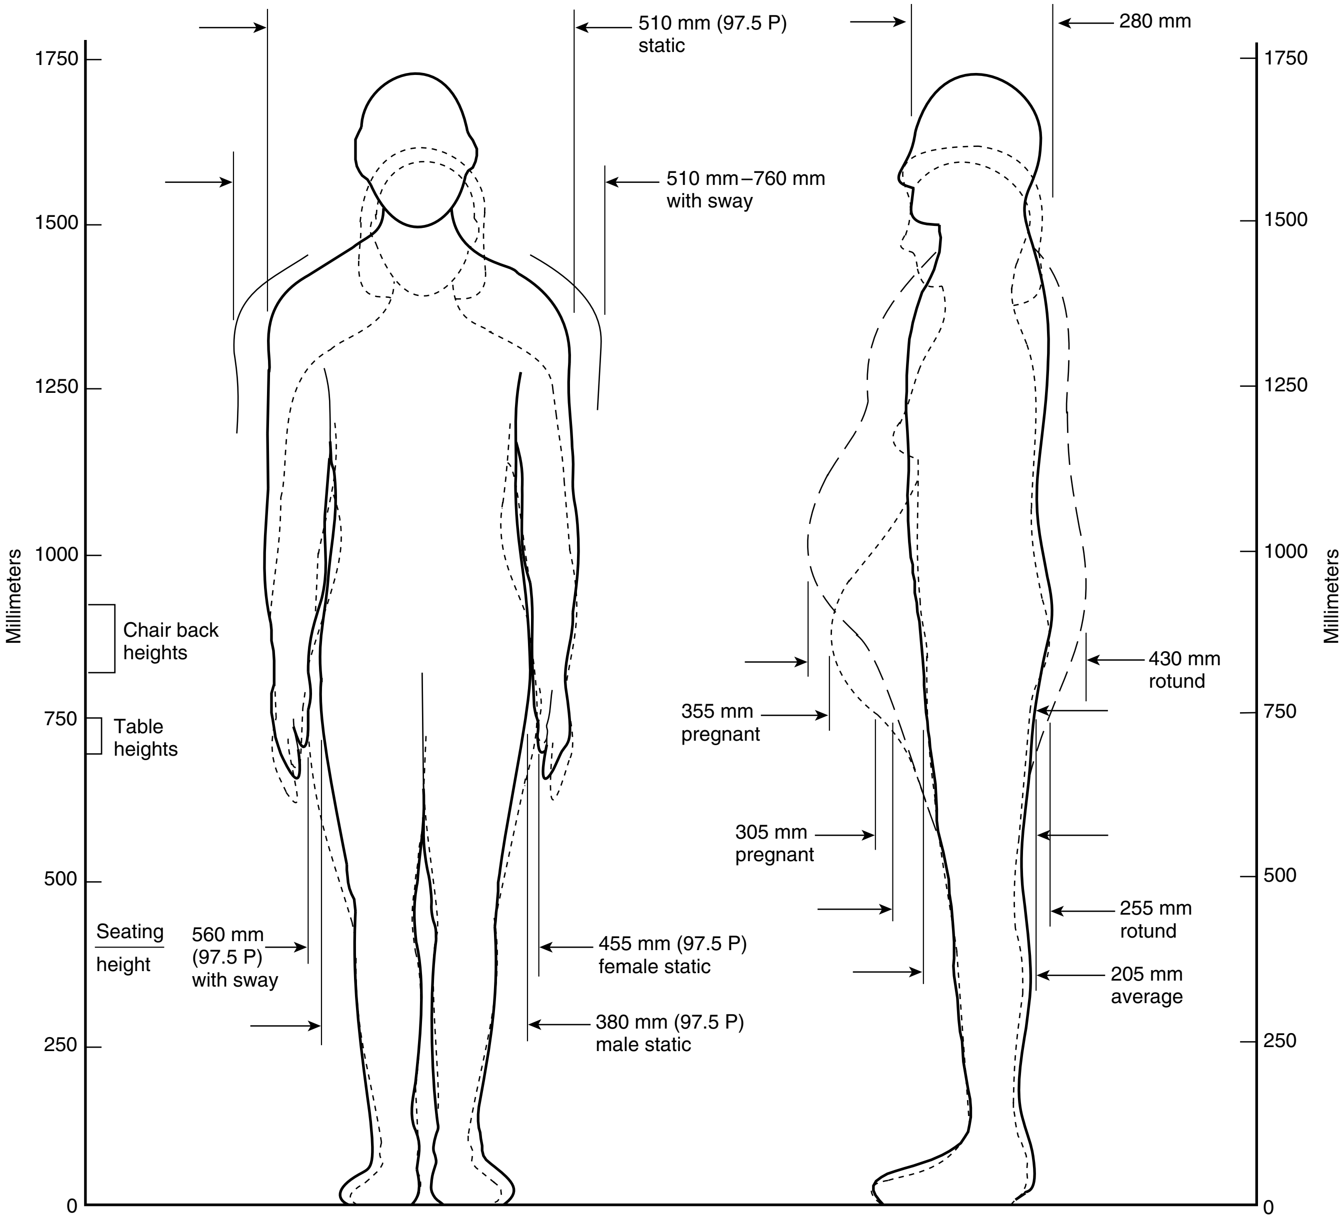

FIGURE A.14.8.3.4.1.1(b) *Anthropometric Data (in mm) for Adults; Males and Females of Average, 50th Percentile, Size; Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults. [**101:**Figure A.7.3.4.1.1(b)]*

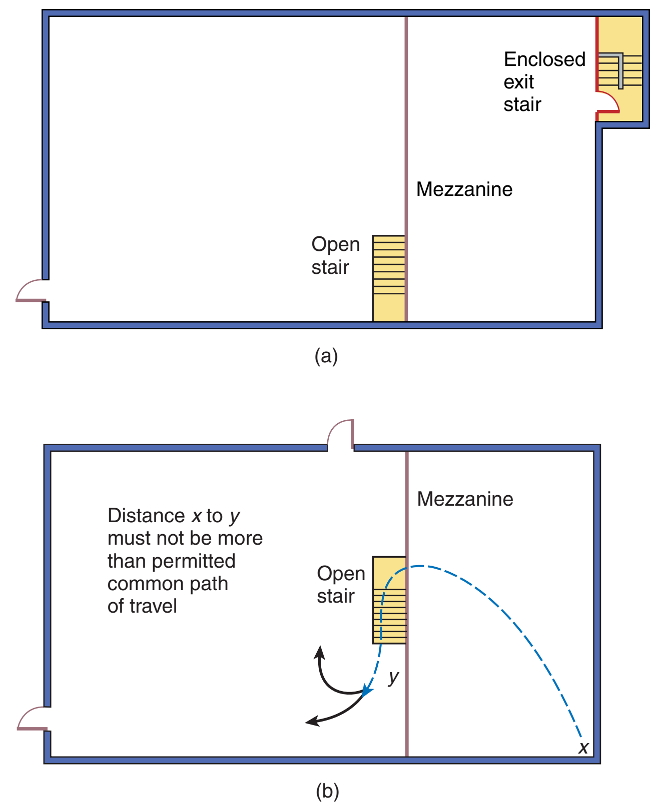
Exhibit 14.42, part (a) illustrates the requirement for a minimum of two means of egress per 14.9.1.1. One means of egress is an open stair to the floor below, and the other is an enclosed exit stair. Both could be open stairs to the floor below, unless the openness requirements of 8.6.10.3 of NFPA *101* are not met. If the mezzanine were enclosed such that the enclosed area had an occupant load of more than 10 persons, 8.6.10.3 of NFPA *101* would require a second means of egress [similar to the enclosed exit stair in part (a)] that provides direct access from the enclosed area to an exit at the mezzanine level. In part (b) of Exhibit 14.42, a single means of egress is permitted in accordance with 14.9.1.1(2), because the common path of travel is within the limits specified for the occupancy involved and the 10-person enclosed area criterion of 8.6.10.3 of NFPA *101* is not exceeded.

See also Section 14.10 with respect to remoteness of exits and common paths of travel, 7.6.5 of NFPA *101* with respect to measuring travel distance in the plane of the tread nosings on open exit access stairs, and 8.6.10 of NFPA *101* on mezzanines.

Exhibit 14.42



Number of means of egress from mezzanines.

Δ **14.9.1.2** The number of means of egress from any story or portion thereof, other than for existing buildings as permitted in Chapters 11 through 43 of NFPA *101*, shall be as follows:

(1) Occupant load more than 500 but not more than 1000 — not less than 3
(2) Occupant load more than 1000 — not less than 4

[***101:***7.4.1.2]

Chapter 14 requires a minimum number of means of egress, unless otherwise specified by the occupancy chapters of NFPA *101*. Several occupancies establish not only the minimum number of means of egress but also the minimum number of actual exits that must be provided on each floor.

In most occupancies, meeting the requirements for egress capacities and travel distances means the required minimum number of means of egress will automatically be met. However, in occupancies characterized by high occupant loads, such as assembly and mercantile occupancies, compliance with requirements for more than two exits per floor might require specific attention.

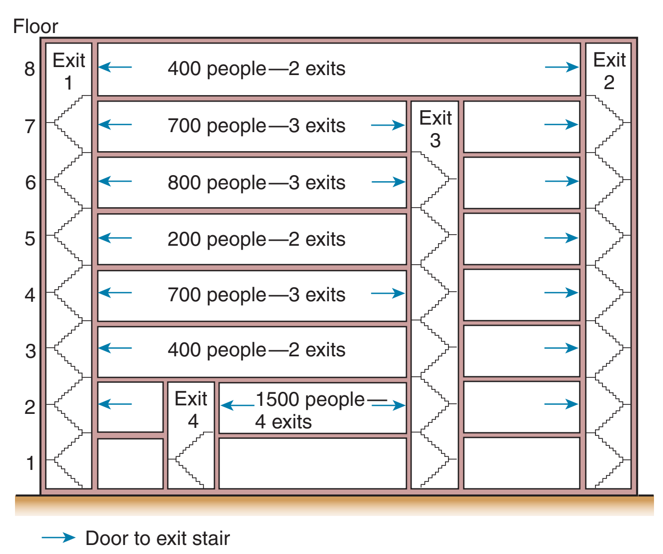
14.9.1.3 Accessible means of egress in accordance with 14.10.4 that do not utilize elevators shall be permitted to serve as any or all of the required minimum number of means of egress. [***101:***7.4.1.3]

Because an accessible means of egress can effectively serve the needs of persons with mobility impairments, the same accessible means of egress should effectively serve the needs of persons without disabilities. Therefore, the *Code* permits accessible means of egress to fulfill any requirements for means of egress. However, this permission does not apply to elevators because of the small number of occupants accommodated during each run of the elevator and concerns that the elevator might be automatically called out of service upon the detection of smoke in the elevator machine room or an elevator lobby or landing on any floor served by the elevator.

14.9.1.4 The occupant load of each story considered individually shall be required to be used in computing the number of means of egress at each story, provided that the required number of means of egress is not decreased in the direction of egress travel. [***101:***7.4.1.4]

Similar to the procedures for determining required egress capacity (see 14.8.1.4), the number of required means of egress is based on a floor-by-floor consideration, rather than the accumulation of the occupant loads of all floors. For example, see Exhibit 14.43, where the fourth floor of the building has an occupant load of 700 persons and would require three means of egress. The third floor of the same building has an occupant load of 400 persons and would require two means of egress; regardless of the fact that the two floors together have an occupant load in excess of 1000 persons, four means of egress are not required. However, the number of means of egress cannot decrease as an occupant proceeds along the egress path. The three exits required from the fourth floor in this example cannot be merged into two exits on the third floor, even though the third floor requires only two

Exhibit 14.43



Minimum number of required means of egress for new construction.

exits. On any floor requiring only two exits, one of the three exits could be left inaccessible (blind) on that floor, as shown at Exit 3 in Exhibit 14.43 on the third and fifth floors. The second floor, with an occupant load of 1500 persons, requires a fourth means of egress.

14.9.1.5 Doors other than the hoistway door; the elevator car door; and doors that are readily openable from the car side without a key, a tool, special knowledge, or special effort, shall be prohibited at the point of access to an elevator car. [***101:***7.4.1.5]

Paragraph 14.9.1.5 prohibits the installation of a door assembly at the entrance to an elevator, unless that door leaf is readily operable by those in the elevator. This prohibition prevents entrapment between the elevator and the door assembly. The primary concern is the potential for an occupant to enter this small space and become trapped during a fire. Exhibit 14.44 shows doors at the entrance to an elevator. Note the door lever on the door leaf at the right side. The door lever provides occupants of the elevator with the required latch release to open the door.

Exhibit 14.44

Permitted doors at entrance to elevator.

14.9.1.6 Elevator Landing and Lobby Exit Access.

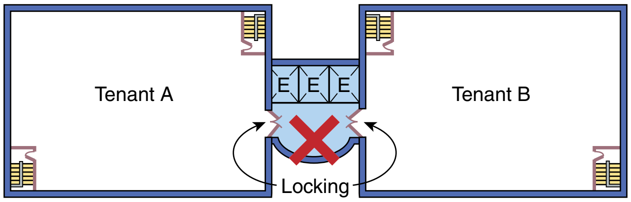
14.9.1.6.1 Each elevator landing and lobby shall have access to at least one exit. [***101:***7.4.1.6.1]

14.9.1.6.2 The elevator landing and lobby exit access required by 14.9.1.6.1 shall not require the use of a key, a tool, special knowledge, or special effort, unless permitted by 14.9.1.6.3. [***101:***7.4.1.6.2]

14.9.1.6.3 Doors separating the elevator lobby from the exit access required by 14.9.1.6.1 shall be permitted to be electronically locked in accordance with 14.5.3.3. [***101:***7.4.1.6.3]

The purpose of 14.9.1.6.1 and 14.9.1.6.2 is to ensure that an occupant who has gained access to an elevator lobby can get out of the lobby without the use of a tool or key. It is not uncommon, especially in office buildings where a tenant occupies an entire floor, for the elevator lobby door assemblies to the tenant space to be locked after normal business hours to prevent entry into the tenant space. This problem is illustrated in Exhibit 14.45. Because the door assemblies between the elevator lobby and the tenant spaces can be locked, access to an exit is not ensured to a person who arrives at the floor via elevator. At least one exit must be accessible from the elevator lobby. The situation can be corrected by repositioning one of the exit stair enclosures depicted at the top of the exhibit so that it is accessed directly from within the elevator lobby.

Exhibit 14.45



Exit access from an elevator lobby.

The provision of 14.9.1.6.3, rather than providing the detailed criteria required of locked elevator lobby exit access door assemblies, references the criteria of 14.5.3.3 as an exemption to the requirements of 14.9.1.6.1 and 14.9.1.6.2. The provisions of 14.5.3.3 for elevator lobby exit access door assemblies locking are correctly positioned within Section 14.5 on door openings and, more important, within 14.5.3, special locking arrangements provisions, because locked elevator lobby exit access doors are a special form of permitted door assembly locking. See the commentary following A.14.5.3.3(14).

14.9.2 Spaces About Electrical Equipment.

14.9.2.1 600 Volts, Nominal, or Less.

14.9.2.1.1 Number of Means of Egress. The minimum number of means of egress for working space about electrical equipment, other than existing electrical equipment, shall be in accordance with *NFPA 70*, Section 110.26(C). [***101:***7.4.2.1.1]

N **14.9.2.1.2 Door Unlatching and Direction of Door Swing.** The method of door unlatching and direction of door swing for working space about electrical equipment, other than existing electrical equipment, shall be in accordance with Section 110.26(C)(3) of *NFPA 70*. [***101:***7.4.2.1.2]

N **14.9.2.2 Over 600 Volts, Nominal.**

N **14.9.2.2.1 Number of Means of Egress.** The minimum number of means of egress for working space about electrical equipment, other than existing electrical equipment, shall be in accordance with *NFPA 70*, Section 110.33(A). [***101:***7.4.2.2.1]

N **14.9.2.2.2 Door Unlatching and Direction of Door Swing.** The method of door unlatching and direction of door swing for working space about electrical equipment, other than existing electrical equipment, shall be in accordance with Section 110.33(A)(3) of *NFPA 70*. [***101:***7.4.2.2.2]

The provisions of 14.9.2 serve as a reminder that *NFPA 70*®, *National Electrical Code*®, has criteria for ingress and egress for working space around electrical equipment that are more specific — and potentially more stringent — than those of this *Code*. Users had complained that, after designing an egress system in accordance with this *Code*, they were cited for not complying with *NFPA 70*. The provisions of 14.9.2 were expanded for the 2018 edition of the *Code* to capture that *NFPA 70* addresses not only the number of means of egress but also the method of door unlatching and direction of door swing for working space about electrical equipment.

14.10 Arrangement of Means of Egress

14.10.1 General.

14.10.1.1 Exits shall be located and exit access shall be arranged so that exits are readily accessible at all times. [***101:***7.5.1.1]

14.10.1.1.1* Where exits are not immediately accessible from an open floor area, continuous passageways, aisles, or corridors leading directly to every exit shall be maintained and shall be arranged to provide access for each occupant to not less than two exits by separate ways of travel, unless otherwise provided in 14.10.1.1.3 and 14.10.1.1.4. [***101:***7.5.1.1.1]

A.14.10.1.1.1 See A.14.10.1.5. [***101:***A.7.5.1.1.1]

14.10.1.1.2 Exit access corridors shall provide access to not less than two approved exits, unless otherwise provided in 14.10.1.1.3 and 14.10.1.1.4. [***101:***7.5.1.1.2]

14.10.1.1.3 The requirements of 14.10.1.1.1 and 14.10.1.1.2 shall not apply where a single exit is permitted in Chapters 11 through 43 of NFPA *101*. [***101:***7.5.1.1.3]

14.10.1.1.4 Where common paths of travel are permitted for an occupancy in Chapters 11 through 43 of NFPA *101*, such common paths of travel shall be permitted but shall not exceed the limit specified. [***101:***7.5.1.1.4]

Paragraphs 14.10.1.1.1 and 14.10.1.1.2 reinforce the desirability of an occupant always having the ability to move in different directions from any location, so as to allow different paths of travel to different exits. However, typical floor layouts and furnishing arrangements often create spaces where travel in a single direction is necessary for a limited distance before it becomes possible to travel in different directions.

Paragraph 14.10.1.1.3 recognizes that a single exit creates a condition under which travel is possible in only one direction. The conditions under which an occupancy chapter permits a single exit usually produce a situation that is as safe as or safer than a building that is provided with two exits but that includes substantial common path of travel before access to both exits is possible.

Paragraph 14.10.1.1.4 recognizes common paths of travel within the limits set by the individual occupancy chapters. For additional information on common paths of travel, see A.14.10.1.5.

14.10.1.2 Corridors shall provide exit access without passing through any intervening rooms other than corridors, lobbies, and other spaces permitted to be open to the corridor, unless otherwise provided in 14.10.1.2.1 and 14.10.1.2.2. [***101:***7.5.1.2]

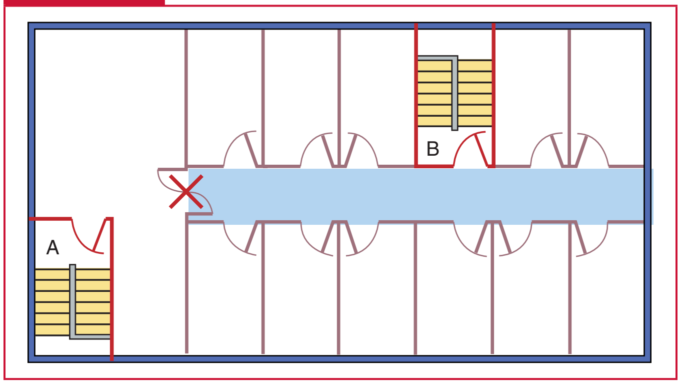
Δ **14.10.1.2.1** Approved existing corridors that require passage through a room to access an exit shall be permitted to continue to be used, provided that all of the following criteria are met:

(1) The path of travel is marked in accordance with Section 14.14.
(2) Doors to such rooms comply with 7.2.1 of NFPA *101*.
(3) Such arrangement is not prohibited by the applicable occupancy chapter in NFPA *101*.

[***101:***7.5.1.2.1]

The exit access arrangement illustrated in Exhibit 14.46 is deficient with respect to the requirement of 14.10.1.2, mandating that corridors provide access to at least two exits without passing through intervening rooms (other than corridors and lobbies). Occupants reaching the corridor have access only to Exit B without leaving the protection afforded by the corridor. Paragraph 14.10.1.2 requires access to both Exit A and Exit B without leaving the corridor and traveling within another use area. One possible solution to this problem would be to extend the corridor walls to the far left of the floor so as to connect directly with exit stair enclosure A.

Exhibit 14.46



Deficient corridor exit access.

Paragraph 14.10.1.2.1 recognizes the continued use of existing corridors that force occupants to travel through a room to access an exit where such existing corridors are approved. Per the definition of 3.2.1, the term *approved* means acceptable to the AHJ, so it is the current AHJ who must approve the existing corridor arrangement in order for it to be continued in use. If the exemption were not permitted, existing arrangements that were in compliance with earlier editions of the *Code* might suddenly be considered noncompliant.

14.10.1.2.2 Corridors that are not required to be fire resistance rated shall be permitted to discharge into open floor plan areas. [***101:***7.5.1.2.2]

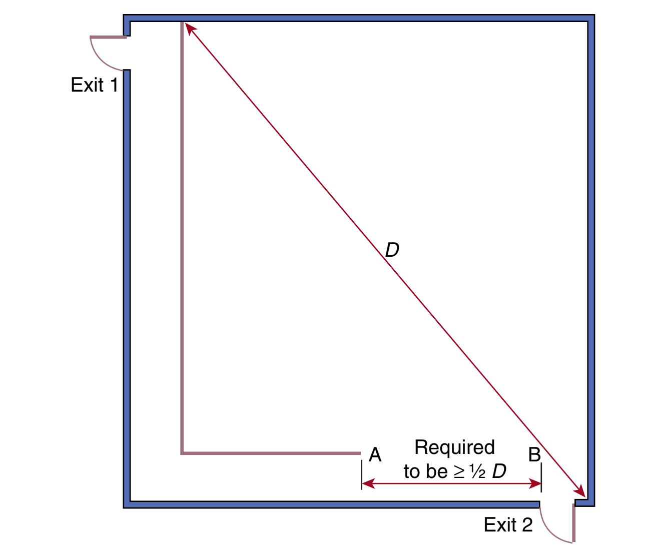
14.10.1.3 Remoteness shall be provided in accordance with 14.10.1.3.1 through 14.10.1.3.7. [***101:***7.5.1.3]

The provisions of 14.10.1.3.1 through 14.10.1.3.7 address the remoteness of exit accesses, the remoteness of exits, and the remoteness of exit discharges.

The concept of remoteness of exit accesses is illustrated in Exhibit 14.47 [which is an adaptation of Figure A.14.10.1.3.2(c)]. For purposes of this illustration, the building is new construction and is not sprinklered, so it is subject to both the qualitative remoteness criterion of 14.10.1.3.1 and the quantitative, one-half diagonal measurement remoteness criterion of 14.10.1.3.2. Exit 1 and Exit 2 — which are about as remotely located from each other as is physically possible — easily comply with the one-half diagonal separation distance criterion of 14.10.1.3.2 for exits. Yet, the L-shaped partition around which occupants must travel to reach Exit 1 has the effect of making the exit accesses less remotely located from each other than the exits, as all occupants are drawn toward Exit 2 before reaching point A, where access to Exit 1 becomes possible. The distance from point A to point B designates the separation distance between exit accesses that the requirements of 14.10.1.3.1 and 14.10.1.3.2 are intended to regulate. Without having to resort to measuring with a scale, it is apparent that the exit accesses do not meet the minimum one-half diagonal (½ *D*) requirement of 14.10.1.3.2. What is not obvious is whether the distance from point A to point B provides sufficient separation between exit accesses to meet the qualitative provision of 14.10.1.3.1, which requires that the exit accesses be remotely located from each other to minimize the possibility that more than one of the exit accesses has the potential to be blocked by any one fire or other emergency condition. Such judgment is left to the AHJ, which might be influenced by the fact that the diagonal measurement criterion of 14.10.1.3.2 was not met. If the building were sprinklered, the provision of 14.10.1.3.3 would be applied in lieu of that of 14.10.1.3.2 to decrease the required separation distance from one-half the diagonal to one-third the diagonal. Although less obvious than before, the remoteness test for the exit accesses would fail, since the distance from point A to point B is less than one-third the diagonal (⅓ *D*).

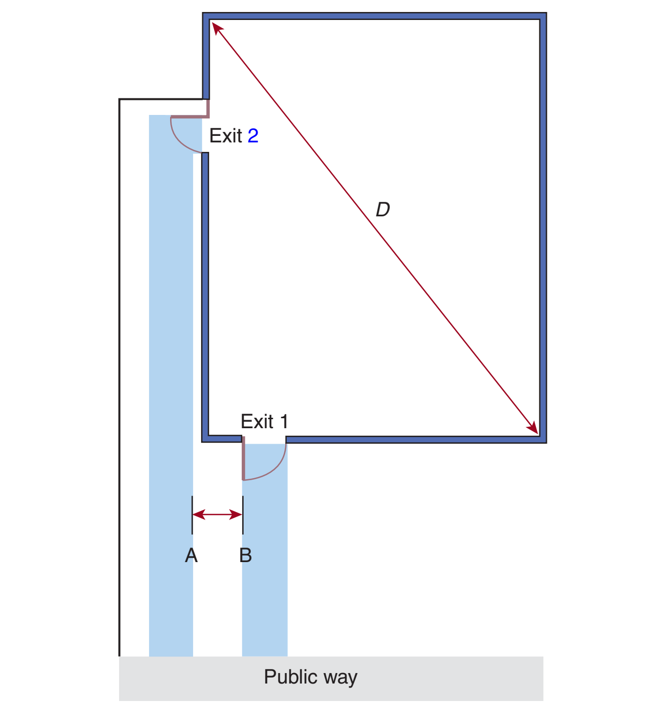
The provisions of 14.10.1.3.1 through 14.10.1.3.3, in addition to regulating the remoteness of exit accesses and the remoteness of exits, require that exit discharges be remotely located from each other. The concept of remoteness of exit discharges is illustrated in Exhibit 14.48. The shaded paths outside the nonsprinklered building are exit discharges. One provides the exit discharge path from Exit 1 to the public way, and the other provides the exit discharge path from Exit 2 to the public way. The proximity of the two exit discharge paths, measured

Exhibit 14.47



Testing the remoteness of exit accesses.

Exhibit 14.48

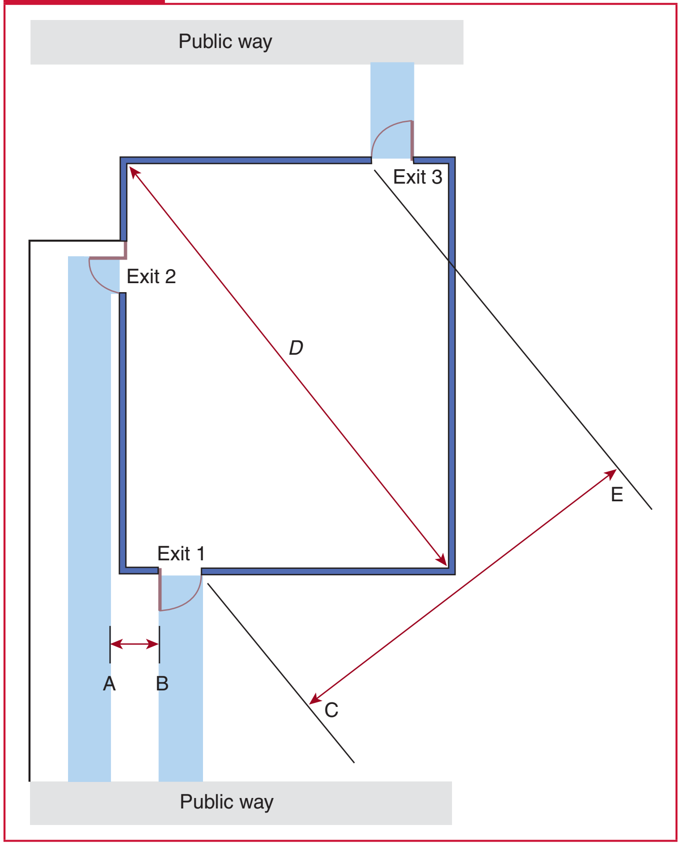


Testing the remoteness of exit discharges.

as the distance between point A and point B, is insufficient to meet the one-half diagonal (½ *D*) requirement of 14.10.1.3.2. Although Exit 1 is sufficiently remote from Exit 2 to comply with 14.10.1.3.2, the exit discharges are not, and the situation must be remedied. One possible solution might be to move Exit 1 to the far right end of the building exterior wall in which it is currently positioned.

Exhibit 14.49 addresses the case of testing the remoteness of exit discharges where three exits are provided. The provision of 14.10.1.3.6 requires that at least two of the required exit discharges be remote from each other. The provision of 14.10.1.3.7 requires that any additional required exit discharges be located so that, if one of the required exit discharges becomes blocked, the others are available. Assume that the single-story, nonsprinklered building depicted has an occupant load of more than 500 persons; it would require three means of egress in accordance with 14.9.1.2. The separation distance between the exit discharges from Exit 1 and Exit 3, measured as the distance from point C to point E, is sufficient to meet the one-half diagonal (½ *D*) requirement of 14.10.1.3.2. Thus, two of the three required exit discharges are remote from each other as required by 14.10.1.3.6. It is left to the AHJ to decide whether the loss of the exit discharge serving Exit 1 leaves the exit discharge serving Exit 2 available as required by 14.10.1.3.7. The *Code* provides no further guidance on what the term *available* means, other than to connote that an exit discharge can be judged as being available without being remote from its nearest neighbor, as defined by the criteria of 14.10.1.3.1, 14.10.1.3.2, or 14.10.1.3.3.

Exhibit 14.49



Testing the remoteness of exit discharges with three exits.

14.10.1.3.1 Where more than one exit, exit access, or exit discharge is required from a building or portion thereof, such exits, exit accesses, or exit discharges shall be remotely located from each other and be arranged to minimize the possibility that more than one has the potential to be blocked by any one fire or other emergency condition. [***101:***7.5.1.3.1]

It is a precept of life safety in buildings, repeated many times in the *Code*, that if multiple exits are required, they need to be not only separate but also remote from one another. Although the objective of this requirement is clear (if one exit is blocked by smoke or fire, the other needs to be maintained available), the term *remote* cannot always be clearly defined.

Where exits are located at each end of a long corridor or at each end or side of a building, they qualify as remotely located exits. However, core-type buildings with elevators, service shafts, and stairs in one central or side core introduce some challenging problems with respect to exit remoteness.

14.10.1.3.2* Where two exits, exit accesses, or exit discharges are required, they shall be located at a distance from one another not less than one-half the length of the maximum overall diagonal dimension of the building or area to be served, measured in a straight line between the nearest edge of the exits, exit accesses, or exit discharges, unless otherwise provided in 14.10.1.3.3 through 14.10.1.3.5. [***101:***7.5.1.3.2]

A.14.10.1.3.2 Figure A.14.10.1.3.2(a) through Figure A.14.10.1.3.2(e) illustrate the method of measurement intended by 14.10.1.3.2. [***101:***A.7.5.1.3.2]

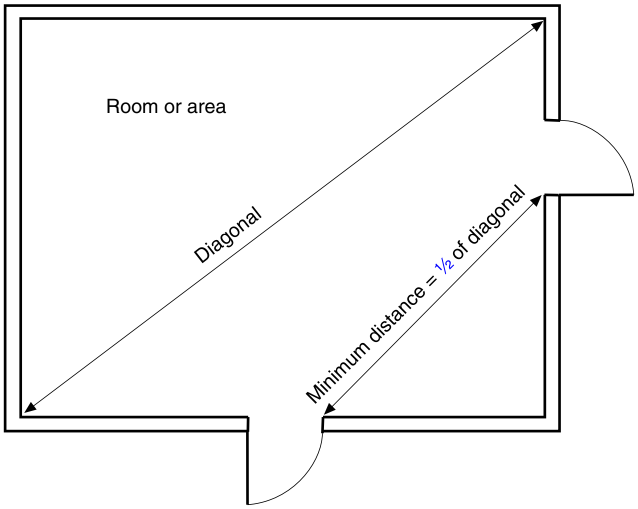


FIGURE A.14.10.1.3.2(a) *Diagonal Rule for Exit Remoteness. [**101:**Figure A.7.5.1.3.2(a)]*

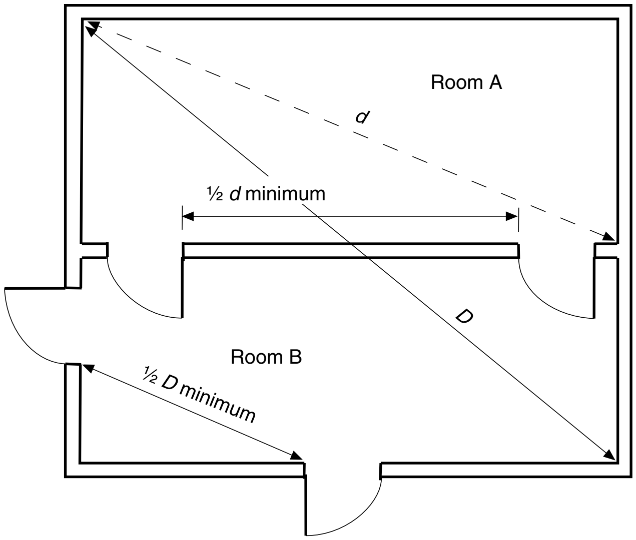

*FIGURE A.14.10.1.3.2(b) Diagonal Rule for Exit and Exit Access Remoteness. [**101:**Figure A.7.5.1.3.2(b)]*

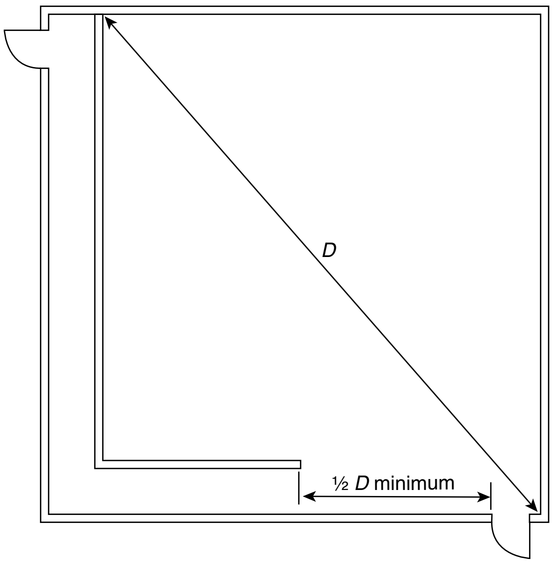

*FIGURE A.14.10.1.3.2(c) Diagonal Rule for Exit and Access Remoteness. [**101:**Figure A.7.5.1.3.2(c)]*

14.10.1.3.3 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3, the minimum separation distance between two exits, exit accesses, or exit discharges, measured in accordance with 14.10.1.3.2, shall be not less than one-third the length of the maximum overall diagonal dimension of the building or area to be served. [***101:***7.5.1.3.3]

14.10.1.3.4* In other than high-rise buildings, where exit enclosures are provided as the required exits specified in 14.10.1.3.2 or

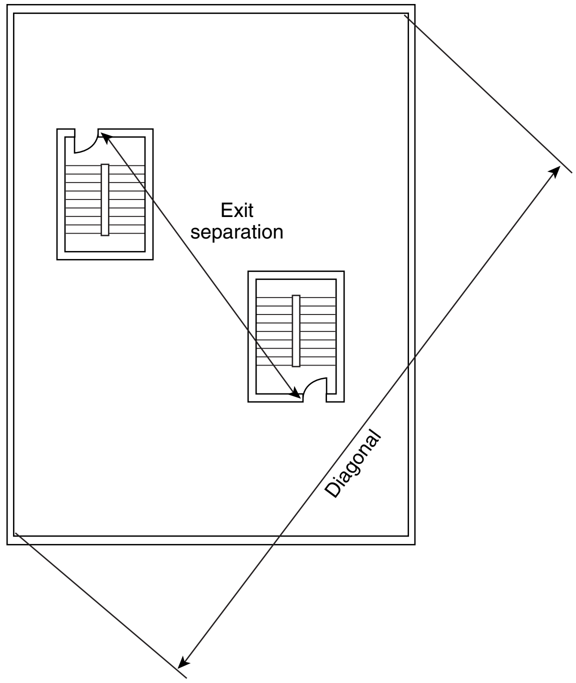

*FIGURE A.14.10.1.3.2(d) Exit Separation and Diagonal Measurement of Area Served. [**101:**Figure A.7.5.1.3.2(d)]*

14.10.1.3.3 and are interconnected by not less than a 1-hour fire resistance–rated corridor, exit separation shall be measured along the shortest line of travel within the corridor [***101:***7.5.1.3.4]

A.14.10.1.3.4 Figure A.14.10.1.3.4 illustrates the method of measuring exit separation distance along the line of travel within a minimum 1-hour fire resistance–rated corridor. [***101:***A.7.5.1.3.4]

14.10.1.3.5 In existing buildings, where more than one exit, exit access, or exit discharge is required, such exits, exit accesses, or exit discharges shall be exempt from the diagonal measurement separation distance criteria of 14.10.1.3.2 and 14.10.1.3.3, provided that such exits, exit accesses, or exit discharges are remotely located in accordance with 14.10.1.3.1. [***101:***7.5.1.3.5]

14.10.1.3.6 In other than existing buildings, where more than two exits, exit accesses, or exit discharges are required, at least two of the required exits, exit accesses, or exit discharges shall be arranged to comply with the minimum separation distance requirement. [***101:***7.5.1.3.6]

14.10.1.3.7 The balance of the exits, exit accesses, or exit discharges specified in 14.10.1.3.6 shall be located so that, if one becomes blocked, the others are available. [***101:***7.5.1.3.7]

Since 1988, NFPA *101* has contained a remoteness formula referred to as the "one-half diagonal rule." This basic rule is stated in 14.10.1.3.2. Figure A.14.10.1.3.2(a) through Figure A.14.10.1.3.2(e) detail the application of the rule. The *Code* uses the one-half diagonal rule to quantify remoteness and to make certain that exit accesses, exits, and exit discharges are

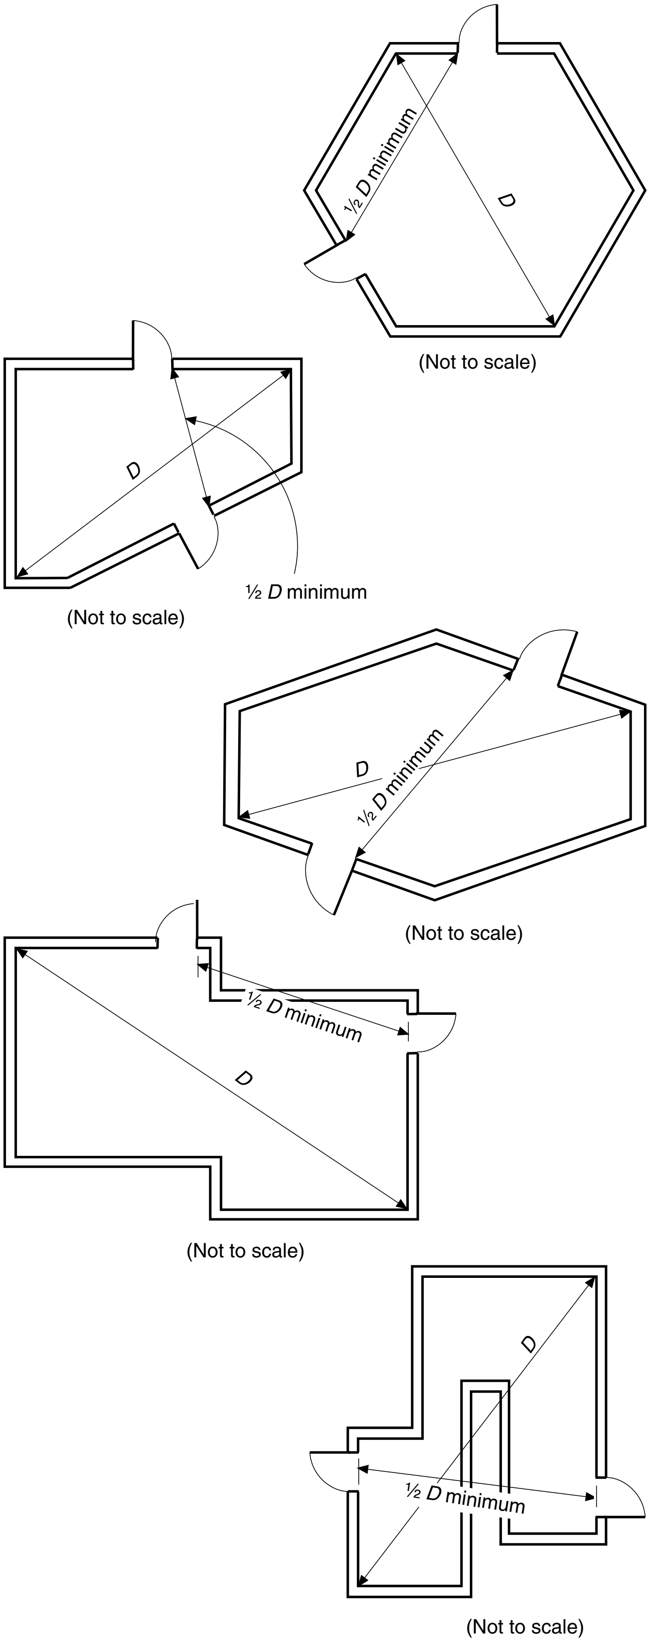

***FIGURE A.14.10.1.3.2(e)** Diagonal Measurement for Unusually Shaped Areas. [**101:**Figure A.7.5.1.3.2(e)]*

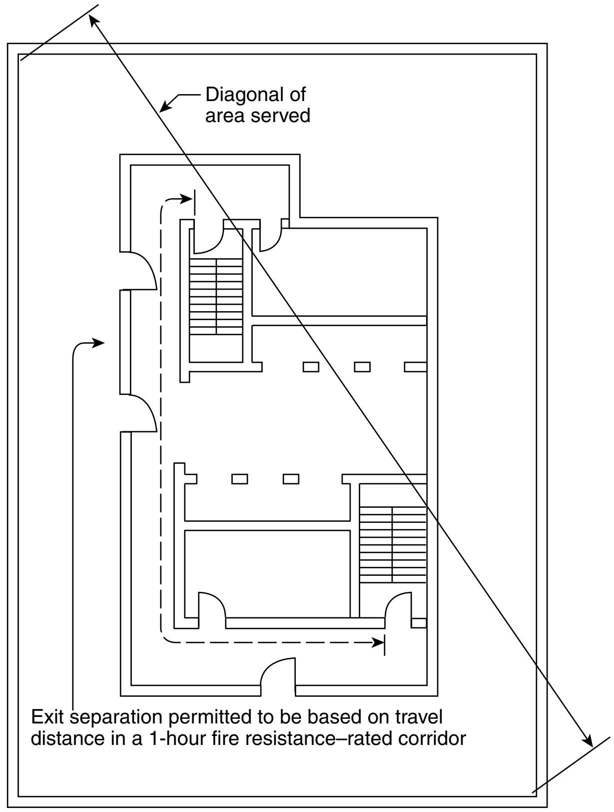

***FIGURE A.14.10.1.3.4** Exit Separation Measured Along Corridor Path. [**101:**A.7.5.1.3.4]*

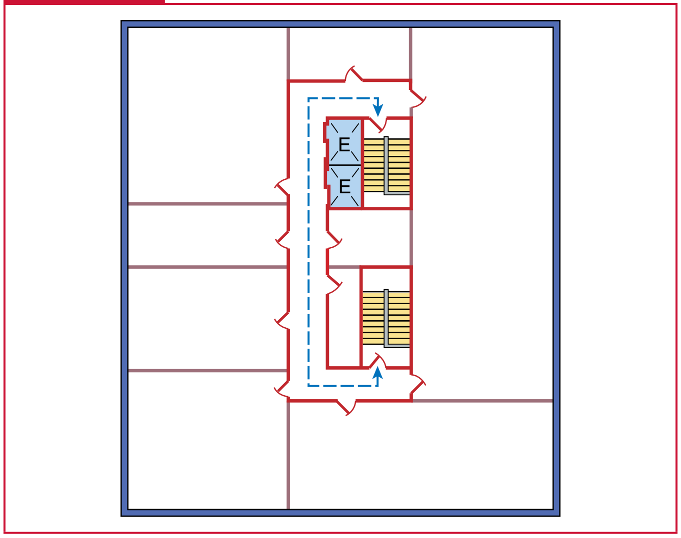
sufficiently remote to ensure, with reasonable certainty, that the same fire will not obstruct multiple egress routes. The exit separation is permitted by 14.10.1.3.3 to be reduced to one-third the maximum overall diagonal measurement in fully sprinklered buildings, because the sprinkler system is expected to control the fire so that the use of multiple egress paths will not be lost.

Although existing buildings are exempted by the provision of 14.10.1.3.5 from the diagonal rule of 14.10.1.3.2 and 14.10.1.3.3, they must meet the remoteness requirement via the performance requirement of 14.10.1.3.1. Therefore, in existing buildings, remoteness is not required to be judged via the diagonal rule; it must be met via the provision of 14.10.1.3.1.

Exhibit 14.50 illustrates the provision of 14.10.1.3.4, which permits — for other than high-rise buildings — the distance between exit enclosures to be measured along a minimum 1-hour fire resistance–rated corridor with appropriate fire protection–rated door assemblies. Although the exit enclosures are physically closer to each other than the dimension measured along the corridor, the exits will behave, under fire conditions, as if they were the corridor length apart.

14.10.1.4 Interlocking or scissor stairs shall comply with 14.10.1.4.1 and 14.10.1.4.2. [***101:***7.5.1.4]

Exhibit 14.50



Exit remoteness measured along 1-hour-rated corridor.

14.10.1.4.1 New interlocking or scissor stairs shall be permitted to be considered only as a single exit. [***101:***7.5.1.4.1]

Δ **14.10.1.4.2*** Existing interlocking or scissor stairs shall be permitted to be considered separate exits, provided that they meet all of the following criteria:

(1) They are enclosed in accordance with Section 14.3.
(2) They are separated from each other by 2-hour fire resistance–rated noncombustible construction.
(3) No protected or unprotected penetrations or communicating openings exist between the stair enclosures.

[***101:***7.5.1.4.2]

A.14.10.1.4.2 It is difficult in actual practice to construct scissor stairs so that products of combustion that have entered one stairway do not penetrate into the other. Their use as separate required exits is discouraged. The term *limited-combustible* is intentionally not included in 14.10.1.4.2. The user's attention is directed to the provisions for noncombustible and limited-combustible in 4.5.9 and 4.5.10, respectively. [***101:***A.7.5.1.4.2]

New scissors stairs are restricted by 14.10.1.4.1 to serving only as a single exit, because it is nearly impossible to ensure that the fire-rated and smoke-resisting separations provided between the two entwined stairs are complete and will stay complete over the life of the building. For example, standpipes are run vertically through the scissor stairs so as to create openings that connect the two stair enclosures.

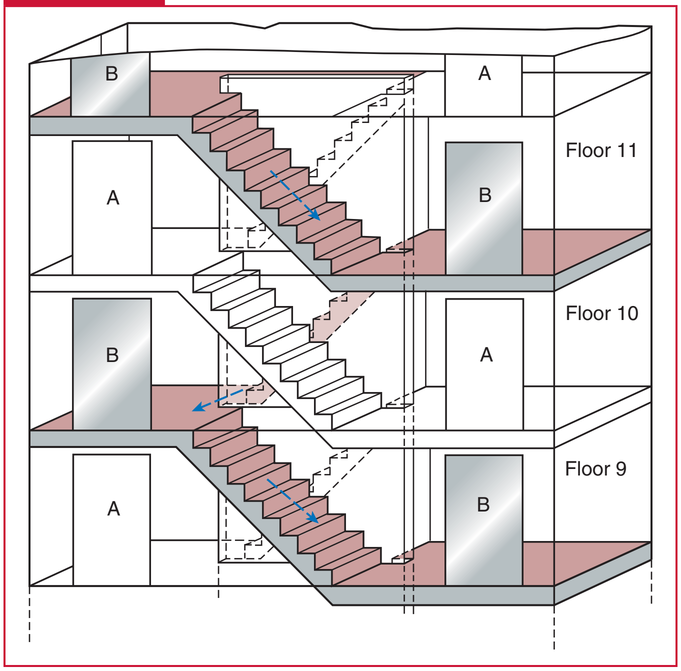
For existing installations, scissors stairs are regulated by 14.10.1.4.2 to ensure that they will perform similarly to two more widely separated exit stairs under fire conditions.

Item (2) of 14.10.1.4.2 requires existing scissors stairs to have noncombustible, 2-hour fire resistance–rated separating construction. Some form of masonry or poured concrete wall, landing, or stair run is normally used to meet the definition of the term *noncombustible (material)* (see 4.5.9). Although scissors stairs can be located with their entrances remotely located from one another and their discharges also remotely placed, the remoteness requirements are applicable to scissors stairs only if they are to be considered as separate exits. Where not sufficiently separated or not remote from each other — or in new construction — scissors stairs cannot be used as separate exits but can be considered as a single exit, with their combined egress width providing increased capacity over that of a single stair. These points are illustrated in Exhibit 14.51 and Exhibit 14.52.

In Exhibit 14.51, the two existing entwined stairways sharing the same enclosing walls are scissors stairs. To be considered separate exits, the existing stairs must be completely separated from each other. In effect, each stair enclosure must consist of a fire resistance–rated tube entwined around the other stair in a form similar to a helix. This arrangement results in space and cost savings by permitting the stairs to share the common enclosing walls that separate them from the remainder of the building. With this arrangement, two independent escape paths are created, similar to those provided by two independent stair enclosures positioned at a distance from one another. The continuity of all walls provides a complete separation at all points. The arrows designate the direction of egress travel in stair B.

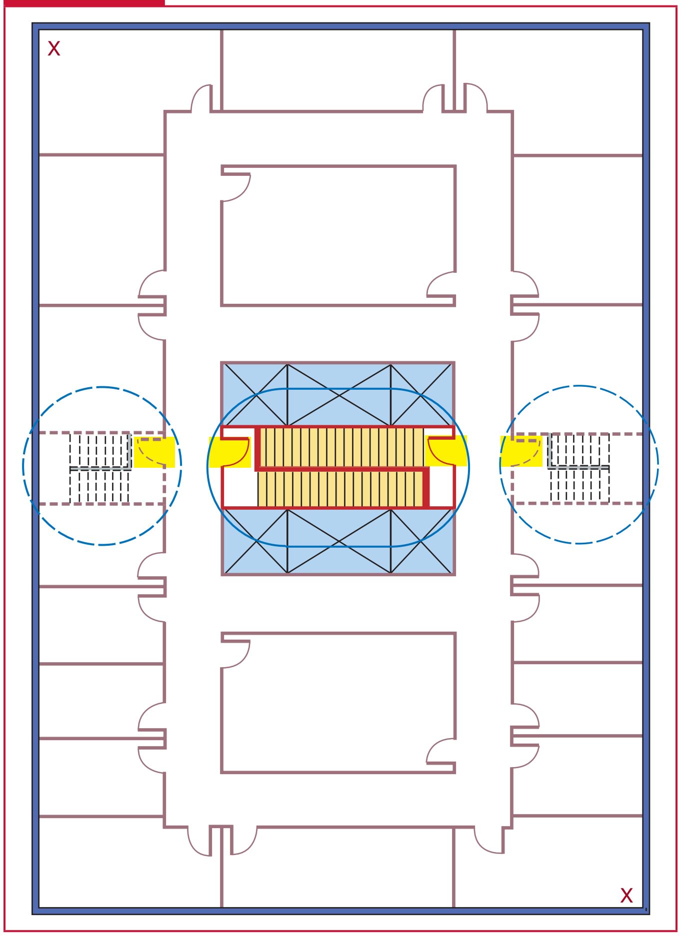
Exhibit 14.52 illustrates some of the advantages of scissors stairs versus conventional exit stairs. The two stairs, positioned at the center of the exhibit and highlighted by placement within the oval, are entwined to create a set of scissors stairs. They provide the same degree of remoteness as the separate and

Exhibit 14.51



Scissors stairs.

Exhibit 14.52



Scissors stairs contrasted with conventional exit stairs.

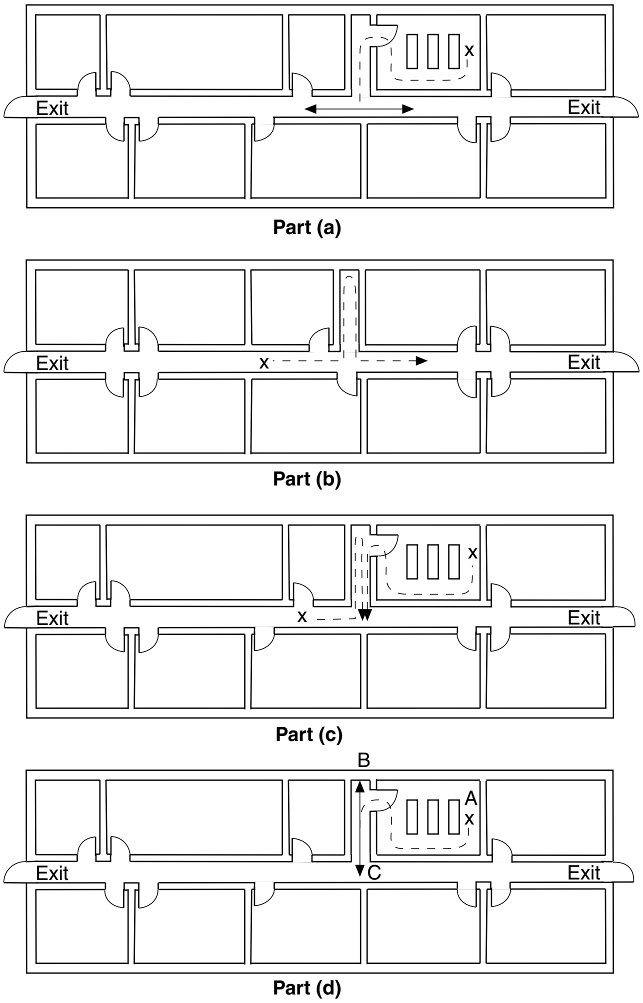


FIGURE A.14.10.1.5 *Common Paths of Travel and Dead-End Corridors. [**101:**Figure A.7.5.1.5]*

independent stairs shown by the dashed lines at the sides of the exhibit and encircled. Travel distance to either the scissors stairs or the independent stairs is equal, even if the independent exit stairs were to be relocated at the opposite corners (X) of the floor.

14.10.1.5* Exit access shall be arranged so that there are no dead ends in corridors, unless permitted by, and limited to the lengths specified in, Chapters 11 through 43 of NFPA *101*. [***101:***7.5.1.5]

A.14.10.1.5 The terms *dead end* and *common path of travel* are commonly used interchangeably. Although the concepts of each are similar in practice, they are two different concepts. [***101:***A.7.5.1.5]

A common path of travel exists where a space is arranged so that occupants within that space are able to travel in only one direction to reach any of the exits or to reach the point at which the occupants have the choice of two paths of travel to remote exits. Part (a) of Figure A.14.10.1.5 is an example of a common path of travel. [***101:***A.7.5.1.5]

While a dead end is similar to a common path of travel, a dead end can exist where there is no path of travel from an occupied space but can also exist where an occupant enters a corridor thinking there is an exit at the end and, finding none, is forced to retrace his or her path to reach a choice of exits. Part (b) of Figure A.14.10.1.5 is an example of such a dead-end arrangement. [***101:***A.7.5.1.5]

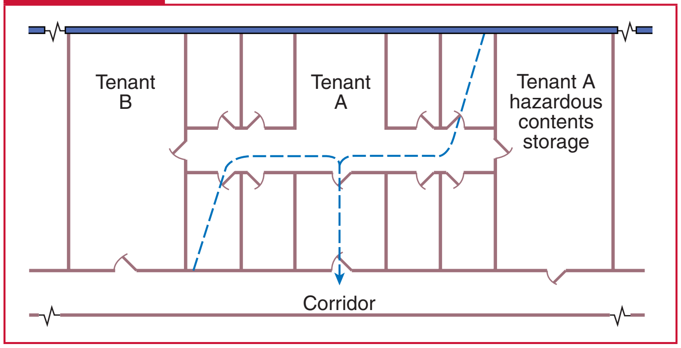
Combining the two concepts, Part (c) of Figure A.14.10.1.5 is an example of a combined dead-end/common path of travel problem. [***101:***A.7.5.1.5]

Common paths of travel and dead-end travel are measured using the same principles used to measure travel distance as described in Section 7.6 of NFPA *101*. Starting in the room shown in Part (d) of Figure A.14.10.1.5, measurement is made from the most remote point in the room, A, along the natural path of travel, and through the doorway along the centerline of the corridor to point C, located at the centerline of the corridor, which then provides the choice of two different paths to remote exits; this is common path of travel. The space between point B and point C is a dead end. *(See 3.3.66 for the definition of common path of travel.)* [***101:***A.7.5.1.5]

14.10.1.6 Exit access from rooms or spaces shall be permitted to be through adjoining or intervening rooms or areas, provided that such rooms or areas are accessory to the area served. Foyers, lobbies, and reception rooms constructed as required for corridors shall not be construed as intervening rooms. Exit access shall be arranged so that it is not necessary to pass through any area identified under Protection from Hazards in Chapters 11 through 43 of NFPA *101*. [***101:***7.5.1.6]

Paragraph 14.10.1.6 permits exit access travel through adjoining spaces if such spaces are accessory to the area served and such travel is not through any area identified under protection from hazards in an occupancy chapter of NFPA *101* (generally subsection __.3.2). Exhibit 14.53 illustrates exit access travel through intervening spaces that are under the control of the tenant and are not hazardous. Even though the hazardous contents storage room is under the control of the occupants of tenant space A, the hazard makes passage through the room unsafe. Passage from tenant space A into tenant space B is not permitted, because there is no assurance that the door assembly into tenant space B will be left unlocked, unblocked, and usable to occupants of tenant space A.

Exhibit 14.53



Exit access through adjoining rooms.

14.10.2 Impediments to Egress. See also 7.1.9 of NFPA *101*, and 14.5.2. [***101:***7.5.2]

14.10.2.1* Access to an exit shall not be through kitchens, storerooms other than as provided in Chapters 36 and 37 of NFPA *101*, restrooms, closets, bedrooms or similar spaces, or other rooms or spaces subject to locking, unless passage through such rooms or spaces is permitted for the occupancy by Chapters 18, 19, 22, or 23 of NFPA *101*. [***101:***7.5.2.1]

A.14.10.2.1 It is not the intent that an area with equipment such as a beverage brewpot, microwave oven, and a toaster be considered a kitchen. [***101:***A.7.5.2.1]

Paragraph 14.10.2.1, in combination with 14.10.1.6, prevents exit access from passing through certain rooms either due to increased relative hazard or potential blockage or locking. The text of A.14.10.2.1 clarifies that the presence of beverage brewpots, microwave ovens, and toasters, commonly found in employee break areas that often are located in spaces not separated from the remainder of an open floor plan, do not cause such spaces to be classified as kitchens through which 14.10.1.6 and 14.10.2.1 restrict exit access.

14.10.2.2* Exit access and exit doors shall be designed and arranged to be clearly recognizable. [***101:***7.5.2.2]

A.14.10.2.2 Doors that lead through wall paneling, and that harmonize in appearance with the rest of the wall to avoid detracting from some desired aesthetic or decorative effect, are not acceptable, because casual occupants might not be aware of such means of egress even though it is visible. [***101:***A.7.5.2.2]

14.10.2.2.1 Hangings or draperies shall not be placed over exit doors or located so that they conceal or obscure any exit, unless otherwise provided in 14.10.2.2.2. [***101:***7.5.2.2.1]

Δ **14.10.2.2.2** Curtains shall be permitted across means of egress openings in tent walls, provided that all of the following criteria are met:

(1) They are distinctly marked in contrast to the tent wall so as to be recognizable as means of egress.
(2) They are installed across an opening that is at least 6 ft (1830 mm) in width.
(3) They are hung from slide rings or equivalent hardware so as to be readily moved to the side to create an unobstructed opening in the tent wall that is of the minimum width required for door openings.

[***101:***7.5.2.2.2]

See the commentary following A.14.4.1 for more information on maintaining means of egress free of obstructions or impediments.

14.10.3 Exterior Ways of Exit Access.

The provisions of 14.10.3 apply to exit access in the typical motel arrangement where exit access from the guest rooms is provided by door openings to an open-air exit access balcony to an open stair. This arrangement is also common in apartment buildings and office buildings in warm climates. An understanding of these provisions is important, because many of the exemptions from the mandatory sprinkler requirements for the various residential occupancies conditionally apply where exterior exit access is provided.

14.10.3.1 Exit access shall be permitted to be by means of any exterior balcony, porch, gallery, or roof that conforms to the requirements of this chapter and Chapter 7 of NFPA *101*. [***101:***7.5.3.1]

14.10.3.2 The long side of the balcony, porch, gallery, or similar space shall be at least 50 percent open and shall be arranged to restrict the accumulation of smoke. [***101:***7.5.3.2]

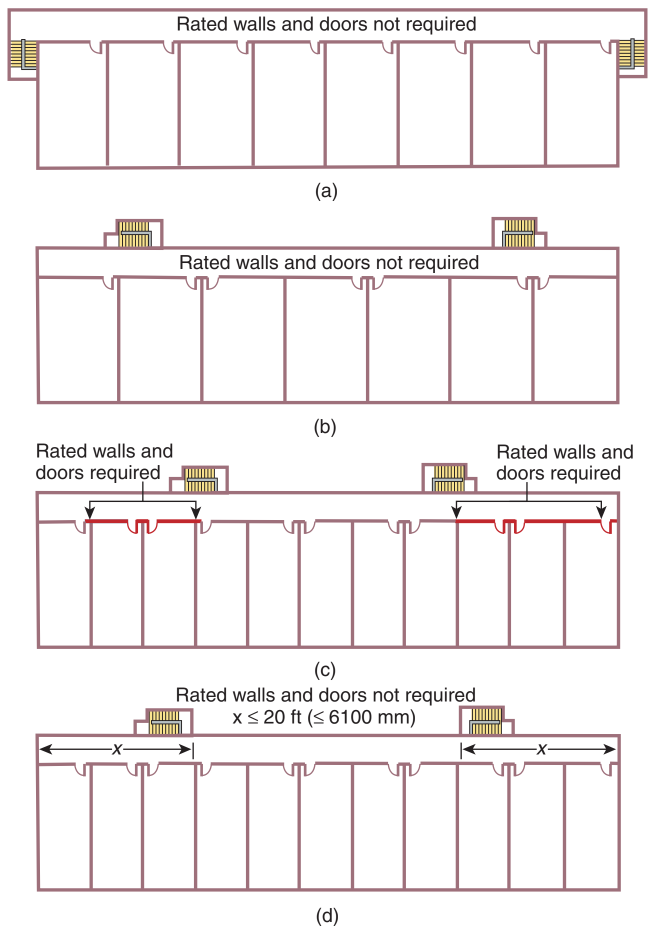
Exterior ways of exit access need significant openings to the exterior so as not to become smoke-logged and unusable. Paragraph 14.10.3.2 establishes that at least 50 percent of the long side of the balcony, porch, gallery, or similar space is required to be open.

14.10.3.3 Exterior exit access balconies shall be separated from the interior of the building by walls and opening protectives as required for corridors, unless the exterior exit access balcony is served by at least two remote stairs that can be accessed without any occupant traveling past an unprotected opening to reach one of the stairs, or unless dead ends on the exterior exit access do not exceed 20 ft (6100 mm). [***101:***7.5.3.3]

Paragraph 14.10.3.3 requires the exterior exit access to be protected by separating construction from the interior of the building via the same rules that are applicable to corridors. However, this requirement does not apply to exit access served by at least two remote stairs, as detailed. Such an arrangement is used more often than the rated construction required by 14.10.3.3. To use this arrangement, access must be possible to both required remote stairs, one of which must be reachable without traveling past an unprotected opening.

Exhibit 14.54 illustrates four arrangements permitted by 14.10.3.3. In part (a) and part (b), it is possible for occupants of all rooms to reach one of the stairs without having to travel past any opening from which fire might issue; thus, fire-rated walls and door assemblies are not required. In part (c), the occupants of rooms at the ends of the building must travel past other rooms to reach a stair; thus, fire resistance–rated walls and fire protection–rated opening protectives, such as windows and door assemblies, are required in the areas indicated.

Exhibit 14.54



Exterior ways of exit access.

In part (d), the alternative of 14.10.3.3, related to limiting the length of the exit access balcony dead end, is used to exempt the fire-rated wall construction and fire-rated opening protectives along the exterior exit access path. Provided that the exit access balcony dead end, denoted by the distance *X*, does not exceed 20 ft (6100 mm), the occupant using the exterior exit access will not be exposed to an excessive number of unprotected openings.

14.10.3.4 Exterior exit access shall be arranged so that there are no dead ends in excess of those permitted for dead-end corridors in Chapters 11 through 43 of NFPA *101*. [***101:***7.5.3.4]

Because 14.10.3.3 permits unrated construction along a maximum 20 ft (6100 mm) dead-end exterior exit access path, it seems logical to recognize longer dead ends, as permitted by some of the occupancy chapters, where the exterior exit access path is protected by rated walls and rated opening protectives.

14.10.4 Accessible Means of Egress.

14.10.4.1* Areas accessible to people with severe mobility impairment, other than in existing buildings, shall have not less than two accessible means of egress, unless otherwise provided in 14.10.4.1.2 through 14.10.4.1.4. [***101:***7.5.4.1]

Δ **A.14.10.4.1** An accessible means of egress should comply with the accessible route requirements of ICC/ANSI A117.1, *Accessible and Usable Buildings and Facilities.* [***101:***A.7.5.4.1]

14.10.4.1.1 Access within the allowable travel distance shall be provided to not less than one accessible area of refuge or one accessible exit providing an accessible route to an exit discharge. [***101:***7.5.4.1.1]

14.10.4.1.2 A single accessible means of egress shall be permitted from buildings or areas of buildings permitted to have a single exit. [***101:***7.5.4.1.2]

14.10.4.1.3 Accessible means of egress shall not be required in health care occupancies protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***7.5.4.1.3]

14.10.4.1.4 Exit access travel along the accessible means of egress shall be permitted to be common for the distances permitted as common paths of travel. [***101:***7.5.4.1.4]

Paragraph 14.10.4.1 requires that, in other than existing buildings, accessible means of egress is to be provided for all areas accessible to persons with severe mobility impairment. The term *accessible means of egress* is defined in 3.3.178.1 of NFPA *101* as "a means of egress that provides an accessible route to an area of refuge, a horizontal exit, or a public way." The term *severe mobility impairment* is defined in 3.3.256 of NFPA *101* as "the ability to move to stairs but without the ability to use the stairs."

For a single-story building with typical exit door assemblies to the exterior at finished ground level (grade), the requirement for accessible means of egress is normally met without having to provide any additional features. For a multistory building involving vertical travel to ground, the requirement for accessible means of egress from the upper floors might be met by providing ramps. Because ramp systems use considerable space, the requirement for accessible means of egress from the upper floors will most often be met by providing areas of refuge meeting the requirements of 7.2.12 of NFPA *101*.

Exhibit 14.55 illustrates arrangements providing accessible means of egress. In part (a) and part (b), accessible means of egress are provided via finished ground level door assemblies or ramps from the second story.

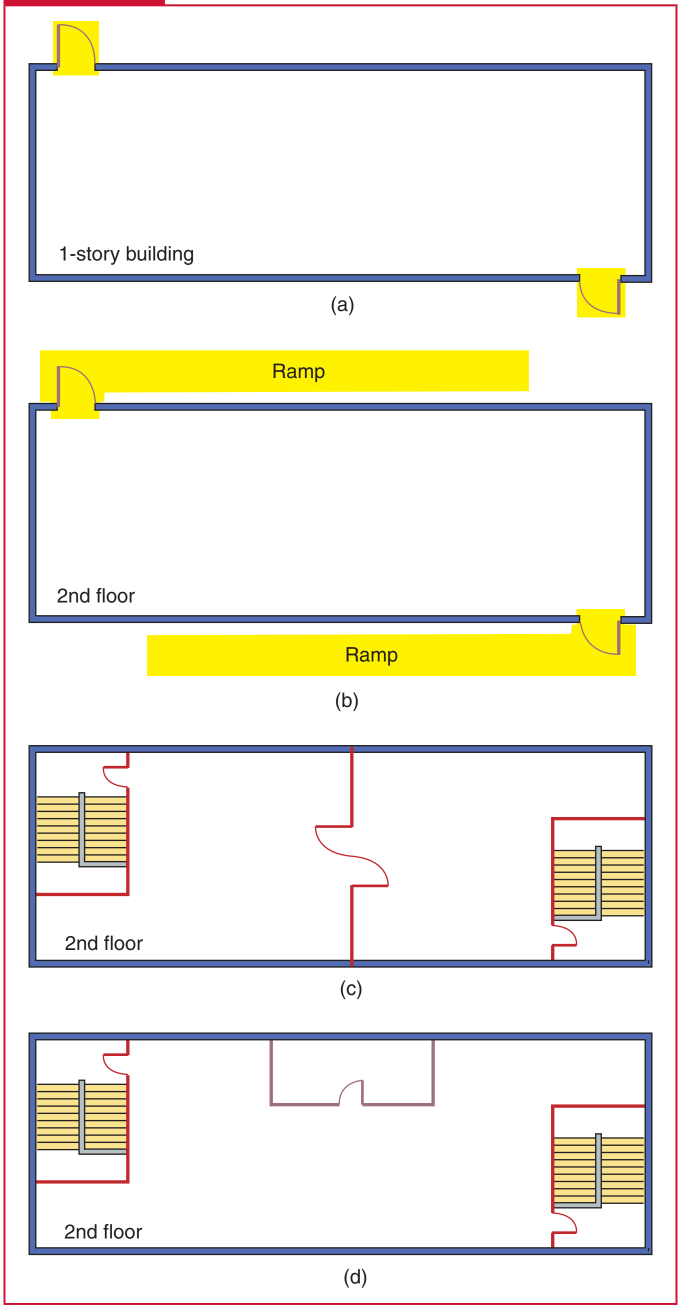
In part (c), areas of refuge with rated barrier and extra-width stairs in accordance with 7.2.12 of NFPA *101* provide accessible means of egress. In part (d), the floor of a fully sprinklered building with a second accessible room on the floor creates an *area of refuge,* as defined in 3.3.23 of NFPA *101,* which provides, via the two stairs and the help of emergency responders, two accessible means of egress paths.

The *Code* does not require areas of refuge; it requires accessible means of egress. The easiest way to meet the requirements for accessible means of egress in multistory buildings is by providing areas of refuge.

Paragraph 14.10.4.1 clarifies that the requirement for accessible means of egress is not retroactively required in existing buildings, unless specifically required by the applicable occupancy chapter.

Paragraph 14.10.4.1.4 does not permit a single accessible means of egress; rather, it permits that, where two accessible means of egress are required, travel is permitted to be along a single accessible path that is not longer than the distance permitted as a common path of travel before travel along two separate accessible paths must become available.

Exhibit 14.55



Accessible means of egress.

14.10.4.2 Where two accessible means of egress are required, the exits serving such means of egress shall be located at a distance from one another not less than one-half the length of the maximum overall diagonal dimension of the building or area to be served. This distance shall be measured in a straight line between the nearest edge of the exit doors or exit access doors, unless otherwise provided in 14.10.4.2.1 through 14.10.4.2.3. [***101:***7.5.4.2]

See A.14.10.1.3.2.

14.10.4.2.1 Where exit enclosures are provided as the required exits specified in 14.10.4.2 and are interconnected by not less than a 1-hour fire resistance–rated corridor, exit separation shall be permitted to be measured along the line of travel within the corridor. [***101:***7.5.4.2.1]

14.10.4.2.2 The requirement of 14.10.4.2 shall not apply to buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***7.5.4.2.2]

14.10.4.2.3 The requirement of 14.10.4.2 shall not apply where the physical arrangement of means of egress prevents the possibility that access to both accessible means of egress will be blocked by any one fire or other emergency condition as approved by the AHJ. [***101:***7.5.4.2.3]

14.10.4.3 Each required accessible means of egress shall be continuous from each accessible occupied area to a public way or area of refuge in accordance with 7.2.12.2.2 of NFPA *101*. [***101:***7.5.4.3]

14.10.4.4 Where an exit stair is used in an accessible means of egress, it shall comply with 7.2.12 of NFPA *101* and either shall incorporate an area of refuge within an enlarged story-level landing or shall be accessed from an area of refuge. [***101:***7.5.4.4]

14.10.4.5 To be considered part of an accessible means of egress, an elevator shall be in accordance with 7.2.12.2.4 of NFPA *101*. [***101:***7.5.4.5]

14.10.4.6 To be considered part of an accessible means of egress, a smoke barrier in accordance with Section 12.9 with not less than a 1-hour fire resistance rating, or a horizontal exit in accordance with 7.2.4 of NFPA *101*, shall discharge to an area of refuge in accordance with 7.2.12 of NFPA *101*. [***101:***7.5.4.6]

14.10.4.7 Accessible stories that are four or more stories above or below a story of exit discharge shall have not less than one elevator complying with 14.10.4.5, except as modified in 14.10.4.8. [***101:***7.5.4.7]

14.10.4.8 Where elevators are required by 14.10.4.7, the smokeproof enclosure required by 7.2.12.2.4 of NFPA *101* shall not be required in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13. [***101:***7.5.4.8]

14.10.4.9 An area of refuge used as part of a required accessible means of egress shall be in accordance with 7.2.12 of NFPA *101*. [***101:***7.5.4.9]

Where it might be necessary to carry persons and their wheelchairs on stairs for four or more stories to the ground level, the provision of 14.10.4.7 requires at least one elevator complying with 14.10.4.5, which imposes special elevator features and protection in accordance with 7.2.12.2.4 of NFPA *101*. However, if automatic sprinklers protect the building throughout, the elevator shaft system is exempted by 14.10.4.8 from the smokeproof enclosure requirement of 7.2.12.2.4(3) of NFPA *101*. This is consistent with the premise that sprinklers control fires so as to limit smoke production.

Paragraph 14.10.4.9 completes the package by requiring areas of refuge used as part of accessible means of egress to follow the detailed criteria for areas of refuge presented in 7.2.12 of NFPA *101*.

14.11 Discharge from Exits

14.11.1* Exit Termination. Exits shall terminate directly, at a public way or at an exterior exit discharge, unless otherwise provided in 14.11.1.2 through 14.11.1.4. [***101:***7.7.1]

A.14.11.1 An exit from the upper stories in which the direction of egress travel is generally downward should not be arranged so that it is necessary to change to travel in an upward direction at any point before discharging to the outside. A similar prohibition of reversal of the vertical component of travel should be applied to exits from stories below the floor of exit discharge. However, an exception is permitted in the case of stairs used in connection with overhead or underfloor exit passageways that serve the street floor only. [***101:***A.7.7.1]

It is important that ample roadways be available from buildings in which there are large numbers of occupants so that exits will not be blocked by persons already outside. Two or more avenues of departure should be available for all but very small places. Location of a larger theater — for example, on a narrow dead-end street — might be prohibited by the AHJ under this rule, unless some alternate way of travel to another street is available. [***101:***A.7.7.1]

Exterior walking surfaces within the exit discharge are not required to be paved and often are provided by grass or similar surfaces. Where discharging exits into yards, across lawns, or onto similar surfaces, in addition to providing the required width to allow all occupants safe access to a public way, such access also is required to meet the following:

(1) Provisions of 7.1.7 of NFPA *101* with respect to changes in elevation
(2) Provisions of 7.2.2 of NFPA *101* for stairs, as applicable
(3) Provisions of 7.2.5 of NFPA *101* for ramps, as applicable
(4) Provisions of 7.1.10 of NFPA *101* with respect to maintaining the means of egress free of obstructions that would prevent its use, such as snow and the need for its removal in some climates

[***101:***A.7.7.1]

14.11.1.1 Yards, courts, open spaces, or other portions of the exit discharge shall be of the required width and size to provide all occupants with a safe access to a public way. [***101:***7.7.1.1]

14.11.1.2 The requirement of 14.11.1 shall not apply to interior exit discharge as otherwise provided in 14.11.2. [***101:***7.7.1.2]

14.11.1.3 The requirement of 14.11.1 shall not apply to rooftop exit discharge as otherwise provided in 14.11.6. [***101:***7.7.1.3]

14.11.1.4 Means of egress shall be permitted to terminate in an exterior area of refuge for detention and correctional occupancies as otherwise provided in Chapters 22 and 23 of NFPA *101*. [***101:***7.7.1.4]

The principle addressed in 14.11.1 is that, once a building occupant reaches an exit (the protected portion of the means of egress), the level of protection afforded by that exit cannot be reduced or eliminated. Therefore, except as noted, all exits must be continuous to a public way or other safe place or to an exit discharge that must, in turn, be continuous to the public way.

It is not sufficient to allow the egress system to terminate at the outside of a building, because there might not be enough space to provide safe movement away from the building. Also, the terminus of the egress system cannot be located at the outside in an enclosed court from which travel back through the building might be necessary to get away from the building. In such a case, an exit passageway at least as wide as the exit itself and constructed as specified for exits is required to provide travel from the enclosed court to the safe place.

14.11.2 Exit Discharge Through Interior Building Areas. Exits shall be permitted to discharge through interior building areas, provided that all of the following are met:

(1) Not more than 50 percent of the required number of exit stairs serving normally occupied areas of each floor, and not more

than 50 percent of the exit stair capacity required for normally occupied areas of each floor, shall discharge through areas on any level of discharge, except as otherwise permitted by one of the following:

(a) One hundred percent of the exits shall be permitted to discharge through areas on any level of discharge in detention and correctional occupancies as otherwise provided in Chapters 22 and 23 of NFPA *101*.

(b) In existing buildings, the 50 percent limit on egress capacity shall not apply if the 50 percent limit on the required number of exits is met.

(2) Each level of discharge shall discharge directly outside at the finished ground level or discharge directly outside and provide access to the finished ground level by outside stairs or outside ramps.

(3) The interior exit discharge shall lead to a free and unobstructed way to the exterior of the building, and such way shall be readily apparent or shall be identifiable by exit signage from the point of discharge from the exit.

(4) The interior exit discharge shall be protected by one of the following methods:

(a) The level of discharge shall be protected throughout by an approved automatic sprinkler system in accordance with Section 13.3, or the portion of the level of discharge used for interior exit discharge shall be protected by an approved automatic sprinkler system in accordance with Section 13.3 and shall be separated from the nonsprinklered portion of the floor by fire barriers with a fire resistance rating meeting the requirements for the enclosure of exits. *(See 14.3.1.)*

(b) The interior exit discharge area shall be in a vestibule or foyer that meets all of the following criteria:

i. The depth from the exterior of the building shall be not more than 10 ft (3050 mm), and the length shall be not more than 30 ft (9.1 m).

ii. The foyer shall be separated from the remainder of the level of discharge by fire barriers with a minimum 1-hour fire resistance rating, and existing installations of wired glass in steel frames shall be permitted to be continued in use.

iii. The foyer shall serve only as means of egress and shall include an exit directly to the outside.

(5) The entire area on the level of discharge shall be separated from areas below by construction having a fire resistance rating not less than that required for the exit enclosure, unless otherwise provided in 14.11.2(6).

(6) Levels below the level of discharge in an atrium shall be permitted to be open to the level of discharge where such level of discharge is protected in accordance with 8.6.7 of NFPA *101*.

[***101:***7.7.2]

The provision of 14.11.2(3) was revised for the 2018 edition of NFPA *101* to clarify that the door in the exterior wall through which interior exit discharge flows, so as to become exterior exit discharge, need not be visible from the point where an occupant leaves the enclosed exit stair. Instead, the direction of travel must be apparent or identified by exit signage. Thus, the old myth that occupants must be able to see the door to the outside dies. The provisions of 14.11.2 were revised for the 2012 edition of the *Code* to permit exit discharge through the interior building area of any floor providing discharge from the building, not just the level of exit discharge.

The provisions of 14.11.2 permit a portion of the exit discharge from exit stairs to pass through interior building areas rather than discharge directly to the outside. Compliance with the criteria of 14.11.2 provides users of an exit stair enclosure that discharges through interior building areas with approximately the same level of protection offered to users of exit enclosures that discharge directly to the outside.

Among the questions most often asked regarding the *Code* are those that concern the requirements of 14.11.2(4)(a) related to providing sprinkler protection on the level of discharge (i.e., the story on which the interior exit discharge occurs). The intent of 14.11.2(4)(a) is to require sprinkler protection in the portion of the level of discharge that is used as interior exit discharge and to provide that portion of the level of discharge with fire-rated separation from all other portions of the level of discharge that are not sprinklered. The requirement of 14.11.2(4)(a) can be met by either of the following means:

1. Protecting the entire level of discharge with automatic sprinklers and separating the level of discharge from any floor below by fire-rated construction with the minimum fire rating required for the exit that discharges occupants though the level of discharge [see 14.3.1(1) and (3)]
2. Providing automatic sprinkler protection in only that portion of the level of discharge used for interior exit discharge travel from the exit stair enclosure door opening to the door opening to the outside; separating the sprinklered portion of the level of discharge from the rest of the level of discharge by construction as required for the exit that discharges occupants though the level of discharge [again, see 14.3.1(1) and (3)]; and separating the level of discharge from any floor below by fire-rated construction with the minimum fire rating required for the exit that discharges occupants though the level of discharge

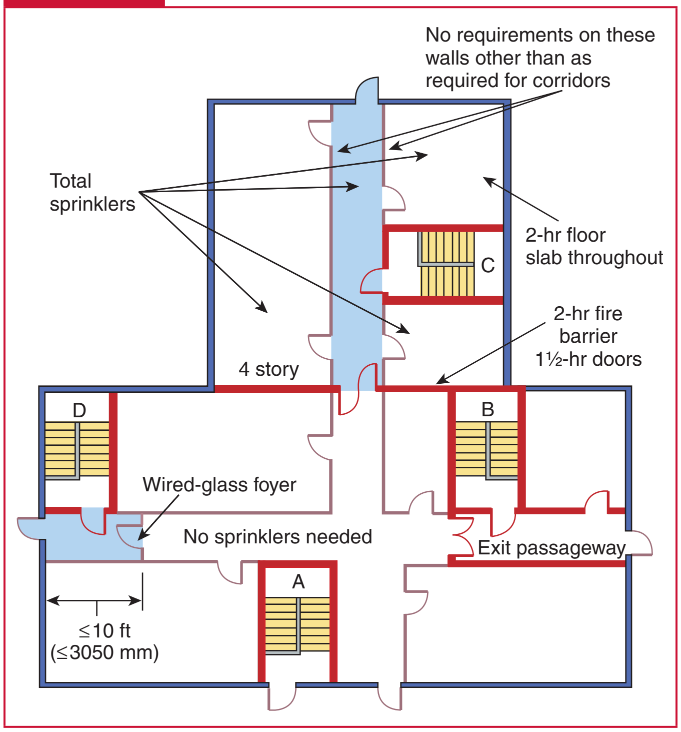
An exemption to the sprinkler requirement of 14.11.2(4)(a) is offered by 14.11.2(4)(b) and involves providing a maximum 10 ft × 30 ft (3050 mm × 9.1 m) wired-glass foyer, which can be used only for egress and, thus, has no occupancy of its own.

Use of the 50 percent rule of 14.11.2 for discharge through the level of discharge is not dependent on occupancy permission; thus, it can be used in all occupancies. However, detention and correctional occupancies (see 22.2.7.3 and 23.2.7.3 and 22.2.7.4 and 23.2.7.4 of NFPA *101*) permit 100 percent of the exits and 100 percent of the egress capacity to discharge through the level of discharge. Hotels and dormitories establish additional requirements limiting the distance occupants are permitted to travel within their interior exit discharge through the level of discharge to the opening to the outside (see 28.2.7.3 and 29.2.7.3 of NFPA *101*).

Exhibit 14.56 illustrates exit discharge arrangements meeting the requirements of 14.11.2. The equally sized stairs provide four required exits from the upper floors. Exit stair A discharges directly outside. Exit stair B is also considered to discharge directly outside, because its attached exit passageway affords protected passage to the door opening to the outside without leaving the protection offered by an exit. The other two exit stairs, C and D, are permitted to discharge across the first floor (the level of discharge), because they do not constitute more than 50 percent of the number of exits from an upper floor or more than 50 percent of the egress capacity of any upper floor. Exit stair C discharges into an area on the discharge level that is sprinklered and separated from the remainder of the floor and the basement, which are not sprinklered. The hourly fire resistance rating of the floor slab and the separating fire barrier are the same as required for the enclosure of exit stair C [e.g., a 2-hour rating if the stair is new and serves four or more stories in accordance with 14.3.1(3)]. Exit stair D discharges into a wired-glass foyer in the nonsprinklered portion of the floor in accordance with 14.11.2(4)(b).

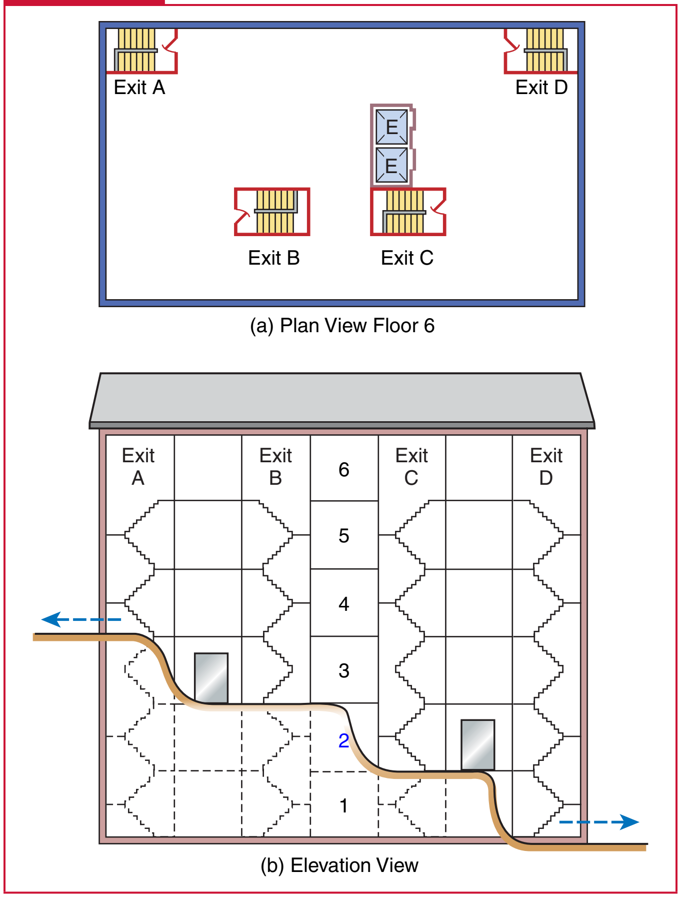
Exhibit 14.57 illustrates interior exit discharge on two floors. Four exits — all by exit stair enclosures — serve all six stories. In part (a), exits A and D are located at exterior building walls, and exits B and C are located away from exterior building walls. In part (b), exits A and D comprise 50 percent of the number of exits, provide 50 percent of the egress capacity for each floor,

Exhibit 14.56



Exit discharge.

Exhibit 14.57



Interior exit discharge on two stories.

and discharge directly to the outside — exit A at story 4 and exit D at story 1. Exits B and C comprise 50 percent of the number of exits, provide 50 percent of the egress capacity for each floor, and discharge to interior areas — exit B onto story 3 and exit C onto story 2. Not more than 50 percent of the exits — both from a number of exits standpoint and from a capacity of exits standpoint — discharge through interior building areas. Such interior exit discharge occurs on two floors, since the *Code* does not restrict interior exit discharge to the level of exit discharge.

14.11.3 Arrangement and Marking of Exit Discharge.

14.11.3.1 Where more than one exit discharge is required, exit discharges shall be arranged to meet the remoteness criteria of 14.10.1.3. [***101:***7.7.3.1]

14.11.3.2 The exit discharge shall be arranged and marked to make clear the direction of egress travel from the exit discharge to a public way. [***101:***7.7.3.2]

14.11.3.3* Stairs and ramps that continue more than one-half story below the level of discharge shall be provided with an approved means to prevent or dissuade occupants from traveling past the level of discharge during emergency building evacuation. [***101:***7.7.3.3]

A.14.11.3.3 Examples include partitions and gates. The design should not obstruct the normal movement of occupants to the exit discharge. Signs, graphics, or pictograms, including tactile types, might be permitted for existing exit enclosures where partitions or gates would obstruct the normal movement of occupants to the exit discharge. [***101:***A.7.7.3.4]

The provision of 14.11.3.1 serves as a reminder that exit discharges, like exits and exit accesses, are required to be remote as addressed in 14.10.1.3.

The provision of 14.11.3.3 was revised for the 2012 edition of the *Code*. Earlier editions required the stair interruption to be provided by partitions, doors, or other effective means. The current language is performance-based and requires an approved means to dissuade occupants from traveling past the level of discharge during building emergency evacuation.

Exhibit 14.58 shows an exit stair landing at the level of discharge to the outside. The gate across the stair to the basement and the large directional exit arrow on the wall are intended to minimize the possibility that occupants traveling on stairs will inadvertently continue their stair descent past the level of exit discharge (LED), stop at the basement level where the stair ends but where there is no discharge, and then have to reverse direction and retrace their steps to the LED. The barrier needed to cue the occupant that the LED has been reached might be a partition with door assembly, a gate, another physical barrier, signage, or a floor marking that effectively interrupts the flow of travel, forcing a person to perform a deliberate act to continue traveling past the LED, but not restricting required egress from floors below the LED. Exhibit 14.59 shows the NO EXIT sign on the side of the gate facing the LED floor landing.

Exhibit 14.58

Interruption of exit stair at LED. (Courtesy of Jake Pauls)

Exhibit 14.59

Sign on gate providing interruption of exit stair. (Courtesy of Jake Pauls)

14.11.4 Components of Exit Discharge. Doors, stairs, ramps, corridors, exit passageways, bridges, balconies, escalators, moving walks, and other components of an exit discharge shall comply with the detailed requirements of this chapter for such components. [***101:***7.7.4]

14.11.5 Signs. See 10.11.3. [***101:***7.7.5]

Δ **14.11.6 Discharge to Roofs.** Where approved by the AHJ, exits shall be permitted to discharge to roofs or other sections of the building or an adjoining building where all of the following criteria are met:

(1) The roof/ceiling assembly construction has a fire resistance rating not less than that required for the exit enclosure.
(2) A continuous and safe means of egress from the roof is available.

[***101:***7.7.6]

An exit discharge to a roof is permitted only where another continuous and safe means of egress from the roof is provided and the roof construction affords protection against fire that is at least equivalent to that of the exit enclosure (e.g., the exit stair) that discharged occupants to the roof. Helicopter rescue from roofs is not dependable enough to be given credit as an exit; many factors in such a rescue are too unpredictable for this method to be a consideration.

Outside stairs leading to the roofs of other sections of the building or onto the roofs of adjoining buildings are acceptable as part of the means of egress, but only with the approval of the AHJ. The conditions and settings of such paths of travel are likely to be so varied that it is virtually impossible to cover them by written provisions. Ideally the AHJ judges each situation individually.

14.12 Illumination of Means of Egress

When fire occurs in a building, the degree of visibility in aisles, corridors, stairs, and exit passageways might mean the difference between orderly evacuation and chaos and, possibly, the difference between life and death.

14.12.1 General.

14.12.1.1* Illumination of means of egress shall be provided in accordance with Section 14.12 for every building and structure where required in Chapters 11 through 43 of NFPA *101*. For the purposes of this requirement, exit access shall include only designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. For the purposes of this requirement, exit discharge shall include only designated stairs, aisles, corridors, ramps, escalators, walkways, and exit passageways leading to a public way. [***101:***7.8.1.1]

A.14.12.1.1 Illumination provided outside the building should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated. [***101:***A.7.8.1.1]

The means of egress (i.e., exit access, exit, and exit discharge) encompasses practically all spaces where persons can be present. The subject addressed by Section 14.12 is illumination of means of egress. It would seem that the title of Section 14.12 indicates that such illumination needs to be provided throughout all portions of the exit access, the exit, and the exit discharge, but this is not so. Illumination is required throughout the exit (e.g., an enclosed exit stair or exit passageway). Yet, 14.12.1.1 clarifies that, for the purposes of applying the requirements of Section 14.12, the portions of the exit access and exit discharge requiring illumination are only the *designated* egress paths, such as aisles, corridors, stairs, and ramps. *Designated* is meant to indicate designation by the AHJ. For example, most AHJs do not designate the space within an individual's work cubicle as a portion of the exit access required to be illuminated, but the aisles serving multiple cubicles are typically designated as requiring illumination.

Illumination of means of egress is not required unless specifically called for in the appropriate occupancy chapter of NFPA *101*. Nearly all occupancy chapters require illumination, but there are a few exemptions. For example, in new assembly occupancies, 12.2.8 of NFPA *101* exempts private-party tents not larger than 1200 ft^2 (112 m^2) from the illumination requirement. Subsection __.2.8 (e.g., 36.2.8 for new mercantile occupancies) of each occupancy chapter of NFPA *101* provides illumination requirements.

14.12.1.2 Illumination of means of egress shall be continuous during the time that the conditions of occupancy require that the means of egress be available for use, unless otherwise provided in 14.12.1.2.2. [***101:***7.8.1.2]

14.12.1.2.1 Artificial lighting shall be employed at such locations and for such periods of time as are necessary to maintain the illumination to the minimum criteria values herein specified. [***101:***7.8.1.2.1]

14.12.1.2.2* Unless prohibited by Chapters 11 through 43 of NFPA *101*, automatic lighting control devices shall be permitted to temporarily turn off the illumination within the means of egress, provided that each lighting control device complies with all of the following:

(1) In new installations, the lighting control device is listed.
(2) The lighting control device is equipped to automatically energize the controlled lights upon loss of normal power and is evaluated for this purpose.
(3) Illumination timers are provided and are set for a minimum 15-minute duration.
(4) The lighting control device is activated by any occupant movement in the area served by the lighting units.
(5) In new installations, the lighting control device is activated by activation of the building fire alarm system, if provided.
(6) The lighting control device does not turn off any lights relied upon for activation of photoluminescent exit signs or path markers.
(7) The lighting control device does not turn off any battery-equipped emergency luminaires, unit equipment, or exit signs.

[***101:***7.8.1.2.2]

A.14.12.1.2.2 Photoluminescent materials and battery-powered luminaires require some period of time to restore themselves to full operational capacity after being de-energized. [***101:***A.7.8.1.2.2]

Photoluminescent products rely on nearby luminaires to maintain their full capacity. When those luminaires are de-energized, the photoluminescent product will gradually deplete its capacity. Listed photoluminescent exit signs and path markers are restored to full rated capacity within one hour and there is no known limit to the number of times they can be discharged and recharged, nor any known degradation of overall capacity or lifetime as a result of discharge/charge cycles. [***101:***A.7.8.1.2.2]

De-energizing the normal (utility) power source will automatically begin the battery discharge cycle of emergency luminaires, unit equipment, and exit signs provided with battery backup. Once drained, these batteries will typically require between 24 to 72 hours, depending on the battery technology and charging circuitry design, to regain full capacity. Frequent discharge/charge cycles can reduce overall battery lifetime and, depending on battery technology, might also prematurely reduce overall battery capacity. [***101:***A.7.8.1.2.2]

14.12.1.2.3* Energy-saving sensors, switches, timers, or controllers shall be approved and shall not compromise the continuity of illumination of the means of egress required by 14.12.1.2. [***101:***7.8.1.2.3]

A.14.12.1.2.3 A consideration for the approval of automatic, motion sensor–type lighting switches, controls, timers, or controllers is whether the equipment is listed as a fail-safe device for use in the means of egress. [***101:***A.7.8.1.2.3]

14.12.1.3 The floors and other walking surfaces within an exit and within the portions of the exit access and exit discharge designated in 14.12.1.1 shall be illuminated as follows:

(1) During conditions of stair use, the minimum illumination for new stairs shall be at least 10 ft-candle (108 lux), measured at the walking surfaces.
(2) The minimum illumination for floors and other walking surfaces, other than new stairs during conditions of stair use, shall be to values of at least 1 ft-candle (10.8 lux), measured at the floor.
(3) In assembly occupancies, the illumination of the walking surfaces of exit access shall be at least 0.2 ft-candle (2.2 lux) during periods of performances or projections involving directed light.
(4)* The minimum illumination requirements shall not apply where operations or processes require low lighting levels.
[***101:***7.8.1.3]

The *Code* requires at least 1 ft-candle (10.8 lux) of illumination at floor level.

Item (1) of 14.12.1.3 requires at least 10 ft-candle (108 lux) for new stairs during conditions of stair use. Note that, during conditions where the stair is not being used but the building is occupied, at least 1 ft-candle (10.8 lux) of illumination must be on the stair walking surfaces in compliance with 14.12.1.3(2). An arrangement that might be used to comply with 14.12.1.3(1) and (2) would include illuminating the stair to a minimum of 1 ft-candle (10.8 lux) during periods that the building is occupied and using motion detectors to sense occupant presence in any portion of the stair enclosure that, upon activation, would increase the illumination level to the minimum 10 ft-candle (108 lux) requirement. Exhibit 14.60 and Exhibit 14.61 show novel lighting techniques — methods that help to ensure that the stair treads are adequately illuminated and tread edges are easily discerned by stair users — for an outdoor stair and an indoor stair, respectively. Exhibit 14.62 shows a stair whose illumination is questionable, especially given that occupants who use the stair in the downward direction are coming from the area near a building window wall with bright outdoor lighting.

When motion pictures, slides, and the like are being shown in theaters, auditoriums, and other assembly occupancies, 14.12.1.3(3) permits the level of illumination to be reduced to 0.2 ft-candle (2.2 lux).

Exhibit 14.60

Exhibit 14.61

Interior stair illumination via lights at stair treads. (Courtesy of Jake Pauls)

Exhibit 14.62

Poorly lighted interior stair near brightly lighted window space. (Courtesy of Jake Pauls)

Item (4) of 14.12.1.3 recognizes that some operations (e.g., photographic film manufacturing) require low lighting levels. Special precautions can be taken for occupant life safety so as to not have to require a minimum illumination level.

A.14.12.1.3(4) Some processes, such as manufacturing or handling of photosensitive materials, cannot be performed in areas provided with the minimum specified lighting levels. The use of spaces with lighting levels below 1 ft-candle (10.8 lux) might necessitate additional safety measures, such as written emergency plans, training of new employees in emergency evacuation procedures, and periodic fire drills. [***101:***A.7.8.1.3(5)]

14.12.1.4* Required illumination shall be arranged so that the failure of any single lighting unit does not result in an illumination level of less than 0.2 ft-candle (2.2 lux) in any designated area. [***101:***7.8.1.4]

All lights, circuits, or auxiliary power must be arranged to ensure continuity of egress lighting, although the performance level is permitted to decline from 1 ft-candle to 0.2 ft-candle (10.8 lux to 2.2 lux) if a system element fails. Continuity of egress lighting can be accomplished by means such as use of duplicate light bulbs in fixtures or overlapping light patterns from neighboring fixtures.

A.14.12.1.4 Failure of a lighting unit is deemed to have occurred when the light output drops below 70 percent of its original level. [***101:***A.7.8.1.4]

14.12.1.5 The equipment or units installed to meet the requirements of Section 14.14 also shall be permitted to serve the function of illumination of means of egress, provided that all requirements of Section 14.12 for such illumination are met. [***101:***7.8.1.5]

14.12.2 Sources of Illumination.

14.12.2.1 Illumination of means of egress shall be from a source considered reliable by the AHJ. [***101:***7.8.2.1]

14.12.2.2 Battery-operated electric lights and other types of portable lamps or lanterns shall not be used for primary illumination of means of egress. Battery-operated electric lights shall be permitted to be used as an emergency source to the extent permitted under Section 14.13. [***101:***7.8.2.2]

14.13 Emergency Lighting

14.13.1 General.

Δ **14.13.1.1*** Emergency lighting facilities for means of egress shall be provided in accordance with Section 14.13 for the following:

(1) Buildings or structures where required in Chapters 11 through 43 of NFPA *101*
(2) Underground and limited access structures as addressed in Section 11.7 of NFPA *101*
(3) High-rise buildings as required by NFPA *101*
(4) Doors equipped with delayed-egress locks
(5) Stair shafts and vestibules of smokeproof enclosures, for which the following also apply:
   (a) The stair shaft and vestibule shall be permitted to include a standby generator that is installed for the smokeproof enclosure mechanical ventilation equipment.
   (b) The standby generator shall be permitted to be used for the stair shaft and vestibule emergency lighting power supply.
(6) New sensor-release of electrical locking systems in accordance with 14.5.3.2

[***101:***7.9.1.1]

A.14.13.1.1 Emergency lighting outside the building should provide illumination to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated. [***101:***A.7.9.1.1]

Emergency lighting is not required unless specifically called for in the appropriate occupancy chapter of NFPA *101* or by a provision of 14.13.1.1.

14.13.1.2 For the purposes of 14.13.1.1, exit access shall include only designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. For the purposes of 14.13.1.1, exit discharge shall include only designated stairs, ramps, aisles, walkways, and escalators leading to a public way. [***101:***7.9.1.2]

The means of egress (i.e., exit access, exit, and exit discharge) encompasses practically all spaces where persons can be present. The subject addressed by Section 14.13 is emergency lighting of means of egress. The title of Section 14.13 seems to indicate that such emergency lighting needs to be provided throughout all portions of the exit access, the exit, and the exit discharge, but this is not so. Emergency lighting is required throughout the exit (e.g., in an enclosed exit stair or exit passageway). Yet, 14.13.1.2 clarifies that, for the purposes of applying the requirements of Section 14.13, the portions of the exit access and exit discharge requiring emergency lighting are only the *designated* egress paths, such as aisles, corridors, stairs, ramps, and passageways. *Designated* is meant to indicate designation by the AHJ. For example, most AHJs do not designate the space within an individual's work cubicle as a portion of the exit access required to be provided with emergency lighting, but the aisles serving multiple cubicles are typically designated as requiring emergency lighting.

14.13.1.3 Where maintenance of illumination depends on changing from one energy source to another, a delay of not more than 10 seconds shall be permitted. [***101:***7.9.1.3]

An on-site generator driven by a prime mover must be automatically started and capable of picking up the emergency lighting load within 10 seconds. If the generator is not able to supply power within this time frame, an auxiliary power source must be provided.

Some turbine-driven emergency generators take longer than 10 seconds to reach operating speed. A backup battery pack, such as an uninterruptible power supply (UPS), capable of delivering emergency power for a few minutes might be used in conjunction with any on-site generator that cannot meet the 10-second requirement. As another alternative, unit lighting packs with their integral batteries might be used to provide emergency lighting immediately upon loss of normal power, with a switchover to other lighting fixtures supplied by power from the generator at a later point in the incident during which normal power was lost.

14.13.2 Periodic Testing of Emergency Lighting Equipment.

14.13.2.1 Required emergency lighting systems shall be tested in accordance with one of the three options offered by 14.13.2.1.1, 14.13.2.1.2, or 14.13.2.1.3. [***101:***7.9.3.1]

Δ **14.13.2.1.1** Testing of required emergency lighting systems shall be permitted to be conducted as follows:

(1) Functional testing shall be conducted monthly with a minimum of 3 weeks and a maximum of 5 weeks between tests, for not less than 30 seconds, except as otherwise permitted by 14.13.2.1.1(2).
(2) The test interval shall be permitted to be extended beyond 30 days with the approval of the AHJ.
(3) Functional testing shall be conducted annually for a minimum of 1½ hours if the emergency lighting system is battery powered.
(4) The emergency lighting equipment shall be fully operational for the duration of the tests required by 14.13.2.1.1(1) and 14.13.2.1.1(3).
(5) Written records of visual inspections and tests shall be kept by the owner for inspection by the AHJ.

[***101:***7.9.3.1.1]

14.13.2.1.2 Testing of required emergency lighting systems shall be permitted to be conducted as follows:

(1) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall be provided.
(2) Not less than once every 30 days, self-testing/self-diagnostic battery-operated emergency lighting equipment shall automatically perform a test with a duration of a minimum of 30 seconds and a diagnostic routine.
(3) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall indicate failures by a status indicator.
(4) A visual inspection shall be performed at intervals not exceeding 30 days.
(5) Functional testing shall be conducted annually for a minimum of 1½ hours.
(6) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall be fully operational for the duration of the 1½ hour test.
(7) Written records of visual inspections and tests shall be kept by the owner for inspection by the AHJ.

[***101:***7.9.3.1.2]

Δ **14.13.2.1.3** Testing of required emergency lighting systems shall be permitted to be conducted as follows:

(1) Computer-based, self-testing/self-diagnostic battery-operated emergency lighting equipment shall be provided.
(2) Not less than once every 30 days, emergency lighting equipment shall automatically perform a test with a duration of a minimum of 30 seconds and a diagnostic routine.
(3) The emergency lighting equipment shall automatically perform annually a test for a minimum of 1½ hours.
(4) The emergency lighting equipment shall be fully operational for the duration of the tests required by 14.13.2.1.3(2) and 14.13.2.1.3(3).
(5) The computer-based system shall be capable of providing a report of the history of tests and failures at all times.

[***101:***7.9.3.1.3]

Periodic testing of emergency lighting equipment is needed to help ensure such equipment will perform as needed upon failure of normal power. The functional test, required to be conducted by 14.13.2.1.1(1), 14.13.2.1.2(2), and 14.13.2.1.3(2), ensures that the bulbs and other equipment work. Additionally, for battery-powered equipment, the 30-second performance criterion for the functional test demonstrates that batteries have more than a residual charge. The 1½-hour performance criterion required yearly for battery-powered equipment ensures sufficient battery life to provide emergency lighting for the 1½ hours required by 14.13.2.1.

The self-testing/self-diagnostic systems permitted by 14.13.2.1.2 and 14.13.2.1.3 use newer technologies and equipment to automate the testing, thereby reducing the manual labor needed to keep the emergency lighting systems in proper operating condition.

Note that 14.13.2.1.1(1) was revised and 14.13.2.1.1(2) was new to the 2009 edition of the *Code*. In prior editions, the functional test, which must be performed manually (as contrasted with the functional testing that is conducted automatically by the self-testing/self-diagnostic systems addressed in 14.13.2.1.2 and 14.13.2.1.3), was required to be conducted at 30-day intervals. Where that requirement was followed exactly, testing performed on January 31 would be performed again the following year on January 25 due to the forward creep caused by 31-day months. The former requirement also offered no leniency for scheduling the testing to avoid weekends when the person responsible for conducting the testing might not normally be present. The current language of 14.13.2.1.1(1) offers flexibility without permitting someone to test, for example, on January 31 and again the next day, February 1, and claim compliance with having tested once in each of those months.

14.14 Marking of Means of Egress

14.14.1 General.

14.14.1.1 Where Required. Means of egress shall be marked in accordance with Section 14.14 where required in Chapters 11 through 43 of NFPA *101*. [***101:***7.10.1.1]

Marking of means of egress is not required unless specifically called for by the applicable occupancy chapter of NFPA *101*. Subsection __.2.10 of each occupancy chapter (e.g., 12.2.10 of NFPA *101* for new assembly occupancies) details where exit signs and directional exit signs are required.

14.14.1.2 Exits.

14.14.1.2.1* Exits, other than main exterior exit doors that obviously and clearly are identifiable as exits, shall be marked by an approved sign that is readily visible from any direction of exit access. [***101:***7.10.1.2.1]

A.14.14.1.2.1 Where a main entrance serves also as an exit, it will usually be sufficiently obvious to occupants so that no exit sign is needed. [***101:***A.7.10.1.2.1]

The character of the occupancy has a practical effect on the need for signs. In any assembly occupancy, hotel, department store, or other building subject to transient occupancy, the need for signs will be greater than in a building subject to permanent or semipermanent occupancy by the same people, such as an apartment house where the residents are presumed to be familiar with exit facilities by reason of regular use thereof. Even in a permanent residence-type building, however, there is need for signs to identify exit facilities such as outside stairs that are not subject to regular use during the normal occupancy of the building. [***101:***A.7.10.1.2.1]

The requirement for the locations of exit signs visible from any direction of exit access is illustrated in Figure A.14.14.1.2.1. [***101:***A.7.10.1.2.1]

14.14.1.2.2* Horizontal components of the egress path within an exit enclosure shall be marked by approved exit or directional exit signs where the continuation of the egress path is not obvious. [***101:***7.10.1.2.2]

Some exit stair enclosures, particularly in high-rise buildings where the upper portion of the tower presents a smaller footprint than the base of the building, include horizontal components (much like exit passageways) at floors where the stair enclosure that serves the next group of floors immediately below shifts horizontally in position. Although exit and directional exit signs are not normally needed within an exit stair enclosure that is stacked vertically without offsets because occupants simply move downward from floor to floor, the presence of the horizontal passageway might confound the egress path. Where the continuation of the egress path is not obvious, 14.14.1.2.2 requires additional exit or directional exit signs.

A.14.14.1.2.2 The direction of travel to the exit discharge within a stair enclosure with horizontal components in excess of the typical landings might need additional signage to be readily visible or obvious. Exit signs should be installed above doors through which the egress path leads. Directional exit signs should be installed where the horizontal egress path changes directions. The stairway marking signs required by 10.12.3, provided within the stair enclosure at each floor landing, indicate the vertical direction to exit discharge. [***101:***A.7.10.1.2.2]

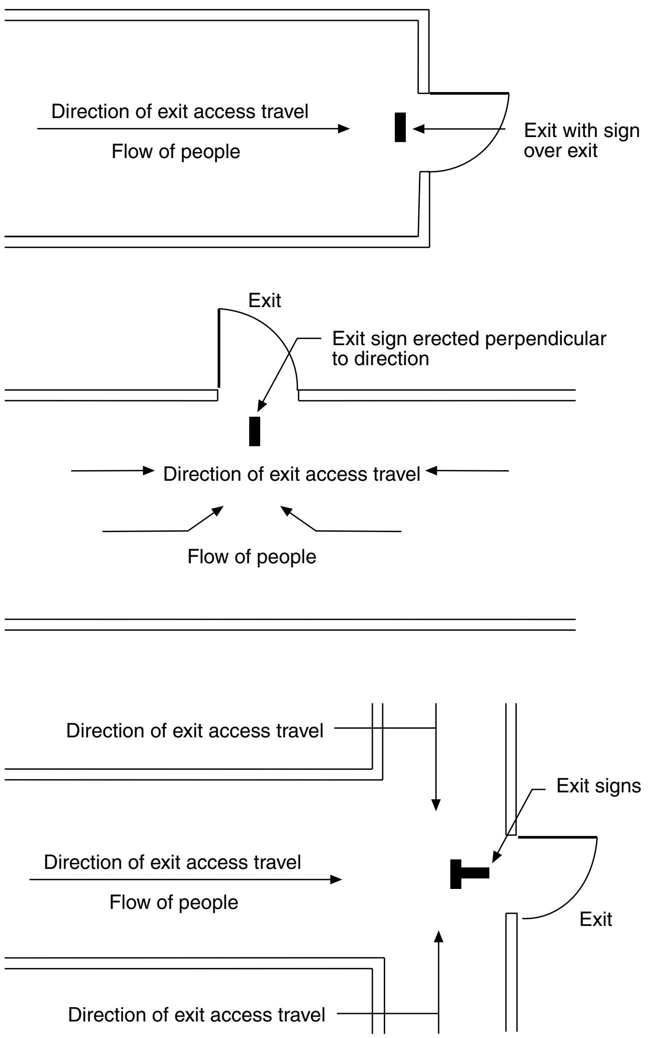

FIGURE A.14.14.1.2.1 *Location of Exit Signs. [**101:**Figure A.7.10.1.2.1]*

14.14.1.3 Exit Stair Door Tactile Signage. Tactile signage shall be provided to meet all of the following criteria, unless otherwise provided in 14.14.1.4:

(1) Tactile signage shall be located at each exit door requiring an exit sign.
(2) Tactile signage shall read as follows: EXIT
(3) Tactile signage shall comply with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

[***101:***7.10.1.3]

14.14.1.4 Existing Exemption. The requirements of 14.14.1.3 shall not apply to existing buildings, provided that the occupancy classification does not change. [***101:***7.10.1.4]

All exit door assemblies required to have an exit sign are also required to have tactile signage, unless the exit door assembly is in an existing building and the occupancy classification does not change. The required tactile signage allows persons with vision impairment to identify the door assembly as an exit. For the same reasons that the requirements of 14.10.4 on accessible means of egress are not required for existing buildings, tactile signage is not required in existing buildings, unless the occupancy classification changes.

The provision of 14.14.1.3(3), requiring that the tactile signage be in accordance with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, has the effect of requiring the EXIT element of the sign to be presented both in raised characters and braille. See the last paragraph of the commentary following 10.11.3.1.16.

14.14.1.5 Exit Access.

14.14.1.5.1 Access to exits shall be marked by approved, readily visible signs in all cases where the exit or way to reach the exit is not readily apparent to the occupants. [***101:***7.10.1.5.1]

14.14.1.5.2* New sign placement shall be such that no point in an exit access corridor is in excess of the rated viewing distance or 100 ft (30 m), whichever is less, from the nearest sign. [***101:***7.10.1.5.2]

The placement distance requirement in 14.14.1.5.2 applies only to new exit sign installations in corridors. Internally illuminated signs are required by 14.14.7.1 to be listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*. The testing procedures of ANSI/UL 924 determine a distance rating for the listed sign. Externally illuminated signs are not required to be listed and do not have a distance rating associated with them; however, they are subject to the maximum 100 ft (30 m) placement distance requirement.

The requirement by 14.14.1.5.2 to position internally illuminated signs based on their listed distance rating is another step toward promoting performance-based design in lieu of the traditional prescription-based approach [i.e., use of the maximum 100 ft (30 m) distance]. Listed exit signs are required to be marked with a distance rating only if the rating is other than the 100 ft (30 m) default value.

A.14.14.1.5.2 For externally illuminated signs in accordance with 14.14.6 and internally illuminated signs listed without a marked viewing distance, the rated viewing distance should be considered to be 100 ft (30 m). Where placing signs at their rated viewing distance requires them to be placed above the line of sight, consideration should be given to increasing the size of the exit legend to compensate for the additional straight-line distance between the viewer and the sign. [***101:***A.7.10.1.5.2]

14.14.1.6* Floor Proximity Exit Signs. Where floor proximity exit signs are required in Chapters 11 through 43 of NFPA *101*, such signs shall comply with 14.14.3, 14.14.4, 14.14.5, and 14.14.6 for externally illuminated signs and 14.14.7 for internally illuminated signs. Such signs shall be located near the floor level in addition to those signs required for doors or corridors. The bottom of the sign shall be not less than 6 in. (150 mm), but not more than 18 in. (455 mm), above the floor. For exit doors, the sign shall be mounted on the door or adjacent to the door, with the nearest edge of the sign within 4 in. (100 mm) of the door frame. [***101:***7.10.1.6]

A.14.14.1.6 See 14.14.3. [***101:***A.7.10.1.6]

Because locations near the ceiling might be the first to become obstructed by smoke, the provision of 14.14.1.6 makes it possible for the occupancy chapters to specify floor proximity signs to supplement the regular exit signs that are usually placed above the exit door opening or near the ceiling in corridors. Such signs are not intended to replace standard exit signs but are designed as an extra asset to a building occupant seeking egress in a smoke-filled environment. Because the signs are positioned near the floor, they will be among the last signs to become obscured by the descending smoke layer. Exhibit 14.63 shows a floor proximity exit sign at the base of an exit door that is equipped with the traditional exit sign above the door opening.

The provisions of 14.14.1.6 can be used as guidance on the placement and installation of floor proximity signs, even though they might not be required.

The only occupancies currently mandating floor proximity exit signs are assembly occupancies, where they are required in special amusement buildings in accordance with the provisions of 20.1.4.

14.14.1.7* Floor Proximity Egress Path Marking. Where floor proximity egress path marking is required in Chapters 11 through 43 of NFPA *101*, an approved floor proximity egress path marking system that is internally illuminated shall be installed within 18 in.

Exhibit 14.63

Floor proximity EXIT sign. (Courtesy of Jake Pauls)

(455 mm) of the floor. Floor proximity egress path marking systems shall be listed in accordance with ANSI/UL 1994, *Standard for Luminous Egress Path Marking Systems*. The system shall provide a visible delineation of the path of travel along the designated exit access and shall be essentially continuous, except as interrupted by doorways, hallways, corridors, or other such architectural features. The system shall operate continuously or at any time the building fire alarm system is activated. The activation, duration, and continuity of operation of the system shall be in accordance with 7.9.2 of NFPA *101*. The system shall be maintained in accordance with the product manufacturing listing. [***101:***7.10.1.7]

A.14.14.1.7 See 3.3.145.2 of NFPA *101* for the definition of *internally illuminated*. [***101:***A.7.10.1.7]

Paragraph 14.14.1.7 provides a standard for floor proximity egress path marking for mandatory use by the occupancy chapters or for voluntary use by any party. This type of marking has been mandatory on aircraft for several years. It is not mandatory for any occupancy under the *Code*. However, it could be used as part of the directional exit marking required for special amusement buildings by the provisions of 20.1.4. Such systems are required by 14.14.1.7 to be listed (see 3.2.6 for the definition of the term *listed*).

The provisions of 14.14.1.7 require that floor proximity egress path marking systems be internally illuminated. Photoluminescent egress path markers (like photoluminescent exit signs addressed in 14.14.7.2) are internally illuminated. The photoluminescent material stores incident electromagnetic radiation, typically from ambient light sources, and releases it in the form of visible light. The intensity and duration of the ambient light needed for charging the photoluminescent material varies by product and manufacturer. Thus, 14.14.1.7 requires that the system be maintained in accordance with the product manufacturing listing.

14.14.1.8* Visibility. Every sign required in Section 14.14 shall be located and of such size, distinctive color, and design that it is readily visible and shall provide contrast with decorations, interior finish, or other signs. No decorations, furnishings, or equipment that impairs visibility of a sign shall be permitted. No brightly illuminated sign (for other than exit purposes), display, or object in or near the line of vision of the required exit sign that could detract attention from the exit sign shall be permitted. [***101:***7.10.1.8]

In some locations, an otherwise adequate exit sign or directional exit sign might be rendered inconspicuous by a high-intensity illuminated advertising sign in the immediate vicinity. For that reason, such signs are not permitted in the line of vision of any required sign addressed by Section 14.14.

The maximum mounting height for directional exit signs not associated with an egress opening is not specified, and the minimum mounting height for exit signs and directional exit signs is not specified (see 14.14.1.9). Usually they are placed above exit door openings and above head height. There are those who argue, with reason, that smoke builds up more rapidly at higher levels, and signs positioned near the floor would be visible for a much longer time during a fire. However, when several people are moving toward an exit, those in the rear might not be able to see signs located near the floor because of the obstruction created by those ahead of them. Also, in the absence of careful housekeeping, such signs might be damaged or blocked. Thus, 14.14.1.8 treats the subject as a visibility issue and requires that the signs be located to be readily visible and to provide contrast with their surroundings. See also 14.14.1.9 and its related commentary.

A.14.14.1.8 In stores, for example, an otherwise adequate exit sign could be rendered inconspicuous by a high-intensity illuminated advertising sign located in the immediate vicinity. [***101:***A.7.10.1.8]

Red is the traditional color for exit signs and is required by law in many places. However, at an early stage in the development of NFPA *101*, a provision made green the color for exit signs, following the concept of traffic lights in which green indicates safety and red is the signal to stop. During the period when green signs were specified by NFPA *101*, many such signs were installed, but the traditional red signs also remained. In 1949, the Fire Marshals Association of North America voted to request that red be restored as the required exit sign color, because it was found that the provision for green involved difficulties in law enactment that were out of proportion to the importance of safety. Accordingly, the 10th edition of NFPA *101* specified red where not otherwise required by law. The present text avoids any specific requirement for color on the assumption that either red or green will be used in most cases and that there are some situations in which a color other than red or green could actually provide better visibility. [***101:***A.7.10.1.8]

14.14.1.9 Mounting Location. The bottom of new egress markings shall be located at a vertical distance of not more than 6 ft 8 in. (2030 mm) above the top edge of the egress opening intended for designation by that marking. Egress markings shall be located at a horizontal distance of not more than the required width of the egress opening, as measured from the edge of the egress opening intended for designation by that marking to the nearest edge of the marking. [***101:***7.10.1.9]

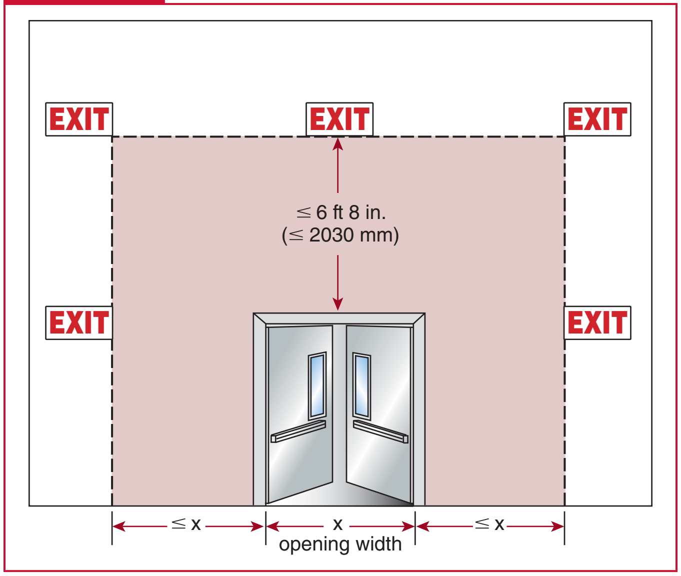
Paragraph 14.14.1.9 addresses the mounting location of exit signs associated with an egress opening such as a door opening, an archway, or a portal. Its provisions are meant to keep the sign from being located too high above the egress opening and too far to the side of the egress opening, at which point the sign would be less effective in designating the opening as the egress route.

Exhibit 14.64 illustrates the maximum distance at which the nearest sign edge is permitted to be positioned above and to the side of the egress opening, which, in this illustration, is a pair of door leaves. Measurement X, shown below the door leaves, is the required width of the egress opening.

14.14.2 Directional Signs.

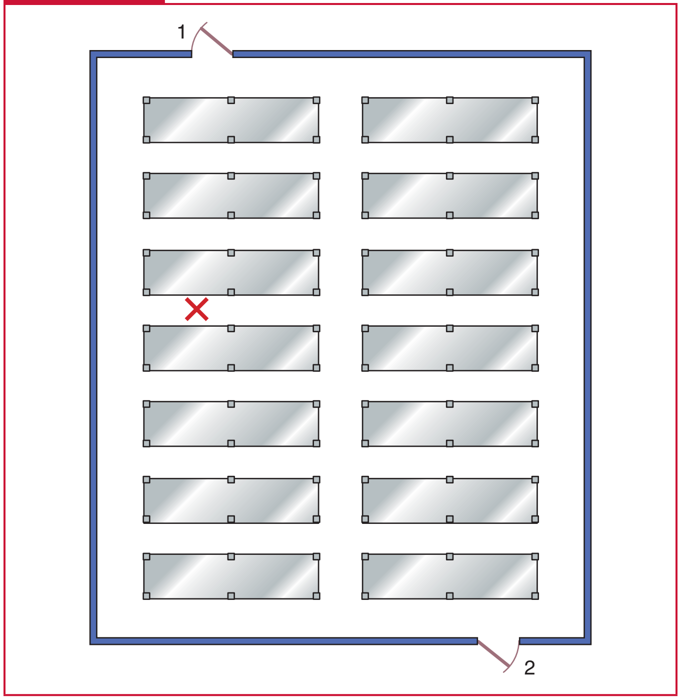
14.14.2.1 A sign complying with 14.14.3 with a directional indicator showing the direction of travel shall be placed in every location

Exhibit 14.64



Maximum permitted distance of sign edge above and to the side of egress opening.

Exhibit 14.65



Warehouse exit sign and directional sign placement to be determined.

where the direction of travel to reach the nearest exit is not apparent. [***101:***7.10.2.1]

The provision of 14.14.2.1 mandates that a directional sign be placed where the direction of travel to reach the nearest exit is not apparent. The directional sign uses an exit sign to which one or two directional indicators are added. For externally illuminated signs, which are not required to be laboratory listed, the detailed criteria for the directional indicator appear in 14.14.6.2. Internally illuminated signs, which are required to be tested and listed in accordance with ANSI/UL 924 have their directional indicators evaluated by the performance criteria of the ANSI/UL 924 test procedure; they are exempt from the specification-based criteria of 14.14.6.2.

The requirement of 14.14.2.1 is somewhat performance based in that it adds another directional exit sign wherever the direction of travel to reach the nearest exit is not apparent. The enforcement of this provision will typically be somewhat subjective, because a judgment call must be made as to whether the direction of travel to reach the nearest exit is apparent. A strict reading and application of the requirement, especially with respect to the word *nearest*, could conceivably lead to the installation of many more signs than are practically needed.

Exhibit 14.65 depicts a warehouse with storage racks and aisles. The racks are of sufficient height and construction to prevent an occupant located within almost any aisle from seeing either of the exit door assemblies from the building. The designer is charged with specifying exit sign and directional sign placement that meets the provisions of Section 14.14. An occupant standing at point X within an aisle has a choice of many possible paths for travel to the two exit door assemblies; there are no dead-end aisles in which to become trapped. The criterion test for exit sign placement is 14.14.2.1, which requires that a directional sign be placed in every location where the direction of travel to reach the "nearest" exit is not apparent. Exit door assembly 1 is the nearest exit, but neither exit door assembly 1 nor exit door assembly 2 can be seen from within the aisle or from within any of the three cross-aisles. A strict interpretation of 14.14.2.1, coupled with the requirement of 14.14.1.2.1 that the exit door assemblies themselves be provided with exit signs, could lead to the installation of 20 signs, as shown in Exhibit 14.66. It could be argued that it is neither unreasonable nor unsafe to reduce the number of signs so as to require the occupant to travel to either of the two nearest cross-aisles in order to see a directional sign that leads to an exit. A check for reasonableness could lead to the placement of eight signs, as shown in Exhibit 14.67.

14.14.2.2 Directional exit signs shall be provided within horizontal components of the egress path within exit enclosures as required by 14.14.1.2.2. [***101:***7.10.2.2]

14.14.3* Sign Legend.

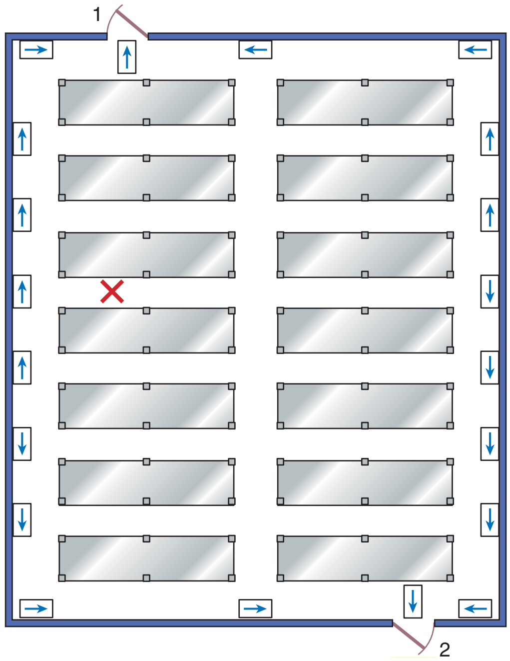
Δ **A.14.14.3** Where graphics are used, the symbols provided in NFPA 170 should be used. Such signs need to provide equal visibility and illumination and are to comply with the other requirements of Section 14.14. [***101:***A.7.10.3]

14.14.3.1 Signs required by 14.14.1 and 14.14.2 shall read as follows in plainly legible letters, or other appropriate wording shall be used:

EXIT

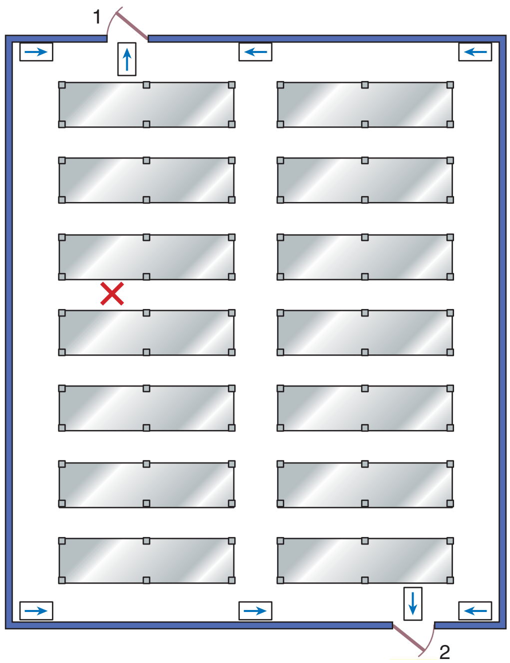
[***101:***7.10.3.1]

Exhibit 14.66



Excessive placement of directional signs.

Exhibit 14.67



Reasonable placement of directional signs.

Δ **14.14.3.2*** Where approved by the AHJ, pictograms in compliance with NFPA 170 shall be permitted. [***101:***7.10.3.2]

A.14.14.3.2 Pictograms are permitted to be used in lieu of, or in addition to, signs with text. [***101:***A.7.10.3.2]

Paragraph 14.14.3.1 permits other wording in lieu of the word EXIT where the alternative wording is appropriate. In countries where Spanish is the predominant language, one might find the word SALIDA. In parts of Canada, where signage appears in both French and English, exit signs have been increased in size to accommodate the words EXIT and SORTIE.

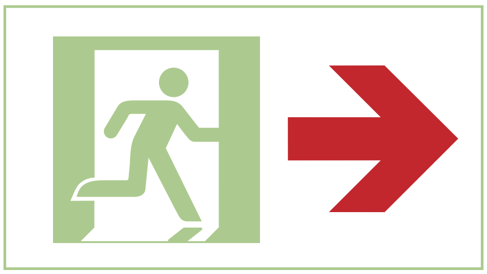
Although 14.14.3.1 refers to wording "in plainly legible letters," it is evident from the language of 14.14.3.2 that graphics, or pictograms, in lieu of words are permitted with the approval of the AHJ in accordance with 14.14.3.2. Graphics have the advantage of being nonspecific to a written language. Paragraph 14.14.3.2 specifies that the pictograms comply with NFPA 170, *Standard for Fire Safety and Emergency Symbols*. NFPA 170 provides a symbol for an emergency exit that should be considered the equivalent of the NFPA *101*'s exit sign. NFPA 170 also provides two symbols that — when used together within the same rectangular field — designate an emergency exit route. This diptych uses the emergency exit symbol and an arrow symbol and should be considered the equivalent of the *Code*'s directional exit sign. See Exhibit 14.68 and Exhibit 14.69. The colors used in the exhibits are consistent with the requirements of NFPA 170.

14.14.4* Power Source. Where emergency lighting facilities are required by the applicable provisions of Chapters 11 through 43 of NFPA *101* for individual occupancies, the signs, other than

Exhibit 14.68

NFPA 170 symbol for emergency exit.

Exhibit 14.69



NFPA 170 symbols for emergency exit route.

approved self-luminous signs and listed photoluminescent signs in accordance with 14.14.7.2, shall be illuminated by the emergency lighting facilities. The level of illumination of the signs shall be in accordance with 14.14.6.3 or 14.14.7 for the required emergency lighting duration as specified in 7.9.2.1 of NFPA *101*. However, the level of illumination shall be permitted to decline to 60 percent at the end of the emergency lighting duration. [***101:***7.10.4]

A.14.14.4 It is not the intent of this paragraph to require emergency lighting but only to have the sign illuminated by emergency lighting if emergency lighting is required and provided. [***101:***A.7.10.4]

It is not the intent to require that the entire stroke width and entire stroke height of all letters comprising the word EXIT be visible per the requirements of 14.14.6.3 under normal or emergency lighting operation, provided that the sign is visible and legible at a 100 ft (30 m) distance under all room illumination conditions. [***101:***A.7.10.4]

The text of A.14.14.4 explains that it is not the intent of 14.14.4 to require an emergency power source for the illumination of exit signs. Rather, it is the intent that the required exit signs be provided with emergency power if the occupancy is required to have emergency lighting. For example, there are business occupancies that are small enough to be exempt from the emergency lighting requirement of 38.2.9.1 and 39.2.9.1 of NFPA *101*. Yet, business occupancies are required to have exit signs in accordance with Section 14.14. Such exit signs are required to be illuminated per 14.14.5.1. In a small business occupancy that is exempt from emergency lighting, if a power failure occurs, the exit signs are permitted to go dark. The business occupancy example can be contrasted with an assembly occupancy. Assembly occupancies are required to have emergency lighting and exit signs. The exit signs must be illuminated in accordance with 14.14.5.1 when the building's normal power is available; the illumination must also be maintained in accordance with 14.14.4 upon failure of the normal power service.

14.14.5 Illumination of Signs.

14.14.5.1* General. Every sign required by 14.14.1.2, 14.14.1.5, or 14.14.8.1, other than where operations or processes require low lighting levels, shall be suitably illuminated by a reliable light source. Externally and internally illuminated signs shall be legible in both the normal and emergency lighting mode. [***101:***7.10.5.1]

A.14.14.5.1 See A.14.12.1.3(4). [***101:***A.7.10.5.1]

Internally illuminated signs are particularly useful in occupancies where reduction of normal illumination is permitted, such as in movie theaters. However, the intent of 14.14.5.1 is to treat externally illuminated and internally illuminated signs equally, with no preference shown to one or the other. Subsequent subsections then treat each type of sign via a specialized package of requirements, such as 14.14.6 for externally illuminated signs and 14.14.7 for internally illuminated signs. This format is provided because externally illuminated signs are not required to be tested and listed by a laboratory. Due to the lack of testing, it is necessary for the *Code* to specify detailed criteria for externally illuminated signs, such as the letter height and stroke width addressed in 14.14.6.1.1 and illumination levels as addressed in 14.14.6.3. Because internally illuminated signs must be laboratory tested and listed, the *Code* can rely on the listing to ensure that necessary criteria are met.

14.14.5.2* Continuous Illumination.

A.14.14.5.2 It is the intent to prohibit a freely accessible light switch to control the illumination of either an internally or externally illuminated exit sign. [***101:***A.7.10.5.2]

14.14.5.2.1 Every sign required to be illuminated by 14.14.6.3, 14.14.7, and 14.14.8.1 shall be continuously illuminated as required under the provisions of Section 14.12, unless otherwise provided in 14.14.5.2.2. [***101:***7.10.5.2.1]

14.14.5.2.2* Illumination for signs shall be permitted to flash on and off upon activation of the fire alarm system. [***101:***7.10.5.2.2]

A.14.14.5.2.2 The flashing repetition rate should be approximately one cycle per second, and the duration of the off-time should not exceed ¼ second per cycle. During on-time, the illumination levels need to be provided in accordance with 14.14.6.3. Flashing signs, when activated with the fire alarm system, might be of assistance. [***101:***A.7.10.5.2.2]

14.14.6 Externally Illuminated Signs.

14.14.6.1* Size of Signs.

A.14.14.6.1 Experience has shown that the word EXIT, or other appropriate wording, is plainly legible at 100 ft (30 m) if the letters are as large as specified in 14.14.6.1. [***101:***A.7.10.6.1]

Δ **14.14.6.1.1** Externally illuminated signs required by 14.14.1 and 14.14.2, other than approved existing signs, unless otherwise provided in 14.14.6.1.2, shall read EXIT or shall use other appropriate wording in plainly legible letters sized as follows:

(1) For new signs, the letters shall be not less than 6 in. (150 mm) high, with the principal strokes of letters not less than ¾ in. (19 mm) wide.
(2) For existing signs, the required wording shall be permitted to be in plainly legible letters not less than 4 in. (100 mm) high.
(3) The word EXIT shall be in letters of a width not less than 2 in. (51 mm), except the letter I, and the minimum spacing between letters shall be not less than ⅜ in. (9.5 mm).
(4) Sign legend elements larger than the minimum established in 14.14.6.1.1(1) through 14.14.6.1.1(3) shall use letter widths, strokes, and spacing in proportion to their height.

[***101:***7.10.6.1.1]

14.14.6.1.2 The requirements of 14.14.6.1.1 shall not apply to marking required by 14.14.1.3 and 14.14.1.7. [***101:***7.10.6.1.2]

Traditionally, the letters in an exit sign have been required to be 6 in. (150 mm) in height, with the principal strokes not less than ¾ in. (19 mm) wide. In an effort to increase visibility, the *Code* requires that the letters, other than capital letter *I*, be at least 2 in. (51 mm) wide and have a minimum spacing between letters of ⅜ in. (9.5 mm). These dimensional criteria have been maintained, but they apply only to externally illuminated signs. Internally illuminated signs are exempt from these criteria, because they must be tested and listed in accordance with ANSI/UL 924. The ANSI/UL 924 test procedures include assessing the readability of a sign's letters.

14.14.6.2* Size and Location of Directional Indicator.

A.14.14.6.2 Figure A.14.14.6.2 shows examples of acceptable locations of directional indicators with regard to left and right orientation. Directional indicators are permitted to be placed under the horizontal stroke of the letter T, provided that spacing of not less than ⅜ in. (9.5 mm) is maintained from the horizontal and vertical strokes of the letter T. [***101:***A.7.10.6.2]

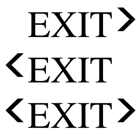


FIGURE A.14.14.6.2 *Directional Indicators. [**101:**Figure A.7.10.6.2]*

Δ **14.14.6.2.1** Directional indicators, unless otherwise provided in 14.14.6.2.2, shall comply with all of the following:

(1) The directional indicator shall be located outside of the EXIT legend, not less than ⅜ in. (9.5 mm) from any letter.
(2) The directional indicator shall be of a chevron type, as shown in Figure 14.14.6.2.1.
(3) The directional indicator shall be identifiable as a directional indicator at a distance of 40 ft (12 m).
(4) A directional indicator larger than the minimum established for compliance with 14.14.6.2.1(3) shall be proportionately increased in height, width, and stroke.
(5) The directional indicator shall be located at the end of the sign for the direction indicated.

[***101:***7.10.6.2.1]

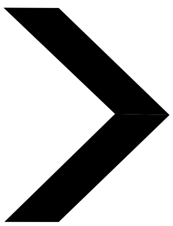

FIGURE 14.14.6.2.1 *Chevron-Type Indicator. [**101:**Figure 7.10.6.2.1]*

14.14.6.2.2 The requirements of 14.14.6.2.1 shall not apply to approved existing signs. [***101:***7.10.6.2.2]

To improve the effectiveness of directional indicators on directional exit signs, the requirements have been changed over the past several editions of the *Code*. The directional indicator cannot be positioned between the letters in the word EXIT. The directional indicator, which formerly was an arrow, must be a chevron, which research has shown is more effective than an arrow. Performance criteria are specified to ensure that the chevron is of adequate size, contrast, and illumination. A specific size is not required, because size depends on factors such as color, contrast, and illumination. However, the directional indicator must be identifiable as a directional indicator at a minimum distance of 40 ft (12 m), which is another performance-based requirement.

14.14.6.3* Level of Illumination. Externally illuminated signs shall be illuminated by not less than 5 ft-candles (54 lux) at the illuminated surface and shall have a contrast ratio of not less than 0.5. [***101:***7.10.6.3]

A.14.14.6.3 Colors providing a good contrast are red or green letters on matte white background. Glossy background and glossy letter colors should be avoided. [***101:***A.7.10.6.3]

The average luminance of the letters and background is measured in footlamberts or candela per square meter. The contrast ratio is computed from these measurements by the following formula:

$$\text{Contrast} = \frac{L_g - L_e}{L_g} \qquad \textbf{[A.14.14.6.3]}$$

Where L_g is the greater luminance and L_e is the lesser luminance, either the variable L_g or L_e is permitted to represent the letters, and the remaining variable will represent the background. The average luminance of the letters and background can be computed by measuring the luminance at the positions indicated in Figure A.14.14.6.3 by numbered spots. [***101:***A.7.10.6.3]

14.14.7 Internally Illuminated Signs.

14.14.7.1 Listing. Internally illuminated signs shall be listed in accordance with ANSI/UL 924, *Standard for Emergency Lighting*

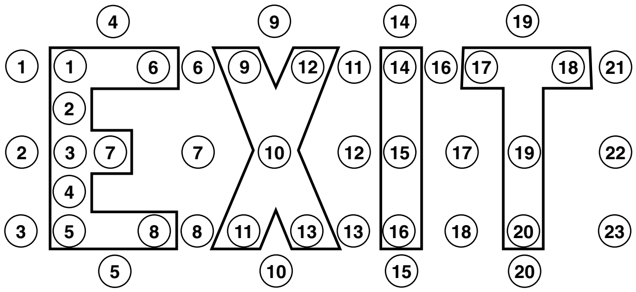

FIGURE A.14.14.6.3 *Measurement of Exit Sign Luminance. [**101:**Figure A.7.10.6.3]* *and Power Equipment*, unless they meet one of the following criteria:

(1) They are approved existing signs.
(2) They are existing signs having the required wording in legible letters not less than 4 in. (100 mm) high.
(3) They are signs that are in accordance with 14.14.1.3 and 14.14.1.6.

[***101:***7.10.7.1]

Internally illuminated signs must be laboratory tested and listed in accordance with ANSI/UL 924. Reliance is placed on the laboratory having conducted a comprehensive examination. By relying on the laboratory listing, the *Code* does not need to address the detailed criteria that it requires of externally illuminated signs, which are not required to be listed.

14.14.7.2* Photoluminescent Signs. The face of a photoluminescent sign shall be continually illuminated while the building is occupied. The illumination levels on the face of the photoluminescent sign shall be in accordance with its listing. The charging illumination shall be a reliable light source as determined by the AHJ. The charging light source shall be of a type specified in the product markings. [***101:***7.10.7.2]

A.14.14.7.2 Photoluminescent signs need a specific minimum level of light on the face of the sign to ensure that the sign is charged for emergency operation and legibility in both the normal and emergency modes. Additionally, the type of light source (for example, incandescent, fluorescent, halogen, metal halide) is important. Each light source produces different types of visible and invisible light (for example, UV) that might affect the ability of some photoluminescent signs to charge and might also affect the amount of light output available during emergency mode. This type of sign would not be suitable where the illumination levels are permitted to decline. The charging light source should not be connected to automatic timers, because the continuous illumination of the sign is needed; otherwise, the sign illumination would not be available, because it would be discharged. [***101:***A.7.10.7.2]

A photoluminescent sign absorbs light from an activation light source in order to emit light (i.e., luminesce). The sign continues to emit light for a time after the activation light source has been removed. The requirements of 14.14.7.2 for photoluminescent signs were new to the 2000 edition of NFPA *101*. Note that these requirements are contained as a subset of the internally illuminated sign requirements of 14.14.7. A photoluminescent sign is an internally illuminated sign. Photoluminescent exit signs are permitted, provided that they are listed in accordance with ANSI/UL 924 and meet the criteria of 14.14.7.2. The criteria of 14.14.7.2 are meant to highlight some of the special considerations needed to use photoluminescent exit signs effectively for life safety.

14.14.8 Special Signs.

14.14.8.1 Sign Illumination.

14.14.8.1.1* Where required by other provisions of this *Code*, special signs shall be illuminated in accordance with 14.14.5, 14.14.6.3, and 14.14.7. [***101:***7.10.8.1.1]

A.14.14.8.1.1 Special signs require sufficient illumination in order for them to be readable at close proximity. They are not expected to be of a size or illumination level necessary to be readable from a distance, as is the case for an exit sign. [***101:***A.7.10.8.1.1]

14.14.8.1.2 Where emergency lighting facilities are required by the applicable provisions of Chapters 11 through 43 of NFPA *101*, the required illumination of special signs shall additionally be provided under emergency lighting conditions. [***101:***7.10.8.1.2]

14.14.8.2 Characters. Special signs, where required by other provisions of this *Code*, shall comply with the visual character requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*. [***101:***7.10.8.2]

14.14.8.3* No Exit.

A.14.14.8.3 The likelihood of occupants mistaking passageways or stairways that lead to dead-end spaces for exit doors and becoming trapped governs the need for exit signs. Thus, such areas should be marked with a sign that reads as follows:

NO EXIT

Supplementary identification indicating the character of the area, such as TO BASEMENT, STOREROOM, LINEN CLOSET, or the like, is permitted to be provided. [***101:***A.7.10.8.3]

14.14.8.3.1 Any door, passage, or stairway that is neither an exit nor a way of exit access and that is located or arranged so that it is likely to be mistaken for an exit shall be identified by a sign that reads as follows:

NO
EXIT

[***101:***7.10.8.3.1]

14.14.8.3.2 The NO EXIT sign shall have the word NO in letters 2 in. (51 mm) high, with a stroke width of 3⁄8 in. (9.5 mm), and the word EXIT in letters 1 in. (25 mm) high, with the word EXIT below the word NO, unless such sign is an approved existing sign. [***101:***7.10.8.3.2]

14.15 Secondary Means of Escape

14.15.1 Secondary means of escape shall comply with NFPA *101*.

14.15.2 Where approved on secondary means of escape, security bars, grates, grilles, or similar devices shall be equipped with approved release mechanisms that are releasable from the inside without the use of a tool, a key, special knowledge, or force greater than that which it takes for normal operation of the door or window.

Fire Department Service Delivery Concurrency Evaluation

15

A key component of fire safety is the ability of the fire department to match service delivery to demand. Large-scale developments have the potential to overwhelm a fire department's ability to provide service without proper planning in the predevelopment stage. Chapter 15 allows the authority having jurisdiction (AHJ) to address such developmental impacts in a proactive, rather than reactive, manner. It is important to note that Chapter 15 does not specify any service delivery standards; it is only intended to prompt the discussion regarding how services are to be maintained and funded when a jurisdiction is subject to a large development project. It is also intended that this evaluation can be utilized as a tool to communicate to elected officials the potential impact of a large development on a fire department's budget needs before the project is approved.

15.1 Application

15.1.1 The AHJ shall be permitted to require a proposed development in the jurisdiction undergo a fire department service delivery concurrency evaluation.

The AHJ has the discretionary authority to specify whether a proposed development should undergo a fire department service delivery concurrency evaluation.

15.1.1.1 Proposed developments that would increase the fire department's service population by less than 1 percent or increase the fire department's total protected building square footage by less than 1 percent shall not be subject to a fire department service delivery concurrency evaluation.

The 1 percent population increase and 1 percent square footage exemption thresholds are intended to exclude smaller developments that will not have a significant impact on the fire department service level demand.

Both a population threshold and a square footage threshold are specified because population increases are generated by residential development and square footage increases are driven more by commercial development. If a proposed development exceeds either of those two thresholds, it would not be exempt under 15.1.1.1. However, under 15.1.1, the AHJ could still choose to not require a fire department service delivery concurrency evaluation if the AHJ is confident that service levels will not be compromised by the development.

15.2 Level of Service Objectives

15.2.1 The fire department shall provide the developer with the current level of service standards for fire protection, emergency medical, prevention, and other operational services provided by the fire department.

The current level of service can be developed with the assistance of documents such as NFPA 1710, *Standard for the Organization and Deployment of Fire Suppression Operations, Emergency Medical Operations, and Special Operations to the Public by Career Fire Departments;* NFPA 1720, *Standard for the Organization and Deployment of Fire Suppression Operations, Emergency Medical Operations, and Special Operations to the Public by Volunteer Fire Departments;* NFPA 1730, *Standard on Organization and Deployment of Fire Prevention Inspection and Code Enforcement, Plan Review, Investigation, and Public Education Operations*; NFPA 450, *Guide for Emergency Medical Services and Systems*; accreditation reports, service level studies, strategic plans, the fire department's budget, and other documents that specify the expected level of performance from fire department services.

15.2.2 The level of service for the proposed development shall not be less than the fire department's current level of service for fire protection, emergency medical, prevention, and other operational services.

It is important to note that fire department levels of service that should be maintained are not just suppression services but also emergency medical services, fire prevention services, and other specialized services provided by the fire department.

15.2.2.1 The AHJ shall be permitted to approve a reduced level of service for the proposed development if a service mitigation plan has been adopted by the jurisdiction.

Revenue used to fund fire department services usually trails the development activity by a couple of years. If the AHJ has approved a service mitigation plan, a reduced level of service could be permitted until revenue from the development supports a restoration to expected service standards.

15.3 Evaluator Qualifications

The fire department service delivery concurrency evaluation shall be prepared by a person with qualifications acceptable to the AHJ.

If the fire department has the available staff with the appropriate expertise, the evaluation could be conducted by the fire department staff. If a third-party consultant is utilized, the consultant needs to demonstrate familiarity with fire department service levels and competence in conducting service level analysis that are acceptable to the AHJ.

15.4 Fire Department Service Delivery Concurrency Evaluation Documentation

15.4.1 The fire department service delivery concurrency evaluation shall include, but not be limited to, the following:

(1) The current level of service for fire protection, emergency medical, and prevention services
(2) The post-development level of service for fire protection, emergency medical, and prevention services
(3) Mitigation recommendations if the level of service in the post-development condition falls below the current level of service

Mitigation recommendations can include, but may not be limited to, additional fire/EMS stations, additional fire/EMS apparatus, personnel staffing, radio communications improvements, and other equipment necessary to maintain service levels.

Ongoing fire prevention services should receive particular attention for mitigation in large-scale development. As an example, if a new covered mall building is proposed in a jurisdiction, not only should inspection and plan review resources for the initial construction be considered for mitigation but also ongoing existing fire occupancy inspections, plans review and new construction services for tenant improvements should be property mitigated for the long-term use of the development.

(4) Short- and long-term funding sources for implementation of the mitigation recommendations

An important part of the service level concurrency evaluation is to identify specific funding sources for each type of mitigation activity that is to occur. Identifying funding sources for each mitigation activity ensures that the developer, AHJ, and the jurisdiction's policy makers are all in agreement as to the source of funding for each mitigation activity. Funding sources may take the form of ad valorem (sales tax) or non-ad valorem property taxes, fees for service, direct funding contributions by the developer, permit fees, impact fees, EMS transport fees or other realistic revenue sources identified by the evaluator.

15.4.2 The fire department service delivery concurrency evaluation shall be provided in a format approved by the AHJ.

The evaluation should be provided in a report format approved by the AHJ that can be presented to and understood by the developer, AHJ, and jurisdiction's policy makers. This may include a presentation to parties that are vested in the outcome of the evaluation.

15.4.3 The fire department service delivery concurrency evaluation shall utilize data sources and standards approved by the AHJ.

NFPA 1710, NFPA 1720, NFPA 1730, NFPA 450, National Fire Incident Reporting System data, accreditation data, a fire department strategic plan, and adopted service levels by the jurisdiction are examples of data sources and standards that could be approved by the AHJ as part of the evaluation.

15.5 Independent Review

The AHJ shall be permitted to require an approved, independent third-party evaluation of the fire department service delivery concurrency evaluation at the expense of the developer.

If a third-party consultant is utilized, the consultant needs to demonstrate familiarity with fire department service levels and competence in conducting service level analysis that are acceptable to the AHJ. The full cost of the evaluation should be funded by the developer.

15.6 Approval

15.6.1 The AHJ shall make the final determination as to whether the level of service objectives have been met for the proposed development and, if applicable, the mitigation strategies are funded and appropriate.

It is intended that the AHJ has final approval of the evaluation report analysis and recommendations. If the AHJ does not concur with the analysis or the recommendations, then the evaluator is responsible for addressing the AHJ's concerns to ensure that the service objectives have been met and the revenue sources are appropriate to fund the mitigation strategies.

15.6.2 If a fire department service delivery concurrency evaluation is required by the AHJ, development shall not proceed until the report has been accepted by the AHJ.

It is the intent of the *Code* that the evaluation study and mitigation strategies are to be integral components of the approval process for the development. Because mitigation strategies may have an impact on both the design and financial feasibility of the development, it is important that acceptance of the evaluation report occur prior to final development approval by the jurisdiction.

Safeguarding Construction, Alteration, and Demolition Operations

16

There have been fires in buildings since humans first started erecting shelters. Buildings in the course of construction have many additional fire hazards not found in completed structures. Fire protection equipment to restrict the spread of fire and extinguish it promptly is not installed until the last stages of construction, and fires are often difficult for the fire department to access. Opportunities abound for serious fire loss, as is amply evidenced by the case study that appears later in this chapter.

16.1 General Requirements

16.1.1 Structures undergoing construction, alteration, or demolition operations, including those in underground locations, shall comply with NFPA 241 and this chapter.

NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*, is a unique standard in that it is not a "brick and mortar" standard but a standard about the process of putting the brick and mortar in place. The standard ceases to apply when the building is finished, that is, when the certificate of occupancy is issued.

The potential for extensive damage during a fire event is greatest when a building is under construction because it is largely unprotected. A building under construction needs constant supervision and inspection not possible or practical by municipal inspectors. What is fine at 8:00 a.m. may have changed and not be fine by 5:00 p.m. that same day or even by noon. A building under construction is not ready to "protect itself." Code-required passive and active fire-suppression systems such as sprinklers, smoke detection, fire alarms, and fire walls typically are nonexistent until a building is near completion. Regardless of the material used in a building's construction, prolonged exposure to fire without mitigation can lead to structural weakness and potential collapse.

16.1.2 A fire protection plan shall be established where required by the AHJ.

Buildings do not spontaneously combust. There must be an ignition source. Fires that occur during the construction process are most often attributable to human error or lack of understanding and training. Ignition sources include, but are not limited to, temporary heaters, welding, cutting, grinding, soldering, and roofing of various kinds. Such ignition sources are not permanent. They are brought on site and into the building by people. They may be there for only a day or two, but one mistake in the safety procedures for using them can destroy the building and spread fire to other buildings. Such fires are apt to cause losses far beyond the actual physical property destroyed by delaying completion of buildings, with consequent loss of revenue. Important business projects, contingent upon occupancy of a structure at a given date, can be seriously deranged even by a fire causing a relatively small direct loss.

Δ **16.1.3*** In buildings under construction, adequate escape facilities shall be maintained at all times for the use of construction workers. Escape facilities shall consist of doors, walkways, stairs, ramps, fire escapes, ladders, or other approved means or devices arranged in accordance with the general principles of Chapter 14 and NFPA *101* insofar as they can reasonably be applied to buildings under construction. [***101:***4.6.10.3]

A.16.1.3 See also NFPA 241. [***101:***A.4.6.10.2]

Subsection 16.1.3 requires that at least one stairway extend upward as each floor of the building is constructed. During construction, unfinished floor areas are often constructed before permanent access to such areas is available. Such areas are often wide open and accessible only by ladders or other temporary scaffolding. Combustible construction forms and lumber are often present, for example, when concrete is poured. A fire that occurs in such an unfinished floor area can quickly threaten the construction or make escape by ladder or scaffolding impossible due to heat and flames.

Workers need to be provided with two means of escape, with one means located as remotely as possible from the ladders and scaffolding, even if both means involve the use of temporary construction to reach the story below. The remote stairway should never be more than one level below that on which a floor is being installed.

Even in large, single-story construction, a construction worker can easily become lost when walls are erected, cutting off the worker's view of the exterior doors. The placement of temporary directional signs that point to exits throughout the building is important, as well as the rearrangement of such signs as the building interior changes during construction.

16.1.4 Fire department access roads provided in accordance with 18.2.3 shall be provided at the start of a project and shall be maintained throughout construction.

Fire department access roads are required throughout the construction process. The minimum 20 ft (6.1 m) of required clear width must be maintained at all times for access to the building and the building site. Maintenance of fire department access roads should be a key component of the fire protection plan (where required; see 16.1.2) and fire safety program (see 16.3.1).

Large construction sites might require two or more fire department access roads to be provided for access to within 150 ft (46 m) of all exterior first floor walls. (See 7.5.5.7 of NFPA 241.)

16.1.5 Permanent fire department access road markings shall not be required until the building is complete or occupied for use.

Signs marking the fire department access road might be required, in accordance with 18.2.3.5. Permanent signs are not required until after construction is completed. Temporary signs might be required to ensure that fire department access roads are kept clear during construction, alteration, or demolition operations. (Also see 7.5.5.6 of NFPA 241.)

16.2 Processes and Hazards

This section covers specific operations that represent likely ignition sources and lists specific combustible, flammable, or explosive materials that are generated or used in the course of construction. If not handled correctly, these materials can cause a disastrous situation.

16.2.1 Temporary Heating Equipment.

16.2.1.1* Temporary heating equipment shall be listed. [**241:**5.2.1]

A.16.2.1.1 Examples of relevant test standards include, but are not limited to, the following:

(1) UL 647, *Standard for Unvented Kerosene-Fired Room Heaters and Portable Heaters*
(2) ANSI/UL 1278, *Standard for Moveable and Wall- or Ceiling-Hung Electric Room Heaters*

[**241:**A.5.2.1]

16.2.1.2 Temporary heating equipment shall be installed in accordance with its listing, including clearance to combustible material, equipment, or construction. [**241:**5.2.2]

16.2.1.3 Temporary heating equipment shall be installed, used, and maintained in accordance with the manufacturer's instructions, except as otherwise provided in 16.2.1.4. [**241:**5.2.3]

16.2.1.4 Where instructions, as addressed in 16.2.1.3, are not available, temporary heating equipment shall be used in accordance with recognized safe practices. [**241:**5.2.4]

16.2.1.5 Temporary heating equipment shall be situated so that it is secured. [**241:**5.2.5]

Paragraph 16.2.1.5 requires temporary heating devices to be secured to prevent them from being tipped over or accidentally moved. Any associated tanks should also be secured. Heaters that tip over or are easily moved can come into contact with combustible materials or spilled fuel. Special care should be taken with the movement of cylinders and the connection of hoses to heating appliances. (See Chapter 69 for requirements pertaining to liquefied petroleum gas and liquefied natural gas.)

16.2.1.6 Only personnel familiar with the operation of the temporary heating equipment shall be allowed to operate such devices. [**241:**5.2.6]

16.2.1.7* Temporary heating equipment, where utilized, shall be monitored for safe operation and maintained by properly trained personnel. [**241:**5.2.7]

A.16.2.1.7 Misuse of temporary heating devices has resulted in numerous fires and millions of dollars in property loss. Temporary heating equipment, while operating, should be visually inspected every hour to ensure that combustibles have not blown or fallen over near the temporary heating device. During windy periods, it might be necessary to reduce the interval between inspections. Any object near the temporary heating device that is hot to the touch should be moved, or the temporary heating device should be relocated. The visual inspection also should ensure that the appliance is operating properly. Any appliance that is not operating properly should be turned off until repairs have been made. [**241:**A.5.2.7]

Where plastic films are used for temporary enclosures, they must comply with Test Method 2 of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*. Plastic film used for temporary enclosure of buildings should be adequately fastened to ensure that it does not rip off and get blown against a heater or other heat-producing device. Storage of combustible construction materials should be kept a safe distance from any heating appliance.

16.2.1.8 Temporary heating equipment and devices noted to be damaged or considered to be a potential safety hazard shall not be used. [**241:**5.2.8]

16.2.1.9 Temporary heating equipment using exposed radiant heating wires shall not be used. [**241:**5.2.9]

16.2.1.10 Temporary electrical heating equipment shall be equipped with tip-over protection and overheat cutoffs. [**241:**5.2.10]

Δ **16.2.1.11** Chimney or vent connectors, where required from direct-fired heaters, shall be maintained at least 18 in. (460 mm) from combustibles and shall be installed in accordance with NFPA 211. [**241:**5.2.11]

16.2.1.12 Oil-fired heaters shall comply in design and installation features with Section 11.5. [**241:**5.2.12]

Δ **16.2.1.13** Fuel supplies for liquefied petroleum gas-fired heaters shall comply with NFPA 54 and Chapter 69. [**241:**5.2.13]

16.2.1.14* Refueling operations shall be conducted in an approved manner. [**241:**5.2.14]

A.16.2.1.14 This might necessitate the removal of the heater prior to refueling. The appliance also should be allowed to cool prior to refueling. [**241:**A.5.2.14]

16.2.2 Waste Disposal.

16.2.2.1* Accumulations of combustible waste material, dust, and debris shall be removed from the structure and its immediate vicinity at the end of each work shift or more frequently as necessary for safe operations. [**241:**5.4.1]

A.16.2.2.1 Failure to remove scrap and trash accumulations provides fuel for the rapid expansion of a fire that might otherwise be confined to a small area. These accumulations also provide a convenient fuel source for malicious fires. Open-topped dumpsters containing combustible materials should be emptied or moved to at least 35 ft (11 m) from combustible structures at the end of each work shift. [**241:**A.5.4.1]

If a chute is employed for the removal of debris, it should be erected on the outside of the building. The chute must be of noncombustible construction or protected by not less than one temporary automatic sprinkler in accordance with 16.2.2.4.3. (See 5.4.4.3 through 5.4.4.6 of NFPA 241.) The chute should be as straight vertically as practical to avoid the accumulation of combustibles or clogging within the chute.

Chutes often discharge into large dumpsters. Dumpsters are often the targets for carelessly discarded smoking materials or malicious fire setters. Dumpsters should be moved away from the building as soon as they are filled. If they are unable to be secured within a fenced area, they should be moved off site at night, on weekends, and when not in use. Dumpsters should be located at least 35 ft (11 m) from buildings of combustible construction or in accordance with Table 4.2.1 of NFPA 241 to prevent a fire in the dumpster from spreading to the building. See Chapter 19 for additional requirements pertaining to combustible waste and refuse.

16.2.2.2 Rubbish shall not be burned on the premises without first obtaining a permit from the AHJ. *(See Section 10.10.)* [**241:**5.4.2]

Section 10.10 specifies requirements for open burning, which include that the fire be constantly attended by personnel with ready access to fire-extinguishing equipment. Many jurisdictions and environmental protection laws prohibit burning construction materials due to air quality issues and the potential for contaminated water runoff.

16.2.2.3 Materials susceptible to spontaneous ignition, such as oily rags, shall be stored in a listed disposal container. [**241:**5.4.3]

16.2.2.4 Trash chutes, where provided, shall comply with 16.2.2.4.1 through 16.2.2.4.6. [**241:**5.4.4]

16.2.2.4.1* A trash chute safety plan shall be submitted to and approved by the AHJ. [**241:**5.4.4.1]

A.16.2.2.4.1 An approved safety plan should include the following:

(1) A fire watch should be in accordance with Section 5.1 of NFPA 241.
(2) Adequate fire protection should include sprinklers, hose, extinguishers, or barriers as needed for the particular hazard present, including the construction of the chute.
(3) Protection of openings in exterior walls and protection of combustible exterior building surfaces should be adjacent to the chute.
(4) At the end of each work day, provisions should be made to assure that exposure fires are minimized. *(See 16.2.2.1.)*
(5) Trash chutes used in the interior of a building should be of noncombustible construction.
(6) The main artery of the chute should be as straight as practical to avoid accumulations or clogging within the chute.

[**241:**A.5.4.4.1]

16.2.2.4.2 Trash chutes used on the exterior of a building shall be of noncombustible construction, or protected in accordance with 16.2.2.4.3 through 16.2.2.4.6 if of combustible construction. [**241:**5.4.4.2]

16.2.2.4.3* The interior of combustible trash chutes shall be provided with not less than one temporary automatic sprinkler within a recess near the top of the chute. [**241:**5.4.4.3]

Δ **A.16.2.2.4.3** The temporary sprinkler or sprinklers are not required to comply with NFPA 13. Where trash chutes have a length exceeding 36 ft (11 m), intermittent levels of sprinkler protection should be provided at intervals not exceeding 36 ft (11 m). The use of fire retardant coatings can be substituted for sprinkler protection provided that the coating is compatible with the substrate, abrasion resistant, and approved by the AHJ. [**241:**A.5.4.4.3]

16.2.2.4.4 The temporary sprinkler required by 16.2.2.4.3 shall be protected by the recess as well as a listed sprinkler guard. [**241:**5.4.4.4]

16.2.2.4.5 The temporary sprinkler required by 16.2.2.4.3 shall be connected to any available water supply with a listed fire hose, or a flexible, commercial rubber hose, with a diameter of not less than ¾ in. (19 mm) and a listed flexible connector. [**241:**5.4.4.5]

16.2.2.4.6 The temporary sprinkler required by 16.2.2.4.3 shall be protected against freezing where required by the AHJ. [**241:**5.4.4.6]

Trash chutes can create a means for fire to travel from outside the building to the inside and from floor to floor. See the commentary following A.16.2.2.1.

16.2.3 Flammable and Combustible Liquids and Flammable Gases.

16.2.3.1 Storage.

16.2.3.1.1 Storage of flammable and combustible liquids shall be in accordance with Chapter 66, unless otherwise modified by 16.2.3. [**241:**5.5.1.1]

16.2.3.1.2* Storage of Class I and Class II liquids shall not exceed 60 gal (227 L) within 50 ft (15 m) of the structure. [**241:**5.5.1.2]

A.16.2.3.1.2 The reference to "structure" is intended to apply to those structures under construction, alteration, or demolition and not to temporary structures on the construction site. Additionally, existing properly protected storage within 50 ft (15 m) of the structure or inside an existing structure under alteration is not intended to be regulated by this provision. [**241:**A.5.5.1.2]

16.2.3.1.3 Storage areas shall be kept free of weeds, debris, and combustible materials not necessary to the storage. [**241:**5.5.1.3]

Weeds, debris, and other combustible materials are an avenue for fire spread to liquid and gas storage areas. See 10.13.10 for additional requirements regarding exterior vegetation.

16.2.3.1.4 Open flames and smoking shall not be permitted in flammable and combustible liquids storage areas. [**241:**5.5.1.4]

16.2.3.1.5 Such storage areas shall be appropriately posted as "No Smoking" areas. [**241:**5.5.1.5]

Δ **16.2.3.1.6** Storage areas shall be appropriately posted with markings in accordance with NFPA 704. [**241:**5.5.1.6]

16.2.3.2 Handling of Flammable and Combustible Liquids at Point of Final Use.

16.2.3.2.1 Handling of flammable and combustible liquids shall be in accordance with Chapter 66, except as modified by 16.2.3.2.2 through 16.2.3.2.4. [**241:**5.5.2.1]

16.2.3.2.2 Class I and Class II liquids shall be kept in approved safety containers. [**241:**5.5.2.2]

16.2.3.2.3 Means shall be provided to dispose of leakage and spills promptly and safely. [**241:**5.5.2.3]

16.2.3.2.4* Class I liquids shall be dispensed only where there are no open flames or other sources of ignition within the possible path of vapor travel. [**241:**5.5.2.4]

A.16.2.3.2.4 The vapors given off by flammable liquids generally have vapor densities greater than those of air. Therefore, these vapors tend to collect in low spots and travel at floor level. Being invisible, these vapors are difficult to detect without the aid of proper instruments designed specifically for the purpose. [**241:**A.5.5.2.4]

Proper ventilation is, therefore, important in the prevention of accidental ignition of these vapors. Proper ventilation can be accomplished by either natural or mechanical means. [**241:**A.5.5.2.4]

16.2.3.3 Storage and Handling of Combustible and Flammable Gases.

Δ **16.2.3.3.1** Storage and handling of combustible and flammable gases shall be in accordance with NFPA 54 and Chapter 69. [**241:**5.5.3.1]

16.2.3.3.2 Open flames and smoking shall not be permitted in flammable gas storage areas. [**241:**5.5.3.2]

Subsection 10.1.6 and Section 10.10 prescribe additional requirements related to open flames and smoking. The AHJ is authorized to prohibit any such activity wherever it poses a hazard.

16.3 Fire Protection

This section covers items that need to be in the fire protection program and apply throughout the duration of the project.

16.3.1 Fire Safety Program.

16.3.1.1 An overall construction or demolition fire safety program shall be developed.

Δ **16.3.1.2** All of the following items shall be addressed in the fire safety program:

(1) Good housekeeping
(2) On-site security
(3) Fire protection systems
  (a) For construction operations, installation of new fire protection systems as construction progresses
  (b) For demolition operations, preservation of existing fire protection systems during demolition
(4) Organization and training of an on-site fire brigade
(5) Development of a prefire plan with the local fire department
(6) Rapid communication
(7) Consideration of special hazards resulting from previous occupancies
(8) Protection of existing structures and equipment from exposure fires resulting from construction, alteration, and demolition operations

[**241:**7.1]

16.3.2 Owner's Responsibility for Fire Protection.

16.3.2.1* The owner shall designate a person who shall be responsible for the fire prevention program and who shall ensure that it is carried out to completion. [**241:**7.2.1]

A.16.3.2.1 One person should be made responsible for the protection of property from fire. This person should ensure that the proper procedures for controlling fire hazards are established and should have full authority to enforce them. [**241:**A.7.2.1]

The responsible person should be appointed by the owner. Where an entirely new structure is being constructed, the owner should ensure that specifications for new buildings contain a clause stating that the "contractor will take all reasonable precautions against fire in accordance with good fire protection engineering practice." [**241:**A.7.2.1]

The responsibility for loss prevention is the owner's. However, loss prevention recommendations normally are accomplished by the contractor. To ensure that recommendations are carried out promptly, the owner's assistance might be needed. [**241:**A.7.2.1]

Fire prevention education should be a topic at contractor safety meetings ("tailgate talks") at least once a month. Topics that could be discussed include maintaining clear access to fire-fighting equipment, reinforcing cutting and welding procedures, flammable liquids use and storage, use of first aid fire-fighting equipment, roofing operations, and precautions for the use of temporary heating equipment. [**241:**A.7.2.1]

All fires should be investigated by the program manager, and necessary fire prevention improvements that are identified by the investigation should be communicated to all employees as soon as possible. [**241:**A.7.2.1]

16.3.2.1.1 The fire prevention program manager shall have the authority to enforce the provisions of NFPA 241 and other applicable fire protection standards. [**241:**7.2.1.1]

16.3.2.1.2 The fire prevention program manager shall have knowledge of the applicable fire protection standards, available fire protection systems, and fire inspection procedures. [**241:**7.2.1.2]

16.3.2.1.3 Inspection records shall be available for review by the AHJ. [**241:**7.2.1.3]

The AHJ should inform the fire prevention program manager of all inspection records, which must be completed and made available for review. The records should be part of an organized filing system so that they are readily accessible.

16.3.2.2 Where guard service is provided, the fire prevention program manager shall be responsible for the guard service. [**241:**7.2.2]

NFPA 601, *Standard for Security Services in Fire Loss Prevention,* provides guidance for incorporating security services into the fire safety program.

16.3.2.3* Prefire Plans.

A.16.3.2.3 Large-scale construction sites change rapidly as construction progresses. The prefire plan should be flexible to allow for different stages of construction. Critical stages that should be considered include access, installation of water mains and fire hydrants, framing/exterior shell, roofing, covering of interior partitions, installation of fixed fire protection, concrete form work, installation of building systems, and construction safety hazards. [**241:**A.7.2.3]

Since construction projects do change, the local fire department should be encouraged to visit the site on a regular basis. Prefire plan visits should be scheduled by the manager at least semiannually and when there have been major revisions to the fire prevention plan. Since municipal fire departments work rotating shifts, a series of prefire plan visits might be necessary to allow all responding fire fighters an opportunity to visit the site. In rural areas and smaller cities, the local fire department might be a volunteer organization or might have only a small career fire fighter crew on duty during the day. It might be necessary for the manager to schedule the prefire plan visit during the evening hours to meet the needs of the local fire department. [**241:**A.7.2.3]

16.3.2.3.1 Where there is public fire protection or a private fire brigade, the manager shall be responsible for the development of prefire plans in conjunction with the fire agencies. [**241:**7.2.3.1]

16.3.2.3.2 Prefire plans shall be updated as necessary. [**241:**7.2.3.2]

16.3.2.3.3 The prefire plan shall include provisions for on-site visits by the fire agency. [**241:**7.2.3.3]

The fire department should tour the construction site during various stages of the project to become familiar with the layout and fire protection systems. The fire department should be notified of changes that could affect its response, such as changes to the building layout or the installation of new fire protection systems. All shifts should be included in the fire department tours to ensure that emergency responders are familiar with the project in the event of a fire.

16.3.2.4 Program Manager Responsibilities.

16.3.2.4.1 The manager shall be responsible for ensuring that proper training in the use of protection equipment has been provided. [**241:**7.2.4.1]

16.3.2.4.2 The manager shall be responsible for the presence of adequate numbers and types of fire protection devices and appliances and for their proper maintenance. [**241:**7.2.4.2]

16.3.2.4.3 The manager shall be responsible for supervising the permit system for hot work operations. *(See Section 5.1 of NFPA 241.)* [**241:**7.2.4.3]

See Chapter 41 for additional requirements related to welding, cutting, and other hot work operations.

16.3.2.4.4 A weekly self-inspection program shall be implemented, with records maintained and made available. [**241:**7.2.4.4]

16.3.2.4.5* Impairments to the fire protection systems or fire alarm, detection, or communications systems shall be authorized only by the fire prevention program manager. [**241:**7.2.4.5]

A.16.3.2.4.5 See NFPA *101* for impairments to fire protection systems or fire alarm, detection, or communication systems where required by that code. In addition, see *NFPA 72* for impairments resulting to fire alarm equipment and NFPA 25 for impairments resulting to water-based fire protection equipment. [**241:**A.7.2.4.5]

Where a fire protection system must be taken out of service to accommodate a project, only the portion of the system directly affected by the work should be shut down. The portion of the building rendered unprotected should be limited to the smallest area possible. The system should be returned to service at the end of the shift or the day where practical. Where a portion of a building's fire protection system is impaired and the remainder of the building is occupied, a fire watch might be required. See 13.3.3.6 for water-based fire protection system impairments and 13.7.1 for fire alarm system impairments.

16.3.2.4.6 Temporary protective coverings used on fire protection devices during renovations, such as painting, shall be removed promptly when work has been completed in the area. [**241:**7.2.4.6]

A designated person should be assigned to walk the construction site and ensure that no fire protection system component is damaged or otherwise impaired and that protective covers are removed following the completion of construction, alteration, or demolition operations.

16.3.2.5 Site Security.

16.3.2.5.1* Guard service shall be provided where required by the AHJ. [**241:**7.2.5.1]

A.16.3.2.5.1 Due to the growing threat of arson, guard service should be provided on major projects even where not required by the AHJ. The requirements for guard service also should be based on, but should not be limited to, the hazards at the site, the size of the risk, the difficulty of the fire-fighting situation, the exposure risk, and the physical security of the site. [**241:**A.7.2.5.1]

Δ **16.3.2.5.2*** Where guard service is provided, the guard(s) shall be trained in all of the following:

(1) Notification procedures that include calling the fire department and management personnel
(2) Function and operation of fire protection equipment
(3) Familiarization with fire hazards
(4) Use of construction elevators, where provided

[**241:**7.2.5.2]

Δ **A.16.3.2.5.2** It is recommended that areas in buildings should be patrolled at all times when construction, alteration, and demolition operations are not in progress by a competent guard registered on an approved security tour supervision system (watch clock) with stations covering all parts of the building in accordance with NFPA 601. Guard rounds should include all parts of the buildings and outside areas where hazardous equipment or materials are located. Rounds should be conducted every ½ hour for 2 hours after suspension of work for the day and every hour thereafter during the night and nonworking days and should include tours of all accessible work areas. [**241:**A.7.2.5.2]

Guards, where utilized, need to be familiar with and have access to a means to contact the fire department in the event of an emergency. They also need to be familiar with fire protection system locations and operations on site. If any specific fire hazards are present, such as certain construction operations, processes, or materials, guards should be familiar with the associated hazards so they can identify the hazards when notifying the fire department during an emergency.

Guards should have access to and the ability to operate construction elevators for emergency use. Security personnel should be trained in the use of portable fire extinguishers and the operation of any special fire protection features. They also should be provided with keys to permit access to all areas of the building.

16.3.2.5.3 Guards shall be informed of any special status of emergency equipment or hazards. [**241:**7.2.5.3]

16.3.2.5.4* Security fences shall be provided where required by the AHJ. [**241:**7.2.5.4]

A.16.3.2.5.4 The requirements for security fencing should be based on, but should not be limited to, the hazards at the site, the size of the risk, the difficulty of the fire-fighting situation, the exposure risk, and the presence of guard service. [**241:**A.7.2.5.4]

16.3.2.5.5* Entrances (e.g., doors and windows) to the structure under construction, alteration, or demolition shall be secured where required by the AHJ. [**241:**7.2.5.5]

A.16.3.2.5.5 Securing the openings (doors and windows) to the structure, where possible, reduces the chance of entry by unauthorized persons. This, in turn, reduces the chance of arson or accidental fires. It could, in some instances, eliminate the need for guard service or security fencing. It also helps prevent freezing or wind damage to fire protection equipment and prevents combustible material from being blown against heating devices and igniting. [**241:**A.7.2.5.5]

16.3.3* Fire Alarm Reporting.

A.16.3.3 In large projects or tall structures, or both, the use of an audible device for an evacuation signal in case of fire or other emergency is recommended. [**241:**A.7.4]

16.3.3.1 There shall be a readily available public fire alarm box near the premises, telephone service to the responding fire department, or equivalent facilities. [**241:**7.4.1]

16.3.3.2 Instructions shall be issued for the immediate notification of the fire department in the case of a fire. Where telephone service is employed, the local fire department number and site address shall be conspicuously posted near each telephone. [**241:**7.4.2]

Workers might not be permanently assigned to the construction project, and many different workers could be brought in daily. These workers might not know the address of the building or the emergency telephone numbers. A plan should be established to inform all workers of this information no matter when they come on the site or how long they will be there.

16.3.4 Access for Fire Fighting.

16.3.4.1 A suitable location at the site shall be designated as a command post and provided with plans, emergency information, keys, communications, and equipment, as needed. [**241:**7.5.1]

The construction trailer typically houses building plans, telephones, keys, tables and chairs, and other items and could be used as the command post required by 16.3.4.1. If the required items are scattered among numerous trailers, relocating the items to one trailer and designating it as the command post might be beneficial.

16.3.4.2 The person in charge of fire protection shall respond to the location command post whenever fire occurs. [**241:**7.5.2]

16.3.4.3 Where access to or within a structure or an area is unduly difficult because of secured openings or where immediate access is necessary for life-saving or fire-fighting purposes, the AHJ shall be permitted to require a key box to be installed in an accessible location. [**241:**7.5.3]

16.3.4.4 The key box shall be an approved type and shall contain keys to gain access as required by the AHJ. *(See Section 18.2.)* [**241:**7.5.4]

Access boxes are required by 18.2.2.1 to be listed in accordance with ANSI/UL 1037, *Standard for Antitheft Alarms and Devices*.

16.3.4.5 Stairs.

16.3.4.5.1 In all buildings over one story in height, at least one stairway shall be provided that is in usable condition at all times and that meets the requirements of NFPA *101*. [**241:**7.5.6.1]

16.3.4.5.2 This stairway shall be extended upward as each floor is installed in new construction and maintained for each floor still remaining during demolition. [**241:**7.5.6.2]

16.3.4.5.3 The stairway shall be lighted. [**241:**7.5.6.3]

Stairway illumination is important during construction and demolition operations. The power source for the lights should be reliable; it should not be subject to accidental disconnection or failure early in a fire. Stairway illumination should be maintained even when construction workers are not in the building, because fire fighters and security personnel might need to use the stairs to access upper stories during hours when construction is not taking place.

16.3.4.5.4 During construction, the stairway shall be enclosed where the building exterior walls are in place. [**241:**7.5.6.4]

16.3.4.5.5 All exit stairs shall be provided with stair identification signs to include the floor level, stair designation, and exit path direction as required to provide for safe egress. [**241:**7.5.6.5]

See 10.11.3 for detailed requirements regarding stairway identification signs.

16.3.5 Standpipes. In all new buildings in which standpipes are required or where standpipes exist in buildings being altered or demolished, such standpipes shall be maintained in conformity with the progress of building construction in such a manner that they are always ready for use. [**241:**7.6]

An operating standpipe system(s) is required to be extended or removed by floor as construction or demolition takes place. When a new floor is added and the stairs required by 16.3.4.5 are installed, the standpipe system is required to be extended at the same time. Conversely, when demolition is taking place, the standpipe is required to be removed floor by floor as floors are removed.

16.3.6* First-Aid Fire-Fighting Equipment.

A.16.3.6 Portable fire extinguishers, water pails, small hose lines, and 1.5 in. (38 mm) standpipe hose are considered first-aid fire-fighting equipment. To be effective, first-aid fire-fighting equipment should be used in the incipient stage of a fire. [**241:**A.7.7]

16.3.6.1* The suitability, distribution, and maintenance of extinguishers shall be in accordance with Section 13.6. [**241:**7.7.1]

A.16.3.6.1 A suitable number and type of spare fire extinguishers should be provided on site for immediate replacement of discharged fire extinguishers. [**241:**A.7.7.1]

Fire extinguishers should be suitable for the type of equipment and hazard. A single, multipurpose (A:B:C) dry chemical extinguisher that has a normal capacity of 5 lb (2.3 kg) of extinguishing agent and a rating of at least 2-A:10-B:C should be the minimum. However, a risk assessment should be performed to determine whether larger extinguishers or additional extinguishers are needed for specific conditions. Extinguishers should be mounted in conspicuous locations, in the vicinity of heating appliances, and on mobile equipment so that they are immediately available in case of fire. See Section 13.6 and NFPA 10, *Standard for Portable Fire Extinguishers*

16.3.6.2 Wherever a toolhouse, storeroom, or other shanty is located in or adjacent to the building under construction or demolition, or where a room or space within that building is used for storage, a dressing room, or a workshop, at least one approved extinguisher shall be provided and maintained in an accessible location, unless otherwise permitted by 16.3.6.3. [**241:**7.7.2]

16.3.6.3 The requirement of 16.3.6.2 shall be permitted to be waived where the structure does not exceed 150 ft^2 (14 m^2) in floor area or is equipped with automatic sprinklers or other approved protection. [**241:**7.7.3]

16.3.6.4 At least one approved fire extinguisher also shall be provided in plain sight on each floor at each usable stairway as soon as combustible material accumulates. [**241:**7.7.4]

16.3.6.5 Suitable fire extinguishers shall be provided on self-propelled equipment. [**241:**7.7.5]

Case Study

On August 18, 2007, two New York City fire fighters died, and another 115 were injured, in a fire that started on the 17th floor of the Deutsche Bank building, which was in the process of being deconstructed after sustaining heavy damage from the collapse of the World Trade Center towers on September 11, 2001. At the time of the fire, the former 41-story building had been reduced to 26 stories and was undergoing asbestos abatement. The fire was reportedly caused by smoking materials. Fire suppression efforts were hampered by the lack of functioning standpipes, which required fire fighters to stretch hose lines up to the fire floor from the ground. The operation was further complicated by a maze of polyethylene sheets, which had been installed to contain asbestos but which also served to contain smoke and hinder fire suppression. This fire vividly illustrates the need to maintain fire protection systems in accordance with NFPA 241 in buildings during demolition operations. (See Section 16.8 for details on asbestos removal.)

16.3.6.6* Free access to permanent, temporary, or portable first-aid fire equipment shall be maintained at all times. [**241:**7.7.6]

Δ **A.16.3.6.6** Clear and unobstructed access to all first-aid fire-fighting equipment should be maintained. Fire-fighting equipment also should be clearly visible from surrounding areas. If visibility to first-aid fire-fighting equipment is obstructed, signs in accordance with NFPA 170 should be installed to indicate the position of the fire-fighting equipment. [**241:**A.7.7.6]

16.4 Safeguarding Construction and Alteration Operations

16.4.1* Scaffolding, Shoring, and Forms.

A.16.4.1 Steel scaffolding or approved fire-retardant lumber and planking should be used on both the outside and inside of the structure. Construction materials (e.g., forms, shoring, bracing, temporary stairways, platforms, tool boxes, plan boxes, solvents, paints, tarpaulins, and similar items) should be of the noncombustible, fire-retardant, safety solvent, or high flash point type, as the case necessitates. A concerted effort should be made to attain as high a level of noncombustibility of materials as possible. *(See the definition of the term "fire retardant-treated wood" in the building code.)* [**241:**A.8.2]

16.4.1.1 Accumulations of unnecessary combustible forms or form lumber shall be prohibited. [**241:**8.2.1]

16.4.1.2 Combustible forms or form lumber shall be brought into the structure only when needed. [**241:**8.2.2]

16.4.1.3 Combustible forms or form lumber shall be removed from the structure as soon as stripping is complete. [**241:**8.2.3]

16.4.1.4 Those portions of the structure where combustible forms are present shall not be used for the storage of other combustible building materials. [**241:**8.2.4]

16.4.1.5* During forming and stripping operations, portable fire extinguishers or charged hose lines shall be provided to protect the additional combustible loading adequately. [**241:**8.2.5]

A.16.4.1.5 The AHJ should be contacted regarding the adequacy of water supplies for hose lines. [**241:**A.8.2.5]

Based on an evaluation of the potential fire loading, the AHJ should establish the level of fire suppression capability needed. Such capability should include the minimum hose stream flow where hose lines are provided. Consideration should be given to whether form work, shoring, or scaffolding materials are of ordinary wood materials or of steel or fire-retardant–treated wood materials. Fire-retardant–treated wood should comply with NFPA 703, *Standard for Fire-Retardant–Treated Wood and Fire-Retardant Coatings for Building Materials*.

16.4.2 Temporary Separation Walls.

16.4.2.1 Protection shall be provided to separate an occupied portion of the structure from a portion of the structure undergoing alteration, construction, or demolition operations when such operations are considered as having a higher level of hazard than the occupied portion of the building. [**241:**8.6.2.1]

The intent of 16.4.2.1 is to provide a fire barrier between the construction area and the normally occupied portion of the building where the AHJ determines such construction activities pose a hazard to building occupants. The barrier protects against fire spread from the construction area to the occupied portion of the building and also prevents occupants from entering the construction area and consequently subjecting themselves to potential hazards created by construction activities.

16.4.2.2 Walls shall have at least a 1-hour fire resistance rating. [**241:**8.6.2.2]

16.4.2.3 Opening protectives shall have at least a 45-minute fire protection rating. [**241:**8.6.2.3]

Doors leading to construction areas are often made of plywood or other inexpensive materials. Where a fire barrier is required to separate the construction area from the remainder of the building, doors in the barrier must have a 45-minute fire protection rating. A plywood door has no fire protection rating. Rated doors must be labeled, self-closing, and positive-latching. See NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, for further details.

Where a portion of the building is walled off for construction purposes, it is important to ensure that means of egress from occupied portions of the building are not compromised. For example, where access to a required exit stair requires travel through a construction area, alternative egress provisions or other protection measures might be required. See Chapter 43 of NFPA *101*®, *Life Safety Code*®, for further details on building rehabilitation.

16.4.2.4* Nonrated walls and opening protectives shall be permitted when an approved automatic sprinkler system is installed. [**241:**8.6.2.4]

A.16.4.2.4 Construction tarpaulins would not be considered appropriate barriers or opening protectives. [**241:**A.8.6.2.4]

Such barriers must be structural in nature and securely fastened at the top and the bottom to structural components of the building.

16.4.3 Fire Protection During Construction.

16.4.3.1 Water Supply.

16.4.3.1.1* A water supply for fire protection, either temporary or permanent, shall be made available as soon as combustible material accumulates. [**241:**8.7.2.1]

A.16.4.3.1.1 No minimum water supply is specified due to the wide range of construction types, sites, and sizes. However, unless combustibles are essentially nonexistent in the completed structure and occupancy, a minimum of 500 gpm (1893 L/min) should be provided. In most instances, the required supply is greater, and AHJs should be consulted. [**241:**A.8.7.2.1]

See Section 18.3 through 18.5 for additional details on water supply and fire hydrant locations and distribution.

16.4.3.1.2 There shall be no delay in the installation of fire protection equipment. *(See A.16.4.1.5.)* [**241:**8.7.2.2]

Where the installation of the permanent water supply is delayed, the contractor should coordinate with the AHJ to ensure that the temporary fire protection water supply is adequate for the hazards present at the site.

16.4.3.1.3* Where underground water mains and hydrants are to be provided, they shall be installed, completed, and in service prior to commencing construction work on any structure. [**241:**8.7.2.3]

A.16.4.3.1.3 It is not intended to prohibit the construction of noncombustible structure foundation elements, such as foundations and footings, prior to the completion of underground water mains and hydrants. [**241:**A.8.7.2.3]

Planned underground water mains and hydrants serving the building site must be installed and in service prior to the start of the construction of the building. If the water for fire protection is provided by some other means, such as a water truck, such alternative water source must be available prior to the start of construction on the site. The *Code* does not intend to prohibit site work prior to the installation of the fire protection water supply.

16.4.3.2 Sprinkler Protection.

16.4.3.2.1* If automatic sprinkler protection is to be provided, the installation shall be placed in service as soon as practicable. [**241:**8.7.3.1]

A.16.4.3.2.1 With proper scheduling and contracting, it is possible for the sprinkler installation to follow the building construction closely as it progresses. This is frequently done in multiple-story buildings to facilitate protection on the lower floors before the upper floors have been built. [**241:**A.8.7.3.1]

16.4.3.2.2 The details of installation shall be in accordance with NFPA 13. [**241:**8.7.3.2]

16.4.3.2.3 Where sprinklers are required for safety to life, the building shall not be occupied until the sprinkler installation has been entirely completed and tested so that the protection is not susceptible to frequent impairment caused by testing and correction, unless otherwise permitted by 16.4.3.2.4. [**241:**8.7.3.3]

There are times when buildings that are still under construction are given temporary or partial certificates of occupancy for specified areas in which construction has been completed. Where the sprinkler system is required for life safety (i.e., required by this *Code* or NFPA *101*), the entire building sprinkler system should be installed, tested, and accepted prior to issuance of the temporary or partial certificate of occupancy. If the system is not complete prior to occupancy, it will be impaired frequently to complete installation, rendering the building and its occupants unprotected.

16.4.3.2.4 The provision of 16.4.3.2.3 shall not prohibit occupancy of the lower floors of a building, even where the upper floors are in various stages of construction or protection, provided that both of the following conditions are satisfied:

(1) The sprinkler protection of the lower occupied floors has been completed and tested in accordance with 16.4.3.2.3.
(2) The sprinkler protection of the upper floors is supplied by entirely separate systems and separate control valves so that the absence or incompleteness of protection in no way impairs the sprinkler protection of the occupied lower floors.

[**241:**8.7.3.4]

16.4.3.2.5 The operation of sprinkler control valves shall be permitted only by properly authorized personnel and shall be accompanied by the notification of duly designated parties. [**241:**8.7.3.5]

See 13.3.3.4.1.11 and NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, for additional requirements pertaining to automatic sprinkler system impairments.

16.4.3.2.6 Where the sprinkler protection is regularly turned off and on to facilitate connection of newly completed segments, the sprinkler control valves shall be checked at the end of each work shift to ascertain that protection is in service. [**241:**8.7.3.6]

16.4.3.3 Standpipes.

16.4.3.3.1 General.

16.4.3.3.1.1* The pipe size, hose valves, hose, water supply, and other details for new construction shall be in accordance with Section 13.2. [**241:**8.7.4.1.1]

A.16.4.3.3.1.1 Threaded plugs should be inserted in fire department hose connections, and they should be guarded properly against physical damage. [**241:**A.8.7.4.1.1]

16.4.3.3.1.2 On permanent Type II and Type III standpipes, hose and nozzles shall be provided and made ready for use as soon as the water supply is available to the standpipe, unless otherwise permitted by 16.4.3.3.1.3. [**241:**8.7.4.1.2]

16.4.3.3.1.3* In combined systems where occupant hose is not required, temporary hose and nozzles shall be provided during construction. [**241:**8.7.4.1.3]

A.16.4.3.3.1.3 The intent of this provision is to permit the permanent standpipes to be used as temporary standpipes during construction. [**241:**A.8.7.4.1.3]

16.4.3.3.2 Standpipe Installations in Buildings Under Construction. Where required by the AHJ, in buildings under construction, a standpipe system, either temporary or permanent in nature, shall be installed in accordance with 16.4.3.3.2.1 through 16.4.3.3.2.10. [**241:**8.7.4.2]

16.4.3.3.2.1 The standpipes shall be provided with conspicuously marked and readily accessible fire department connections on the outside of the building at the street level and shall have at least one standard hose outlet at each floor. [**241:**8.7.4.2.1]

Standpipe systems must be installed in stairways as required by 16.4.3.3 and marked for easy identification. A fire department connection must be provided, must be conspicuously marked, and must be kept clear of debris and other items in accordance with 13.1.3 and 13.1.4.

16.4.3.3.2.2 The pipe sizes, hose valves, hose, water supply, and other details for new construction shall be in accordance with NFPA 241. [**241:**8.7.4.2.2]

16.4.3.3.2.3 The standpipes shall be securely supported and restrained at each alternate floor. [**241:**8.7.4.2.3]

16.4.3.3.2.4* At least one approved hose valve for attaching fire department hose shall be provided at each intermediate landing or floor level in the exit stairway, as determined by the AHJ. [**241:**8.7.4.2.4]

A.16.4.3.3.2.4 A substantial box, preferably of metal, in which a sufficient amount of hose to reach all parts of the floor, appropriate nozzles, spanner wrenches, and hose straps are kept should be maintained at the highest hose outlet. [**241:**A.8.7.4.2.4]

16.4.3.3.2.5 Valves shall be kept closed at all times and guarded against mechanical injury. [**241:**8.7.4.2.5]

Δ **16.4.3.3.2.6** Hose valves shall have NH standard external threads for the valve size specified in accordance with NFPA 1963 unless modified by 16.4.3.3.2.7. [**241:**8.7.4.2.6]

16.4.3.3.2.7 Where local fire department connections do not conform to NFPA 1963, the AHJ shall designate the connection to be used. [**241:**8.7.4.2.7]

16.4.3.3.2.8* The standpipes shall be extended up with each floor and shall be securely capped at the top. [**241:**8.7.4.2.8]

A.16.4.3.3.2.8 A supply of fire hose and nozzles should be ordered in advance so that it is available as soon as the standpipes are ready. Hose lines should be connected in areas where construction is in progress. [**241:**A.8.7.4.2.8]

16.4.3.3.2.9 Top hose outlets shall be not more than one floor below the highest forms, staging, and similar combustibles at all times. [**241:**8.7.4.2.9]

16.4.3.3.2.10 Temporary standpipes shall remain in service until the permanent standpipe installation is complete. [**241:**8.7.4.2.10]

16.4.4 Alteration of Buildings.

16.4.4.1 Where the building is protected by fire protection systems, such systems shall be maintained operational at all times during alteration.

16.4.4.2 Where alteration requires modification of a portion of the fire protection system, the remainder of the system shall be kept in service and the fire department shall be notified.

16.4.4.3 When it is necessary to shut down the system, the AHJ shall have the authority to require alternate measures of protection until the system is returned to service.

16.4.4.4 The fire department shall be notified when the system is shut down and when the system is returned to service.

See 13.3.3.4.1.5, 13.3.3.4.1.11, 13.3.3.6, and NFPA 25 for additional requirements pertaining to water-based fire protection system impairments. See 13.7.1.5 and *NFPA 72®, National Fire Alarm and Signaling Code*, for fire alarm system impairments.

16.4.4.5 All required exit components shall be maintained in accordance with this *Code* as deemed necessary by the AHJ.

16.4.4.6 Fire-resistive assemblies and construction shall be maintained.

16.5 Fire Safety During Demolition

16.5.1 If a building intended to be demolished contains a sprinkler system, such system shall not be rendered inoperative without approval of the AHJ.

The intent of 16.5.1 is to ensure that the responding fire suppression forces know that the building is no longer protected by an automatic sprinkler system. Emergency responders can then appropriately revise their tactical approach to a fire in the building. The sprinkler system should be maintained in service until the actual demolition begins and should not be shut off days or weeks before the start of the demolition process. If the building is to be demolished in sections and the protection in certain sections can be maintained during the demolition of other sections, such protection should be maintained for as long as possible.

16.5.2 Demolition operations involving the use of cutting and welding shall be done in accordance with Chapter 41.

16.5.3 Combustible waste material shall not be burned at the demolition site unless approved by the AHJ. Combustible materials shall be removed from the site as often as necessary to minimize the hazards therefrom. *(See 16.2.2 and Section 10.10.)*

See Section 10.10 for open burning requirements.

16.5.4 Where in the opinion of the AHJ the demolition site is of a hazardous nature, qualified personnel shall serve as an on-site fire watch.

16.6 Torch-Applied Roofing Systems

16.6.1 Permits. Permits, where required, shall comply with Section 1.12.

Δ **16.6.2** Torch-applied roofing systems shall be installed in accordance with Chapter 9 of NFPA 241.

16.7 Tar Kettles and Rubberized Asphalt Melters

16.7.1 General.

16.7.1.1 The provisions of Section 16.7 shall apply to any type of equipment including, but not limited to, chassis-mounted equipment used for preheating or heating tar, asphalt, rubberized asphalt, pitch, or similar substances for roofs, floors, pipes, or similar objects.

Equipment addressed in Section 16.7 includes tar kettles and rubberized asphalt melters.

16.7.1.2 Permits. Permits, where required, shall comply with Section 1.12.

•

Section 1.12 of this *Code* gives the AHJ the authority to issue permits for tar kettles.

N **16.7.2 Tar Kettles.**

N **16.7.2.1** Operating kettles shall not be located inside of or on the roof of any building.

Tar and asphalt kettles must be located outdoors, away from combustibles. Uninsulated fuel containers must be kept at least 10 ft (3 m) from the burner flame and should be secured to prevent them from tipping or falling over. Kettles are not permitted to be operated on the roofs of buildings.

16.7.2.2 Tar Kettle Location. The kettle shall be operated in a controlled area. The area shall be identified by the use of traffic cones, barriers, and other suitable means as approved by the AHJ.

The area in which tar kettles are operating should be protected from entry by unauthorized persons. Protection is best accomplished by fencing. Rope, tape, or other barriers can be used with the approval of the AHJ. In addition, warning signs should be posted if the kettle is in an area that is easily accessible to the public.

16.7.2.3 Kettle Supervision.

16.7.2.3.1 An operating kettle shall be attended by a minimum of one employee who is knowledgeable of the operations and hazards.

16.7.2.3.2 The employee shall be within 25 ft (7.6 m) of the kettle and shall have the kettle within sight.

At least one attendant familiar with the operation of the kettle needs to be within 25 ft (7.6 m) of an operating kettle at all times. It is the attendant's responsibility to ensure that no unauthorized personnel enter the control area, to monitor the kettle, to extinguish fires, and to perform other necessary duties. Although the *Code* does not specify where within the required distance this attendant must be located, the designated individual should be on the ground, rather than on a ladder or a roof, in order to effectively perform the required duties.

16.7.2.4 Fire Extinguishers.

16.7.2.4.1 Two approved 4-A:40-B:C fire extinguishers shall be provided and maintained within 25 ft (7.6 m) of the operating kettle.

Fire extinguishers are to be maintained at the site and are not to be kept on a vehicle that might be away from the site when a fire extinguisher is needed. The AHJ should specify where and how the extinguishers are to be stored, giving consideration to the site and the need to quickly access the extinguishers without having to pass by a burning kettle. If a fire extinguisher is used, it should be recharged or replaced immediately so an extinguisher is available in the event of another fire.

16.7.2.4.2* A minimum of one approved 4-A:40-B:C fire extinguisher shall be provided and maintained on the roof in close proximity to the roofing operations while the roofing material is being applied.

A.16.7.2.4.2 Appropriate means should be provided to prevent portable fire extinguishers from damage and secured from falling when roofing operations are being conducted.

16.7.2.4.3 Fire extinguishers shall be mounted in an accessible and visible or identified location.

16.7.2.5 Exits.

16.7.2.5.1 Roofing kettles shall not block exits, means of egress, gates, roadways, or entrances.

16.7.2.5.2 Kettles shall not be closer than 10 ft (3 m) from exits or means of egress.

16.7.2.6 Fuel System.

16.7.2.6.1 Fuel containers shall be constructed and approved for the use for which they were designed.

16.7.2.6.2 Liquefied petroleum gas (LP-Gas) containers, hose, regulators, and burners shall conform to the requirements in Chapter 69.

16.7.2.6.3 LP-Gas cylinders shall be secured to prevent accidental tipover.

16.7.2.7 Regulators shall be required on any cylinders.

16.7.2.8 Where, in the opinion of the AHJ, physical damage to the container is a danger, protection shall be provided to prevent such physical damage.

If the location of a tar kettle makes it susceptible to being hit by passing traffic, physical barriers acceptable to the AHJ should be provided to protect the fuel container and workers.

16.7.2.9 LP-Gas containers for roofing kettles shall not be used in any building.

16.7.2.10 Maintenance.

16.7.2.10.1 Roofing kettles and all integral working parts shall be in good working condition and shall be maintained free of excessive residue.

16.7.2.10.2 All piping used for pumping heated material to the roof shall be installed in a manner to prevent loss of heated material.

The requirement of 16.7.2.10.2 is intended to ensure that joints between lengths of piping are tight and that the piping is adequately supported so that it is not in danger of breaking or collapsing, particularly in long vertical runs.

16.7.2.10.3 Flexible steel piping shall not be used on the vertical extension of piping systems.

16.7.2.10.4 Flexible steel piping shall be limited to those connections that are immediately adjacent to the pump kettle or discharge outlet.

16.7.2.10.5 No single length of flexible piping shall exceed 6 ft (1.8 m) in length, and all piping shall be able to withstand a pressure of at least four times the working pressure of the pump.

16.7.2.11 Roofing Kettle Doors.

16.7.2.11.1 All roofing kettles shall have doors permanently attached.

16.7.2.11.2 Roofing kettle doors shall be installed in a workmanlike manner and shall be provided with handles that allow them to be opened without the operator having to stand in front of same.

Roofing kettle doors are an integral part of providing for the extinguishing of a kettle fire. These doors should be in good operating condition, be free of residue, and close tightly.

16.7.2.11.3 All kettles shall have an approved, working visible temperature gauge that indicates the temperature of the material being heated.

16.7.2.12 All kettle doors shall be tightly closed and latched when in transit.

•

N **16.7.2.13 Construction.**

16.7.2.13.1 The materials and methods of construction of roofing kettles shall be acceptable to the AHJ.

16.7.2.13.2 Minimum Requirements.

16.7.2.13.2.1 Paragraph 16.7.2.13.2 shall apply to all roofing kettles or tar pots in excess of 1 gal (3.8 L) capacity.

16.7.2.13.2.2 No roofing kettle shall have a capacity in excess of 5 barrels (bbl).

16.7.2.13.2.3 Roofing kettles of 2 bbl capacity or less shall be constructed of steel sheet having a thickness of not less than 0.105 in. (No. 12 Manufacturers' Standard Gauge). Kettles of more than 2 bbl capacity shall be constructed of steel sheet having a thickness of not less than 0.135 in. (No. 10 Manufacturers' Standard Gauge). All supports, corners, and the top and bottom of the fire box shall be bound with angle iron or other reinforcements approved by the AHJ. All doors shall be hinged, closely fitted, and adequately latched. Fire boxes shall be of sufficient height from the ground or shall be provided with a system of shields or insulation to prevent heat damage to the street surface.

16.7.2.13.2.4 Lids that can be gravity operated shall be provided on all roofing kettles. The tops and covers of all kettles shall be constructed of steel sheet having a thickness of not less than 0.075 in. (1.90 mm) (No. 14 Manufacturers' Standard Gauge) that is close fitting and attached to the kettle with hinges that allow gravity to close the lid.

16.7.2.13.2.5 The chassis shall be substantially constructed and capable of carrying the load imposed upon it whether it is standing still or being transported.

16.7.2.13.2.6 Fuel containers, burners, and related appurtenances of roofing kettles in which LP-Gas is used for heating shall comply with all the requirements of Chapter 69.

16.7.2.13.2.7 Fuel containers that operate under air pressure shall not exceed 20 gal (76 L) in capacity and shall be subject to the approval of the AHJ.

16.7.2.13.2.8 All fuel containers shall be maintained in accordance with applicable NFPA codes and standards or shall be at least 10 ft (3 m) from the burner flame or at least 2 ft (0.6 m) therefrom when properly insulated from heat or flame.

N **16.7.3 Rubberized Asphalt Melters for Roof Deck Systems.**

Section 16.7.3 is new to the 2018 edition of the *Code*. Section 16.7 was reorganized to include 16.7.1 for general requirements and the past requirements for tar kettles became 16.7.2. The addition of new 16.7.3 is important in distinguishing the differences between safe use of torches or tar kettles and rubberized asphalt melters on roof decks. Both operations need safeguards against the potential for fire, but with different constraints. The reorganized Section 16.7 separates out rubberized asphalt melters for use on roof decks brings with it recognition of fire safety as a part of that process.

Rubberized asphalt melters are defined in 3.3.231 as "Portable equipment used for the heating of rubberized asphalt material that is a mix of asphalt, rubber polymer, and filler material." They operate and perform differently from tar kettles. Importantly, the fuel used to provide indirect heating to the rubberized asphalt melter is diesel. There are temperature controls inherent in melters in part due to the need to maintain the roofing material at 350 to 380 degrees F. Overheating into the temperature range of ordinary combustibles makes the rubberized asphalt product unsuitable for roof deck application. Because of the lower application temperature on noncombustible roof decks the opportunity for fire with this method is greatly decreased when compared to tar kettles and torches.

The new text for rubberized asphalt melters provides important differentiations from the more hazardous operations involving open flames and tar kettles.

N **16.7.3.1 General.**

N **16.7.3.1.1** Fully enclosed chassis-mounted and portable rubberized asphalt melters shall comply with 16.7.3.

N **16.7.3.1.2** Fully enclosed chassis-mounted and portable rubberized asphalt melters for heating a mix of asphalt and inert material for application on roof decks shall use an indirect method of heating that complies with all of the following:

(1) The heating system shall use a fully enclosed oil or air system that transfers heat from a burner to the oil or air around the outside of a material vat which then heats the rubberized material.

(2) The material vat shall not be subject to direct burner or flame impingement.
(3) The temperature rise in the material vat shall be gradual and controlled.

N **16.7.3.2 Permits.**

N **16.7.3.2.1** Permits, where required, shall comply with Section 1.12.

N **16.7.3.2.2** Permits for the operation of a rubberized asphalt melter on a roof deck shall not be deemed a permit for torches or burners. Any use of torches or burners will require a separate permit.

N **16.7.3.3 Rubberized Asphalt Melter Location.** The melter shall be located and operated in a controlled area identified by the use of traffic cones, barriers, and other suitable means as designated by the AHJ.

N **16.7.3.3.1** Melters shall not be located or operated on combustible roof decks.

N **16.7.3.3.2** The design load of the roof deck shall be capable of supporting the weight of the melter when loaded to capacity with rubberized asphalt material. The design load of the roof deck shall be as determined on building drawings or by a design professional acceptable to the AHJ.

N **16.7.3.3.3** Melters shall be chocked in place on the roof deck at locations identified by the design professional and acceptable to the AHJ.

N **16.7.3.3.4** Rubberized asphalt cakes for use in melters shall be located on the roof at a location agreed upon by the design professional and the AHJ.

N **16.7.3.3.5** Rubberized asphalt melters shall not be located inside of any building.

N **16.7.3.4 Exits.**

N **16.7.3.4.1** Melters shall not block exits or a means of egress or escape to an exit.

N **16.7.3.4.2** Melters shall not be closer than 10 ft from exits.

N **16.7.3.5 Fire Extinguishers.**

N **16.7.3.5.1** Two approved 4-A:40-B:C fire extinguishers shall be provided and maintained within 25 ft of the melter.

N **16.7.3.5.2** A minimum of one approved 4-A:40-B:C fire extinguisher shall be provided in close proximity to the roofing material application.

N **16.7.3.5.3** Each worker shall be instructed on the proper use of fire extinguishers and in the event of a fire to turn off all Melter engines and burners and notify the fire department.

N **16.7.3.6 Melter Operation.**

N **16.7.3.6.1** Melters shall be operated according to manufacturer instructions. Melters shall operate using integral control systems that include shut off controls for the diesel fired burner and temperature controls for the oil system and the material vat.

N **16.7.3.6.2** The diesel burner shall fire into an oil or air jacketed tank for uniform transfer.

N **16.7.3.6.3** Melters shall have melter lids permanently attached and closed at all times during operation.

N **16.7.3.7 Melter Supervision.**

N **16.7.3.7.1** An operating melter shall be constantly attended by an employee who is knowledgeable and solely dedicated to the operation of the equipment and associated hazards.

N **16.7.3.7.2** The employee shall be within 25 ft of the melter and shall have the melter within sight.

N **16.7.3.7.3** The employee shall remain in the area of the melter for a minimum of one-hour after the device is shut down.

N **16.7.3.7.4** The roofing contractor shall have the capability to immediately notify the fire department of an emergency on the site.

N **16.7.3.8 Fuel System.**

N **16.7.3.8.1** Fuel containers shall be constructed and approved for the use for which they were designed. Melter fuel tanks shall be attached to the frame of the melter.

N **16.7.3.8.2** Melters shall be diesel fuel or electrically powered.

N **16.7.3.8.3** Portable fuel tanks shall not be utilized to power melters.

N **16.7.3.8.4** Diesel tanks and engines integral to melters shall be maintained in accordance with manufacturer instructions.

N **16.7.3.8.5** Refueling of diesel tanks shall be performed when the melter is off.

N **16.7.3.8.5.1** A refueling and spill prevention plan acceptable to the AHJ shall be utilized.

N **16.7.3.8.5.2** Refueling shall be conducted using approved safety cans.

N **16.7.3.8.5.3** No open flames shall be present within 20 ft of the refueling operation.

N **16.7.3.9 Maintenance.** Melters and all integral working parts shall be in good working condition and shall be maintained free of excessive residue.

N **16.7.3.10 Minimum Requirements.**

N **16.7.3.10.1** Melters shall be operated as a complete unit as designed and built by the manufacturer. Field changes that override controls or safety features shall not be permitted.

N **16.7.3.10.2** Material vats on melters shall have a capacity of 230 gal or less. Material vats shall be a permanent integral part of the melter unit.

N **16.7.3.10.3** The melter chassis shall be substantially constructed and capable of carrying the load imposed upon it whether it is standing still or being transported.

16.8 Asbestos Removal

16.8.1 Notification. The AHJ and the fire department shall be notified 24 hours prior to the commencement and closure of asbestos removal operations.

Due to the blocking of egress, location of containment areas, accumulation of materials, and housekeeping issues, the fire department should be notified when asbestos removal is scheduled to take place. Asbestos removal is also a safety issue both for fire fighters and for anyone in the vicinity when it is airborne with the likelihood of being inhaled.

16.8.2 Permits. Permits, where required, shall comply with Section 1.12.

16.8.3 Signs. Approved signs shall be posted at the entrance, exit and exit access door, decontamination areas, and waste disposal areas for asbestos removal operations.

16.8.3.1 The signs shall state that asbestos is being removed from the area, that asbestos is a suspected carcinogen, and that proper respiratory protection is required.

16.8.3.2 Signs shall have a reflective surface, and lettering shall be a minimum of 2 in. (51 mm) high.

Wildland Urban Interface

17

"A person's home is his or her castle." There is a sense of accomplishment, a sense of pride, and truly a sense of ownership, and little can be done to take it away, by law or other means — except by catastrophe. In a discussion about permanent damage to a home caused by nature, typically hurricanes, earthquakes, and tornadoes top the list with the most devastating effects. However, there are many people who would add wildfires to the list of nature's worst.

The evidence suggests otherwise. Yes, the number of wildland fires across North America and the world are on the increase; yes, some are started "naturally," that is, by lightning strikes; and yes, the number of acres of lost property in on the rise, but so-called natural wildfires are minimal and in most cases not the ones that cause the greatest damage. Human-caused fires in the wildland are responsible for at least 80 percent of the fires in the United States in recent years. Fires caused by out-of-control campfires, careless disposal of smoking material, improper prescribed burns, and arson are all preventable human causes of wildfires.

Homeowners can still help themselves to better protect their "castles" and their families to understand how wildland-urban fire disasters occur, how homes can ignite related to ignition zones, the factors that increase ignition potential, and recommendations to mitigate the wildfire potential all contribute to a safe home environment. NFPA 1144, *Standard for Reducing Structure Ignition Hazards from Wildland Fire*, provides minimum requirements for planning, construction, maintenance, education, and management elements for the protection of life and property in areas where wildland fire poses a potential threat to structures.

Traditional fire responses have not reduced home fire losses in the wildland. Research and observations have challenged the premise of home ignition during wildfires. Applying new knowledge and implementing new approaches can more effectively reduce the loss of structures. Considerable research has been spent on conducting, evaluating, and formulating realistic recommendations and communicating those findings to homeowners.

Wildland fires are a natural disturbance. The following factors should be considered in any discussions that address wildfire control:

1. Wildland fire occurrence is inevitable.
2. Most ecosystems in the United States were developed with and were maintained by fire.
3. Grazing, agriculture, urban development, and the fire exclusion policy, along with elimination of aboriginal burning, has greatly reduced and changed wildland fire occurrence.
4. Ecologically significant wildland fires now largely occur during extreme wildfire conditions.

So, how do we define the problem in order to prevent residential fire disasters? Recent thinking suggests preventing wildland fire disasters largely through control and structure protection. Recent research indicates that home ignition during extreme wildfires is determined primarily by the conditions of the home in relation to its immediate surroundings. An effective home ignition zone plan approach can prevent home destruction during extreme wildfires.

The Firewise Communities Program, an NFPA project cosponsored by the USDA Forest Service, the U.S. Department of the Interior, and the National Association of State Foresters, offers training programs on managing wildland fire risk to the public and to fire protection professionals, both online and through workshops. Visit www.firewise.org for the most current information on managing wildland fire risk. In addition, NFPA offers a professional, two-day, on-site training course on assessing wildland fire hazards to structures. For more information, search for "Assessing Structure Ignition Potential from Wildfire" on NFPA's website, www.nfpa.org.

17.1 General

Δ The planning, construction, maintenance, education, and management elements for the protection of life and property from wildfire shall meet the requirements of this chapter and NFPA 1144.

NFPA 1144 offers fundamental criteria for fire agencies, land use planners, architects, developers, and local governments that formulate areas of property and land use development that might be threatened by wildfire. NFPA 1144 provides a methodology for assessing wildland fire ignition hazards around existing structures, residential developments, and subdivisions as well as for evaluating improved property or planned property improvement that is to be located in a wildland/urban interface area. The standard provides minimum requirements for new construction, grounded on science-based testing research, to reduce the potential of structure ignition from wildland fires.

17.1.1 In cases in which the local jurisdiction declares that an area within the jurisdiction is a wildland urban interface as determined by an assessment tool based upon accepted fire services practices, or where new structures will be located in a wildland/urban interface or intermix area, the AHJ shall perform, or cause to be performed, a wildland fire hazard assessment of each structure ignition zone in the development to determine relative risk, the extent of wildland fire hazard, and applicable mitigation measures.

Individuals conducting structure assessments in accordance with NFPA 1144 are encouraged to meet the qualifications of Wildland/Urban Interface Protection Specialist or Wildland/Urban Interface Coordinator in accordance with the job performance requirements (JPRs) found in NFPA 1051, *Standard for Wildland Firefighting Personnel Professional Qualifications*.

Δ **17.1.2*** The structure assessment shall, at a minimum, include the following:

(1) Identification and documentation of the wildland fire hazards in the ignition zone(s) for each structure within wildland fire hazard areas, according to the elements and conditions in 17.1.4
(2) Determination of mitigation measures for vegetation, other combustibles, and the structure, including the periodic maintenance associated with such measures
(3) Establishment of priorities relative to mitigating the risks from wildland fire
(4) Evaluation of the site for conflagration hazards associated with the property to provide information for fire operations strategies should the site or surrounding properties become involved with fire.

[**1144:**4.1.2]

Assessment of the site, including property and structures, should be reinforced at every opportunity, so fire protection agencies can determine risks and thus allow for the most desirable outcomes.

Δ **A.17.1.2** Figure A.17.1.2 and Table A.17.1.2 are examples of two different approaches to hazard assessment. [**1144:**A.4.1.2]

Figure A.17.1.2 is an example of an assessment guide with assessment information based on observation of the areas around the structure. This form, intended to be given to the resident, can be very useful by indicating the most serious hazards and the mitigation recommendation(s) that can be taken to reduce the ignition hazard. In this example, samples of the kind of information noted in an assessment are given as observations and suggestions for mitigation. [**1144:**A.4.1.2]

This example of an assessment guide is designed to help determine how vulnerable the structure will be during a wildland fire and to convey to the resident those items that should be corrected (mitigated) so that their home will have a better chance to survive a wildland fire. This form is offered as an example of the kind of tool that might be useful during a site visit as a guide for assessing the structure ignition zone. Remember, the following assessment items are for *prevention/mitigation* measures to be done *well in advance* of wildland fire season. [**1144:**A.4.1.2]

Figure A.17.1.2 is a form used to document observations, collect data, provide a hazard assessment, and give mitigation recommendations for the resident. From the mitigation recommendations, a mitigation plan and schedule is developed in accordance with 17.1.10. For more information on the use of this assessment form, refer to the course *Assessing Wildfire Hazards in the Home Ignition Zone*, available from the national Firewise Communities Program (www.firewise.org). [**1144:**A.4.1.2]

Table A.17.1.2 is a modified rating form based on the previous edition of NFPA 1144. Infrastructure elements of water supply, signage, and other fire suppression resources have been deleted, since the presence or absence of such resources does not modify the existing hazards of the structure. The table is presented only as an example of a rating system and should be modified to meet the environmental conditions of the area under consideration. For more information on creating an assessment system, consult *Wildland/Urban Interface Fire Hazards: A New Look at Understanding Assessment Methodologies Pamphlet*, produced by the national Firewise Communities Program (www.firewise.org). [**1144:**A.4.1.2]

A numeric rating form that will yield a hazard rating number can have a variety of uses, for example, determining relative hazards among several properties and mapping overall hazard ratings on a map. However, residents and homeowners often accept the rating number as finite and undertake mitigation measures that will merely reduce the rating rather than actually reduce the ignition potential of the structure. [**1144:**A.4.1.2]

17.1.3 The wildland fire hazard assessment shall be the basis for recommended mitigation measures relative to the vegetation, other combustibles, and structures on the site. [**1144:**4.1.3]

17.1.4* Structure Assessment Elements and Conditions. As a minimum, the structure assessment shall cover elements and conditions indicated in 17.1.5 through 17.1.9. [**1144:**4.2]

A.17.1.4 It is critical to keep in mind that the ignition of the structure might occur from one or more of the following sources:

(1) Big flames (crown fire or intense surface fire). One objective of observation of the conditions and elements and subsequent mitigation recommendations is to keep crown fire and high intensity

STRUCTURE ASSESSMENT GUIDE

Date of assessment: *22 Nov*   Property address: *70 Norris Rd.*

Resident: *John and Jane Doe*   Property owner: *Same*

PRIMARY INFORMATION

Assessment Items	Mitigation Recommendations
1. OVERVIEW OF SURROUNDINGS	
How is the structure positioned in relationship to severe fire behavior? *The house is located near peak of a ridge at local map reference Q-4-12. The setbacks from the lot lines are approximately 15–20 ft. There is a slight sloping of the lot away from the house within 50 ft of the lot line on the north.*	*Since prevailing winds during fire season are most likely from the west-southwest, keep pine needles and leaf litter cleaned up on roadside berm.*
Type of construction: *Wood frame construction with brick façade on the front. Vinyl siding on back and two sides.*	
2. CHIMNEY TO EAVES	
Inspect the roof — noncombustible? shingles missing? shingles flat with no gaps? *Noncombustible roofing in good shape.*	*Inspect roof each spring for damage, especially after a hard winter or wind storm.*
Gutters — present? Noncombustible? *Aluminum gutters at all eaves. No overhanging limbs nearby. Pine needles and leaf litter not likely to collect in deep quantities.*	*Keep gutters free of pine needles and leaves. Check early spring and fall.*
Litter on roof, in gutters, and crevices? *Fairly clean. Not much of a concern. Easy to maintain.*	
3. TOP OF THE EXTERIOR WALL TO FOUNDATION	
Attic, eave, soffit vents, and crawl spaces: *Not much of a concern.*	
Inspect windows and screens — metal screens? Multi-paned windows? Picture windows facing vegetation? *Metal screens on all windows. Some windows on west side are double-paned. Some high vegetation near front windows. Low vegetation in rear.*	*Keep front bushes pruned and watered during fire season. Replace any missing or torn screens immediately, especially the front.*
Walls and attachments — noncombustible? Will they collect litter? *Not much of a concern.*	
Decks — combustible materials? *Wooden deck and privacy fence on south side. No skirting or screening beneath deck. Deck in good condition. Small vegetation around deck but overhanging tree limbs. Some collection of leaves and needles near deck and wooden stairs.*	*Prune trees closest to deck and privacy fence. Remove the pine needles and leaves. Store combustibles elsewhere — perhaps the shed in the backyard — especially during high fire danger periods. Put skirting or 1/4" wire mesh around deck openings.*

   NFPA 1144 (p. 1 of 2)

Δ ***FIGURE A.17.1.2*** *Structure Assessment—Guide Example with Notations. [**1144:***Figure A.4.1.2]*

STRUCTURE ASSESSMENT GUIDE *(continued)*

Assessment Items	Mitigation Recommendations
3. TOP OF THE EXTERIOR WALL TO FOUNDATION *(continued)*	
Fences. *Wooden stockade fence joins house on north side. Wooden fencing also on south side. Chain link in rear along lot line. Neighbor's wooden fence is less than 2–3 ft from their wooden fence — will allow leaves and embers to accumulate.*	*Keep wooden fence perimeter clear of dry leaves and other combustible materials like chairs, wood, etc. If the chance presents itself to use noncombustible materials to separate fence from house, you should consider it.*
Flammable material next to or under the structure. *None observed.*	
Combustible materials near or on the structure where walls meet roof or decking surfaces. *Plastic outdoor furniture pads on deck might pose problem from ember shower.*	*Keep combustible chair pads put away except when in use.*
Crawl space, attic vents, soffits. *All appear to be in excellent condition and protected.*	
Nooks and crannies and other small spaces. *All appear to be in excellent condition and protected.*	
4. FOUNDATION TO IMMEDIATE LANDSCAPED AREA	
Landscaped (managed) vegetation — separation distances, maintenance, plant selection? Firewise Landscaping Zones? *Lawn well cared for. Leaf and needle accumulation along east side (rear of property) with small stand of trees. Front and south side have mix of pine and other vegetation.*	*Be sure to keep these areas well tended, pine needles cleared and limbs pruned. Lawn needs to be kept green and mowed. Plants irrigated, pruned and raked — especially during high fire danger periods.*
Propane tanks. *No large ones. Outdoor grill small tank.*	*Make sure this area is kept clear of any combustibles — especially when using the grill.*
Vehicle and RV use and parking, including lawn mowers, etc. *Parking in front. Mower storage in shed which is 40–50 ft from NE corner of house. Plastic children's play house etc. near wooden fence along north side but over 30 ft from house.*	
5. IMMEDIATE LANDSCAPED AREA TO EXTENT OF THE HOME IGNITION ZONE	
Inspect vegetation clearance and crown separation. *Lot is rather small and the neighboring properties' vegetation is more dense than this one. Trees in back should pose little concern as prevailing winds will not communicate fire towards house.*	*Work with neighbors to improve all three lots to reduce the hazards on this corner. The neighbors behind this address and those on either side might benefit from some clearance that might take place but the separation of those properties appears to be sufficient.*

 NFPA 1144 (p. 2 of 2)

Δ *TABLE A.17.1.2 Example of Structure Assessment Rating Form*

Rating Values by Areas Assessed	Overview of Surrounding Environment (4.2.1)	From Chimney to Eaves (4.2.2)	From Top of the Exterior Wall to Foundation (4.2.3)	From Foundation to Immediate Landscaped Area (4.2.4)	From Immediate Landscaped Area to Extent of Structure Ignition Zone (4.2.5)
Topographical Features					
(1) Topographical features that adversely affect wildland fire behavior (4.2.1)	0–5				
(2) Areas with history of high fire occurrence (4.3.4)	0–5				
(3) Areas exposed to unusually severe fire weather and strong, dry winds (4.2.1.3)	0–5				
(4) Local weather conditions and prevailing winds (4.2.1.2)	0–5				
(5) Separation of structure on adjacent property that can contribute to fire spread/behavior (4.2.1.3)	0–5			0–5	0–5
Vegetation — Characteristics of predominant vegetation					
(1) Light (e.g., grasses, forbs, sawgrasses, and tundra) NFDRS Fuel Models A, C, L, N, S, and T	5			15	5
(2) Medium (e.g., light brush and small trees) NFDRS Fuel Models D, E, F, H, P, Q, and U	10			20	5
(3) Heavy (e.g., dense brush, timber, and hardwoods) NFDRS Fuel Models B, G, and O	15			25	15
(4) Slash (e.g., timber harvesting residue) NFDRS Fuel Models J, K, and L	15			30	20
Topography (4.2.1.1, 4.2.4, 4.2.5)					
(1) Slope 5–9%				1	1
(2) Slope 10–20%				4	2
(3) Slope 21–30%				7	3
(4) Slope 31–40%				10	6
(5) Slope >41%				15	10
Building Setback, relative to slopes of 30% or more (4.2.1.5, 5.1.3.2)					
(1) 30 ft (9.14 m) to slope	1				
(2) 30 ft (9.14 m) to slope	5				
Roofing Materials and Assembly, nonrated (4.2.2.1, 4.2.2.3)		50*			
Ventilation Soffits, without metal mesh or screening (4.2.3.4)		20			
Gutters, combustible (4.2.2.4, 4.2.2.5)		5			
Building Construction (predominant)† (4.2.4)					
(1) Noncombustible/fire-resistive/ignition-resistant siding and deck			Low		

(continues)

△ *TABLE A.17.1.2 Continued*

Rating Values by Areas Assessed	Overview of Surrounding Environment (4.2.1)	From Chimney to Eaves (4.2.2)	From Top of the Exterior Wall to Foundation (4.2.3)	From Foundation to Immediate Landscaped Area (4.2.4)	From Immediate Landscaped Area to Extent of Structure Ignition Zone (4.2.5)
(2) Noncombustible/fire-resistive/ ignition-resistant siding and combustible deck			Medium		
(3) Combustible siding and deck			High		
Fences and Attachments, combustible (4.2.4.3)				15	
Placement of Gas and Electric Utilities					
(1) One underground, one aboveground	3				
(2) Both aboveground	5				
Fuel Modification within the structure ignition zone (4.2.4, 4.2.5)					
(1) 71–100 ft (21–30 m) of vegetation treatment from the structure(s)					5
(2) 30–70 ft (9–21 m) of vegetation treatment from the structure(s)				7	
(3) <30 ft (9 m) of vegetation treatment from the structure(s)				15	
No Fixed Fire Protection (NFPA 13, 13R, 13D sprinkler system)			5		
TOTALS (if numerical ranking is desired)					
Hazard Rating Scale (Compare with above totals)					
Slight Structure Ignition Hazards from Wildland Fire	0–14	0–14	0–14	0–14	0–14
Moderate Structure Ignition Hazards from Wildland Fire	15–29	15–29	15–29	15–29	15–29
Significant Structure Ignition Hazards from Wildland Fire	30–49	30–49	30–49	30–49	30–49
Severe Structure Ignition Hazards from Wildland Fire	50+	50+	50+	50+	50+

*Nonrated and combustible roof assemblies are predominantly structural exposures and severely increase the ignition hazard from wildland fire.

†The table provides both numerical and value rankings (low, medium, high). The user is urged to assign the value ranking of low, medium, or high based on the other ignition factors prevalent at the assessment site. For example, a deck made of combustible materials might rank low if it is small in size and the rest of the site is in a low fuel loading area that will not promote a large amount of firebrands. That same deck might rate high if it is in an area of high fuel loading that will promote numerous firebrands. Numeric values can be substituted as a local option. [**1144:** Table A.4.1.2]

surface fire at a distance of 100–200 ft (30–60 m) or more from home and other potential hazards (combustibles, buildings, etc.).

(2) Small flames (surface fire). Another objective is to keep small flames at a distance of 30 ft (9 m) or more from home(s) and combustible attachments (decks).

(3) Firebrands (embers). A final and essential objective is to eliminate beds of fine fuel and entry points for firebrands on and near home(s).

[**1144:**A.4.2]

17.1.5 Overview of the Surrounding Environment. The structure assessment shall document the conditions of 17.1.5.1 through 17.1.5.5 in the assessment of the surrounding environment, as they will place the structure in the most risk from ignition by a wildland fire. [**1144:**4.2.1]

17.1.5.1* The structure assessment shall document the location of the structure in relation to predominant topographical features, such as flat open areas, ridges, saddles, steep slopes, natural chimneys like steep narrow draws, or small canyons, that will increase the ignition potential of the structure. [**1144:**4.2.1.1]

A.17.1.5.1 Wildland fire dangers exist in flat land areas, as well as in mountainous terrain. In addition, property line limitations often preclude effective vegetation mitigation, and alternatives for mitigation are needed. [**1144:**A.4.2.1.1]

17.1.5.2* The structure assessment shall document local weather conditions, including wind, relative humidity, temperature, and fine fuel moisture content. [**1144:**4.2.1.2]

A.17.1.5.2 Local weather conditions or prevailing winds play a role in fire behavior (e.g., from which direction a fire is most likely to come, to the intensity and speed of fire travel, depending on the degree of slope), and the direction from which a wildland fire is most likely to approach the structure is an important exposure consideration. Sources of local weather records and fire weather history from the National Weather Service, National Oceanic and Atmospheric Administration (NOAA), local weather bureaus, or wildland fire agencies can be a valuable resource in assessing existing structures or in planning for new construction. [**1144:**A.4.2.1.2]

17.1.5.3* The structure assessment shall document nearby structures using the same criteria as the primary structure. [**1144:**4.2.1.3]

A.17.1.5.3 Adjacent ignitible structures (garages, carports, sheds, gazebos, utility cabinets) can contribute to heat intensity, flame contact, and fire spread from firebrands. [**1144:**A.4.2.1.3]

17.1.5.4* The structure assessment shall document any neighboring properties that could impact the ignition zone of the property being assessed. [**1144:**4.2.1.4]

A.17.1.5.4 Overlapping zones could have a positive result in that the outermost extent of a structure ignition zone might be a neighboring parking lot or already treated vegetation area, such as a fuel modification. On the other hand, the overlap might include other private or public lands, which could make mitigation more difficult because it could involve state or federal agencies or absentee landowners who do little or no vegetation management or hazard mitigation. [**1144:**A.4.2.1.4]

17.1.5.5* The structure assessment shall document the structure's location on the slope relative to the structure's potential exposure to heat from a wildland fire. [**1144:**4.2.1.5]

A.17.1.5.5 Structure location on a slope increases the structure's exposure to heat (e.g., structure setback from the slope is sufficient to reduce its radiant heat exposure). Setback distances of the structure can be measured in accordance with A.5.1.3.2 of NFPA 1144. [**1144:**A.4.2.1.5]

17.1.6 From Chimney to Eaves. The structure assessment shall document the conditions of 17.1.6.1 through 17.1.6.6 to observe construction and vegetation as they place the structure in the most risk from ignition by a wildland fire. [**1144:**4.2.2]

17.1.6.1* The structure assessment shall document the type and construction of roofing materials. [**1144:**4.2.2.1]

A.17.1.6.1 All common coverings (composition shingles, tile, and, in many cases, metal) typically have a fire-resistive roofing classification adequate for interface fire protection if the covering material is tightly assembled to resist firebrand intrusion. [**1144:**A.4.2.2.1]

Untreated wood roofing is easily ignited and a major hazard. The only wood roof coverings that can be considered acceptable are wood shakes or shingles that have been treated at the factory by a pressure-impregnation fire-retardant process, tested for fire resistance, and certified with a fire-resistant roofing classification of Class A, Class B, or Class C. Pressure treated wood roofing looks very similar to the hazardous untreated wood roofing, and currently there is no permanent identification method. If in doubt, assume wood roofing is untreated unless documentation is provided. [**1144:**A.4.2.2.1]

17.1.6.2* The structure assessment shall document the condition of roofing materials and assemblies. [**1144:**4.2.2.2]

A.17.1.6.2 Look for gaps in the roof covering that might allow small wind-blown firebrands to penetrate under the covering and ignite material below. [**1144:**A.4.2.2.2]

Some fire-resistive roof coverings are designed or installed with gaps that allow firebrand intrusion under the covering and have resulted in firebrand intrusion and ignition of the building under the roof covering. The worst example is roof coverings that allow combustible debris to blow under the covering or that allow rodents and birds to bring nesting material in under the roof covering. Clay (Spanish or straight barrel mission) tile roof covering can have this problem unless eave closures or "bird stops" are used to close the convex opening created by the shape of the tile at the eave. Metal tile roofing installed on top of old wood roofing left in place has been a problem. If you can see wood through gaps in metal tile roof covering, firebrands can penetrate and ignite the building. [**1144:**A.4.2.2.2]

17.1.6.3* The structure assessment shall document all skylights in roof assemblies. [**1144:**4.2.2.3]

A.17.1.6.3 Plastic skylights can melt from radiant heat or flaming embers or both. Deformation can result in large openings that can allow the entry of embers and other flaming materials. Skylights constructed of multilayered glazed panels or tempered glass provide increased protection from heat and embers. [**1144:**A.4.2.2.3]

17.1.6.4*

A.17.1.6.4 The roof is the most vulnerable part of the structure and is subject to the collection of combustible vegetative litter (e.g., leaves, pine needles) or other debris and buildup that can be ignited by firebrands. Can litter build up and accumulate on surfaces next to combustible, perpendicular walls? Will combustible decking or roofing provide ember beds next to combustible, perpendicular walls? [**1144:**A.4.2.2.4]

Heat trapping under eaves does not occur until the wall supports flaming combustion as indicated by the portions of the wall that were protected (shaded) and did not char during experiments conducted by the USDA Forest Service Fire Sciences Lab in Missoula, MT. [**1144:**A.4.2.2.4]

17.1.6.5* The structure assessment shall document the construction materials of gutters, downspouts, and connectors. [**1144:**4.2.2.5]

A.17.1.6.5 Gutters and downspouts collect leaves and pine needles. Gutters and eave troughs made from combustible materials (e.g., wood, vinyl) are as vulnerable to firebrand collection as the roof and other parts of the structure. If leaf litter is allowed to gather in gutters, firebrands or embers can ignite the leaf litter, which in turn could ignite combustible eave materials or overhangs. If gutters are attached to combustible fascia boards, the fascia board should be considered as a possible fuel that can be ignited by fine fuels burning in the gutters. [**1144:**A.4.2.2.5]

Gutters that pose a fire threat from an approaching wildland fire are often pulled down by attending fire fighters. For the resident, an alternative might be to remove the gutters along the side(s) of the house most prone to the collection of leaves and needles and install a noncombustible drip line shown in Figure A.17.1.6.5. Removing gutters eliminates the collection of dry leaves and needles along the roof line and fascia board. Also reduced is the possibility of ice damage to the roof in the winter. The use of a gravel bed for drip lines along the leeward side(s) of the house provides reduced ignition potential and reduced wind hazard, since the gravel would be less likely to be blown by high winds on the leeward elevations. The windward sides of the house can be landscaped with mulch (less impact damage in case of wind events) if protected with low volume sprinklers to raise the fine fuel moisture levels in times of high fire danger. [**1144:**A.4.2.2.5]

17.1.6.6* The structure assessment shall document the materials and construction used in eaves of roof overhangs. [**1144:**4.2.2.6]

A.17.1.6.6 Eaves should be boxed to prevent flying embers from entering small spaces. [**1144:**A.4.2.2.6]

17.1.7 From Top of Exterior Wall to Foundation. The structure assessment shall document the conditions of 17.1.7.1 through 17.1.7.6 to observe construction and vegetation as they place the structure in the most risk from ignition by a wildland fire. [**1144:**4.2.3]

FIGURE A.17.1.6.5 *Mitigating Risk of Leaf- and Needle-Filled Gutters. [***1144:*** Figure A.4.2.2.5]*

17.1.7.1* The structure assessment shall document the materials and construction used in exterior walls and exterior siding. [**1144:**4.2.3.1]

A.17.1.7.1 Identify the wall covering or siding (e.g., wood, vinyl, brick, stucco) and determine the possibility of litter buildup and accumulation on surfaces next to walls. Under low radiant heat levels, vinyl siding is damaged and falls off a wall, which can leave openings for firebrands exposing the interior of the home to ignition through eave vents and other possible openings. Vinyl is difficult to ignite by firebrands or radiant heat, but will sustain combustion when directly contacted by flames. [**1144:**A.4.2.3.1]

Hanging ½ in. (12.5 mm) or thicker drywall on the exterior wall studs prior to adding stucco, siding, and so forth can increase the fire rating. [**1144:**A.4.2.3.1]

17.1.7.2 The structure assessment shall document the materials used for gutter downspouts and connectors on exterior walls. [**1144:**4.2.3.2]

17.1.7.3* The structure assessment shall document the materials used in windows and other openings in vertical surfaces. [**1144:**4.2.3.3]

A.17.1.7.3 Windows should be constructed of multi-paned or tempered glass that will resist fracture from intense heat in accordance with 5.7.1 of NFPA 1144, and window screens made from a material that will not allow hot firebrands to enter the home's interior in accordance with 5.7.2 of NFPA 1144. [**1144:**A.4.2.3.3]

17.1.7.4* The structure assessment shall document the location, size, and screening of ventilation openings. [**1144:**4.2.3.4]

A.17.1.7.4 Check attic, crawl space, eave, and soffit vents for appropriate protection (e.g., metal screening, noncombustible skirting) to prevent entry of firebrands. Roof turbine vents should be screened to prevent the entry of firebrands into attic spaces. [**1144:**A.4.2.3.4]

17.1.7.5* The structure assessment shall document all attached accessory structures as part of the primary structure. [**1144:**4.2.3.5]

A.17.1.7.5 Examples of attached structures include decks, lean-to overhangs, patio covers, carports, balconies, fences, and similar structures that could be ignited by convection or firebrands. [**1144:**A.4.2.3.5]

17.1.7.6* The structure assessment shall document areas next to or under a structure where combustible materials that present a source of flame exposure to the structure might collect. [**1144:**4.2.3.6]

A.17.1.7.6 Areas on, next to, or under a structure should be kept free of combustible fuel such as debris, vegetation, wooden furniture, brooms, welcome mats, furniture cushions, gasoline cans, firewood stacks, or piled construction materials. Look for combustible walkways, fencing, or decking attached to the structure, highly combustible fuels adjacent to the structure (e.g., junipers near decks and walkways), combustible materials (e.g., building materials, firewood) stored under decks or adjacent to the structure, animal nests among combustible structural fuels, and landscaping materials (e.g., bark mulch, ground cover plants) near the structure and surrounding plants that might support flaming combustion or that could easily be ignited by firebrands. [**1144:**A.4.2.3.6]

Structures that are attached to the main structure, such as decking, must be kept free of combustible fuels. Exhibit 17.1 shows inspectors looking for potential fuel sources on and around the combustible decking. This should be included in the structure assessment in accordance with 17.1.7.6.

Exhibit 17.1

Inspecting a property for wildfire ignition potential. (Image courtesy of NFPA Firewise® program)

17.1.8* From Foundation to the Immediate Landscaped Area. The structure assessment shall document the conditions of 17.1.8.1 through 17.1.8.5 to observe construction and vegetation, as they place the structure in the most risk from ignition by a wildland fire. [**1144:**4.2.4]

A.17.1.8 The structure ignition zone includes the spatially arranged traditional landscaping zones, but can exceed the extent of the property line. Figure A.17.1.8 illustrates the relationship of the structure and immediate landscaped area to the larger structure ignition zone. Within the immediate landscaped area [from the structure to approximately 30 ft (9 m)], often referred to as the defensible space, special consideration should be given that any combustible materials (e.g., plants, lawn furniture, litter, construction materials) should be removed in the 0 ft to 5 ft (0 m to 1.5 m) zone immediately adjacent to the structure and reduced in the zone from 5 ft to 30 ft (1.5 m to 9 m) to minimize the chance for ignition of the structure. The total structure ignition zone includes any spatially arranged landscaping area and can exceed the extent of the property line. The level of risk of ignition within the total area of the ignition zone depends on the type of construction and is further influenced by slope, soils, and other site-specific conditions. [**1144:**A.4.2.4]

The AHJ should require the development of a landscape plan for the property. Such plans should address four zones around the property as follows:

(1) The most immediate landscaped area is the closest to the house and includes the area encircling the structure for at least 30 ft (9 m) on all sides. The landscaped vegetation within 30 ft (9 m) of structures should be irrigated as needed, cleared of dead vegetation, and/or planted with succulents and other plants (where appropriate) that are low in combustibility potential. Plantings should be limited to carefully spaced, low-growing, low-combustibility species, grasses, and lawns. Shrubs planted next to the structure should be of low combustibility, no more than 18 in. (45 cm) in height, and not planted against the home. The planting bed should be noncombustible (e.g., stone, gravel, bare ground) or irrigated if combustible materials (e.g., bark mulch) are used. All highly combustible plants, such as junipers and ornamental conifers, should be removed or trimmed and maintained to be ignition-resistant. Vegetation deposits (dry leaf and pine litter) that can support surface fire and flames should be removed regularly. Areas of vegetation (natural areas, undeveloped areas, landscaped areas, fields, etc.) that exist near the structure should be evaluated for the possibility of causing ignition of the structure.
(2) Progressing outward from the structure, the types and densities of vegetation should change to reduce the continuity of vegetation fuels. For example, plantings can be done in islands. Trees can be introduced into this zone with careful consideration of their combustibility and continued maintenance to separate crowns and avoid ladder fuels. Tree placement should be planned so that the edge of the canopy of the tree when fully mature is no closer than 10 ft (3 m) to the edge of the structure.
(3) Progressing even farther from the structure, more medium-sized plants and well-spaced trees can be planted in well-spaced groupings to reduce exposure to wildland fire and help maintain privacy. The volume of vegetation (i.e., fuel) should be kept as low as possible or practical.
(4) The most distant area [100 ft to 200 ft (30 m to 60 m)] from the structure determines the extent of the structure ignition zone. Plants in this furthermost area should be carefully pruned and thinned, and highly combustible vegetation removed. Particular attention should be paid to the types and densities of the vegetation in this area. For example, some vegetation and trees generate more firebrands than others and require additional thinning, removal, or replacement.

[**1144:**A.4.2.4]

17.1.8.1* The structure assessment shall document all vegetative fuels and other combustible materials adjacent to and within 30 ft (9 m) of the structure for their potential to contribute to the intensity and spread of wildland fire. [**1144:**4.2.4.1]

A.17.1.8.1 Vegetative fuels include live vegetation, mulch and landscaping materials, slash piles, composting piles, and firewood storage. [**1144:**A.4.2.4.1]

FIGURE A.17.1.8 *The Structure Ignition Zone. [***1144:***Figure A.4.2.4]*

Combustible vegetation close enough to windows to provide intense radiant heat or flame contact should be pruned, moved, or substituted with smaller, lower combustibility plants. Figure A.17.1.8.1(a) illustrates the use of low combustibility plants separated by a gravel area next to the foundation. [**1144:**A.4.2.4.1]

Mulch is an alternative to noncombustible landscaping materials such as gravel and rock. The size and texture of mulching materials affects its ignition and fire spread potential. Larger organic materials are preferable to smaller materials. [**1144:**A.4.2.4.1]

Landscaping with mulch can be acceptable if the mulch is protected with low volume sprinklers to raise the fine fuel moisture levels and offset its combustibility in times of high fire danger. The installation of sprinklers for areas using mulch for landscaping is shown in Figure A.17.1.8.1(b). [**1144:**A.4.2.4.1]

FIGURE A.17.1.8.1(a) *Foundation Planting and Landscaping. [***1144:***Figure A.4.2.4.1(a)]*

FIGURE A.17.1.8.1(c) *Sample of a Physical Description Similarity Chart of NFDRS and FBO Fuel Models. [**1144:***Figure A.4.2.4.1(c)]*

Figure A.17.1.8.1(c) describes the physical similarities of the NFDRS fuel models with fire behavior fuel models. See Annex B of NFPA 1144 for fuel model classifications. [**1144:**A.4.2.4.1]

17.1.8.2* The structure assessment shall document the presence and location of all heat and flame sources within 30 ft (9 m) of the primary structure. [**1144:**4.2.4.2]

A.17.1.8.2 Typical heat and flame sources include, but are not limited to, propane heaters, barbecue cookers, and grills. [**1144:**A.4.2.4.2]

17.1.8.3* The structure assessment shall document all projections attached to the primary structure. [**1144:**4.2.4.3]

A.17.1.8.3 Attachments include, but are not limited to, permanent and temporary construction such as decks, fences, awnings, lean-to buildings; and combustible walkways, fencing, or decking attached to the home. [**1144:**A.4.2.4.3]

Figure A.17.1.8.3(a) shows a typical deck where combustible decking materials could result in the gathering of embers next to combustible walls and where the construction and design of decks, balconies, and porches with open spaces underneath could allow leaf and needle debris and embers to collect. [**1144:**A.4.2.4.3]

Figure A.17.1.8.3(b) illustrates one method of separating a combustible fence from the structure by the installation of a transitional section of noncombustible (iron) fencing. Similar use of masonry or stone can provide the same fire-resistant separation. [**1144:**A.4.2.4.3]

17.1.8.4* The structure assessment shall document detached structures within 30 ft (9 m) of the primary structure that might be

*FIGURE A.17.1.8.3(b) Transition Fence Separates Combustible Fence from Structure. (Courtesy of Firewise Communities Program. Photo by G. Johnston.) [**1144:**Figure A.4.2.4.3(b)]*

ignited by flames, radiant heat, or firebrands from wildland fires. [**1144:**4.2.4.4]

A.17.1.8.4 Examples of such structures include, but are not limited to, hot tubs, utility sheds, outbuildings, detached garages and carports, gazebos, trellises, auxiliary structures, stables, barns and other structures within 30 ft (9 m) of the primary structure, outdoor furniture, and recreational structures (e.g., children's playhouses, swing sets). In some cases, separation distances from lot lines might require the inclusion of neighboring residential structures in the assessment. [**1144:**A.4.2.4.4]

17.1.8.5* The structure assessment shall document vehicle parking areas within 30 ft (9 m) of any surface of the structure. [**1144:**4.2.4.5]

A.17.1.8.5 Parking vehicles on areas of dry grasses and fine fuels could result in ignition by hot exhaust systems or firebrands. Also, a fire that originates from a parked vehicle could present an exposure hazard to the primary structure or nearby vegetation. Any dry vegetation beneath the vehicle could cause ignition of the vehicle, which in turn could cause structure ignition; conversely, the ignition of the structure could cause ignition of the vehicle, which could present additional dangers to responding fire fighters. [**1144:**A.4.2.4.5]

17.1.9 From the Immediate Landscaped Area to the Extent of the Structure Ignition Zone. The structure assessment shall document the conditions of 17.1.9.1 through 17.1.9.8 to observe construction and vegetation, as they place the structure in the most risk from ignition by a wildland fire. [**1144:**4.2.5]

17.1.9.1* The structure assessment shall document vegetation within the area between the outer edge of the immediate landscaped area and the extent of the structure ignition zone as potential fuel that can convey the fire to the structure. [**1144:**4.2.5.1]

A.17.1.9.1 Evaluation of the vegetative fuels should include the following:

(1) Can vegetative fuels lead surface fire and flames to the structure?
(2) Have ladder fuels been eliminated within the structure ignition zone?
(3) Are tree crowns separated enough to prevent big flames from coming within 30 ft (9 m) of the structure?

[**1144:**A.4.2.5.1]

17.1.9.2* The structure assessment shall document the species and location of trees and the separation of tree crowns within the area between the outer edge of the immediate landscaped area and the extent of the structure ignition zone. [**1144:**4.2.5.2]

A.17.1.9.2 The location (placement) of trees and the separation between them is important to prevent ignition of the structure from radiant heat and to reduce the concentration of leaf fall and needle drop near the structure. Adequate separation and control of ignition potential are factors that affect fire intensity and are dependent on the size, density, and species of trees and vegetation. [**1144:**A.4.2.5.2]

Consider using islands of trees that offer separation of trees from the structure and other combustibles. Figure A.17.1.9.2(a) illustrates the use of such planting islands that preserve key trees for aesthetics while providing shade and exposure separation from structures. Figure A.17.1.9.2(b) shows that small planting islands within an expanse of maintained lawn provides both separation and low combustibility protection from ignition close the structure. [**1144:**A.4.2.5.2]

FIGURE A.17.1.9.2(a) Planting Islands Offer Exposure Protection, Preserve Aesthetics. (Courtesy of Firewise Communities Program. Photo by G. Johnston.) [1144:Figure A.4.2.5.2(a)]

FIGURE A.17.1.9.2(b) Small Planting Islands Within an Expanse of Maintained Lawn. (Courtesy of Firewise Communities Program. Photo by D. Frazier.) [1144:Figure A.4.2.5.2(b)]

17.1.9.3* The structure assessment shall document the presence and location of all heat and flame sources within the area between the outer edge of the immediate landscaped area and the extent of the structure ignition zone. [**1144:**4.2.5.3]

A.17.1.9.3 Typical heat and flame sources include, but are not limited to, propane- and charcoal-fired barbecue cookers, heaters, and grills. [**1144:**A.4.2.5.3]

17.1.9.4* The structure assessment shall document detached structures within the area between the outer edge of the immediate landscaped area and the extent of the structure ignition zone that might be ignited by flames, radiant heat, or firebrands from wildland fires. [**1144:**4.2.5.4]

A.17.1.9.4 Examples of such structures include, but are not limited to, hot tubs, utility sheds, outbuildings, detached garages and carports, gazebos, trellises, auxiliary structures, stables, barns and other structures between the immediate landscaped area and the extent of structure ignition zone, outdoor furniture, recreational structures (children's playhouses, swing sets). In some cases, separation distances from lot lines might require the inclusion of neighboring residential structures in the assessment. [**1144:**A.4.2.5.4]

17.1.9.5* The structure assessment shall document vehicle parking areas within the area between the outer edges of the immediate landscaped area and the extent of the structure ignition zone. [**1144:**4.2.5.5]

A.17.1.9.5 See A.17.1.8.5. [**1144:**A.4.2.5.5]

17.1.9.6* The structure assessment shall document all projections attached to the primary structure that extend beyond the immediate landscaped area. [**1144:**4.2.5.6]

A.17.1.9.6 Attachments include, but are not limited to, permanent and temporary construction such as decks, fences, awnings, and lean-to buildings. [**1144:**A.4.2.5.6]

17.1.9.7 The structure assessment shall document all other factors that can affect the risk of ignition or the spread of wildland fire on improved property within the structure ignition zone, including the risk of structure fires spreading to vegetation. [**1144:**4.2.5.7]

17.1.9.8 Any structure that fails to comply with the requirements of Chapter 5 of NFPA 1144 shall be deemed to increase the risk of the spread of wildland fire to improved property and the risk of fires on improved property spreading to wildland fuels. [**1144:**4.2.5.8]

17.1.10 Development of Wildland Fire Hazard Mitigation Plan.

17.1.10.1 From the information gathered in each structure assessment, the AHJ shall require or cause to be developed a wildland fire hazard mitigation plan and schedule to address the wildland fire hazards identified in the specific structure ignition zone assessment. [**1144:**4.3.1]

17.1.10.2 The AHJ shall work with applicable agencies and organizations to resolve any conflicts between recommended wildland fire hazard mitigation measures and mitigation measures or objectives of other hazards. [**1144:**4.3.2]

Δ **17.1.10.3*** This plan shall include, but not be limited to, the following:

(1) Specific mitigation recommendations based on the hazard assessment to reduce the ignition potential around and including the structure
(2) Construction modification or retrofit necessary to reduce the identified hazards as a minimum or to comply with the provisions of Chapter 5 of NFPA 1144

(3) Fuel modification recommendations as specified in Chapter 6 of NFPA 1144
(4) A hazard mitigation implementation and maintenance schedule approved by the AHJ

[**1144:**4.3.3]

Δ **A.17.1.10.3** Access and evacuation concerns along with fire suppression capabilities (such as fire station location, water supply, road widths, and grades) are important to overall fire protection and safety. Likewise, vegetation clearance and maintenance along private roadways, driveways, and water supplies are important elements in fire suppression and emergency evacuation. Since these elements do not relate specifically to reducing the ignition potential of the structure, these are covered in NFPA 1141; NFPA 1142; and 17.3.5.3. [**1144:**A.4.3.3]

17.1.10.4* The history of wildland fire in the area under assessment shall be considered in determining required hazard mitigation plan. [**1144:**4.3.4]

A.17.1.10.4 The frequency of wildland fire occurrence will affect the priorities of the mitigation measures and the periodic maintenance schedule of the property being assessed. [**1144:**A.4.3.4]

17.1.10.5* The AHJ shall approve the mitigating measures relative to access, water supply, and construction based upon the structure assessment established in 17.1.2. [**1144:**4.3.5]

Δ **A.17.1.10.5** NFPA 1141 provides guidance on planning and installing fire protection infrastructure. [**1144:**A.4.3.5]

17.1.10.6 From the information gathered in each structure assessment, the AHJ shall require or cause to be developed a wildland fire hazard severity map of each residential development area addressed. [**1144:**4.3.6]

Δ **17.1.10.7** The map shall include, but not be limited to, the following data elements:

(1) Lot designations
(2) Structure locations on each lot
(3) Locations of wildland fire evacuation centers or safety zones
(4) Hazard severity for each lot
(5) Overlapping ignition zones
(6) Location of fire hydrants, cisterns, or other water sources for fire fighting

[**1144:**4.3.7]

17.1.11 Mitigation Implementation and Enforcement.

17.1.11.1 The AHJ shall require the property owner to develop and comply with the approved wildland fire hazard mitigation plan and schedule according to 17.1.10.1. [**1144:**4.4.1]

17.1.11.2 No permit associated with construction shall be issued if the provisions of this *Code* are not addressed. [**1144:**4.4.2]

17.1.11.3 No permit associated with occupancy shall be issued until the provisions of this *Code* are satisfied. [**1144:**4.4.3]

17.2 Plans

The plans for construction and development within the wildland urban interface shall be submitted to the AHJ for review and approval.

In accordance with Section 17.2, plans must be submitted to the AHJ for review and approval. (See Section 1.14.) The AHJ determines which plans must be submitted for review based on the scope of the project. Plan submittals should meet the following criteria:

1. Plans should be submitted in at least two sets, with one set of plans retained by the AHJ and one set kept on site at all times during which work is in progress.
2. Plans should be drawn to scale indicating the location, nature, and extent of the work proposed.
3. Site plans should include topography, location, width and percent of grade of access roads and driveways, landscaping or vegetation details, locations of existing and proposed structures, building occupancy classifications, proposed or existing aboveground utilities, site water systems or supplies, and types of building construction, including appendages.
4. Details regarding the vicinity within 300 ft (91 m) of property lines, including other structures, access roads, percentage of slope, vegetation, and water systems or water supplies that might be furnished, should be included.
5. Vegetation management plans should be prepared and submitted when a planned development is to be within a wildland/urban interface area. Classification of fuel loading, fuel models, and fire-resistive vegetation is to be included when required by the AHJ.

NFPA 1141, *Standard for Fire Protection Infrastructure for Land Development in Wildland, Rural, and Suburban Areas*, and local building requirements and codes should be incorporated into the plans and the development, design, and location of structures in the wildland interface.

NFPA 1144 offers specific considerations as to what should be included with construction documentation; location with respect to distances from other structures; vegetation and topography; construction design and types of building materials; assembly features limiting embers from settling in areas on or around the structure, including overhangs; and exterior walls, exterior openings, and exterior exposure hazards that could contribute to fire spread and intensity.

Construction design and materials should be ignition resistant and meet fire and mechanical performance–related standard test methods. Flame spread, flame front, weathering, overhangs, exterior use, and exterior openings are various factors that are taken into consideration during testing. Standard tests include ASTM E2652, *Standard Test Method for Behavior of Materials in a Tube Furnace with a Cone-shaped Airflow Stabilizer at 750°C;* ASTM E84, *Standard Test Method for Surface Burning*

Characteristic of Building Materials; ANSI/UL 723, *Standard for Test for Surface Burning Characteristic of Building Materials;* ASTM D7032, *Standard Specification for Establishing Performance Ratings for Wood-Plastic Composite Deck Boards and Guardrail Systems (Guards or Handrails);* ANSI/UL 790, *Standard for Safety for Tests for Fire Resistance of Roof Covering Materials*; and ASTM E2886, *Test Method for Evaluating the Ability of Exterior Vents to Resist the Entry of Embers and Direct Flame Impingement*, to name only a few.

See Chapter 5 of NFPA 1144 for additional details on plan requirements, building design, location, and construction for wildland areas.

17.3 Wildland Fire–Prone Areas

17.3.1* Safeguards. Safeguards to prevent the occurrence of fires and to provide adequate fire protection and mitigation measures in hazardous fire areas shall be provided and maintained in accordance with Section 17.3.

A.17.3.1 The unrestricted use of grass-, grain-, brush-, or forest-covered lands under the jurisdiction of the AHJ presents a potential hazard to life and property from fire and resulting erosion.

17.3.2* Permits and Approvals. Permits for use of hazardous areas shall not be issued when public safety would be at risk, as determined by the AHJ. *(See Section 1.12 for additional requirements for permits.)*

A.17.3.2 Possible uses include recreation (e.g., camping, hunting, hiking), construction, and seasonal habitation.

17.3.3 Restricted Entry.

To prevent wildland fires, the AHJ might close fire-prone areas to the public when conditions are hazardous. When fire-prone areas are closed, authorized persons — such as residents (full-time and seasonal) and property owners and their guests traveling to or from their properties, public officials, fire service and emergency personnel, and employees of the U.S. government — have right of entry.

17.3.3.1 The AHJ shall determine and publicly announce when hazardous fire areas shall be closed to entry, and when such areas shall again be opened to entry.

17.3.3.2 Unauthorized persons shall not be permitted to enter or remain in closed hazardous fire areas.

17.3.3.3 Signs. Approved signs prohibiting entry by unauthorized persons shall be placed on every closed area and access point.

17.3.4 Use of Flammable Materials and Procedures.

The AHJ can permit or approve the use of flammable materials, explosives, outdoor fires, and open flame devices. Permits or approvals for the use of flammable materials and operations must contain terms and conditions to safeguard the public and property during certain fire danger ratings and during unusual climatic conditions and other weather anomalies. Also see Section 10.10 for additional guidance on the use of open flames, candles, open fires, and incinerators.

17.3.4.1 Smoking. Lighting, igniting, or otherwise setting fire to any smoking material shall be prohibited unless within structures or smoking areas approved by the AHJ. *(See Section 10.9 for additional requirements on smoking.)*

17.3.4.2 Tracer Bullets, Tracer Charges, Rockets, and Model Aircraft.

17.3.4.2.1 Tracer bullets and tracer charges shall not be possessed, fired, or caused to be fired into or across hazardous fire areas.

17.3.4.2.2 Rockets, model planes, gliders, and balloons powered with an engine, propellant, or other feature liable to start or cause fire shall not be fired or projected into or across hazardous fire areas.

17.3.4.3 Explosives and Blasting. Explosives shall not be possessed, kept, stored, sold, offered for sale, given away, used, discharged, transported, or disposed of within hazardous fire areas except as permitted by the AHJ. *(See Chapter 65 for additional guidance.)*

17.3.4.4 Fireworks. Fireworks shall not be used or possessed in hazardous fire areas unless permitted by the AHJ. *(See Chapter 65 for additional guidance.)*

17.3.4.5 Apiaries. Lighted and smoldering material used in connection with smoking bees shall not be allowed in or upon hazardous fire areas except as permitted by the AHJ.

17.3.5 Clearance of Brush and Vegetative Growth.

17.3.5.1 Electrical Transmission Lines.

17.3.5.1.1 Clearance of brush and vegetative growth from electrical transmission and distribution line(s) shall be provided and maintained in accordance with 17.3.5.1.

17.3.5.1.2 A combustible-free space around poles and towers shall consist of a clearing of not less than 10 ft (3.05 m) in each direction from the outer circumference of the pole or tower during such periods of time as designated by the AHJ.

17.3.5.1.3 Trimming Clearance.

17.3.5.1.3.1 At the time of trimming, clearances not less than those established by Table 17.3.5.1.3.1 shall be provided.

17.3.5.1.3.2 The radial clearances in Table 17.3.5.1.3.1 are minimum clearances that shall be established at time of trimming between the vegetation and the energized conductors and associated live parts.

17.3.5.1.4 Clearances not less than those established by Table 17.3.5.1.4 shall be maintained during such periods of time as designated by the AHJ.

TABLE 17.3.5.1.3.1 *Minimum Clearances Between Vegetation and Electrical Lines at Time of Trimming*

	Minimal Radial Clearance from Conductor	
Line Voltage	**ft**	**m**
2400–72,000	4	1.2
72,001–110,000	6	1.8
110,001–300,000	10	3.0
300,001 or more	15	4.6

TABLE 17.3.5.1.4 *Minimum Clearances Between Vegetation and Electrical Lines to Be Maintained*

	Minimum Clearance	
Line Voltage	**in.**	**mm**
750–35,000	6	152
35,001–60,000	12	305
60,001–115,000	19	483
115,001–230,000	30.5	775
230,001–500,000	115	2920

17.3.5.1.4.1 The site-specific clearance achieved, at the time of pruning, shall vary based on species' growth rates, the utility company specific trim cycle, the potential line sway due to wind, line sway due to electrical loading and ambient temperature, and the tree's location in proximity to the high voltage lines.

17.3.5.1.4.2 The AHJ shall establish minimum clearances different than those specified by Table 17.3.5.1.4 when evidence substantiating such other clearances is submitted to the AHJ and approved.

17.3.5.1.5* Electrical Power Line Emergencies. During emergencies, the utility company shall perform the required work to the extent necessary to clear the hazard.

A.17.3.5.1.5 An emergency can include situations such as trees falling into power lines or trees' location in violation of Table 17.3.5.1.3.1.

17.3.5.2 Structures.

17.3.5.2.1 Persons owning, leasing, controlling, operating, or maintaining buildings or structures in, upon, or adjoining hazardous fire areas, and persons owning, leasing, or controlling land adjacent to such buildings or structures, shall maintain an effective defensible space in accordance with 17.3.5.2.1.1 through 17.3.5.2.1.11.5.

Exhibit 17.2 shows a property with defensible space that was saved from fires that pushed through southern New Mexico in March 2002.

Exhibit 17.2

A home that survived the Kokopelli Fire in 2002, Ruidoso, New Mexico. (Image courtesy of NFPA Firewise® program)

17.3.5.2.1.1* Ground fuels, including native vegetation and plants used for landscaping within the defined landscaping zones, shall be treated or removed. [**1144:**6.2.1]

A.17.3.5.2.1.1 Acceptable methods of fuel treatment include, but are not limited to, prescribed burning by qualified personnel, mowing, pruning, removing, substitution, mulching, converting to compost, and grazing. [**1144:**A.6.2.1]

Vegetation. Fire resistance in plants depends on many variables, including location, growing conditions, and maintenance. Plants should be chosen that are suitable for the geographic region and the location in the landscape, and plants with similar needs should be grouped to minimize care. Plant characteristics that reduce maintenance needs include the following:

(1) Drought-resistant
(2) Pest-resistant
(3) Native
(4) Noninvasive
(5) Slow-growing
(6) Wind-resistant
(7) Thriving without supplemental fertilizing
[**1144:**A.6.2.1]

High Combustibility (fire-prone, fire-tolerant) Plants. Some plants burn readily because they are adapted to survive in fire-dependent ecosystems and can contain volatile compounds that support fire. Fire-prone plants have traits (i.e., adaptations) that help them to survive fire, such as thick bark or extensive roots. They often contain resins, oils, or waxes that ignite easily and burn intensely. Fire-prone plants will flame, not smolder, when preheated and ignited with a match. They should be removed from Zone 1 of the landscape, as illustrated in Figure A.17.1.8, Figure A.17.1.9.2(a), and Figure A.17.1.9.2(b). Where it is not practical or desirable to remove a fire-prone plant, surrounding it with open space or fire-resistant plants can reduce the hazard. Typical characteristics of fire-prone plants include the following:

(1) Volatile resins, oils, or waxes, indicated by leaves that are aromatic when crushed
(2) Narrow leaves or needles (often evergreen)
(3) Waxy or fuzzy leaves
(4) Accumulation of fine, twiggy, dry, or dead material on the plant or on the ground under the plant
(5) Loose, papery, or thick bark

[**1144:**A.6.2.1]

Low Combustibility Plants. In place of fire-prone plants, landscapers and homeowners should use low combustibility plants, often referred to as fire-resistant plants. Although all plants will burn at some point, wildland fire researchers have shown that some types of plants, including many native plants, resist burning more than others. Additionally, some ornamental plants, when properly irrigated and maintained, are more resistant to fire than others. Low combustibility plants are typically low fuel volume, non-oily, nonresinous plants that are also drought-resistant, have small thick leathery leaves, and produce very little dead plant material. Typical characteristics of fire-resistant plants include the following:

(1) High moisture content in leaves
(2) Low oil or resin content (not aromatic)
(3) Drought tolerance or drought resistance
(4) Minimal seasonal accumulation of dead vegetation, or accumulation of dead leaves that are somewhat resistant to fire because they hold moisture in the soil (large, flat leaves)
(5) Limited foliage and few dead branches
(6) Open or loose branching habit
(7) Easy maintenance and pruning

[**1144:**A.6.2.1]

17.3.5.2.1.2 Live vegetation within the fuel modification area shall have dead material removed and shall be thinned and pruned in conformance with the wildland fire mitigation plan, as approved by the AHJ. [**1144:**6.2.2]

17.3.5.2.1.3 Dead and downed fuels within 30 ft (9 m) of all buildings shall be removed or treated to maintain the fuel modification area in conformance with the wildland fire mitigation plan, as approved by the AHJ. [**1144:**6.2.3]

17.3.5.2.1.4 Vegetation under trees within the fuel modification area shall be maintained at a height that will preclude ground fire from spreading in the tree crown. [**1144:**6.2.4]

17.3.5.2.1.5* Tree crowns within the structure ignition zone shall be spaced to prevent structure ignition from radiant heat. [**1144:**6.2.5]

A.17.3.5.2.1.5 Studies of structural ignition from radiant heat indicate that ignitions are unlikely to occur from burning vegetation beyond 120 ft (36.6 m) from a structure. Therefore, clearing of vegetation and thinning of trees to a distance of 120 ft (36.6 m) from a dwelling — as in a zoned Firewise landscape — will prevent ignition of a structure from the radiant heat from a flame front in a high-risk ecosystem (Cohen and Butler, 1996). [**1144:**A.6.2.5]

TABLE A.17.3.5.2.1.5 *Recommended Tree Crown Spacing to Prevent Structural Ignition from Wildland Fire Radiant Heat*

Zone	Distance from Structure	Recommended Tree Crown Spacing
1	0–30 ft (0–9 m)	18 ft (5.5 m)
2	30–60 ft (9–18 m)	12 ft (3.7 m)
3	60–100 ft (18–30 m)	6 ft (1.8 m)
4	Beyond 100 ft (30 m)	No restrictions

[**1144:** Table A.6.2.5]

A tree crown spacing of 18 ft (5.5 m) for trees within the Zone 1 defensible space [within 30 ft (9 m) of a structure] will reduce radiant heat to at or below the level where ignition of wood occurs, with closer spacing of trees allowed in the zones further from the structure, as described in Table A.17.3.5.2.1.5. These tree-spacing recommendations apply equally to thinning of mature trees or planting of new trees in high- or extreme-risk areas. Tree spacing is measured between the outer edges of the crowns of mature trees, so new trees must be planted with spacing equivalent to the estimated diameter of the mature crown. [**1144:**A.6.2.5]

Table A.17.3.5.2.1.5 illustrates general clearance distances for tree crowns. However, these distances can be adjusted by the AHJ in consideration of species of trees and understory vegetation, slope of the property, the proximity to other neighboring structures, overlapping ignition zones, and other site-specific factors. [**1144:**A.6.2.5]

17.3.5.2.1.6 The fuel modification plan shall include a maintenance element identifying and defining the responsibility for continued and periodic maintenance. [**1144:**6.2.6]

17.3.5.2.1.7 Chimneys and Flues.

17.3.5.2.1.7.1 Every fireplace and wood stove chimney and flue shall be provided with an approved spark arrester constructed of a minimum 12-gauge welded wire or woven wire mesh, with openings not exceeding ½ in. (12.7 mm). [**1144:**5.8.1]

17.3.5.2.1.7.2 Vegetation shall not be allowed within 10 ft (3 m) of a chimney outlet. [**1144:**5.8.2]

17.3.5.2.1.8* Accessory Structure(s). Accessory structures shall be constructed to meet the requirements of Chapter 5 of NFPA 1144 or shall be separated from the main structure by a minimum of 30 ft (9 m). [**1144:**5.9]

A.17.3.5.2.1.8 Accessory structures include, but are not limited to, outbuildings, patio covers, gazebos, palapas, and similar outdoor structures. [**1144:**A.5.9]

17.3.5.2.1.9 Mobile and Manufactured Homes.

17.3.5.2.1.9.1 Permanently located mobile and manufactured homes with an open space beneath shall have a skirt of noncombustible materials, exterior fire-retardant-treated wood, or other ignition-resistant material. [**1144:**5.10.1]

17.3.5.2.1.9.2 Any enclosed space beneath the mobile or manufactured home shall be vented according to 5.2.2 of NFPA 1144. [**1144:**5.10.2]

17.3.5.2.1.10 Vehicle Parking Areas. Vehicle parking areas within the immediate landscaped zone shall be maintained free of dry grasses and fine fuels that could be ignited by hot exhaust systems or firebrands. [**1144:**5.11]

17.3.5.2.1.11 Exterior Exposure Hazards.

17.3.5.2.1.11.1* Heat and flame sources that are unprotected or unsupervised shall not be permitted within 30 ft (9 m) of the primary structure. [**1144:**5.12.1]

A.17.3.5.2.1.11.1 Unprotected heat and flame sources include, but are not limited to, open burning without spark protection, barbecue pits, clay or stone fireplaces, and fire pits. Supervision of burning includes the presence of a source of water or other extinguishing equipment. [**1144:**A.5.12.1]

17.3.5.2.1.11.2 Incinerators, outdoor fireplaces, permanent barbecues, and grills shall not be built, installed, or maintained in hazardous fire areas without prior approval of the AHJ. [**1144:**5.12.2]

17.3.5.2.1.11.3 Openings in incinerators, outdoor fireplaces, permanent barbecues, and grills shall be provided with an approved spark arrester, screen, or door. [**1144:**5.12.3]

Δ **17.3.5.2.1.11.4** Propane tanks and other combustible liquids storage shall conform to NFPA 58 and the wildland fire hazard mitigation plan required in 17.1.10. [**1144:**5.12.4]

17.3.5.2.1.11.5 Other combustible materials within 30 ft (9 m) of any structure shall be removed or stored in conformance with the wildland fire hazard mitigation plan as approved by the AHJ. [**1144:**5.12.5]

The immediate landscaped area within approximately 30 ft (9 m) of the structure is often referred to as the *defensible space*. Within the defensible space, any combustible materials (e.g., plants, lawn furniture, trash, construction materials) should be removed or reduced to prevent their ignition, which, in turn, could ignite the structure. Reducing ignition hazards around a structure should be a combination of modifying the structure fuel package (the structure and its components) and the vegetative fuel package (the natural vegetation and landscape plantings). Reducing ignition hazards associated with the structure fuel package can be achieved through the use of noncombustible roof coverings, siding, and decking; removal of light combustibles from decks and porches (e.g., lawn furniture cushions, brooms, paper, and cardboard); and separation of combustible fences from direct contact with the structure. Exhibit 17.3 depicts a home constructed of ignition-resistant materials that withstood the effects of a wildland fire.

Exhibit 17.3

Home survival, High Park Fire, Rist Canyon, Colorado, 2012. (Image provided courtesy of Chief Robert Gann, Rist Canyon Volunteer Fire Department)

Vegetative fuel load modifications might include removing highly flammable vegetation and planting vegetation that has a lower ignitability (e.g., those with higher moisture content and/or less resinous oils). Ornamental vegetation and cultivated ground covers, such as maintained green grass, succulents, low-growing annual flowers, and other similar plants, might be permitted within the designated ignition zone as long as they do not provide a continuous means of transmitting fire to any adjacent structures. The first 5 ft to 6 ft (1.5 m to 1.8 m) around the structure's foundation are the most important for vegetation management. Keeping plants and shrubs from contacting the structure or being placed directly under soffits will aid in reducing the structure's ignition potential. When assessing ignition potential, keep in mind that, if a plant or shrub is connected to the structure, it is part of the structure's fuel package.

No plants are fireproof. Any plant can burn under extreme conditions; however, some plants are more difficult to ignite, burn more slowly, and produce less heat with shorter flame lengths. Plants that possess high moisture content, low growing habits, low fuel volume, and desirable chemical content are good choices for high hazard areas, as are plants that grow to a height not greater than 18 in. (45 mm) and are less than ½ in. (13 mm) in diameter. Plants with resinous, oily, or waxy parts should be avoided.

The risk associated with plants in high hazard areas can be reduced by pruning, by removing dead leaves and branches, and by using other appropriate horticultural practices. The area within the structure ignition zone needs to be maintained in a manner that reduces ignition hazards as identified in the hazard assessment process outlined in Section 17.1 and NFPA 1144.

Exhibit 17.4

Structure ignition zone.

For additional information on structure ignition zones, go to www.firewise.org. (See Exhibit 17.4.)

17.3.5.2.2 Where required by the AHJ because of extra hazardous conditions, additional areas shall be maintained to include additional defensible space from buildings or structures, trees adjacent to or overhanging a building shall be maintained free of deadwood, and the roof of a structure shall be free of leaves, needles, or other dead vegetative growth.

Some trees might be permitted within the structure ignition zone, provided that the horizontal distance between crowns of adjacent trees is at least 18 ft (5.5 m) where located within 30 ft (9 m) of the structure. Creating and maintaining planting islands is one way to provide shade and aesthetics while eliminating or reducing crown-to-crown continuity and achieving separation between tree crowns and the structure. Paragraph 17.3.5.2.2 requires that dead limbs on trees and downed fuels beneath trees be removed to maintain the area and prevent a ground fire from spreading into tree crowns. Trees within the ignition zone should be pruned to 6 ft to 10 ft (2 m to 3 m) above the ground surface and within 10 ft (3 m) of a chimney outlet. See Chapters 5 and 6 of NFPA 1144 for more information.

17.3.5.3 Roadways. Areas within 10 ft (3 m) on each side of portions of highways and private streets shall be cleared of combustible vegetation and other combustible growth. Single specimens of trees, shrubbery, or cultivated ground cover such as green grass, ivy, succulents, or similar plants used as ground covers shall be permitted to be exempt provided that they do not form a means of readily transmitting fire.

NFPA 1141 defines *roadway* as "any public or private street, including bridges and rights of way" and describes how roadways should be constructed and maintained. A roadway should be able to accommodate drainage, erosion control, and provisions for utilities. Also defined is the minimum clear width for each lane of travel, curves, parking permitted, intersections with slopes for drainage, and such. Bridges and culverts should be designed to a minimum of 100-year flood elevations and flows. Easements should be incorporated to permit vegetation clearing and also allow for evacuation and access by fire crews to wildland areas. Clearing roadways of combustible vegetation and growth allows access and egress for emergency responders and provides additional time for the use of the roadway for evacuation by removing means of the ready transmission of fire.

See Chapter 18 for minimum requirements for emergency vehicle access, bridges, angles of approach, gates, dead ends, and turning radius. Also see Chapter 5 of NFPA 1141 for additional information on roadways.

17.3.6 Unusual Circumstances. The AHJ shall determine that difficult terrain, danger of erosion, or other unusual circumstances could require additional safeguards.

17.3.7 Fire Roads, Firebreaks, and Emergency Access.

17.3.7.1 The provisions of 17.3.7 and Section 18.2 shall be used to determine the design, clearances, and provisions for emergency access (ingress and egress).

NFPA 1141 offers specific recommendations for means of access whether defined as public or private roadways, ranging from general information to the number of means of access based on the number of households, roadway grades typically not to exceed 8 degrees, dead ends more than 300 ft (91 m) to provide turnarounds not less than 120 ft (366 m) in outside diameter, signage to be addressed in a logical, consistent manner, as well as stipulations for fire lanes and parking lots. For additional guidance, see Chapter 5 of NFPA 1141.

Much of the building access and separation requirements addressed in Chapter 6 of NFPA 1141 are associated to NFPA 13, *Standard for the Installation of Sprinkler Systems*, or NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*.

17.3.7.2 Unauthorized vehicles shall not be driven upon fire roads or firebreaks. Vehicles shall not be parked in a manner that obstructs the entrance to a fire road or firebreak.

17.3.7.3 Radio and television aerials, guy wires, and other obstructions shall not be installed or maintained on fire roads or firebreaks unless the vertical clearance is sufficient to allow the movement of fire and emergency apparatus.

17.3.7.4 Motorcycles, motor scooters, and motor vehicles shall not be operated within hazardous fire areas, except upon clearly established public or private roads.

17.3.8 Tampering with Fire Safety Equipment. See Section 10.7 for requirements on tampering with fire safety equipment.

17.3.9 Maintenance. See 4.5.8 for requirements on maintenance.

Fire Department Access and Water Supply

18

Chapter 18 includes most site design issues in one location. Fire department access fire lane marking requirements, minimum water supply requirements for manual fire suppression operations, and fire hydrant spacing provisions are all contained within this chapter. Criteria for fire hydrant locations and distribution were contained in Annex E of the 2012 edition of the *Code*; for the 2015 edition, the former Annex E criteria were revised and incorporated into Section 18.5, making the provisions mandatory rather than optional, adoptable requirements.

18.1 General

Fire department access and water supplies shall comply with this chapter.

18.1.1 Application.

18.1.1.1 This chapter shall apply to public and privately owned fire apparatus access roads.

Regardless of who owns a road, if it is utilized as a fire apparatus access road, it must comply with this chapter. There is no exemption for roads owned by a state, county, or municipality.

18.1.1.2 This chapter shall apply to public and privately owned fire hydrant systems.

Regardless of who owns a fire hydrant water system, that system must comply with this chapter. There is no exemption or distinction between private fire service mains, private utilities, and public utility systems.

18.1.2 Permits. Permits, where required, shall comply with Section 1.12.

18.1.3 Plans.

18.1.3.1 Fire Apparatus Access. Plans for fire apparatus access roads shall be submitted to the AHJ for review and approval prior to construction.

For new developments, this review should occur as part of the jurisdiction's site plan review process. If a public or private agency is conducting stand-alone roadway work, the plans for such road work should be submitted to the AHJ as part of the approval process.

18.1.3.2 Fire Hydrant Systems. Plans and specifications for fire hydrant systems shall be submitted to the AHJ for review and approval prior to construction.

For new developments, this review should occur as part of the jurisdiction's site plan review process. If a public or private utility is conducting stand-alone work on the utility system, such as adding new water mains or replacing existing water mains, the design for such work should be submitted to the AHJ as part of the approval process.

18.2 Fire Department Access

18.2.1 Fire department access and fire department access roads shall be provided and maintained in accordance with Section 18.2.

18.2.2* Access to Structures or Areas.

A.18.2.2 Access control devices take many forms such as remote opening devices, card keys, key codes, keys, and so forth.

18.2.2.1 Access Box(es). The AHJ shall have the authority to require an access box(es) to be installed in an accessible location where access to or within a structure or area is difficult because of security. The access box(es) shall be of an approved type listed in accordance with UL 1037.

Access boxes provide an orderly system of gaining access to buildings or areas while maintaining a high level of security. These heavy-duty key repository boxes provide a high-security system that ensures that only the fire department can access the keys or other devices within them. A definition of *access box* is provided in 3.3.2.

Some access box systems have provisions for securing the keys to the key box inside the cabs of fire apparatus. With these systems, the fire company must contact central dispatch to have the key released for use. Central dispatch keeps a log that indicates exactly when and where fire companies are accessing buildings or other secure areas. The dispatch center can also determine when the key has been returned to its secure position

Exhibit 18.1

UL-listed access box. (Courtesy of Knox, Co.)

in the apparatus. This type of system provides a high level of security. If a fire department does not have a good master key control system, the loss of a master key can create potential liability and expense to the department, with the accompanying bad press.

Some fire departments require access boxes to be mounted on a wall at a height of 10 ft to 12 ft (3 m to 3.66 m) to prevent the lock from being vandalized. The fire department can quickly access the box, using a ladder from the apparatus. Exhibit 18.1 illustrates a UL-listed access box in accordance with 18.2.2.1.

Most manufacturers that supply access boxes also provide a variety of other products, such as safety data sheet (SDS) cabinets, which can be used to keep important site information in a secure location for access by the fire department. Padlocks keyed to a master key system are also available. These locks can be used to secure gates and other locations where only the fire department is allowed access.

Factors to consider in determining the keys that should be provided in an access box include the fire department's operational procedures, the presence of fire protection systems, the hazards and hazardous materials present, and the nature of the occupancy and occupants.

18.2.2.2 Access to Gated Subdivisions or Developments. The AHJ shall have the authority to require fire department access be provided to gated subdivisions or developments through the use of an approved device or system.

Access to gated communities or other developments must comply with the same requirements for buildings or areas outlined in 18.2.2.1. Key systems that are compatible with access box master keys are available to facilitate access through electronic gates. Access gates might also use card access readers, siren-operated devices, infrared receivers, or other approved devices rather than keys. Since access codes and card access readers can sometimes change programing or fail without notice to the fire department, the AHJ should consider requiring a primary and a backup method to access electronic gates. For example, a primary access system could be a siren-operated system and a backup system could be a key switch. Exhibit 18.2 shows an example of a gate with an access box attached.

When considering the approval of such systems to access gated subdivisions or developments, the AHJ should consider other jurisdictional needs for access. Law enforcement, public works, garbage disposal, and other services may require access. Therefore, the AHJ should consult with these other entities to make them aware of the restricted access condition and the potential need to develop an access approach that is beyond the fire department and emergency medical services (EMS).

18.2.2.3 Access Maintenance. The owner or occupant of a structure or area, with required fire department access as specified in 18.2.2.1 or 18.2.2.2, shall notify the AHJ when the access is modified in a manner that could prevent fire department access.

Maintaining access devices is often difficult. During inspections and pre-fire planning, all access devices should be checked to ensure that they contain the proper keys and that the access devices function as intended. The on-site maintenance personnel

Exhibit 18.2

Example of gate access and access box.

may be aware of changes to locks or gate access systems that the building owner might have forgotten about or is not familiar with. All building owners with access boxes, gated developments, and area locksmiths should be notified in writing that they should contact the fire department when any front door, gate access programing, or other specified locks are changed. This process should help ensure that appropriate keys and access are available when needed. Jurisdictions should also consider issuing a permit for the initial installation of an access device to ensure it is installed in accordance with the manufacturer's instructions and meets the jurisdiction's specifications. Permitting also assists in creating a database that can be utilized for future maintenance checks by the fire department, and the location of the access box can be added to the dispatch computer-aided design (CAD) system.

18.2.3 Fire Department Access Roads.

18.2.3.1 Required Access.

18.2.3.1.1 Approved fire department access roads shall be provided for every facility, building, or portion of a building hereafter constructed or relocated.

To provide effective manual fire suppression operations, the fire department must be able to gain reasonable access to a building. Paragraph 18.2.3.1.1 addresses this need by requiring fire department access roads to all new facilities and buildings. A fire department access road, such as the one shown in Exhibit 18.3, can be a public or private roadway that meets the requirements of 18.2.3 and is not mandated to be marked as a fire lane unless so required by the AHJ.

Note that 18.2.3.1.1 requires fire department access only for newly constructed or relocated buildings and facilities. The *Code* does not require the modification of previously approved access to existing buildings to meet the current *Code* requirements in 18.2.3.1.1. Maintaining existing access is addressed in 18.2.2.3 and 18.2.4.

Exhibit 18.3

Fire department access road.

Buildings under construction are addressed in 16.1.4, which requires that fire department access roads be provided and maintained during building construction.

18.2.3.1.2 Fire department access roads shall consist of roadways, fire lanes, parking lot lanes, or a combination thereof.

Fire lanes are considered fire apparatus access roads, which are required to be marked in accordance with 18.2.3.6 where required by the AHJ. The term *fire lane* is defined in 3.3.126 as a fire department access road marked with approved signs or other approved notices.

18.2.3.1.3* The provisions of 18.2.3.1 through 18.2.3.2.2.1 shall be permitted to be modified by the AHJ where any of the following conditions exists:

(1) One- and two-family dwellings protected by an approved automatic sprinkler system in accordance with Section 13.1
(2) Existing one- and two-family dwellings
(3) Private garages having an area not exceeding 400 ft^2
(4) Carports having an area not exceeding 400 ft^2
(5) Agricultural buildings having an area not exceeding 400 ft^2
(6) Sheds and other detached buildings having an area not exceeding 400 ft^2

A.18.2.3.1.3 The intent of 18.2.3.1.3 is to not require fire department access roads to detached gazebos and ramadas, independent buildings associated with golf courses, parks, and similar uses such as restrooms or snack shops that are 400 ft^2 (37 m^2) or less in area, and detached equipment or storage buildings for commercial use that are 400 ft^2 (37 m^2) or less in area.

18.2.3.1.4 When fire department access roads cannot be installed due to location on property, topography, waterways, nonnegotiable grades, or other similar conditions, the AHJ shall be authorized to require additional fire protection features.

Site conditions or unique structural designs can result in a fire department access road design that does not meet the specific requirements of this *Code*. An example of such a situation would be a group of zero lot line buildings in a downtown area with no access to the sides or rear of the buildings. Another example would be an environment education building constructed in wetlands that is accessible only via a pedestrian path. Paragraph 18.2.3.1.4 recognizes such situations are sometimes unavoidable from a design standpoint. In these circumstances, the AHJ is authorized to require additional fire protection to offset the increased hazard or the delays created by an access road design that does not comply with 18.2.3. For example, additional fire protection could be in the form of an automatic sprinkler system and standpipe protection where not otherwise required.

18.2.3.2 Access to Building.

18.2.3.2.1 A fire department access road shall extend to within 50 ft (15 m) of at least one exterior door that can be opened from the outside and that provides access to the interior of the building.

Fire department access roads are required to be such that fire apparatus can drive within 50 ft (15 m) of an exterior door that allows access to the interior of the building.

Fire departments typically carry 150 ft or 200 ft (46 m or 61 m), or both, of preconnected hose lines on their apparatus. The access design configuration required in 18.2.3.2 allows fire fighters to quickly extend preconnected hose lines into the building from fire apparatus. If the fire apparatus can access the building within 50 ft (15 m), fire fighters can extend hose lines 100 ft to 150 ft (30 m to 46 m) into the building without undue delay.

Although not a mandatory requirement, in a multiple-tenant building, the exterior door should be placed at a location that allows access to a common hall or common lobby area or, if the building does not have a common interior area, to the largest tenant area. In single-tenant buildings, the exterior door should be placed at a location that allows unobstructed access to the tenant floor area.

Δ **18.2.3.2.1.1** Where a one- or two-family dwelling, or townhouse, is protected with an approved automatic sprinkler system that is installed in accordance with Section 13.3, the distance in 18.2.3.2.1 shall be permitted to be increased to 150 ft (46 m).

This paragraph recognizes that the presence of automatic sprinkler protection in one- and two-family dwellings and townhouses significantly reduces the risk to the occupants and fire fighters along with reducing the consequences of a fire. Due to this significantly reduced risk, the distance to the exterior door can be increased while still maintaining an improved level of building and life safety protection.

18.2.3.2.2 Fire department access roads shall be provided such that any portion of the facility or any portion of an exterior wall of the first story of the building is located not more than 150 ft (46 m) from fire department access roads as measured by an approved route around the exterior of the building or facility.

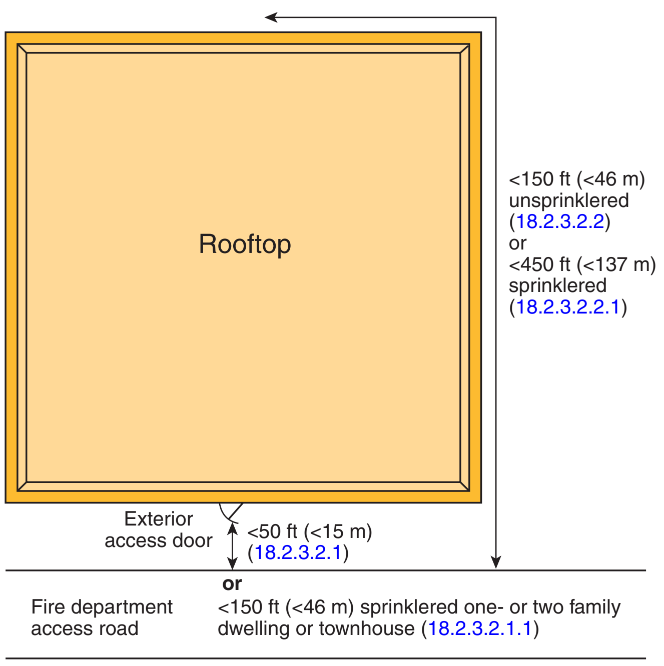
Fire department access is essential to providing effective manual fire suppression operations. Remote sections of the building need to be limited to ensure that hose streams, aerial fire apparatus, and fire fighters can access most portions of the building. Exhibit 18.4 illustrates an acceptable arrangement for compliance with 18.2.3.

18.2.3.2.2.1 When buildings are protected throughout with an approved automatic sprinkler system that is installed in accordance with NFPA 13, NFPA 13D, or NFPA 13R, the distance in 18.2.3.2.2 shall be permitted to be increased to 450 ft (137 m).

Paragraph 18.2.3.2.2.1 recognizes the significant benefits of automatic sprinkler protection in reducing the severity of fire incidents. If there is a fire sprinkler system, the access distance required by 18.2.3.2.2 is permitted to be increased to 450 ft (137 m).

18.2.3.3* Multiple Access Roads. More than one fire department access road shall be provided when it is determined by the AHJ that access by a single road could be impaired by vehicle congestion, condition of terrain, climate conditions, or other factors that could limit access.

Exhibit 18.4



Acceptable fire department access configuration.

N **A.18.2.3.3** Access roads that are below the 100-year base flood elevation and roadways that could be blocked by frequent rail traffic are two conditions that could limit access in an emergency and warrant an additional access roadway. Requiring additional access roads because of possible congestion should be based on a traffic impact analysis of the proposed development. This type of analysis is typically conducted by a transportation or traffic engineer and occurs at the cost of the developer. This *Code* avoids establishing a specific threshold for mandating multiple-access roads; potential congestion conditions are so variable that prescriptive language is not justified. The AHJ has the authority to require a study of the traffic conditions resulting from a development and the subsequent need for additional access via Section 1.15.

The following examples might warrant multiple fire department access roads:

1. Railroad tracks that cross a single fire department access road
2. Potential for mudslides along a single fire department access road
3. Single fire department access road that is below the 100-year flood elevation
4. Commercial or residential projects that generate large traffic counts on fire apparatus access roads

A traffic engineer should review the traffic counts and access design in large-scale development projects to ensure an appropriate access design for emergency vehicles. Even where it might not be feasible to provide multiple fire department access roads for large-scale developments, the traffic engineer can be consulted to provide potential mitigation methods to facilitate improved fire department access. These methods could include items such as mountable curbs, wider travel lanes, traffic signal preemption, or dedicated emergency access lanes.

N **18.2.3.4 Traffic Signal Pre-emption.** Where fire department apparatus are equipped with traffic signal pre-emption devices, newly installed traffic signals shall be equipped with traffic signal pre-emption.

Many fire departments have deployed traffic signal pre-emption systems. These systems reduce the risk of accidents in intersections during emergency responses and improve response times to both emergency and nonemergency incidents. As new traffic signals are installed or existing traffic signal equipment is replaced, it is important that traffic signal pre-emption be provided as part of the new or replacement equipment. AHJs should also be aware of what type of pre-emption technology is being utilized in their jurisdiction and adjacent jurisdictions. Coordination with the jurisdiction's traffic engineers is important to ensure that the AHJ is specifying the appropriate traffic signal equipment compatible with the equipment on fire apparatus.

18.2.3.5 Specifications.

The *Code* provides broad minimum design requirements for fire department access roads. For more specific design information on roadway design, see *A Policy on Geometric Design of Highways and Streets*, published by the American Association of State Highway and Transportation Officials (AASHTO), available for purchase at www.transportation.org, or consult applicable state and local roadway design standards.

18.2.3.5.1 Dimensions.

18.2.3.5.1.1* Fire department access roads shall have an unobstructed width of not less than 20 ft (6.1 m).

The minimum 20 ft (6.1 m) width required by 18.2.3.5.1.1 allows for two-way vehicular traffic and for one fire apparatus vehicle to pass while another is working at a fire hydrant or conducting aerial operations.

N **A.18.2.3.5.1.1** Where parking is permitted along the access road, the unobstructed width is not intended to include the width of the parking.

The AHJ should pay close attention to the parking arrangements in new residential subdivisions and apartment developments. Not all jurisdictions have adequate minimum parking regulations to ensure that a sufficient number of parking spaces are provided on-site for homes and dwelling units at apartments. If adequate parking is not provided for each home or dwelling unit, residents will attempt to park in the fire department access roads. In those circumstances, the 20 ft (6.1 m) minimum width required by 18.2.3.5.1.1 will not be sufficient. Use of the term *unobstructed* in 18.2.3.5.1.1 and emphasized by A.18.2.3.5.1.1 is intended to convey that the minimum 20 ft (6.1 m) width is not to be utilized for parking or any other use. Correction of this type of parking problem after a development has been built will be problematic. Therefore, the AHJ should address this type of issue during the site plan review.

N **18.2.3.5.1.1.1*** Where approved by the AHJ, the width of fire department access roads shall be permitted to be less than the minimum specified in 18.2.3.5.1.1.

N **A.18.2.3.5.1.1.1** One condition to consider in reducing access road width would be intended travel in one direction only.

In considering a reduction in the 20 ft (6.1 m) minimum required under 18.2.3.5.1.1, the AHJ should consider the following:

1. The potential for parking on the fire department access road. The greater the potential for parking to occur on the access roadway, the more difficult it is to justify reducing the width.
2. The length of the access road where the reduced width will be place. If the length of the roadway where the reduced width will be in place is relatively short, the potential for a hazard created by the reduction is also decreased.
3. Whether traffic moves in a single direction or in multiple directions. For one-way access roadways with no parking potential, it may be appropriate to permit roadway width reductions to 14 ft (4.3 m) or even 12 ft (3.7 m).
4. The typical amount of traffic on the roadway. If the roadway is congested during typical use times, it will be more difficult to justify a reduced width.

N **18.2.3.5.1.1.2** The width of fire department access roads shall be increased when the minimum width specified in 18.2.3.5.1.1 is not adequate to accommodate fire apparatus.

A typical example of this situation is an access road where on-street parking will be permitted or is anticipated due to inadequate on-site parking.

18.2.3.5.1.2 Fire department access roads shall have an unobstructed vertical clearance of not less than 13 ft 6 in. (4.1 m).

The minimum 13 ft 6 in. (4.1 m) vertical clearance ensures that fire apparatus can safely pass under power lines, bridges, and other obstructions. *A Policy on Geometric Design of Highways and Streets*, published by AASHTO, recommends a minimum 14 ft (4.3 m) clearance for local and collector roads. A 16 ft (4.9 m) clearance is recommended for rural and urban arterials. The 14 ft or 16 ft (4.3 m or 4.9 ft) recommendations allow for snow accumulation and future changes in roadway depth if additional roadway material is added.

Maintaining the minimum 13 ft 6 in. (4.1 m) clearance is also a consideration where trees are located next to the roadway. Where tree limbs grow to obstruct the 13 ft 6 in. (4.1 m) minimum clearance, the AHJ should require the private property owner or the public right-of-way owner to trim the trees to the appropriate minimum height.

AHJs should also be aware of building design elements that can obstruct the fire department movements. Where porte-cocheres or other overhead structures are utilized to allow vehicles to drive under, the AHJ should consider if the area under the porte-cochere should be considered a fire department access road and thus required to meet the minimum height of 13 ft 6 in. (4.1 m). Consideration should also be given to the need to park EMS vehicles in such locations even if the fire apparatus might not park or drive through the porte-cochere. If a porte-cochere is provided at the building main entrance, it should be designed to the 13 ft 6 in. (4.1 m) minimum.

18.2.3.5.1.2.1 Vertical clearance shall be permitted to be reduced where approved by the AHJ, provided such reduction does not impair access by fire apparatus, and approved signs are installed and maintained indicating the established vertical clearance when approved.

One example of acceptable reduced vertical clearance would be the entrance to a parking garage. Where low clearances are permitted, the *Code* mandates that approved warning signs be provided to notify emergency responders of the restricted access condition.

Δ **18.2.3.5.1.2.2** Vertical clearances shall be increased when vertical clearances are not adequate to accommodate fire apparatus.

An example of the need for an increased vertical clearance might be to accommodate an aircraft rescue fire-fighting (ARFF) vehicle in areas on and adjacent to airports. Many of these vehicles exceed standard apparatus dimensions and require greater vertical clearances.

18.2.3.5.2* Surface. Fire department access roads shall be designed and maintained to support the imposed loads of fire apparatus and shall be provided with an all-weather driving surface.

Fire department access roads need to be able to withstand the live loads of fire apparatus, but they are not required to be constructed of any specific material. The roadway design needs to accommodate water runoff and ice and snow accumulations in locations subject to freezing temperatures.

Special consideration should be given to the design of subsurface structures and their placement relative to the location of the fire department access road. Examples of such subsurface structures include drainage pipes and septic tanks. If improperly designed, these subsurface structures have the potential to collapse under standard fire apparatus loads or the load imposed by an aerial fire apparatus stabilizer. The proposed design should be in accordance with a local, state, or nationally recognized standard for roadway design.

The AHJ might not have sufficient expertise to review the access roadway design to determine if it is appropriately stabilized. Therefore, it is appropriate for the AHJ to request that the access roadway design be completed by a registered design professional and reviewed by individuals with expertise in the area of roadway construction.

N **A.18.2.3.5.2** It is not the intent of 18.2.3.5.2 to restrict the design of fire department access roads to traditional, non-permeable materials such as asphalt or concrete. Permeable materials, pavers, or other designs can be used if approved by the AHJ and meet the loading requirements in all weather conditions. In considering whether to approve non-traditional materials, the AHJ should consider maintenance issues due to weather and traffic.

The designer and AHJ should consider the point loads created by fire department aerial apparatus stabilizers in the design of fire department access roads. NFPA 1901 limits the pressure exerted over the ground contact under the apparatus stabilizer to 75 psi (517 kPa). The 75 psi (517 kPa) design specification, along with a safety margin, should be included in the design of fire department access roads that would be used as a base to operate fire department aerial apparatus.

18.2.3.5.3 Turning Radius.

18.2.3.5.3.1 The turning radius of a fire department access road shall be as approved by the AHJ.

Local authorities should review their current and future apparatus needs and specifications to determine the appropriate design standard for their jurisdictions. In lieu of a specific local design requirement, the dimensions in Exhibit 18.5 should be used as a turning radius guide for most fire apparatus.

Determining turning movements within a development has become much easier in recent years. Software solutions are available that allow the designer to overlay fire apparatus turning movements directly on site plans utilizing the exact specifications of the fire department's apparatus.

18.2.3.5.3.2 Turns in fire department access roads shall maintain the minimum road width.

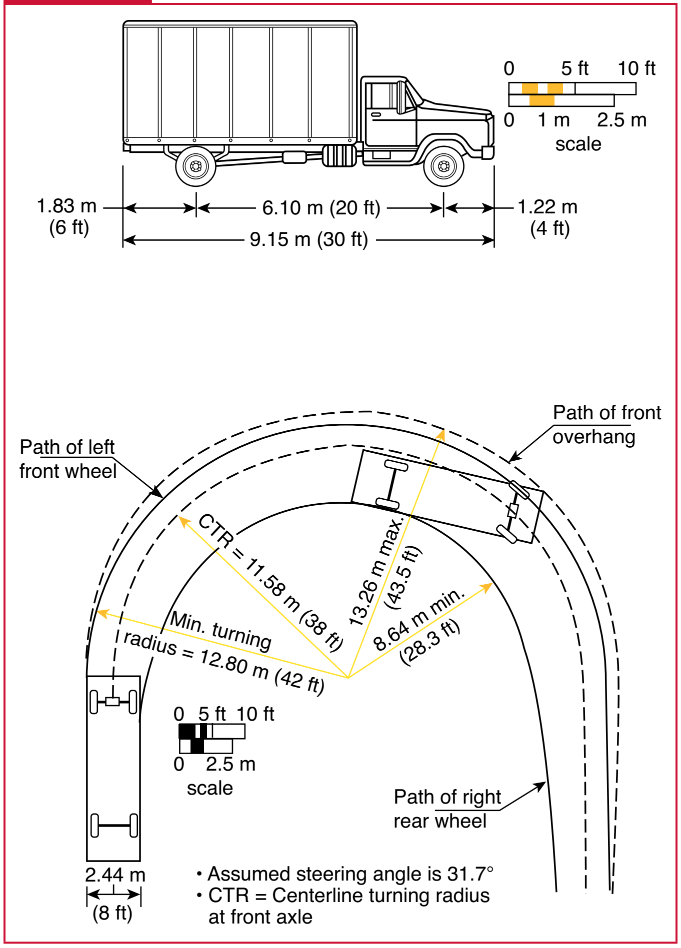
N **18.2.3.5.3.3** Fire department access roads connecting to roadways shall be provided with curb cuts extending at least 2 ft (0.61 m) beyond each edge of the fire department access road.

18.2.3.5.4 Dead Ends. Dead-end fire department access roads in excess of 150 ft (46 m) in length shall be provided with approved provisions for the fire apparatus to turn around.

Where a fire department access road exceeds 150 ft (46 m) in length and is also a dead end, an approved turnaround is required. Appropriate turning radii must be provided for the turnaround, as indicated in 18.2.3.5.3. Acceptable turnarounds can include a U-turn movement, as shown in Exhibit 18.5, or a T-turn or a Y-turn, as shown in Exhibit 18.6.

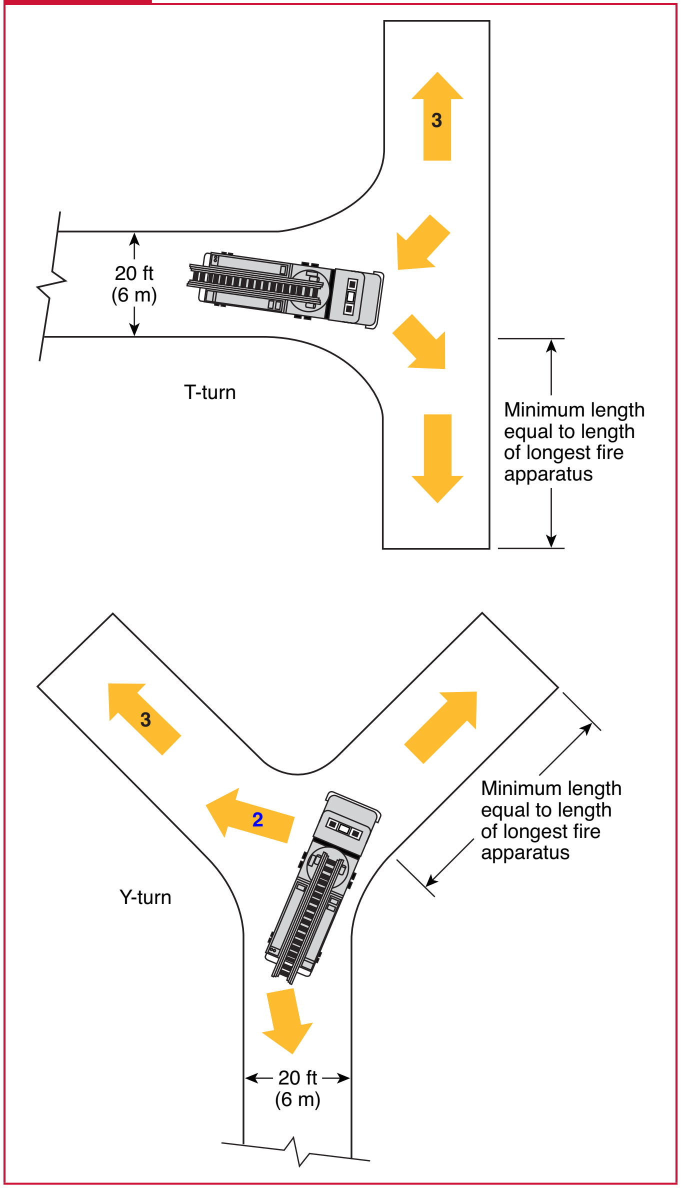
A common question is whether fire department access roads exceeding 150 ft (46 m) in length, but not required to

Exhibit 18.5



Minimum turning path for single unit truck design vehicle. (Source: A Policy on Geometric Design of Highways and Streets, 2011, by the American Association of State Highway and Transportation Officials, Washington, DC; Used by Permission.)

Exhibit 18.6



T-turn and Y-turn turnaround arrangements.

exceed 150 ft (46 m) to meet the building access requirements of 18.2.3.2, are required to be provided with approved turnarounds. The AHJ might determine no turnaround would be required if the dead-end road length were reduced to not greater than 150 ft (46 m). While such reduction of the dead-end road length would eliminate the turnaround requirement, it might be more beneficial to the fire department to provide the longer, nonrequired dead-end road with no turnaround. Such determination should be made by the AHJ on a case-by-case basis.

18.2.3.5.5 Bridges.

18.2.3.5.5.1 When a bridge is required to be used as part of a fire department access road, it shall be constructed and maintained in accordance with nationally recognized standards.

The most widely used nationally recognized standard is *Standard Specifications for Highway Bridges*, published by the American Association of State Highway and Transportation Officials (AASHTO). The AHJ should consult with a registered design profession if there is a question as to the specifications used for the design of a bridge.

18.2.3.5.5.2 The bridge shall be designed for a live load sufficient to carry the imposed loads of fire apparatus.

Bridges must be designed to support the live load of the heaviest piece of fire apparatus likely to be driven on them. All bridges should be designed for an HS-20 highway vehicle load rating in accordance with *Standard Specifications for Highway Bridges*. The AHJ should consult with a registered design professional for assistance if there is there is a question as to the structural design of a bridge.

Exhibit 18.7

Bridge load limit sign.

18.2.3.5.5.3 Vehicle load limits shall be posted at both entrances to bridges where required by the AHJ.

Signage that indicates vehicle load limits should be designed so that it is readily obvious to fire apparatus drivers approaching the bridge. See Exhibit 18.7 for an example of a bridge load limit sign.

18.2.3.5.6 Grade.

The access road gradient should allow fire apparatus use of the fire department access road during all conditions, such as snow, ice, and rain. The grade should not be too steep, which could prevent a speedy response. Fire apparatus designs vary so widely that a specific requirement could be found to be burdensome for some jurisdictions and insufficient for others. Local authorities should review their current and future apparatus needs and specifications to determine a specific design standard in their jurisdiction.

18.2.3.5.6.1 The gradient for a fire department access road shall not exceed the design limitations of the fire apparatus of the fire department and shall be subject to approval by the AHJ.

18.2.3.5.6.2* The angle of approach and departure for any means of fire department access road shall not exceed 1 ft drop in 20 ft (0.3 m drop in 6 m) or the design limitations of the fire apparatus of the fire department, and shall be subject to approval by the AHJ.

A.18.2.3.5.6.2 The design limits of fire department apparatus should take into account mutual aid companies and other response agencies that might respond to emergencies.

The 1 in 20 slope is a reasonable design standard if the AHJ has not adopted specific design limitations based on the needs of the fire department's apparatus.

18.2.3.5.7 Traffic Calming Devices. The design and use of traffic calming devices shall be approved by the AHJ.

The most common type of traffic calming device is the speed bump. Other types of traffic calming devices can include traffic circles, intentional turning movements put into the roadway, rumble strips, and speed humps. Regardless of the type of traffic calming device, the AHJ should review the placement, the size, and other factors of traffic calming devices to ensure response time is not reduced and fire apparatus can navigate the installed devices. The requirement for the AHJ to review and approve traffic calming devices applies to both private and public fire apparatus access roads.

Security devices are often placed to prevent, reduce, or make access more difficult. Security device installation can be a form of traffic calming and should be reviewed to ensure that fire apparatus can maneuver, gain access, and perform fire-fighting operations. (See Exhibit 18.8.)

Exhibit 18.8

Example of a traffic calming security device.

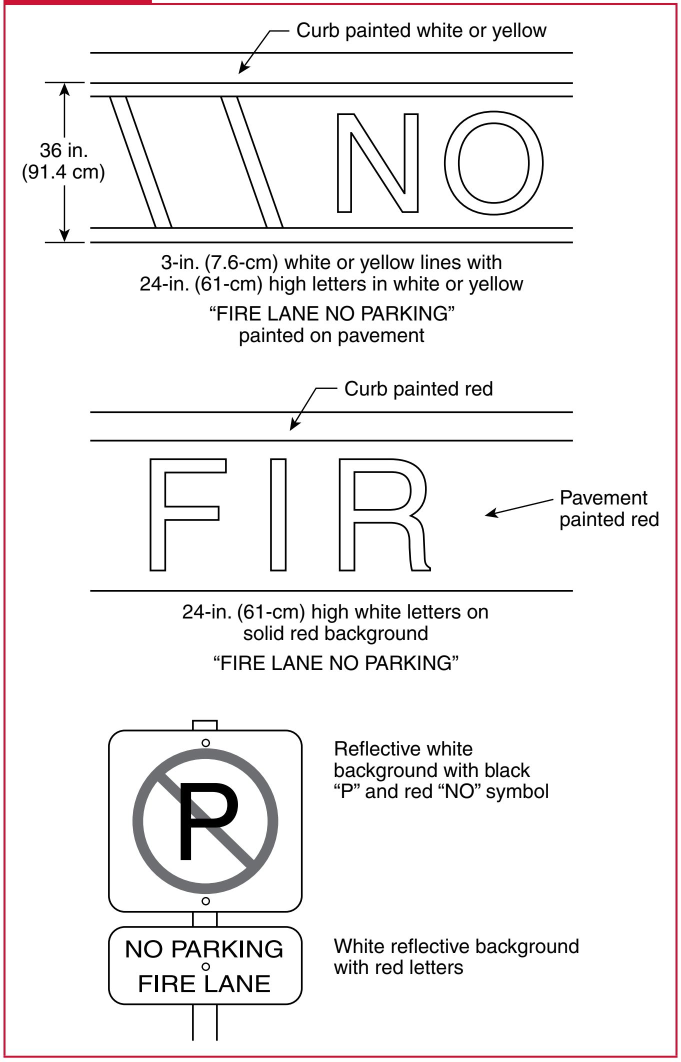
18.2.3.6 Marking of Fire Apparatus Access Road.

18.2.3.6.1 Where required by the AHJ, approved signs, approved roadway surface markings, or other approved notices shall be provided and maintained to identify fire department access roads or to prohibit the obstruction thereof or both.

The *Code* does not require that all fire apparatus roads be marked as fire lanes. Marking is required only where the AHJ determines it is necessary to prohibit obstructions of the fire apparatus access road. In addition to determining if the fire apparatus access road needs to be marked, the AHJ should determine if specific fire protection features require marking to prohibit obstructions of the features. For example, the AHJ might determine that marking is necessary around fire hydrants, fire department connections, and access gates to prevent parking or standing.

The AHJ should ensure that approved markings, signs, and notices are consistent with the requirements of local and state laws. See Exhibit 18.9 for examples of fire department access road markings.

Exhibit 18.9



Examples of fire lane markings.

18.2.3.6.2 A marked fire apparatus access road shall also be known as a fire lane.

The term *fire lane* is sometimes confused with and used interchangeably with the term *fire apparatus access road*. The terms are not the same. A fire apparatus access road can exist without being a fire lane. A fire lane exists only when a fire apparatus access road gets marked in accordance with 18.2.3.6.1 and thus becomes a fire lane. The term *fire lane* is defined in 3.3.126 and further explained in A.3.3.126.

18.2.4* Obstruction and Control of Fire Department Access Road.

A.18.2.4 Fire department access roads should be kept clear of obstructions such as parked vehicles, fences and other barriers, dumpsters, and excess vegetation. However, it should be understood that a severe snowstorm can make these roads temporarily inaccessible. In many parts of the country, the annual snowfall is of such magnitude that alternative arrangements such as temporary roads over the snow accumulation could be necessary.

An AHJ in such an area of the country should pay close attention to the placement of fire hydrants and fire department connections along fire department access roads.

18.2.4.1 General.

18.2.4.1.1 The required width of a fire department access road shall not be obstructed in any manner, including by the parking of vehicles.

18.2.4.1.2 Minimum required widths and clearances established under 18.2.3.5 shall be maintained at all times.

18.2.4.1.3* Facilities and structures shall be maintained in a manner that does not impair or impede accessibility for fire department operations.

A.18.2.4.1.3 These obstructions include those obscuring or interfering with fire department connections to sprinkler systems or standpipe systems or both.

18.2.4.1.4 Entrances to fire department access roads that have been closed with gates and barriers in accordance with 18.2.4.2.1 shall not be obstructed by parked vehicles.

Where necessary, the AHJ should consult 18.2.2 regarding the requirements for access boxes, gated subdivisions, and access maintenance.

18.2.4.2 Closure of Accessways.

18.2.4.2.1 The AHJ shall be authorized to require the installation and maintenance of gates or other approved barricades across roads, trails, or other accessways not including public streets, alleys, or highways.

18.2.4.2.2 Where required, gates and barricades shall be secured in an approved manner.

18.2.4.2.3 Roads, trails, and other accessways that have been closed and obstructed in the manner prescribed by 18.2.4.2.1 shall not be trespassed upon or used unless authorized by the owner and the AHJ.

18.2.4.2.4 Public officers acting within their scope of duty shall be permitted to access restricted property identified in 18.2.4.2.1.

Individuals accessing private property should check with local legal counsel prior to accessing property without permission of the property owner. See 1.7.7 and 1.8.

18.2.4.2.5 Locks, gates, doors, barricades, chains, enclosures, signs, tags, or seals that have been installed by the fire department or by its order or under its control shall not be removed, unlocked, destroyed, tampered with, or otherwise vandalized in any manner.

N **18.2.4.2.6** Gates shall comply with 18.2.4.2.6.1 and 18.2.4.2.6.2.

N **18.2.4.2.6.1** Electric gate operators and systems, where provided, shall be installed, maintained, listed, and labeled in accordance with UL 325, *Door, Drapery, Gate, Louver, and Window Operators and Systems*.

Section 18.2.4.6 is new to the 2018 edition of the *Code*. UL 325, *Door, Drapery, Gate, Louver, and Window Operators and Systems*, covers electric operators for doors, draperies, gates, louvers, windows, exterior awnings, and other opening and closing appliances rated 600 V or less to be employed in ordinary locations in accordance with the locally adopted electrical code. If electric gates are used to control access on fire access roads, gate operators listed to UL 325 have been evaluated to prevent entrapment, and to reliably operate.

The Consumer Product Safety Commission worked with UL to develop tougher safety standards that require automatic gates to have at least two mechanisms to prevent entrapment. These UL 325 provisions are similar to the standards in effect for automatic garage doors. The UL 325 standard, which UL adopted in March 2000, requires an internal sensing device that will reverse the gate if it encounters an obstruction when opening or closing; and a secondary external sensing mechanism, such as an electric eye or an edge sensor that will reverse the gate if an obstruction is detected.

N **18.2.4.2.6.2** Gates intended for automatic operation shall be designed, constructed, installed, and maintained to comply with ASTM F2200, *Standard Specification for Automated Vehicular Gate Construction*.

ASTM F2200, *Standard Specification for Automated Vehicular Gate Construction*, establishes the performance-based and prescriptive-based methods of evaluating various classes of automated gate constructions that are used for vehicular traffic. The gate types addressed in ASTM F2200 include horizontal slide gates, horizontal swing gates, vertical lift gates, vertical pivot gates, and overhead pivot gates.

18.2.4.2.7 When authorized by the AHJ, public officers acting within their scope of duty shall be permitted to obtain access through secured means identified in 18.2.4.2.1.

18.3 Water Supplies

18.3.1* An approved water supply capable of supplying the required fire flow for fire protection shall be provided to all premises upon which facilities, buildings, or portions of buildings are hereafter constructed or moved into the jurisdiction. The approved water supply shall be in accordance with Section 18.4.

A.18.3.1 See Section 18.4 for determining required fire flow.

An approved water supply capable of supplying the needed fire flow must be provided for all new buildings and all buildings moved into the jurisdiction. Section 18.4 specifies the method for determining the required fire flow. The *Code* also provides broad discretion to the AHJ in approving how the water supply can be provided. While fire flow water supply typically is provided via fire hydrants, in rural or suburban locations, the AHJ may approve alternative methods to provide the required fire flow water supply. Such alternative methods could include dry hydrants, drafting locations, ground storage tanks, wells, tanker shuttle operations, longer-than-normal hose lays from remote water supplies, or some combination of these water supply delivery methods. The AHJ has the final authority to determine if the proposed water supply delivery method(s) are appropriate and can be approved.

AWWA M31, *Distribution System Requirements for Fire Protection;* NFPA 1142, *Standard on Water Supplies for Suburban and Rural Fire Fighting;* and the *NFPA Fire Protection Handbook* provide additional guidance on water distribution system designs for fire protection.

18.3.1.1* Where no adequate or reliable water distribution system exists, approved reservoirs, pressure tanks, elevated tanks, fire department tanker shuttles, or other approved systems capable of providing the required fire flow shall be permitted.

A.18.3.1.1 NFPA 1141 and NFPA 1142 can serve as references for additional water supply and fire flow information.

Paragraph 18.3.1.1 gives the AHJ the authority to approve alternative fire flow water supply sources where no adequate or reliable water distribution system exists. See NFPA 1142 for additional guidance on water supplies for suburban and rural fire fighting.

18.4 Fire Flow Requirements for Buildings

Section 18.4 is performance based, which means it does not specify the type of system to be used to provide the required fire flow. Methods of delivering the required fire flow include, but are not limited to, the methods listed in 18.3.1.1. The AHJ has the final authority to determine if the proposed water supply delivery method(s) are appropriate and can be approved.

18.4.1* Scope.

A.18.4.1 Section 18.4 and the associated tables are only applicable for determining minimum water supplies for manual fire suppression efforts. Water supplies for fire protection systems are not addressed by this section. It is not the intent to add the minimum fire protection water supplies, such as for a fire sprinkler system, to the minimum fire flow for manual fire suppression purposes required by this section.

The explanatory material in A.18.4.1 clarifies that the intent of the *Code* is not to add the fire flow calculated in accordance with Section 18.4 to an automatic sprinkler system demand. For sprinklered buildings, the required water supply is the greater of either the fire flow specified by Section 18.4 or the demand for the automatic sprinkler system. Section 18.4 is used to calculate the required fire flow for manual fire-fighting purposes and does not take into account fire suppression systems or hose stream requirements required by other codes and standards, such as NFPA 13, *Standard for the Installation of Sprinkler Systems*. Water supply requirements for fire protection system designs, such as NFPA 13, are not permitted to take advantage of the reduction in fire flow in 18.4.5.

18.4.1.1* The procedure determining fire flow requirements for buildings hereafter constructed or moved into the jurisdiction shall be in accordance with Section 18.4.

A.18.4.1.1 For the purpose of this section, a building subdivided by fire walls constructed in accordance with the building code is considered to be a separate building.

Fire flow area should be determined based on the area within the surrounding exterior walls and fire separation walls used to create separate buildings as modified by 18.4.4. Areas of the building without surrounding exterior walls should be included in the fire area, if such areas are within the horizontal projection of the roof or the floor above. In most cases, what constitutes a “fire wall” is defined by NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*, and the building code. Typically, fire walls are fire-resistance rated walls with a 2-hour, 3-hour, or 4-hour rating (depending on the hazards the wall is protecting) and are continuous from foundation to or through the roof with structural stability to allow collapse on either side of the wall while maintaining the integrity of the wall. Fire walls are different from fire barrier walls. Fire barrier walls alone would not create sufficient subdivision of the building spaces under a building code or Section 18.4 of this *Code* to be considered separate buildings.

18.4.1.2 Section 18.4 shall not apply to structures other than buildings.

18.4.2 Definitions. See definitions 3.3.14.4, Fire Flow Area, and 3.3.120, Fire Flow.

18.4.3 Modifications.

18.4.3.1 Decreases in Fire Flow Requirements.

The AHJ is permitted to use discretion in reducing the required fire flow in rural areas with isolated buildings where providing the required fire flow would be impractical and the risk can be reasonably managed. It is important to note that reducing the fire flow is at the sole discretion of the AHJ. Before reducing the fire flow, the AHJ should determine if the site conditions warrant a reduction and whether additional protection methods, such as automatic sprinkler protection, limiting the type of building construction, or mandatory setbacks created with easements to prohibit the construction of future exposure hazards, are necessary to justify a reduction while maintaining a reasonable level of property protection and life safety (see 18.4.3.1.1).

18.4.3.1.1* Fire flow requirements shall be permitted to be decreased by the AHJ for isolated buildings or a group of buildings in rural areas or suburban areas where the development of full fire flow requirements is impractical as determined by the AHJ.

A.18.4.3.1.1 The intent of 18.4.3.1.1 is to provide some limited flexibility in those circumstances where there is no water supply available and the fire department’s capabilities to deliver water via a tanker shuttle or drafting operation are also limited. The AHJ should consider establishing additional conditions, such as those contained in 18.4.3.1.2, prior to permitting decreased fire flow capability.

18.4.3.1.2 The AHJ shall be authorized to establish conditions on fire flow reductions approved in accordance with 18.4.3.1.1 including, but not limited to, fire sprinkler protection, type of construction of the building, occupancy, development density, building size, and setbacks.

When establishing conditions to allow for a reduction in the required fire flow, the AHJ should ensure that such conditions are legally attached to the site. Methods to attach those conditions to the site could be via site plan permit approval, building permit approval, or the certificate of occupancy and recorded as part of the public record. It is important to ensure that future owners and tenants are made aware of the conditions that are tied to the property as part of the fire flow reduction.

18.4.3.2 Increases in Fire Flow Requirements. The minimum required fire flow shall be permitted to be increased by the AHJ where conditions indicate an unusual susceptibility to group fires or conflagrations. An upward modification shall not be more than twice that required for the building under consideration.

One condition under which the AHJ might consider increasing the minimum required fire flow is where existing buildings on adjacent sites create significant fire exposures. For example, an existing adjacent building may be of combustible construction, located close to the property line, and constructed with exterior walls not having a fire resistance rating. Those types of existing conditions may not be consistent with the current construction practices mandated in the building code. Therefore, the AHJ might determine that an increase in the required fire flow is necessary to provide for exposure protection fire streams.

18.4.4 Fire Flow Area.

18.4.4.1 General. The fire flow area shall be the total floor area of all floor levels of a building except as modified in 18.4.4.2.

The fire flow area should be determined based on the area within the surrounding exterior walls and fire separation walls used to create *separate* buildings. The type of walls necessary to create separate buildings is typically determined by the applicable building code. Typically, fire walls are fire-resistance rated walls with a 2-hour, 3-hour, or 4-hour rating (depending on the hazards the wall is protecting) and are continuous from foundation to or through the roof with structural stability to allow collapse on either side of the wall while maintaining the integrity of the wall. Fire walls are different from fire barrier walls. Fire barrier walls would not create sufficient subdivision of the building spaces under a building code or Section 18.4 of this *Code* to be considered separate buildings and separate fire flow areas.

Areas of the building without surrounding exterior walls should be included in the fire area, if such areas are within the horizontal projection of the roof or the floor above. The fire area includes the total of all floor areas within the building, except as specified in 18.4.4.2.

18.4.4.2 Type I (443), Type I (332), and Type II (222) Construction. The fire flow area of a building constructed of Type I (443), Type I (332), and Type II (222) construction shall be the area of the three largest successive floors.

Due to their inherent fire resistance, the fire flow areas of buildings of Type I (443), Type I (332), and Type II (222) construction are limited to the three largest successive floors. See NFPA 220, *Standard on Types of Building Construction,* and *NFPA 5000®, Building Construction and Safety Code®*, for more information on building construction types. See A.12.2 and Table A.12.2 for a cross-reference of building construction types used by the various model building codes throughout the United States.

18.4.5 Fire Flow Requirements for Buildings.

18.4.5.1 One- and Two-Family Dwellings Not Exceeding 5000 ft² (464.5 m²).

18.4.5.1.1 The minimum fire flow and flow duration requirements for one- and two-family dwellings having a fire flow area that does not exceed 5000 ft² (464.5 m²) shall be 1000 gpm (3785 L/min) for 1 hour.

For one- and two-family dwellings that do not exceed 5000 ft² (464.5 m²), a standard minimum fire flow of 1000 gpm (378 L/min) is established. Most new homes will not exceed this square footage. Therefore, the 1000 gpm (378 L/min) standardized minimum fire flow avoids forcing the AHJ to calculate separate fire flows demands for each one- or two-family dwelling that is less than 5000 ft² (464.5 m²).

The scope of one- and two-family dwellings is not intended to include townhomes, apartments, or condominiums. Fire flow requirements for those types of dwellings should be calculated under 18.4.5.3.

18.4.5.1.2* A reduction in required fire flow of 75 percent shall be permitted where the one- and two-family dwelling is provided with an approved automatic sprinkler system.

The significant property preservation benefits of automatic sprinkler system protection in one- and two-family dwellings are recognized by permitting a 75 percent reduction in the required fire flow where automatic sprinkler systems are provided. A one- or two-family dwelling that is less than 5000 ft² (464.5 m²) in area and protected by an automatic sprinkler system would have a required fire flow of 250 gpm (946 L/min) with the 75 percent reduction applied under 18.4.5.1.2, rather than the 1000 gpm (3785 L/min) that is required for a nonsprinklered dwelling of the same size. However, 18.4.5.1.5 states that the required fire flow shall not be reduced below 500 gpm (1893 L/min). Therefore, 500 gpm (1893 L/min) would be the minimum required fire flow for a one- and two-family dwelling that is fire sprinkler protected and does not exceed 5000 ft² (464.5 m²).

Δ **A.18.4.5.1.2** Approved automatic sprinkler systems for one- and two-family dwellings include those meeting the requirements of NFPA 13, NFPA 13D, and NFPA 13R.

18.4.5.1.3* Where one- and two-family dwellings are proposed to be constructed in areas where water distribution systems providing fire flow were designed and installed prior to the effective date of this *Code*, the AHJ shall be authorized to accept the previously designed system fire flow where the one- and two-family dwellings are provided with approved automatic sprinkler systems.

The provision of 18.4.5.1.3 recognizes the installation of public water supplies that were approved prior to the adoption of the fire flow provisions of this *Code*. The intent of the *Code* is to not prohibit the construction of new one- and two-family dwellings where such previously approved water supply conditions exist. Because residential sprinkler systems, installed in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, are intended to provide for life safety only and do not necessarily provide complete coverage, building separation distances should be evaluated to reduce the probability of fire spread from one building to another where such diminished water supplies exist. Most building codes also require the rating of exterior walls of one- and two-family dwellings where minimum setbacks are not achieved to the property line or to adjacent buildings.

Δ **A.18.4.5.1.3** Approved automatic sprinkler systems for one- and two-family dwellings include those meeting the requirements of NFPA 13, NFPA 13D, and NFPA 13R.

18.4.5.1.4 A reduction in fire flow shall be permitted for building separation distance in accordance with 18.4.5.1.4 and Table 18.4.5.1.4.

18.4.5.1.4.1 Where multiple buildings are located on a single lot, the building separation distance shall be the distance between the buildings.

***TABLE 18.4.5.1.4** Permitted Fire Flow Reduction for Building Separation*

Separation Distance Between Buildings on a Single Lot		Separation Distance to Lot Line or Easement[a]		Permitted Fire Flow Reduction
ft	M	Ft	M	
>30 and ≤50	>9.1 and ≤15.2	>15 and ≤25	>4.6 and ≤7.6	25%
>50	>15.2	>25	>7.6	40%

[a]See 18.4.5.1.4.3.

18.4.5.1.4.2 Where a building abuts a lot line, the building separation distance shall be the distance between the building and the lot line.

18.4.5.1.4.3 Where a building is contiguous to a public right of way or no-build easement, the separation distance shall be the distance between the building to the opposite side of the right of way or no-build easement.

18.4.5.1.4.4 Where multiple buildings are located on a single lot and abut a lot line, the building separation distance for determining fire flow reduction shall be the smallest of the two distances.

Where one- and two-family dwellings are separated from other buildings by a minimum of 30 ft (9.1 m), exposure fire risk is significantly reduced. Therefore, the 1000 gpm (3785 L/min) fire flow specified by 18.4.5.1.1 is permitted to be reduced by 25 percent, or 250 gpm (946 L/min), in accordance with Table 18.4.5.1.4. A nonsprinklered one- or two-family dwelling, separated from other buildings by at least 30 ft (9.1 m), would have a required fire flow of 750 gpm (2839 L/min). Table 18.4.5.1.4 permits an increased fire flow reduction of 40 percent where the building separation distance exceeds 50 ft (15.2 m). A nonsprinklered one- or two-family dwelling, separated from other buildings by more than 50 ft (15.2 m), would have a required fire flow of 600 gpm (2270 L/min). Equivalent separation distance criteria are provided in Table 18.4.5.1.4 for lot lines and no-build easements. When an AHJ approves a fire flow reduction under the provisions of section 18.4.5.1.4, the AHJ should ensure that a method is utilized to memorialize the conditions of the fire flow reduction so that future owners are legally restricted from new construction that would violate the setback limits of Table 18.4.5.1.4.

18.4.5.1.5* The reductions in 18.4.5.1.2, 18.4.5.1.3, and 18.4.5.1.4 shall not reduce the required fire flow to less than 500 gpm (1900 L/min).

A.18.4.5.1.5 The fire flow reductions specified in 18.4.5.1.2, 18.4.5.1.3, and 18.4.5.1.4 are permitted to be combined. However, where the reductions are combined, the resulting required fire flow is not permitted to be reduced to less than 500 gpm (1900 L/min) for 1 hour.

A minimum fire flow of 500 gpm (1893 L/min) is required for one- and two-family dwellings regardless of the reductions that may be allowed under 18.4.5.1.2, 18.4.5.1.3, and 18.4.5.1.4. If fire flow were permitted to be reduced below 500 gpm (1893 L/min), there is a significant potential to reduce the pressure in a water distribution system below 20 psi (139.9 kPa) residual if a fire hydrant were to be opened. This would have the potential to create contamination of the potable drinking water system. In addition, insurance companies may not recognize fire flows that are provided from fire hydrants that flow less than 500 pm (1893 L/min.)

18.4.5.2 One- and Two-Family Dwellings Exceeding 5000 ft² (464.5 m²).

18.4.5.2.1 Fire flow and flow duration for dwellings having a fire flow area in excess of 5000 ft² (464.5 m²) shall not be less than that specified in Table 18.4.5.2.1.

Where a one- or two-family dwelling exceeds 5000 ft² (464.5 m²), the dwelling's required fire flow needs to be individually calculated under the provisions of Table 18.4.5.2.1 as opposed to utilizing the standard fire flow of 1000 gpm (3785 L/min) under 18.4.5.1.1 for one- and two-family dwellings that are 5000 ft² (464.5 m²) or less.

The fire flow requirements in Table 18.4.5.2.1 are based on buildings without automatic sprinkler system protection. Buildings with sprinkler protection in accordance with NFPA 13, NFPA 13D, or NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies,* as applicable, are permitted a reduction in the fire flow required by Table 18.4.5.2.1. See 18.4.5.2.2, 18.4.5.2.3, 18.4.5.2.4, 18.4.5.3.2, 18.4.5.3.3, 18.4.5.3.4, and 18.4.5.3.5 for the permitted fire flow reductions based on specific conditions or the presence of automatic sprinkler systems.

The building construction types specified by Table 18.4.5.2.1 are defined in NFPA 220 and *NFPA 5000*. See A.12.2 and Table A.12.2 for a cross-reference of building construction types used by the various model building codes throughout the United States.

18.4.5.2.2 Required fire flow shall be reduced by 75 percent and the duration reduced to 1 hour where the one- and two-family dwelling is provided with an approved automatic sprinkler system.

The significant property preservation benefits of automatic sprinkler system protection in one- and two-family dwellings are recognized by permitting a 75 percent reduction in the required fire flow where automatic sprinkler systems are provided.

18.4.5.2.3 A reduction in the required fire flow shall be permitted where a one- and two-family dwelling is separated from all lot lines in accordance with Table 18.4.5.1.4.

The fire flow reduction percentages specified in Table 18.4.5.1.4 also apply to one- and two-family dwellings that exceed 5000 ft² (464.5 m²).

18.4.5.2.4 Required fire flow for one- and two-family dwellings protected by an approved automatic sprinkler system shall not exceed 2000 gpm (7571 L/min) for 1 hour.

The *Code* establishes a maximum cap for required fire flow of 2000 gpm (7571 L/min) where one- and two-family dwellings are protected by an approved automatic sprinkler system. If the dwelling is not provided with an approved automatic sprinkler system, there is no maximum fire flow cap established under the *Code.*

18.4.5.2.5* The reductions in 18.4.5.2.2, and 18.4.5.2.3 shall not reduce the required fire flow to less than 500 gpm (1900 L/min) for 1 hour.

A.18.4.5.2.5 The fire flow reductions specified in 18.4.5.2.2 and 18.4.5.2.3 are permitted to be combined. However, where the reductions are combined, the resulting required fire flow is not permitted to be reduced to less than 500 gpm (1900 L/min) for 1 hour.

Δ ***TABLE 18.4.5.2.1*** *Minimum Required Fire Flow and Flow Duration for Buildings*

Fire Flow Area ft² (× 0.0929 for m²)					Fire Flow gpm† (× 3.785 for L/min)	Flow Duration (hours)

		179,401–191,400	129,601–138,300	79,801–85,100	7750	
		Greater than 191,400	Greater than 138,300	Greater than 85,100	8000	

*Types of construction are based on NFPA 220.

†Measured at 20 psi (139.9 kPa).

A minimum fire flow of 500 gpm (1893 L/min) is required for one- and two-family dwellings regardless of the reductions that may be allowed under 18.4.5.2.2, and 18.4.5.2.3. If fire flow were permitted to be reduced below 500 gpm (1893 L/min), there is a significant potential to reduce the pressure in a water distribution system below 20 psi (139.9 kPa) residual if a fire hydrant were to be opened. This would have the potential to create contamination of the potable drinking water system. In addition, insurance companies may not recognize fire flows that are provided from fire hydrants that flow less than 500 gpm (1893 L/min).

18.4.5.3 Buildings Other Than One- and Two-Family Dwellings.

18.4.5.3.1 The minimum fire flow and flow duration for buildings other than one- and two-family dwellings shall be as specified in Table 18.4.5.2.1.

18.4.5.3.2 Required fire flow shall be reduced by 75 percent when the building is protected throughout by an approved automatic sprinkler system. The resulting fire flow shall not be less than 1000 gpm (3785 L/min).

Recognizing the significant benefits of automatic sprinkler system protection in extinguishing or controlling fires, the *Code* provides for a 75 percent reduction in required fire flow for sprinklered buildings. However, a minimum fire flow of not less than 1000 gpm (3785 L/min) must be provided unless the conditions of 18.4.5.3.3, which specifies the use of quick response sprinklers, are met. The example that follows illustrates the reduction in fire flow for a sprinklered building.

Example

Determine the required fire flow for a building of Type II (000) construction with a fire flow area of 26,000 ft^2 (2415 m^2) that is sprinklered with standard response sprinklers in accordance with NFPA 13.

Solution:

From Table 18.4.5.2.1, the minimum required fire flow for a building of the specified area and construction type is 3500 gpm (13,250 L/min) for not less than 3 hours. Because the building is sprinklered in accordance with NFPA 13, a 75 percent reduction is permitted by 18.4.5.3.2, as follows:

$$\frac{3500 \text{ gpm}}{(13{,}250 \text{ L/min})} \times 75 \text{ percent} = \frac{2625 \text{ gpm}}{(9937 \text{ L/min})} \left(\begin{array}{c}\text{fire flow}\\ \text{credit}\end{array}\right)$$

$$\frac{3500 \text{ gpm}}{(13{,}250 \text{ L/min})} - \frac{2625 \text{ gpm}}{(9937 \text{ L/min})} \left(\begin{array}{c}\text{fire flow}\\ \text{credit}\end{array}\right) = \frac{875 \text{ gpm}}{(3312 \text{ L/min})}$$

The calculated fire flow of 875 gpm (3312 L/min) is less than 1000 gpm (3785 L/min), the minimum permitted by 18.4.5.3.2. In this case, a minimum of 1000 gpm (3875 L/min) must be provided for a duration of not less than 2 hours. The 2-hour maximum duration for sprinklered buildings is specified by 18.4.5.3.4. Note that, if the building is provided with quick response sprinklers throughout, the minimum fire flow is permitted to be reduced to not less than 600 gpm (2270 L/min) in accordance with 18.4.5.3.3.

In most circumstances, the minimum fire flow required by Section 18.4 will be greater than the automatic sprinkler system demand. However, in a small number of circumstances, the fire flow required by Section 18.4 might be less than the demand required by NFPA 13 for the automatic sprinkler system. In those cases, the minimum water supply required by NFPA 13 must be provided. However, as stated in 18.4.5.4, it is not the intent to require the minimum fire flow required by this *Code* to be added to the water supply required by an automatic sprinkler system.

18.4.5.3.3 Required fire flow shall be reduced by 75 percent when the building is protected throughout by an approved automatic sprinkler system, which utilizes quick response sprinklers throughout. The resulting fire flow shall not be less than 600 gpm (2270 L/min).

18.4.5.3.4* Required fire flow for buildings protected by an approved automatic sprinkler system shall not exceed 2000 gpm (7571 L/min) for 2 hours.

Δ **A.18.4.5.3.4** The provision of 18.4.5.3.4 is intended to limit the required fire flow duration to not more than 2 hours where the building is sprinklered. The 2000 gpm (7571 L/min) limit is based on a 75% reduction of 8000 gpm (30,283 L/min), which is the maximum fire flow required by Table 18.4.5.2.1. The required 2-hour duration is consistent with the maximum hose stream duration requirements of NFPA 13.

18.4.5.3.5 Required fire flow for open parking structures that are not protected throughout by an approved automatic sprinkler system shall be reduced by 75 percent where all of the following conditions are met:

(1) The structure complies with the building code.
(2) The structure is of Type I or Type II construction.
(3) The structure is provided with a Class I standpipe system in accordance with NFPA 14. Class I standpipe systems of the manual dry type shall be permitted.
(4) The resulting fire flow is not less than 1000 gpm (3785 L/min).

The provisions of 18.4.5.3.5 recognize that the risk of significant fire spread in a fire fully involving an open, noncombustible parking structure is minimal, even where not protected by automatic sprinklers. The term *open parking structure* is defined in 3.3.192.26.3 as a parking structure that meets the requirements of Section 5.5 of NFPA 88A, *Standard for Parking Structures*. Section 5.5 of NFPA 88A specifies the exterior wall opening requirements for open parking structures as follows:

> **5.5 Opening Requirements for Open Parking Structures.**
>
> **5.5.1** Each parking level shall have wall openings open to the atmosphere, for an area of not less than 0.4 m^2 for each linear meter (1.4 ft^2 for each linear foot) of its exterior perimeter.
>
> **5.5.2** Such openings shall be distributed over 40 percent of the building perimeter or uniformly over two opposing sides.
>
> **5.5.3** Interior wall lines and column lines shall be at least 20 percent open, with openings distributed to provide ventilation.

18.4.5.4* Required Fire Flow and Automatic Sprinkler System Demand. For a building with an approved fire sprinkler system, the fire flow demand and the fire sprinkler system demand shall not be required to be added together. The water supply shall be capable of delivering the larger of the individual demands.

A.18.4.5.4 The fire sprinkler system demand is generally significantly less than the demands in Table 18.4.5.2.1, even after hose stream demands are applied. The sprinkler system demand can be a part of the overall flow available to a building site. There is no need to add these flow demands together, which would penalize the building owner that has decided to put fire sprinkler systems in place.

18.5 Fire Hydrants

18.5.1 Fire Hydrant Locations and Distribution. Fire hydrants shall be provided in accordance with Section 18.5 for all new buildings, or buildings relocated into the jurisdiction unless otherwise permitted by 18.5.1.1 or 18.5.1.2.

18.5.1.1 Fire hydrants shall not be required where the water distribution system is not capable of providing a fire flow of greater than 500 gpm (1893 L/min) at a residual pressure of 20 psi (139.9 kPa).

Where a water main system is incapable of supplying a theoretical flow of at least 500 gpm (1893 L/min) at a residual pressure of 20 psi (139.9 kPa), there is a risk of fire apparatus drawing a vacuum on the system, potentially resulting in damage to the underground piping and to the fire apparatus pump. Such a condition also has the potential of contaminating the public water supply.

18.5.1.2* Fire hydrants shall not be required where modification or extension of the water distribution system is deemed to be impractical by the AHJ.

A.18.5.1.2 The conditions where a local jurisdiction might determine that a modification or extension of the water distribution system is deemed to be impractical are varied and should be evaluated on a case-by-case basis. Conditions that should be considered in determining if an extension is impractical should include, but not be limited to, the following:

(1) Distance required to extend the water distribution system
(2) Capability of the existing water distribution system to meet the fire flow demand
(3) Density and occupancy of the proposed development
(4) Potential additional future development in the area of the extension
(5) Other codes and standards, which might warrant extension of the water distribution system
(6) Future anticipated improvements to the water distribution system
(7) Buildings within a previously approved development

If the AHJ determines that the current conditions to modify or extend the water distribution system might be impractical, the AHJ should consider requiring a developer to provide escrow funds that will facilitate the system modification or extension when it does become practical to provide the fire hydrants. In lieu of providing funding by the developer up front, AHJ should consider having the developer execute legal agreements to ensure that the fire hydrants and water are provided, at the developer's/owner's cost, when certain conditions are satisfied making the modification or extension of the water distribution system practical at a future date.

18.5.1.3 The provisions of 18.5.1.1 and 18.5.1.2 shall not eliminate the fire flow requirements of Section 18.4.

The developer is required to provide the needed fire flow under Section 18.4 even if it is impractical to extend or modify the water distribution system to provide fire hydrants. The AHJ maintains the authority to approve the methods that the developer is proposing in lieu of providing the required fire flow via fire hydrants. See Section 18.3.

18.5.1.4* The distances specified in Section 18.5 shall be measured along fire department access roads in accordance with 18.2.3.

A.18.5.1.4 Fire department access roads are intended to include public streets provided they meet the requirements of 18.2.3.

18.5.1.5 Where fire department access roads are provided with median dividers incapable of being crossed by fire apparatus, or where fire department access roads have traffic counts of more than 30,000 vehicles per day, hydrants shall be placed on both sides of the fire department access road on an alternating basis, and the distances specified by Section 18.5 shall be measured independently of the hydrants on the opposite side of the fire department access road.

18.5.1.6 Fire hydrants shall be located not more than 12 ft (3.7 m) from the fire department access road.

Fire hydrants that are set back too far from the fire department access road are difficult to access because hose must be manually dragged from the fire apparatus to the fire hydrant. In addition, fire hydrants that are set back far from the fire department access road can be difficult to locate.

18.5.2 Detached One- and Two-Family Dwellings. Fire hydrants shall be provided for detached one- and two-family dwellings in accordance with both of the following:

(1) The maximum distance to a fire hydrant from the closest point on the building shall not exceed 600 ft (183 m).
(2) The maximum distance between fire hydrants shall not exceed 800 ft (244 m).

Fire hydrants serving one- and two-family dwellings must be arranged so that the distance between each building and the nearest hydrant does not exceed 600 ft (183 m). Additional hydrants might be required to limit the distance between hydrants to not more than 800 ft (244 m) along the fire department access road as stated in 18.5.1.4. Only those hydrants within 1000 ft (305 m) of a building are permitted to be given credit for supplying the building's required fire flow in accordance with 18.5.4.2. This criterion combined with the 600 ft (183 m) maximum building distance criterion might result in hydrants spaced less than 800 ft (244 m) apart.

The distance should be measured as the fire apparatus would lay hose out down the fire department access road to the subject building. The distance should not be measured across adjacent lots, through fences, gates or other obstructions that would prevent the normal movement of a fire apparatus performing a hose lay to a fire hydrant.

18.5.3 Buildings Other than Detached One- and Two-Family Dwellings. Fire hydrants shall be provided for buildings other than detached one- and two-family dwellings in accordance with both of the following:

(1) The maximum distance to a fire hydrant from the closest point on the building shall not exceed 400 ft (122 m).
(2) The maximum distance between fire hydrants shall not exceed 500 ft (152 m).

Fire hydrants serving buildings other than one- and two-family dwellings must be arranged so that the distance between each building and the nearest hydrant does not exceed 400 ft (122 m). Additional hydrants might be required to limit the distance between hydrants to not more than 500 ft (152 m) along the fire department access road as stated in 18.5.1.4. Only those hydrants within 1000 ft (305 m) of a building are permitted to be given credit for supplying the building's required fire flow in accordance with 18.5.4.2. This criterion combined with the 400 ft (122 m) maximum building distance criterion might result in hydrants spaced less than 500 ft (152 m) apart.

The distance should be measured as the fire apparatus would lay hose out down the fire department access road to the subject building. The distance should not be measured across adjacent lots, through fences, gates, or other obstructions that would prevent the normal movement of a fire apparatus performing a hose lay to a fire hydrant.

18.5.4 Minimum Number of Fire Hydrants for Fire Flow.

18.5.4.1 The minimum number of fire hydrants needed to deliver the required fire flow for new buildings in accordance with Section 18.4 shall be determined in accordance with Section 18.5.4.

In some cases, the fire flow required under Section 18.4 and 18.5.4 may result in additional hydrants or closer spaced hydrants than required by the spacing criteria of 18.5.2 or 18.5.3. In other cases, the spacing criteria of 18.5.2 or 18.5.3 may require additional hydrants than is necessary to provide the minimum required fire flow under Section 18.4 and 18.5.4. The minimum number of hydrants required for the fire flow contained in Section 18.4 and 18.5.4 and minimum spacing for fire hydrants under 18.5.2 and 18.5.3 both need to be complied with separately.

18.5.4.2 The aggregate fire flow capacity of all fire hydrants within 1000 ft (305 m) of the building, measured in accordance with 18.5.1.4 and 18.5.1.5, shall be not less than the required fire flow determined in accordance with Section 18.4.

The distance should be measured as the fire apparatus would lay hose out down the fire department access road to the subject building. The distance should not be measured across adjacent lots, through fences, gates, or other obstructions that would prevent the normal movement of a fire apparatus performing a hose lay to a fire hydrant.

Δ **18.5.4.3*** The maximum fire flow capacity for which a fire hydrant shall be credited shall be as specified by Table 18.5.4.3. Capacities exceeding the values specified in Table 18.5.4.3 shall be permitted when local fire department operations have the ability to accommodate such values as determined by the fire department.

TABLE 18.5.4.3 *Maximum Fire Hydrant Fire Flow Capacity*

Distance to Building[a]		Maximum Capacity[b]	
(ft)	(m)	(gpm)	(L/min)
≤250	≤76	1500	5678
>250 and ≤500	>76 and ≤152	1000	3785
>500 and ≤1000	>152 and ≤305	750	2839

[a]Measured in accordance with 18.5.1.4 and 18.5.1.5.
[b]Minimum 20 psi (139.9 kPa) residual pressure.

A.18.5.4.3 It is not the intent of Table 18.5.4.3 to limit the actual fire flow capacity of a fire hydrant, only the fire flow capacity for which a fire hydrant is credited based on its distance from the building.

See the commentary for 18.5.4.1.

18.5.4.4 Fire hydrants required by 18.5.2 and 18.5.3 shall be included in the minimum number of fire hydrants for fire flow required by 18.5.4.

The provisions of 18.5.4 ensure a sufficient number of fire hydrants are available within reasonable proximity to the building in question to deliver the building's required fire flow in accordance with Section 18.4. For example, a building might have a required fire flow of 4000 gpm (15,142 L/min) based on its size and type of construction in accordance with Table 18.4.5.2.1. The water distribution system in the vicinity of the building might be fully capable of delivering a theoretical fire flow of at least 4000 gpm (15,142 L/min) at 20 psi (139.9 kPa); however, if only one fire hydrant is located near the building, it likely will not be possible for one fire department pumper to extract 4000 gpm (15,142 L/min) from the water distribution system due to the physical constraints of the hydrant outlets and pump capacity — typical fire department pumpers are rated between 750 gpm (2840 L/min) to 1500 gpm (5680 L/min). The following example illustrates the application of 18.5.4.

Example

Determine the number of required fire hydrants for a proposed new manufacturing building with a fire area of 50,000 ft^2 (4645 m^2) and a construction classification of Type II (000) (noncombustible and unprotected). The building will be protected throughout by an approved automatic sprinkler system with standard response sprinklers.

Solution:

A flow test is conducted on the water distribution system serving the site using the guidance contained in NFPA 291, *Recommended Practice for Fire Flow Testing and Marking of Hydrants*; the test results indicate the theoretical available fire flow is 3500 gpm (13,200 L/min) at a residual pressure of 20 psi (139.9 kPa).

Using Table 18.4.5.2.1, the designer determines the building's required fire flow is 4750 gpm (18,000 L/min). However, because the building will be protected by an automatic sprinkler system with standard response sprinklers, a 75 percent reduction is permitted in accordance with 18.4.5.3.2. The adjusted required fire flow is calculated as follows:

4750 gpm − [0.75 (4750 gpm)] = 1187.5 gpm, which is rounded to approximately 1200 gpm

18,000 L/min − [0.75 (18,000 L/min)] = 4500 L/min

The water distribution system is capable of delivering the required fire flow (RFF) based on the available fire flow (AFF):

AFF: 3500 gpm (13,200 L/min) ≥ RFF: 1200 gpm (4500 L/min)

To minimize cost, the designer chooses to locate one fire hydrant on the existing public water mains at a distance of 350 ft (107 m) from the building, which meets the maximum 400 ft (122 m) distance criterion of 18.5.3(1), rather than extend a private fire service main onto the building's property. Using Table 18.5.4.3, it is determined that a hydrant located 400 ft (122 m) from the building can be credited with not more than 1000 gpm (3785 L/min). Because this is less than the required fire flow of 1200 gpm (4500 L/min), one additional hydrant is required within 1000 ft (305 m) of the building, or the designer could choose to extend a private fire service main onto the property and locate a hydrant at a distance of not more than 250 ft (76 m) from the building. In accordance with Table 18.5.4.3, such a hydrant would be permitted to be credited with up to 1500 gpm (5678 L/min), which exceeds the required fire flow of 1200 gpm (4500 L/min). If the designer chooses to add a second hydrant on the public main, they should be spaced so the distance between them does not exceed 500 ft (152 m) in accordance with 18.5.3.

The AHJ should require an additional flow test following the installation of the new hydrant or hydrants to verify that they are capable of delivering the required fire flow.

18.5.5 Testing and Maintenance.

Δ **18.5.5.1** Private water supply systems shall be tested and maintained in accordance with NFPA 25.

18.5.5.2 Public water supply systems providing fire flow shall be tested and maintained in accordance with ANSI/AWWA G200, *Standard for Distribution Systems Operation and Management*.

18.5.6 Accessibility. Fire hydrants and connections to other approved water supplies shall be accessible to the fire department.

Fire hydrants and connections to approved water supplies must be installed and maintained in a manner that allows the fire department to access the water supply point without being delayed by fences, landscaping, signs, utility poles, utility boxes, or other obstructions.

18.5.7 Clear Space Around Hydrants.

18.5.7.1 A 36 in. (914 mm) clear space shall be maintained around the circumference of fire hydrants except as otherwise required or approved.

Fire hydrants are subject to a number of types of obstructions that can impede the ability of the fire department to access and utilize a fire hydrant. A typical location for a fire hydrant is in a landscape island in a parking lot. This type of placement has the potential to create obstructions due to parking and landscaping conflicts. If parking is provided next to the landscape island, the parking needs to be placed at least 36 in. (914 mm) away from the fire hydrant. In addition, no landscaping should be provided within 36 in. (914 mm) of the fire hydrant. In addition to landscaping and parking, fences, signs, utility poles, and other similar types of obstructions should not be allowed in the 36 in. (914 mm) clear space surrounding the fire hydrant.

The provision of 18.5.7.1 should be used in conjunction with 18.5.7.2 and 18.5.6. Fire hydrant placement should comply with all three of those requirements to ensure that the fire hydrant is visible, accessible, and usable by the fire department. Exhibit 18.10 shows a fire hydrant that does not maintain a 36 in. clearance around the entire circumference of the hydrant.

18.5.7.2 A clear space of not less than 60 in. (1524 mm) shall be provided in front of each hydrant connection having a diameter greater than 2½ in. (64 mm).

This paragraph is intended to ensure that fire department pumper apparatus have the ability to park adjacent to a fire hydrant and have adequate room to connect a large-diameter hose from the hydrant's steamer outlet to the pump inlet. Parked vehicles and

Exhibit 18.10

Fire hydrant without proper clearance maintained.

other obstructions within 60 in. (1524 mm) of the front of the hydrant pose an undue hindrance to fire suppression operations.

The provisions of 18.5.7.2 should be used in conjunction with 18.5.7.1 and 18.5.6. For example, 18.5.7.2 requires a 60 in. (1524 mm) clearance in front of the fire hydrant steamer port. This does not mean that a landscaping hedge row can be placed at 65 in. in front of the steamer port. The placement of this type of obstruction would violate 18.5.6.

18.5.8 Protection. Where required by the AHJ, fire hydrants subject to vehicular damage shall be protected unless located within a public right of way.

Protection of fire hydrants with bollards or curbs are a couple of methods to assist in preventing vehicular damage. If bollards are utilized, they should be placed in locations that do not obstruct access or use of the fire hydrant. These methods are more effective in the low-speed environments of parking lots.

18.5.9 Hydrants Out of Service. Where water supplies or fire hydrants are out of service for maintenance or repairs, a visible indicator acceptable to the AHJ shall be used to indicate that the hydrant is out of service.

Where fire hydrants or other water supplies are found to be out of service, it is important that the fire hydrant or water supply is immediately marked with an indicator so responding fire department units will quickly observe the out-of-service condition prior to attempting to utilize the fire hydrant or water supply. One of the easiest methods to mark a fire hydrant as being out of service is with an out-of-service plastic ring inserted between the hydrant steamer cap and the threads. See NFPA 291. Exhibit 18.11 shows a fire hydrant with an 'out of service ring' indicating that the hydrant is out of service and not available for use.

18.5.10 Marking of Hydrants.

18.5.10.1 Fire hydrants shall be marked with an approved reflector affixed to the roadway surface where required by the AHJ.

If fire hydrants are difficult to locate due to topography, landscaping, or other visual obstructions, the AHJ has the authority to require that the hydrant location be identified with a marker affixed to the roadway surface. Typically, this is a blue reflector placed in the center of the travel lane closest to the fire hydrant.

18.5.10.2 Fire hydrants shall be marked with an approved flag or other device affixed to or proximate to the fire hydrant where required by the AHJ.

In areas where significant snowfall is common or if a fire hydrant is placed at a much lower elevation than the fire department access roadway, the use of an elevated flag or other device attached to the fire hydrant can be required by the AHJ to improve the ability of the fire department to local the fire hydrant.

18.5.10.3* Where required by the AHJ, fire hydrants shall be color coded or otherwise marked with an approved system indicating the available flow capacity.

Exhibit 18.11

Fire hydrant with out of service indicator.

Δ **A.18.5.10.3** Color coding or stenciling a fire hydrant with the actual flow capacity are two methods to accomplish the capacity marking of fire hydrants when it is required by the AHJ. NFPA 291, Recommended Practice for Fire Flow Testing and Marking of Hydrants, specifies the following approach to hydrant marking for flow indication:

Classification of Hydrants. Hydrants should be classified in accordance with their rated capacities [at 20 psi (1.4 bar) residual pressure or other designated value] as follows:

(1) Class AA — Rated capacity of 1500 gpm (5680 L/min) or greater
(2) Class A — Rated capacity of 1000–1499 gpm (3785–5675 L/min
(3) Class B — Rated capacity of 500–999 gpm (1900–3780 L/min)
(4) Class C — Rated capacity of less than 500 gpm (1900 L/min)

The tops and nozzle caps should be painted with the following capacity-indicating color scheme:

(1) Class AA — Light blue
(2) Class A — Green
(3) Class B — Orange
(4) Class C — Red paint

The capacity colors should be of a reflective-type paint.

19 Combustible Waste and Refuse

Chapter 19 addresses combustible waste and refuse and includes sections on rubbish containers, dumpsters, and commercial rubbish-handling operations.

19.1 General

19.1.1 Permits. Permits, where required, shall comply with Section 1.12.

19.1.2 Persons owning or having control of any property shall not allow any combustible waste material to accumulate in any area or in any manner that creates a fire hazard to life or property.

The problem of accumulating combustible waste has increased with the advent of recycling efforts. Many building owners supply small personal recycling containers at each worker's desk (see Exhibit 19.1) and larger storage containers, or bins, to collect the recyclable material from the individual containers (see Exhibit 19.2). The bins are then emptied at a larger collection point. The collection and storage of recycling material has resulted in delayed removal of many types of combustible waste from a building or property. Recognition of this situation is important. The attempt to control the location and amount of recyclable material in buildings, as well as the ignition sources in the vicinity of its storage, especially in work areas such as desks, is critical. Proper storage prevents the spread of fire from or to these areas.

Exhibit 19.1

Typical personal recycling container.

Exhibit 19.2

Storage bin for recyclables.

19.1.3 Combustible waste or refuse shall be properly stored or disposed of to prevent unsafe conditions.

19.1.4 Fire extinguishing capabilities approved by the AHJ including, but not limited to, fire extinguishers, water supply and hose, and earth-moving equipment shall be provided at waste disposal sites.

Waste disposal sites should be equipped with the means to extinguish or control the spread of fire in the disposal area until the arrival of the fire department. The fire department should evaluate the fire potential and work with the property owner to ensure adequate water supplies for fire department use in case of fire. Ensuring adequate water supplies might require extending water mains with additional hydrants or, if the site is remote from a municipal water system, the provision of on-site water storage.

19.1.5 Burning debris shall not be dumped at a waste disposal site except at a remote location on the site where fire extinguishment can be accomplished before compacting, covering, or other disposal activity is carried out. *(See Section 10.10 for additional guidance.)*

Burning or smoldering debris should be dumped at a specific site used exclusively for hot debris. The debris should be monitored, wet down if necessary, and, when cold, placed with normal waste.

19.1.6 Electrical Wiring.

Δ **19.1.6.1** Electrical wiring and equipment in any combustible fiber storage room or building shall be installed in accordance with the requirements of Section 11.1 and NFPA 70 for Class III hazardous locations.

19.1.6.2 The AHJ shall be responsible for designating the areas that require hazardous location electrical classifications and shall classify the areas in accordance with the classification system set forth in NFPA 70.

19.1.7 No Smoking.

See Section 10.9 for additional restrictions on smoking.

19.1.7.1 No smoking or open flame shall be permitted in any area where combustible fibers are handled or stored or within 50 ft (15 m) of any uncovered pile of such fibers.

19.1.7.2 "No Smoking" signs shall be posted.

19.1.8 Vehicles or Conveyances Used to Transport Combustible Waste or Refuse.

19.1.8.1 Vehicles or conveyances used to transport combustible waste or refuse over public thoroughfares shall have all cargo space covered and maintained tight enough to ensure against ignition from external fire sources and the scattering of burning and combustible debris that can come in contact with ignition sources.

19.1.8.2 Transporting burning waste or refuse shall be prohibited.

Δ **19.1.8.3** Trucks or automobiles, other than mechanical handling equipment and approved industrial trucks as listed in NFPA 505 shall not enter any fiber storage room or building but shall be permitted to be used at loading platforms.

19.2 Combustible Waste and Refuse

19.2.1 Rubbish Containers.

19.2.1.1 General. Rubbish containers kept outside of rooms or vaults shall not exceed 40.5 ft³ (1.15 m³) capacity.

Exhibit 19.3

Large rubbish container in a protected room.

The capacity of a container that holds 40.5 ft³ (1.15 m³) converts to 303 gal (1150 L). These larger rubbish containers need to be placed in properly protected rooms. See NFPA *101*®, *Life Safety Code*®, for additional requirements on hazardous area protection. See Exhibit 19.3 for an example of a large rubbish container that is located in a protected room.

19.2.1.1.1 Containers exceeding a capacity of 5⅓ ft³ [40 gal (0.15 m³)] shall be provided with lids.

Containers of 40 gal (0.15 m³) capacity are used as receptacles into which employees can empty smaller containers during normal working hours. They are usually found at strategically located sites that are easily accessible throughout the occupancy. Such containers are also used in many occupancies as collection points for occupants or residents to discard trash. They are typically located in common areas accessible to all occupants. See Exhibit 19.2 for an example of a 40 gal (0.15 m³) container.

19.2.1.1.2 Such containers and lids as described in 19.2.1.1.1 shall be constructed of noncombustible materials or nonmetallic materials complying with 19.2.1.2.

19.2.1.2 Nonmetallic Containers.

19.2.1.2.1* Nonmetallic rubbish containers exceeding a capacity of 5⅓ ft³ [40 gal (0.15 m³)] shall be manufactured of materials having a peak rate of heat release not exceeding 300 kW/m² at a flux of 50 kW/m² when tested in the horizontal orientation, at a thickness as used in the container but not less than of 0.25 in. (6 mm), in accordance with ASTM E1354, *Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*.

A.19.2.1.2.1 Nonmetallic or plastic rubbish containers should be limited in their combustibility and should be tested for heat release with the cone calorimeter, to the recognized standard of ASTM E1354 referred to as the cone or oxygen consumption calorimeter. The cone calorimeter test standard does not indicate the exact conditions (heat flux and orientation) needed for testing. This test is intended to give detailed information as to how the fire performance of materials perform under actual fire conditions. The value of 300 kW/m^2 for peak rate of heat release of the rubbish container material corresponds to the value that Douglas fir wood emits under the same conditions. Rubbish containers are often manufactured of polyethylene [effective heat of combustion ca. 19,000 Btu/lb (45 MJ/kg)], which releases much more heat in a fire than the typical contents of the container, much of which is paper (effective heat of combustion ca. 6400 Btu/lb (15 MJ/kg]). For comparison purposes, Table A.19.2.1.2.1 shows peak heat release rates of a series of materials (34 plastics and Douglas fir wood) at an incident heat flux of 40 kW/m^2, in the horizontal orientation and at a thickness of 0.25 in. (6 mm) [Hirschler 1992]. For further comparison, a fire test conducted with a small ignition source on a 22.4 lb polyethylene rubbish container resulted in the release of 1.34 MW within 13.35 minutes of ignition (before it had to be manually extinguished) and caused flashover in the test room. The maximum a container can release is 300 kW/m^2 or maximum heat release rate. Douglas fir has a constant of 300 kW/m^2 where polyethylene has a peak heat release rate of 1268 kW/m^2. Nonmetallic containers such as polyethylene can represent more fuel than their contents (high density polyethylene 19,994 Btu/lb versus newsprint at 8000). A detailed review of listings or approvals is advised prior to acceptance.

TABLE A.19.2.1.2.1 *Peak Rate of Heat Release of Materials in the Cone Calorimeter at an Incident Heat Flux of 40 kW/m^2, in the Horizontal Orientation, at a Thickness of 6 mm*

	Material Description	Abbreviation	Peak Rate of Heat Release (kW/m^2)
1	Polytetrafluorethylene	PTFE	14
2	Poly(vinyl chloride) flexible 1	PVC Plenum 1	43
3	Poly(vinyl chloride) flexible 2	PVC Plenum 2	64
4	Poly(vinyl chloride) flexible 3	PVC Plenum 3	87
5	Polycarbonate 1	PolyCarb 1	429
6	Poly(vinyl chloride) flexible 4	PVC Plenum 4	77
7	Chlorinated PVC	CPVC	84
8	Poly(vinyl chloride) rigid computer housing	PVC computer	175
9	Poly(vinyl chloride) flexible wire FR	PVC flex FR	92
10	Poly(vinyl chloride) rigid low smoke	PVC low smoke	111
11	Cross linked polyethylene FR	XLPE FR	192
12	Poly(vinyl chloride) flexible wire semi FR	PVC Flex semi FR	142
13	Poly(vinyl chloride) rigid window	PVC window	183
14	Poly(vinyl chloride) flexible wire non FR	PVC Flex non FR	167
15	Poly(methyl methacrylate) FR Blend	PMMA FR	176
16	Polycarbonate 2	Polycarb 2	420
17	Polyphenylene Oxide FR Blend 1	PPO/PS 1	276
18	Polyphenylene Oxide FR Blend 2	PPO/PS 2	265
19	Acrylonitrile butadiene styrene FR 1	ABS FR 1	291
20	Acrylonitrile butadiene styrene FR 2	ABS FR 2	402
21	Poly(vinyl chloride) flexible bath curtain	PVC Flex Poor	237
22	Douglas fir	D Fir	221
23	Polystyrene FR	PS FR	334
24	Polyacetal	P Acetal	360
25	Polyurethane Flexible Foam non FR	PU	710
26	Poly(methyl methacrylate)	PMMA	665
27	Polyurethane Thermoplastic	TPU	221
28	Nylon	Nylon	1313
29	Acrylonitrile butadiene styrene	ABS	944
30	Polystyrene	PS	1101
31	Styrene acrylonitrile EPDM blend	EPDM SAN	956
32	Poly(butylene terephthalate)	PBT	1314
33	Poly(ethylene terephthalate)	PET	534
34	Polyethylene	PE	1408
35	Polypropylene	PP	1509

Source: Hirschler 1992. "Heat release from plastic materials", M.M. Hirschler, Chapter 12 a, in "Heat Release in Fire," Elsevier, London, UK, Eds. V. Babrauskas and S.J. Grayson, 1992. pp. 375–422.

19.2.1.2.2 Such containers shall be permanently labeled indicating capacity and peak rate of heat release.

19.2.1.3 Removal. Combustible rubbish stored in containers outside of noncombustible vaults or rooms shall be removed from buildings at least once each working day.

19.2.1.4 Rubbish Within Dumpsters. Dumpsters and combustible waste containers with an individual capacity of 1.5 yd^3 [40.5 ft^3 (1.15 m^3)] or more shall not be stored in buildings or placed within 10 ft (3050 mm) of combustible walls, openings, or combustible roof eave lines unless otherwise permitted by 19.2.1.4.1 or 19.2.1.4.2.

19.2.1.4.1 The requirement of 19.2.1.4 shall not apply to building areas protected by an approved automatic sprinkler system and enclosed by fire barriers having a fire resistance rating not less than of 1 hour.

19.2.1.4.2 The requirement of 19.2.1.4 shall not apply to structures meeting all of the following requirements:

(1) Structures shall be Type I or Type II construction.
(2) Structures shall be located not less than 10 ft (3050 mm) from other structures.
(3) Structures shall be used only for storage of dumpsters and combustible waste containers.

Many dumpster fires have extended into adjacent buildings because the dumpster was located too close to the adjacent building. See Exhibit 19.4, which depicts a dumpster located directly against the building's exterior wall. A fire in such a dumpster can quickly spread to the building's combustible walls.

Dumpsters should be placed a minimum of 10 ft (3 m) from combustible walls, openings, combustible roof eaves, or any other area that might pose a fire risk. The 10 ft (3 m) distance is measured perpendicularly from the farmost projection. Permanent barriers should be installed to ensure that dumpsters are not inadvertently placed within 10 ft (3 m) of the hazard area.

Exhibit 19.4

Dumpster against building exterior. (Thinkstock)

19.2.1.5 Commercial Rubbish-Handling Operations. Occupancies exclusively performing commercial rubbish handling or recycling shall maintain rubbish or product to be processed or recycled in one of the following ways:

(1) In approved vaults
(2) In covered metal or metal-lined receptacles or bins
(3) Completely baled and stacked in an orderly manner in an approved location

19.2.1.6 Approved metal receptacles with self-closing covers shall be provided for the storage or disposal of oil-soaked waste or cloths.

NFPA *101*®, *Life Safety Code*®, 2018 edition.

20

Occupancy Fire Safety

Chapter 20 extracts occupancy-based requirements from NFPA *101*®, *Life Safety Code*®. Each occupancy section contains requirements for interior finish, operating features (such as inspections, furnishings, and decorations), drills, emergency plans, smoking, heating equipment, and other provisions specific to the occupancy. The format of Chapter 20 is as follows:

20.1 Assembly Occupancies

The requirements for assembly occupancies are based on protecting concentrations of occupants in a building or area. The occupant load factors for assembly uses (see Table 14.8.1.2) accurately reflect the large numbers of occupants in a given area that are characteristic of such use. Large numbers of occupants present unique challenges, such as arranging and designing the egress facilities to move the occupants efficiently and quickly. In addition, there are issues that must be balanced, such as sloping the floor to achieve line of sight for audience spectators (e.g., during theater performances, sporting events, or concerts) without creating stepped aisles that are too steep to use effectively.

Assembly occupancies include, but are not limited to, buildings or portions of buildings used for gatherings of 50 or more people for such purposes as deliberation, worship, entertainment, eating, drinking, amusement, or awaiting transportation. Assembly occupancies also include special amusement buildings (such as a fun house attraction at an amusement park or a multilevel play structure in a fast-food restaurant), regardless of occupant load (see item 2 of 6.1.2.1 and 20.1.4).

For other than special amusement buildings, the criteria for assembly occupancy classification include the 50-person threshold addressed in the preceding paragraph and consideration of the activities in which those persons are involved. The activities that lead to the classification of an occupancy as an assembly occupancy include those detailed in item 1 of 6.1.2.1 — deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses. For example, working at a desk in a large open plan office area is not an assembly use, so the presence of 50 or more persons in the office space constitutes a business occupancy, not an assembly occupancy. Examples of assembly occupancies can be found in A.6.1.2.1, if they have an occupant load of at least 50 persons.

Passenger stations and terminals of air, surface, underground, and marine public transportation facilities are also considered assembly occupancies. If the jurisdiction enforcing the *Code* has adopted NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems*, requirements for transit stations might fall under NFPA 130 rather than this *Code*. See NFPA 130 for additional details.

Assembly occupancies with an occupant load of fewer than 50 persons (except for special amusement buildings) are considered incidental to the predominant occupancy in which they are located. For example, a conference room with an occupant load of fewer than 50 persons (see 14.8.1.2) that is located in an office area is considered part of the overall business occupancy. A freestanding diner with an occupant load of fewer than 50 persons is normally assigned a mercantile occupancy classification. Regardless of occupancy classification, the occupant load for areas of assembly use needs to be calculated based on the use of the space, not the occupancy classification, using the occupant load factors of Table 14.8.1.2 for assembly uses.

20.1.1 Application. New and existing assembly occupancies shall comply with Section 20.1 and NFPA *101*.

20.1.1.1 Permits. Permits, where required, shall comply with Section 1.12.

20.1.1.2 Indoor children's playground structures shall also comply with Section 10.19.

20.1.2 Flame-Retardant Requirements.

Δ **20.1.2.1** Combustible scenery of cloth, film, vegetation (dry), and similar materials shall comply with one of the following:

(1) They shall meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701.
(2) They shall exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source.

[***101:***12.4.6.11.1; ***101:***13.4.6.11.1]

Δ **20.1.2.2** Foamed plastics *(see definition of cellular or foamed plastic in 3.3.41 of* NFPA *101)* shall be permitted to be used if they exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source or by specific approval of the AHJ. [***101:***12.4.6.11.2; ***101:***13.4.6.11.2]

20.1.2.3 Scenery and stage properties not separated from the audience by proscenium opening protection shall be of noncombustible materials, limited-combustible materials, or fire-retardant-treated wood. [***101:***13.4.6.11.3]

Δ **20.1.2.4** In theaters, motion picture theaters, and television stage settings, with or without horizontal projections, and in simulated caves and caverns of foamed plastic, any single fuel package shall have a heat release rate not to exceed 100 kW where tested in accordance with one of the following:

(1) ANSI/UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*
(2) NFPA 289 using the 20 kW ignition source

[***101:***12.4.6.11.4; ***101:***13.4.6.11.4]

20.1.3 Interior Finish.

20.1.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***12.3.3.1]

20.1.3.2 Corridors, Lobbies, and Enclosed Stairways. New and existing interior wall and ceiling finish materials complying with Section 12.5 shall be Class A or Class B in all corridors and lobbies and shall be Class A in enclosed stairways. [***101:***12.3.3.2; ***101:***13.3.3.2]

20.1.3.3 Assembly Areas. New and existing interior wall and ceiling finish materials complying with Section 12.5 shall be Class A or Class B in general assembly areas having occupant loads of more than 300 and shall be Class A, Class B, or Class C in assembly areas having occupant loads of 300 or fewer. [***101:***12.3.3.3; ***101:***13.3.3.3]

20.1.3.4 Screens. New and existing screens on which pictures are projected shall comply with requirements of Class A or Class B interior finish in accordance with Section 12.5. [***101:***12.3.3.4; ***101:***13.3.3.4]

Evaluation of existing interior finish is sometimes difficult. Where flame spread characteristics cannot be readily determined, the questionable material should be removed or treated with approved flame retardants. Where treatment cannot reduce flame spread to the required limits, automatic sprinklers might be provided to help compensate for the deficiency.

20.1.3.5 Interior Floor Finish.

20.1.3.5.1 New interior floor finish shall comply with Section 12.5. [***101:***12.3.3.5.1]

20.1.3.5.2 New interior floor finish in exit enclosures and exit access corridors and in spaces not separated from them by walls complying with 12.3.6 of NFPA *101* shall be not less than Class II. [***101:***12.3.3.5.2]

20.1.3.5.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***12.3.3.5.3]

20.1.3.5.4 Existing Interior Floor Finish. (Reserved) [***101:***13.3.3.5]

20.1.4* Special Amusement Buildings.

A.20.1.4 Where a special amusement building is installed inside another building, such as within an exhibit hall, the special amusement building requirements apply only to the special amusement building. For example, the smoke detectors required by 20.1.4.4 are not required to be connected to the building's system. Where installed in an exhibit hall, such smoke detectors are also required to comply with the provisions applicable to an exhibit. [***101:***A.12.4.8; ***101:***A.13.4.8]

20.1.4.1* General. Special amusement buildings, regardless of occupant load, shall meet the requirements for assembly occupancies in addition to the requirements of 20.1.4, unless the special amusement building is a multilevel play structure that is not more than 10 ft (3050 mm) in height and has aggregate horizontal projections not exceeding 160 ft^2 (15 m^2). [***101:***12.4.8.1; ***101:***13.4.8.1]

A.20.1.4.1 The aggregate horizontal projections of a multilevel play structure are indicative of the number of children who might be within the structure and at risk from a fire or similar emergency. The word "aggregate" is used in recognition of the fact that the platforms and tubes that make up the multilevel play structure run above each other at various levels. In calculating the area of the projections, it is important to account for all areas that might be expected to be occupied within, on top of, or beneath the components of the structure when the structure is used for its intended function. [***101:***A.12.4.8.1; ***101:***A.13.4.8.1]

20.1.4.2* Automatic Sprinklers. Every special amusement building, other than buildings or structures not exceeding 10 ft (3050 mm) in height and not exceeding 160 ft^2 (15 m^2) in aggregate horizontal projection, shall be protected throughout by an approved, supervised automatic sprinkler system installed and maintained in accordance with Section 13.3. [***101:***12.4.8.2; ***101:***13.4.8.2]

A.20.1.4.2 See A.20.1.4.1. [***101:***A.12.4.8.2; ***101:***A.13.4.8.2]

20.1.4.3 Temporary Water Supply. Where the special amusement building required to be sprinklered by 20.1.4.2 is movable or portable, the sprinkler water supply shall be permitted to be provided by an approved temporary means. [***101:***12.4.8.3; ***101:***13.4.8.3]

20.1.4.4 Smoke Detection. Where the nature of the special amusement building is such that it operates in reduced lighting levels, the building shall be protected throughout by an approved automatic smoke detection system in accordance with Section 13.7. [***101:***12.4.8.4; ***101:***13.4.8.4]

20.1.4.5 Alarm Initiation. Actuation of any smoke detection system device shall sound an alarm at a constantly attended location on the premises. [***101:***12.4.8.5, ***101:***13.4.8.5]

Δ **20.1.4.6 Illumination.** Actuation of the automatic sprinkler system, or any other suppression system, or actuation of a smoke detection system having an approved verification or cross-zoning operation capability shall provide for the following:

(1) Increase in illumination in the means of egress to that required by Section 14.12
(2) Termination of any conflicting or confusing sounds and visuals

[***101:***12.4.8.6; ***101:***13.4.8.6]

20.1.4.7 Exit Marking.

20.1.4.7.1 Exit marking shall be in accordance with Section 14.14. [***101:***12.4.8.7.1; ***101:***13.4.8.7.1]

20.1.4.7.2 Floor proximity exit signs shall be provided in accordance with 14.14.1.6. [***101:***12.4.8.7.2; ***101:***13.4.8.7.2]

20.1.4.7.3* In special amusement buildings where mazes, mirrors, or other designs are used to confound the egress path, approved directional exit marking that becomes apparent in an emergency shall be provided. [***101:***12.4.8.7.3; ***101:***13.4.8.7.3]

A.20.1.4.7.3 Consideration should be given to the provision of directional exit marking on or adjacent to the floor. [***101:***A.12.4.8.7.3; ***101:***A.13.4.8.7.3]

20.1.4.8 Interior Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be Class A throughout. [***101:***12.4.8.8; ***101:***13.4.8.8]

Any special amusement building is considered an assembly occupancy, even if the occupant load is not 50 or more persons. However, special amusement buildings do not include theaters, movie houses, and other similar types of assembly occupancies. An example of a special amusement building that typically has an occupant load of not more than 49 persons is a children's play structure, complete with chutes, slides, and ladders, installed as an attraction at a fast-food restaurant.

Paragraph 20.1.4.6 addresses the importance of the exits and means of egress being well lighted upon the activation of a smoke detection or fire suppression system. It is also important that any conflicting or confusing sounds or visuals be stopped and that, where a person's relative position to an exit is changed, additional exit signs be provided.

In special amusement buildings, the provision of directions to an exit is particularly important. Floor proximity exit signs, as required by 20.1.4.7.2, should provide patrons an additional tool to assist them in finding their way out under emergency conditions. Exhibit 20.1 shows a floor proximity exit sign as well as exit signs mounted above the door opening height in a large special amusement attraction in a Florida amusement park.

20.1.5 Operating Features.

20.1.5.1 Means of Egress Inspection.

20.1.5.1.1 The building owner or agent shall inspect the means of egress to ensure it is maintained free of obstructions, and correct

Exhibit 20.1

Floor proximity exit sign in special amusement building.

any deficiencies found, prior to each opening of the building to the public. [***101:***12.7.1.1; ***101:***13.7.1.1]

20.1.5.1.2 The building owner or agent shall prepare and maintain records of the date and time of each inspection on approved forms, listing any deficiencies found and actions taken to correct them. [***101:***12.7.1.2; ***101:***13.7.1.2]

20.1.5.1.3 Inspection of Door Openings. Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***12.7.1.3]

The means of egress features for assembly occupancies cannot be ensured to be effective unless maintained. The requirement for inspection and correction of the deficiencies found helps to keep the means of egress features usable. The required record keeping serves as an enforcement tool for the authority having jurisdiction (AHJ) to help ensure that such inspection is conducted as specified.

20.1.5.2 Special Provisions for Food Service Operations.

20.1.5.2.1 All devices in connection with the preparation of food shall be installed and operated to avoid hazard to the safety of occupants. [***101:***12.7.2.1; ***101:***13.7.2.1]

20.1.5.2.2 All devices in connection with the preparation of food shall be of an approved type and shall be installed in an approved manner. [***101:***12.7.2.2; ***101:***13.7.2.2]

20.1.5.2.3 Food preparation facilities shall be protected in accordance with Chapter 50 (NFPA 96) and shall not be required to have openings protected between food preparation areas and dining areas. [***101:***12.7.2.3; ***101:***13.7.2.3]

Δ **20.1.5.2.4** Portable cooking equipment that is not flue-connected shall be permitted only as follows:

(1) Equipment fueled by small heat sources that can be readily extinguished by water, such as candles or alcohol-burning equipment, including solid alcohol, shall be permitted to be used, provided that precautions satisfactory to the AHJ are taken to prevent ignition of any combustible materials.
(2) Candles shall be permitted to be used on tables used for food service where securely supported on substantial noncombustible bases located to avoid danger of ignition of combustible materials and only where approved by the AHJ.
(3) Candle flames shall be protected.
(4) "Flaming sword" or other equipment involving open flames and flamed dishes, such as cherries jubilee or crêpes suzette, shall be permitted to be used, provided that precautions subject to the approval of the AHJ are taken.
(5) Listed and approved LP-Gas commercial food service appliances shall be permitted to be used where in accordance with Chapter 69.

[***101:***12.7.2.4; ***101:***13.7.2.4]

An approved type of device, as required by 20.1.5.2.2, is one that, with regard to potential fire hazards, is acceptable to the AHJ. An "approved manner" of installation means installation acceptable to the AHJ. See definition of *approved* in 3.2.1.

The *Code* depends on the automatic extinguishing system mandated by Chapter 50 to control any fire on the cooking surfaces; thus, 20.1.5.2.3 does not require enclosure by rated construction.

The list of tragic fires in assembly occupancies caused by "friendly" fires (e.g., alcohol or solid alcohol fires in restaurants, flames used for dramatic effects in theaters) is well documented. The requirements of 20.1.5.2.4 and 20.1.5.3 attempt to prevent fires by strictly controlling the use of open flame devices.

20.1.5.2.4.1 Permits. Permits, where required, shall comply with Section 1.12.

Δ **20.1.5.3 Open Flame Devices and Pyrotechnics.** No open flame devices or pyrotechnic devices shall be used in any assembly occupancy, unless otherwise permitted by one of the following:

(1) Pyrotechnic special effect devices shall be permitted to be used on stages before proximate audiences for ceremonial or religious purposes, as part of a demonstration in exhibits, or as part of a performance, provided that both of the following criteria are met:
    (a) Precautions satisfactory to the AHJ are taken to prevent ignition of any combustible material.
    (b) Use of the pyrotechnic device complies with Section 65.3.
(2) Flame effects before an audience shall be permitted in accordance with Section 65.4.
(3) Open flame devices shall be permitted to be used in the following situations, provided that precautions satisfactory to the AHJ are taken to prevent ignition of any combustible material or injury to occupants:
    (a)* For ceremonial or religious purposes
    (b) On stages and platforms where part of a performance
    (c) Where candles on tables are securely supported on substantial noncombustible bases and candle flame is protected
(4) The requirement of 20.1.5.3 shall not apply to heat-producing equipment complying with 11.2.2.
(5) The requirement of 20.1.5.3 shall not apply to food service operations in accordance with 20.1.5.2.
(6) Gas lights shall be permitted to be used, provided that precautions are taken, subject to the approval of the AHJ, to prevent ignition of any combustible materials.

[***101:***12.7.3; ***101:***13.7.3]

A.20.1.5.3(3)(a) Securely supported altar candles in churches that are well separated from any combustible material are permitted. On the other hand, lighted candles carried by children wearing cotton robes present a hazard too great to be permitted. There are many other situations of intermediate hazard where the AHJ will have to exercise judgment. [***101:***A.12.7.3(3)(a); ***101:***A.13.7.3(3)(a)]

20.1.5.3.1 Permits. Permits, where required, shall comply with Section 1.12.

20.1.5.4 Furnishings, Decorations, and Scenery.

20.1.5.4.1* Fabrics and films used for decorative purposes, all draperies and curtains, and similar furnishings shall be in accordance with the provisions of 12.6.2. [***101:***12.7.4.1; ***101:***13.7.4.1]

A.20.1.5.4.1 Fabric applied over unused seating sections should meet the requirements of 20.1.5.4. [***101:***A.12.7.4.1; ***101:***A.13.7.4.1]

20.1.5.4.2 The AHJ shall impose controls on the quantity and arrangement of combustible contents in assembly occupancies to provide an adequate level of safety to life from fire. [***101:***12.7.4.2; ***101:***13.7.4.2]

Δ **20.1.5.4.3*** Exposed foamed plastic materials and unprotected materials containing foamed plastic used for decorative purposes or stage scenery shall have a heat release rate not exceeding 100 kW where tested in accordance with one of the following:

(1) UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*
(2) NFPA 289 using the 20 kW ignition source

[***101:***12.7.4.3; ***101:***13.7.4.3]

A.20.1.5.4.3 The phrase "unprotected materials containing foamed plastic" is meant to include foamed plastic items covered by "thermally thin" combustible fabrics or paint. *(See A.12.5.4.4.)* [***101:***A.12.7.4.3; ***101:***A.13.7.4.3]

20.1.5.4.4 The requirement of 20.1.5.4.3 shall not apply to individual foamed plastic items and items containing foamed plastic where the foamed plastic does not exceed 1 lb (0.45 kg) in weight. [***101:***12.7.4.4; ***101:***13.7.4.4]

20.1.5.5 Special Provisions for Exposition Facilities.

20.1.5.5.1 Permits. Permits, where required, shall comply with Section 1.12.

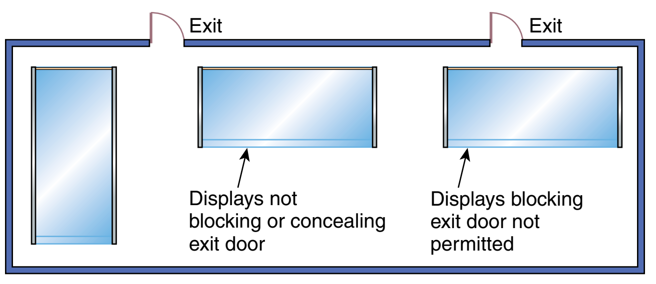
20.1.5.5.2 General. No display or exhibit shall be installed or operated to interfere in any way with access to any required exit or with the visibility of any required exit or required exit sign; nor shall any display block access to fire-fighting equipment. [***101:***12.7.5.1; ***101:***13.7.5.1]

20.1.5.5.3 Materials Not on Display. A storage room having an enclosure consisting of a smoke barrier having a minimum 1-hour fire resistance rating and protected by an automatic extinguishing system shall be provided for combustible materials not on display, including combustible packing crates used to ship exhibitors' supplies and products. [***101:***12.7.5.2; ***101:***13.7.5.2]

Exposition facilities have potential problems that differ from those of theaters, restaurants, or other assembly occupancies. They are generally large, multi-use facilities with high ceilings appropriate to their size. Combustible materials are frequently displayed, and the containers in which the exhibits are shipped contribute to the fuel load. Due to the size of exhibition halls, most are required by 12.1.6 and 13.1.6 of NFPA *101* and by 13.3.2.7, and 13.3.2.8 of this *Code* to be protected by automatic sprinklers.

The AHJ at the local level often works with organizations that exhibit on a national basis and that are unaware of local fire safety regulations. The intent is that this *Code* provide the more consistent and universal treatment needed in these occupancies and, at the same time, encourage more uniform enforcement practices.

Exhibit 20.2



Arrangement of displays in an exhibition hall.

Prior to the inclusion of 20.1.5.5, the trade show and exposition hall regulations used by many jurisdictions were similar; however, no nationally recognized model code could be referenced. This lack of a model code presented a hardship, as well as confusion between the local AHJ and persons responsible for the various functions of the trade show or exposition.

To meet the intent of 20.1.5.5.2, it is advisable to have prepared plans or diagrams to show the arrangement of displays or exhibits, including any that are to be suspended from the ceiling or housed within an overhead structure. Displays or exhibits must not interfere with access to any required exit, and they must not conceal exit signs. This point is illustrated in Exhibit 20.2. A display should not block access to fire-fighting equipment or interfere with the normal operation of automatic extinguishing equipment or devices for smoke evacuation.

Aisles serving rows of booths are exit accesses; therefore, booths and other temporary construction should be of minimal combustible construction or should be protected to avoid undue hazard of fire that might endanger occupants before they can reach available exits.

Displays or exhibits of combustible material must be limited in quantity to reduce the fuel load to an acceptable level. In accordance with 20.1.5.5.3, excess combustible display material and all other combustible materials that are not in use must be kept in a separate storage room until needed. A separation with a fire resistance rating of 1 hour is required between such a storage room and all other parts of the building, and the room must be protected by an automatic sprinkler system.

20.1.5.5.4 Exhibits.

20.1.5.5.4.1 Exhibits shall comply with 20.1.5.5.4.2 through 20.1.5.5.4.11. [***101:***12.7.5.3.1; ***101:***13.7.5.3.1]

20.1.5.5.4.2 The travel distance within the exhibit booth or exhibit enclosure to an exit access aisle shall not exceed 50 ft (15 m). [***101:***12.7.5.3.2; ***101:***13.7.5.3.2]

20.1.5.5.4.3 The upper deck of multilevel exhibits exceeding 300 ft^2 (28 m^2) shall have not less than two remote means of egress. [***101:***12.7.5.3.3; ***101:***13.7.5.3.3]

Δ **20.1.5.5.4.4** Exhibit booth construction materials shall be limited to the following:

(1) Noncombustible or limited-combustible materials
(2) Wood exceeding ¼ in. (6.3 mm) nominal thickness
(3) Wood that is pressure-treated, fire-retardant wood meeting the requirements of NFPA 703
(4) Flame-retardant materials complying with one of the following:
  (a) They shall meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701.
  (b) They shall exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source.
(5) Textile wall coverings, such as carpeting and similar products used as wall or ceiling finishes, complying with the provisions of 10.2.2 and 10.2.4 of NFPA *101*
(6) Plastics limited to those that comply with Sections 12.3.3 and 10.2 of NFPA *101*
(7) Foamed plastics and materials containing foamed plastics having a heat release rate for any single fuel package that does not exceed 100 kW where tested in accordance with one of the following:
  (a) UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*
  (b) NFPA 289 using the 20 kW ignition source
(8) Cardboard, honeycombed paper, and other combustible materials having a heat release rate for any single fuel package that does not exceed 150 kW where tested in accordance with one of the following:
  (a) UL 1975
  (b) NFPA 289, using the 20 kW ignition source

[***101:***12.7.5.3.4; ***101:***13.7.5.3.4]

20.1.5.5.4.5 Curtains, drapes, and decorations shall comply with 12.6.2. [***101:***12.7.5.3.5; ***101:***13.7.5.3.5]

20.1.5.5.4.6 Acoustical and decorative material including, but not limited to, cotton, hay, paper, straw, moss, split bamboo, and wood chips shall be flame-retardant treated to the satisfaction of the AHJ. [***101:***12.7.5.3.6; ***101:***13.7.5.3.6]

20.1.5.5.4.6.1 Materials that cannot be treated for flame retardancy shall not be used. [***101:***12.7.5.3.6.1; ***101:***13.7.5.3.6.1]

Δ **20.1.5.5.4.6.2** Foamed plastics, and materials containing foamed plastics and used as decorative objects such as, but not limited to, mannequins, murals, and signs, shall have a heat release rate for any single fuel package that does not exceed 150 kW where tested in accordance with one of the following:

(1) UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*
(2) NFPA 289 using the 20 kW ignition source

[***101:***12.7.5.3.6.2; ***101:***13.7.5.3.6.2]

20.1.5.5.4.6.3 Where the aggregate area of acoustical and decorative materials is less than 10 percent of the individual floor or wall area, such materials shall be permitted to be used subject to the approval of the AHJ. [***101:***12.7.5.3.6.3; ***101:***13.7.5.3.6.3]

Δ **20.1.5.5.4.7** The following shall be protected by automatic extinguishing systems:

(1) Single-level exhibit booths exceeding 300 ft^2 (28 m^2) and covered with a ceiling
(2) Each level of multilevel exhibit booths, including the uppermost level where the uppermost level is covered with a ceiling

[***101:***12.7.5.3.7; ***101:***13.7.5.3.7]

Δ **20.1.5.5.4.7.1** The requirements of 20.1.5.5.4.7 shall not apply where otherwise permitted by the following:

(1) Ceilings that are constructed of open grate design or listed dropout ceilings in accordance with NFPA 13 shall not be considered ceilings within the context of 20.1.5.5.4.7.
(2) Vehicles, boats, and similar exhibited products having over 100 ft^2 (9.3 m^2) of roofed area shall be provided with smoke detectors acceptable to the AHJ.
(3)* The requirement of 20.1.5.5.4.7(2) shall not apply where fire protection of multilevel exhibit booths is consistent with the criteria developed through a life safety evaluation of the exhibition hall in accordance with 12.4.1 or 13.4.1 of NFPA *101*, subject to approval of the AHJ.

[***101:***12.7.5.3.7.1; ***101:***13.7.5.3.7.1]

A.20.1.5.5.4.7.1(3) See A.10.14.3.1. [***101:***A.12.7.5.3.7.1(3); ***101:***A.13.7.5.3.7.1(3)]

20.1.5.5.4.7.2 A single exhibit or group of exhibits with ceilings that do not require sprinklers shall be separated by a distance of not less than 10 ft (3050 mm) where the aggregate ceiling exceeds 300 ft^2 (28 m^2). [***101:***12.7.5.3.7.2; ***101:***13.7.5.3.7.2]

20.1.5.5.4.7.3 The water supply and piping for the sprinkler system shall be permitted to be of an approved temporary means that is provided by a domestic water supply, a standpipe system, or a sprinkler system. [***101:***12.7.5.3.7.3; ***101:***13.7.5.3.7.3]

The requirement of 20.1.5.5.4.2 applies to a standard exhibit booth arrangement, whether it is constructed of pipe supports and cloth or paper drapes or is a large exhibit enclosure designed and built from other materials, which could include small booths, open displays, large board displays, or other arrangements. This requirement also includes exhibit enclosures created by the arrangement of products such as machinery or vehicles. The intent is that travel distance is not to be more than 50 ft (15 m) for occupants who are inside the enclosure, whether they are employees or patrons. Note that this travel distance is not to an exit, but only to an aisle.

The requirement of 20.1.5.5.4.3 ensures that larger exhibits with a second level will provide at least two means of egress to prevent occupants from being entrapped on the upper level.

Paragraph 20.1.5.5.4.4 is intended to provide direction to manufacturers of exhibit booths as well as decorators, exhibitors, and AHJs. This paragraph focuses on the construction components of the ceilings, walls, and floors of an exhibit booth or display area in addition to the finish treatment. The intent is to regulate the materials used for large signs and display boards; small signs might be considered interior finish materials per the criteria of 12.5.6.3. Paragraph 20.1.5.5.4.4 does not apply to the goods or products that are being displayed.

Plastics are limited to Class A and Class B for wall and ceiling finishes. The intent of 20.1.5.5.4.4(7) is to prohibit the use of foamed plastics because of their inherent burning characteristics, unless they have been tested for heat release rate in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, and meet the maximum 100 kW threshold. Foamed plastics are used in sign construction and display boards, and, in some cases, the entire booth is constructed of foamed plastics.

Large booths and multistory booths pose special life safety problems in exhibit halls. A fire in such booths could grow to proportions large enough to have a significant negative impact on the performance of the building's sprinkler system. The intent of 20.1.5.5.4.7 is to provide sprinkler protection in these booths by means of a temporary tap into the existing sprinkler system. Sprinklers should provide the protection necessary to extinguish a fire in its incipient stage, thus reducing the life hazard to occupants.

Item (1) of 20.1.5.5.4.7.1 is not really an exemption to 20.1.5.5.4.7, because the exemption of sprinklers below drop-out ceilings is already permitted by the reference document, NFPA 13, *Standard for the Installation of Sprinkler Systems*. The exemption was added to emphasize that the intent is not to prohibit this provision of the sprinkler installation standard from being applied.

Item (2) of 20.1.5.5.4.7.1 exempts large vehicles (e.g., boats, mobile homes, and recreational vehicles) from the sprinkler requirement but requires a smoke detector if the vehicle is larger than 100 ft^2 (9.3 m^2) to provide early warning in the immediate area to allow for orderly evacuation. This provision most probably could be met by single-station, battery-operated smoke alarms.

Item (3) of 20.1.5.5.4.7.1 permits exposition hall operators to work with the AHJ to devise alternative methods of compliance via the life safety evaluation of 12/13.4.1 of NFPA *101*.

20.1.5.5.4.8 Open flame devices within exhibit booths shall comply with 20.1.5.3. [***101:***12.7.5.3.8; ***101:***13.7.5.3.8]

Δ **20.1.5.5.4.9** Cooking and food-warming devices in exhibit booths shall comply with 20.1.5.2 and all of the following:

(1) Gas-fired devices shall comply with the following:
  (a) Natural gas-fired devices shall comply with Section 11.4.
  (b) The requirement of 20.1.5.5.4.9(1)(a) shall not apply to compressed natural gas where permitted by the AHJ.
  (c) The use of LP-Gas cylinders shall be prohibited.
  (d) Nonrefillable LP-Gas cylinders shall be approved for use where permitted by the AHJ.
(2) The devices shall be isolated from the public by not less than 48 in. (1220 mm) or by a barrier between the devices and the public.
(3) Multi-well cooking equipment using combustible oils or solids shall comply with Chapter 50.
(4) Single-well cooking equipment using combustible oils or solids shall meet all of the following criteria:
  (a) The equipment shall have lids available for immediate use.
  (b) The equipment shall be limited to 2 ft^2 (0.2 m^2) of cooking surface.
  (c) The equipment shall be placed on noncombustible surface materials.
  (d) The equipment shall be separated from each other by a horizontal distance of not less than 24 in. (610 mm).
  (e) The requirement of 20.1.5.5.4.9(4)(d) shall not apply to multiple single-well cooking equipment where the aggregate cooking surface area does not exceed 2 ft^2 (0.2 m^2).
  (f) The equipment shall be kept at a horizontal distance of not less than 24 in. (610 mm) from any combustible material.
(5) A portable fire extinguisher in accordance with Section 13.6 shall be provided within the booth for each device, or an approved automatic extinguishing system shall be provided.

[***101:***12.7.5.3.9; ***101:***13.7.5.3.9]

20.1.5.5.4.10 Combustible materials within exhibit booths shall be limited to a one-day supply. Storage of combustible materials behind the booth shall be prohibited. *(See 20.1.5.4.2 and 20.1.5.5.3.)* [***101:***12.7.5.3.10; ***101:***13.7.5.3.10]

20.1.5.5.4.11 Plans for the exposition, in an acceptable form, shall be submitted to the AHJ for approval prior to setting up any exhibit. [***101:***12.7.5.3.11; ***101:***13.7.5.3.11]

20.1.5.5.4.11.1 The plan shall show all details of the proposed exposition. [***101:***12.7.5.3.11.1; ***101:***13.7.5.3.11.1]

20.1.5.5.4.11.2 No exposition shall occupy any exposition facility without approved plans. [***101:***12.7.5.3.11.2; ***101:***13.7.5.3.11.2]

Open flame devices, as noted in 20.1.5.5.4.8, need to comply with the provisions of 20.1.5.3. Any use of open flames requires the approval of the AHJ.

The provisions of 20.1.5.5.4.9 recognize the inherent dangers in cooking and food-warming devices that are used in an exhibit hall subject to large, transient crowds.

Item (2) of 20.1.5.5.4.9 requires separation distance or a barrier between the public and the device. The purpose is to guard against the dangers of accidental spills of hot greases or foods and to minimize the potential for ignition of combustibles, especially clothing worn by patrons.

Item (3) of 20.1.5.5.4.9 requires that multi-vat, or multi-well, cooking equipment comply with Chapter 50.

The intent of requiring the lid in 20.1.5.5.4.9(4)(a) is to provide the operator with a ready method of smothering the fire.

The requirement in 20.1.5.5.4.9(4)(c) is important, because the bottom surface of many devices could be subject to heating to temperatures that could ignite combustible surfaces.

The minimum separation distance in 20.1.5.5.4.9(4)(d) is necessary to minimize the danger of a fire in one device extending into another device; the same principle applies to 20.1.5.5.4.9(4)(f), except that the exposure of concern is to combustible decorations or other products, as opposed to another cooking device.

Item (5) of 20.1.5.5.4.9 requires a portable extinguisher for each cooking device. The intent is to provide an extinguisher near each cooking device so the operator is able to access the extinguisher readily if a lid does not extinguish the fire or cannot be applied. The intent is not to permit all extinguishers to be located in one place. The reference to Section 13.6 leads the user to NFPA 10, *Standard for Portable Fire Extinguishers*, which provides the necessary information with regard to the appropriate type and size of extinguisher.

Paragraph 20.1.5.5.4.10 limits the amount of literature, brochures, boxes, giveaways, and other products that are kept in the exhibit booth. The number of items necessary to constitute a one-day supply obviously varies. However, the AHJ should be able to make a judgment after reviewing the activity anticipated by the exhibitor. Additional supplies and combustible crates (such as those used for shipping) should be kept in a separate storage area having a fire resistance rating of 1 hour and protected by an automatic sprinkler system, as required by 20.1.5.5.3.

The intent of 20.1.5.5.4.11 is to provide the AHJ with a set of plans that shows aisle widths, travel distances, exits, booth locations, display area configurations, types of displays (e.g., cooking, machinery, drapery, arts and crafts), location of fire protection equipment (extinguishers, manual fire alarm boxes, hose cabinets), and lobby and registration area usage. This list is not complete, but it provides some guidance in determining the contents of the plan that should be submitted. The plan should be drawn to scale, but the scale used is not usually critical, provided that it is indicated on the plan.

20.1.5.5.4.12 Vehicles. Vehicles on display within an exposition facility shall comply with 20.1.5.5.4.12.1 through 20.1.5.5.4.12.5. [***101:***12.7.5.4; ***101:***13.7.5.4]

20.1.5.5.4.12.1 All fuel tank openings shall be locked and sealed in an approved manner to prevent the escape of vapors; fuel tanks shall not contain in excess of one-half their capacity or contain in excess of 10 gal (38 L) of fuel, whichever is less. [***101:***12.7.5.4.1; ***101:***13.7.5.4.1]

20.1.5.5.4.12.2 At least one battery cable shall be removed from the batteries used to start the vehicle engine, and the disconnected battery cable shall then be taped. [***101:***12.7.5.4.2; ***101:***13.7.5.4.2]

20.1.5.5.4.12.3 Batteries used to power auxiliary equipment shall be permitted to be kept in service. [***101:***12.7.5.4.3; ***101:***13.7.5.4.3]

20.1.5.5.4.12.4 Fueling or defueling of vehicles shall be prohibited. [***101:***12.7.5.4.4; ***101:***13.7.5.4.4]

20.1.5.5.4.12.5 Vehicles shall not be moved during exhibit hours. [***101:***12.7.5.4.5; ***101:***13.7.5.4.5]

Paragraph 20.1.5.5.4.12 on vehicles is intended to minimize the danger from both fuel and ignition sources. In accordance with 20.1.5.5.4.12.1, it is important that fuel tank openings be locked to prevent tampering with and accessibility to fuel. It is also important that the tank openings be taped to prevent the escape of flammable vapors. When these *Code* requirements were written, the issue of the quantity of fuel permitted in a tank was studied. Some jurisdictions preferred empty tanks to eliminate fuel, while others preferred full tanks to prevent vapors. It was determined that most exhibitors were unaware of the local regulation until they arrived at the exhibit hall. After learning the specific rule (empty or full), exhibitors proceeded to make their adjustment in the adjacent parking area or some other unsuitable area. It is also difficult for the AHJ to determine whether a tank is absolutely full or empty. Fueling and defueling by exhibitors outside the hall presented a greater danger than the level of fuel in the tanks, given that the tanks are locked and sealed, and ignition sources are eliminated from the vehicle. However, to avoid excessive quantities of fuel in the exhibition hall, the *Code* does limit the quantity of fuel in tanks.

In accordance with 20.1.5.5.4.12.2, it is important that at least one of the battery cables be removed from each battery. Many vehicles have more than one battery. The intent is to eliminate the possibility of a spark from the battery that might ignite fuel or surrounding combustibles. Battery cable connectors should be thoroughly taped after they have been removed.

The provision of 20.1.5.5.4.12.3 permits batteries that cannot be used to start the vehicle to remain in service. These batteries present no more of an ignition hazard than does providing house electrical power to the item on display.

Vehicle movement is addressed in 20.1.5.5.4.12.5. The movement of vehicles inside the exhibit hall potentially compromises the means of egress by blocking the exit access; vehicles should, therefore, be positioned before the hall is opened to the public. The effects of carbon monoxide (CO) inside an exhibit hall that is occupied is also a concern.

20.1.5.5.4.13 Prohibited Materials.

Δ **20.1.5.5.4.13.1** The following items shall be prohibited within exhibit halls:

(1) Compressed flammable gases
(2) Flammable or combustible liquids
(3) Hazardous chemicals or materials
(4) Class II or greater lasers, blasting agents, and explosives

[***101:***12.7.5.5.1; ***101:***13.7.5.5.1]

20.1.5.5.4.13.2 The AHJ shall be permitted to allow the limited use of any items specified in 20.1.5.5.4.13.1 under special circumstances. [***101:***12.7.5.5.2; ***101:***13.7.5.5.2]

Compressed gas containers, as addressed by 20.1.5.5.4.13.1, are subject to fire damage that could cause an explosion or create a serious threat to life safety. Flammable and combustible liquids compromise life safety by their inherent capability to contribute to rapid fire spread. Hazardous materials present a variety of hazards to life safety, from their flammability to their toxicity. Class II or greater lasers can cause tissue damage to humans, and blasting agents and explosives can cause a large loss of life or injury if handled improperly.

Exhibitors who wish to display explosives, pesticides, or a type of compressed gas container, among other items, can effectively do so without bringing the actual product into the hall by using empty containers instead.

Paragraph 20.1.5.5.4.13.2 gives the AHJ the discretion to permit small amounts of otherwise prohibited materials under special circumstances. For example, an exhibit or trade show for collectors of small arms ammunition or a highly supervised and closed (to the public) vocational trade show using such materials is permitted where special controls and professional supervision are provided.

20.1.5.6 Crowd Managers.

Δ **20.1.5.6.1** Assembly occupancies shall be provided with a minimum of one trained crowd manager or crowd manager supervisor. Where the occupant load exceeds 250, additional trained crowd managers or crowd manager supervisors shall be provided at a ratio of 1 crowd manager or crowd manager supervisor for every 250 occupants, unless otherwise permitted by one of the following:

(1) This requirement shall not apply to assembly occupancies used exclusively for religious worship with an occupant load not exceeding 500.
(2) The ratio of trained crowd managers to occupants shall be permitted to be reduced where, in the opinion of the AHJ, the existence of an approved, supervised automatic sprinkler system and the nature of the event warrant.

[***101:***12.7.6.1; ***101:***13.7.6.1]

20.1.5.6.2* The crowd manager and crowd manager supervisor shall receive approved training in crowd management techniques. [***101:***12.7.6.2; ***101:***13.7.6.2]

Since the 2006 edition of the *Code*, a minimum of one crowd manager has been required for each assembly occupancy, regardless of occupant load. Where the occupant load exceeds 250, additional crowd managers are required at the specified ratio. In editions prior to 2006, a crowd manager was required only if the occupant load exceeded 1000. The change was made in reaction to The Station nightclub fire of 2003 in West Warwick, Rhode Island, in which 100 occupants perished.

The procedures for providing trained crowd managers must be part of the written emergency action plan as required by 20.1.5.6.3. The delineation of duties and responsibilities of crowd managers, as listed in 20.1.5.6.4, will lead to standardization in the training the crowd managers receive and consistency in the services they provide in the various assembly venues in which they work. The provisions of 20.1.5.6.5 charge the crowd manager supervisors with understanding the workings of the specific venue. The crowd manager supervisors are expected to provide the venue-specific training that elevates a generalist crowd manager to a specialist crowd manager for a particular venue.

Crowd management meshes the design features of a facility, the established operating features of the facility, and an understanding of the occupants' expected natural behavior in the facility for a specific type of event. Chapter 56 of the *SFPE Handbook of Fire Protection Engineering*, "Egress Concepts and Design Approaches," cites numerous technical references that provide additional detail on crowd management concepts. Included is "The Causes and Prevention of Crowd Disasters," by John J. Fruin, a leading expert on pedestrian movement and crowd safety. Fruin differentiates crowd control from crowd management by defining crowd management as "the systematic planning for, and supervision of, the orderly movement and assembly of people. Crowd control is the restriction or limitation of group behavior. Crowd management involves the assessment of the people handling capabilities of a space prior to use. It includes evaluation of projected levels of occupancy, adequacy of means of ingress and egress, processing procedures such as ticket collection, and expected types of activities and group behavior."

The options for training programs for crowd managers increased greatly beginning in 2010 with the introduction of a readily available and affordable web-based program from the International Association of Venue Managers (IAVM), formerly the International Association of Assembly Managers, which can be accessed at http://www.iaamtraining.com/tcm.html. The web-based program provides 6 hours of training that can be completed in multiple sessions. The enrollee is awarded a certificate upon successful completion of a comprehensive examination. The recipient of the certificate then needs to complete, on-site, venue-specific training and receives a certificate from the venue before being officially designated as a trained crowd manager. An individual can complete multiple venue-specific training programs so as to qualify to serve as a trained crowd manager at the multiple venues.

The IAVM also conducts live training and hosts the annual GuestX Guest Experience & Crowd Management Conference (visit www.iavm.org for more information). Additional crowd manager certification programs are available online. The determination of acceptability of such programs must be made by the AHJ.

A.20.1.5.6.2 Crowd managers and crowd manager supervisors need to clearly understand the required duties and responsibilities specific to the venue's emergency plan. The crowd management training program should include a clear appreciation of crowd dynamics factors including space, energy, time, and information, as well as specific crowd management techniques, such as metering. Training should involve specific actions necessary during normal and emergency operations, and include an assessment of people handling capabilities of a space prior to its use, the identification of hazards, an evaluation of projected levels of occupancy, the adequacy of means of ingress and egress and identification of ingress and egress barriers, the processing procedures such as ticket collection, and the expected types of human behavior. Training should also involve the different types of emergency evacuations and, where required by the emergency plan, relocation and shelter-in-place operations, and the challenges associated with each. [***101:***A.12.7.6.2; ***101:***A.13.7.6.2]

20.1.5.6.3 Duties and responsibilities for the crowd manager and crowd manager supervisor shall be documented within a written emergency plan as required by 12.7.13 of NFPA 101. [***101:***12.7.6.3; ***101:***13.7.6.3]

20.1.5.6.4* The training for the duties and responsibilities of crowd managers shall include the following:

(1) Understanding crowd manager roles and responsibilities
(2) Understanding safety and security hazards that can endanger public assembly
(3) Understanding crowd management techniques
(4) Introduction to fire safety and fire safety equipment
(5) Understanding methods of evacuation and movement
(6) Understanding procedures for reporting emergencies
(7) Understanding crowd management emergency response procedures
(8) Understanding the paths of travel and exits, facility evacuation and emergency response procedures and, where provided, facility shelter-in-place procedures
(9) Familiarization with the venue and guest services training
(10) Other specific event-warranted training

[***101:***12.7.6.4; ***101:***13.7.6.4]

A.20.1.5.6.4 In large facilities, crowd managers typically have a specific area of responsibility. In such facilities, the requirements of 20.1.5.6.4 might apply only to the crowd managers' area of responsibility. [***101:***A.12.7.6.4; ***101:***A.13.7.6.4]

20.1.5.6.5 The training for the duties and responsibilities of crowd manager supervisors shall include the following:

(1) The duties described in 20.1.5.6.4
(2) Understanding crowd manager supervisor roles and responsibilities
(3) Understanding of incident management procedures
(4) Understanding the facility evacuation plan
(5) Understanding the facility command structure

[***101:***12.7.6.5; ***101:***13.7.6.5]

20.1.5.7* Fire Detail. Fire details, if deemed necessary in any assembly occupancy, shall be determined by the AHJ.

A.20.1.5.7 Because of the variety of types of places of assembly covered in this *Code*, no general requirement for patrols or fire watchers has been included. The NFPA 102 Committee fully recognizes the importance of this feature of fire protection, however, and believes that a system of well-trained patrols or fire watchers should be maintained in every place of assembly where fire hazards might develop. Such locations would include, among others, the spaces underneath grandstands and the areas inside and outside tents and air-supported structures. The fire watchers serve to detect incipient fires and to prevent an accumulation of materials that will carry fire. The number of such watchers required will, of course, vary for the different types of assembly occupancies, depending upon the combustibility of the construction and the number of persons accommodated. Provided with an adequate supply of portable fire extinguishing equipment located at readily accessible points, such a fire watch or detail should be able to prevent small fires from reaching serious proportions.

20.1.5.8* Drills.

A.20.1.5.8 It is important that an adequate number of competent attendants are on duty at all times when the assembly occupancy is occupied. [***101:***A.12.7.7; ***101:***A.13.7.7]

20.1.5.8.1 The employees or attendants of assembly occupancies shall be trained and drilled in the duties they are to perform in case of fire, panic, or other emergency to effect orderly exiting. [***101:***12.7.7.1; ***101:***13.7.7.1]

20.1.5.8.2 Employees or attendants of assembly occupancies shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment where provided. [***101:***12.7.7.2; ***101:***13.7.7.2]

Δ **20.1.5.8.3*** In the following assembly occupancies, an audible announcement shall be made, or a projected image shall be shown, prior to the start of each program that notifies occupants of the location of the exits to be used in case of a fire or other emergency:

(1) Theaters
(2) Motion picture theaters
(3) Auditoriums
(4) Other similar assembly occupancies with occupant loads exceeding 300 where there are noncontinuous programs

[***101:***12.7.7.3; ***101:***13.7.7.3]

A.20.1.5.8.3 It is not the intent of this provision to require an announcement in bowling alleys, cocktail lounges, restaurants, or places of worship. [***101:***A.12.7.7.3; ***101:***A.13.7.7.3]

20.1.5.8.4 The requirement of 20.1.5.8.3 shall not apply to assembly occupancies in schools where used for nonpublic events. [***101:***12.7.7.4; ***101:***13.7.7.4]

The provisions of 20.1.5.8.2 do not require fire extinguishers for life safety in an assembly occupancy. They do specify, however, that, if fire extinguishers are provided, the staff must be trained in their use to prevent a false sense of security and possible injury. The AHJ determines the extent of this training, whether instruction only or instruction and hands-on use.

The relatively simple requirement of 20.1.5.8.3 for notifying occupants of the location of exits can make a significant difference during an emergency. Note that the requirement does not apply to assembly occupancies where the flow of people is constantly changing, such as in a restaurant. Movie theaters commonly meet the provisions of 20.1.5.8.3 through means of sound and screen projection that are presented prior to the main feature, during the same period that notifications of restroom, trash container, and snack bar locations are made and previews are shown. The same complete message is thereby delivered to each audience without the need for human intervention.

20.1.5.9 Smoking.

20.1.5.9.1 Smoking in assembly occupancies shall be regulated by the AHJ. [***101:***12.7.8.1; ***101:***13.7.8.1]

20.1.5.9.2 In rooms or areas where smoking is prohibited, plainly visible signs shall be posted that read as follows:

NO SMOKING

[***101:***12.7.8.2; ***101:***13.7.8.2]

Δ **20.1.5.9.3** No person shall smoke in prohibited areas that are so posted, unless permitted by the AHJ under both of the following conditions:

(1) Smoking shall be permitted on a stage only where it is a necessary and rehearsed part of a performance.
(2) Smoking shall be permitted only where the smoker is a regular performing member of the cast.

[***101:***12.7.8.3; ***101:***13.7.8.3]

20.1.5.9.4 Where smoking is permitted, suitable ashtrays or receptacles shall be provided in convenient locations. [***101:***12.7.8.4; ***101:***13.7.8.4]

20.1.5.10 Seating.

20.1.5.10.1 Secured Seating.

20.1.5.10.1.1 Seats in assembly occupancies accommodating more than 200 persons shall be securely fastened to the floor, except where fastened together in groups of not less than three and as permitted by 20.1.5.10.1.2 and 20.1.5.10.2. [***101:***12.7.9.1.1; ***101:***13.7.9.1.1]

20.1.5.10.1.2 Balcony and box seating areas that are separated from other areas by rails, guards, partial-height walls, or other physical barriers and have a maximum of 14 seats shall be exempt from the requirement of 20.1.5.10.1.1. [***101:***12.7.9.1.2; ***101:***13.7.9.1.2]

20.1.5.10.2 Unsecured Seating.

20.1.5.10.2.1 Seats not secured to the floor shall be permitted in restaurants, night clubs, and other occupancies where fastening seats to the floor might be impracticable. [***101:***12.7.9.2.1; ***101:***13.7.9.2.1]

20.1.5.10.2.2 Unsecured seats shall be permitted, provided that, in the area used for seating, excluding such areas as dance floors and stages, there is not more than one seat for each 15 ft^2 (1.4 m^2) of net floor area, and adequate aisles to reach exits are maintained at all times. [***101:***12.7.9.2.2; ***101:***13.7.9.2.2]

20.1.5.10.2.3 Seating diagrams shall be submitted for approval by the AHJ to permit an increase in occupant load per 14.8.1.3. [***101:***12.7.9.2.3; ***101:***13.7.9.2.3]

The function of 20.1.5.10.1 is to prevent the movement of seats so that aisles, rows, and access to the exits do not become blocked in an assembly occupancy during the jostling that occurs when people flee from a fire.

The provision of 20.1.5.10.1.1 for fastening seats together in groups was revised for the 2009 edition of the *Code*. In prior editions, the seats were required to be fastened together in groups of not fewer than three and not more than seven. The maximum number of seats in a group was deleted, as it served no practical purpose.

The provision of 20.1.5.10.1.2 was revised for the 2012 edition of the *Code*. It replaces a requirement for all seats in balconies and galleries to be securely fastened to the floor. Its wording results in the 200-seat criterion of 20.1.5.10.1.1 becoming the threshold for balcony and gallery seat fastening. Then, private boxlike seating areas are exempted from the requirement for fastening seats to the floor if the box is separated from other boxes and the area has not more than 14 seats.

Paragraph 20.1.5.10.2.3 requires that seating diagrams be provided to the AHJ to support a request for an increase in occupant load above that calculated using the occupant load factors of Table 14.8.1.2 characteristic of the uses of the space. Such increase in occupant load must not exceed the limits imposed by 12.1.7 and 13.1.7 of NFPA *101*.

Δ **20.1.5.10.3 Festival Seating.** Festival seating, as defined in 3.3.114, shall be prohibited within a building, unless otherwise permitted by one of the following:

(1) Festival seating shall be permitted in assembly occupancies having occupant loads of 250 or less.
(2) Festival seating shall be permitted in assembly occupancies where occupant loads exceed 250, provided that an approved life safety evaluation has been performed. *(See 10.15.3.)*

[***101:***12.2.5.4.1; ***101:***13.2.5.4.1]

20.1.5.10.4 Occupant Load Posting.

20.1.5.10.4.1 Every room constituting an assembly occupancy and not having fixed seats shall have the occupant load of the room posted in a conspicuous place near the main exit from the room. [***101:***12.7.9.3.1; ***101:***13.7.9.3.1]

20.1.5.10.4.2 Approved signs shall be maintained in a legible manner by the owner or authorized agent. [***101:***12.7.9.3.2; ***101:***13.7.9.3.2]

20.1.5.10.4.3 Signs shall be durable and shall indicate the number of occupants permitted for each room use. [***101:***12.7.9.3.3; ***101:***13.7.9.3.3]

The provisions of 20.1.5.10.4 for occupant load posting are unique to assembly occupancies. All occupancies use occupant load for capacity calculations to ensure that the means of egress system is adequately sized. Assembly occupancies use occupant load for the additional purpose of posting the occupant load as a tool to help avoid overcrowding.

Exhibit 20.3 shows an occupant load posting in an airline membership club at an airport. The maximum occupant load of

Exhibit 20.3

Occupant load posting indicative of one consistent use of a space.

Exhibit 20.4

Dual occupant load postings indicative of two common uses of a space.

825 persons is indicative of the club's singular use as a seating area with many chairs and some tables. Exhibit 20.4 shows two occupant load postings for a ballroom in a hotel. The maximum occupant load of 182 persons is for use of the room with tables and chairs; the maximum occupant load of 391 persons is for use of the room with chairs only.

Δ **20.1.5.11 Clothing.** Clothing and personal effects shall not be stored in corridors, and spaces not separated from corridors, unless otherwise permitted by one of the following:

(1) In new assembly occupancies, this requirement shall not apply to corridors, and spaces not separated from corridors, that are protected by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***12.7.12(1)]

(2) In existing assembly occupancies, this requirement shall not apply to corridors, and spaces not separated from corridors, that are protected by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***13.7.12(1)]

(3) This requirement shall not apply to corridors, and spaces not separated from corridors, that are protected by a smoke detection system in accordance with Section 13.3. [***101:***12.7.12(2); ***101:***13.7.12(2)]

(4) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

[***101:***12.7.12(3); ***101:***13.7.12(3)]

Clothing hung on hooks along corridor walls or on racks in lobbies greatly increases the combustible load and will generally allow flames to spread quickly. Each of the exemptions (control of fire by sprinklers, early warning of incipient-stage fire via smoke detection, or isolation of fuel packages by locating the clothing in metal lockers) helps to mitigate the chance that a clothing fire would render the exit access unusable. The wording of 20.1.5.11 clarifies that the provision applies to clothing in spaces not separated from the corridor as well as in the corridor.

20.1.5.12 Projection Rooms.

20.1.5.12.1 Film or video projectors or spotlights utilizing light sources that produce particulate matter or toxic gases, or light sources that produce hazardous radiation, without protective shielding shall be located within a projection room complying with 12.3.2.1.2 of NFPA *101*. [***101:***12.4.7.3; ***101:***13.4.7.3]

Δ **20.1.5.12.2** Every projection room shall be of permanent construction consistent with the building construction type in which the projection room is located and shall comply with the following:

(1) Openings shall not be required to be protected.

(2) The room shall have a floor area of not less than 80 ft^2 (7.4 m^2) for a single machine and not less than 40 ft^2 (3.7 m^2) for each additional machine.

(3) Each motion picture projector, floodlight, spotlight, or similar piece of equipment shall have a clear working space of not less than 30 in. (760 mm) on each side and at its rear, but only one such space shall be required between adjacent projectors.

[***101:***12.4.7.4; ***101:***13.4.7.4]

The requirements for projection booths were developed jointly with those of NFPA 40, *Standard for the Storage and Handling of Cellulose Nitrate Film*, and the motion picture industry when cellulose nitrate film was still being used. Although only safety film is now used (except at film festivals or revivals) in those facilities still utilizing film projectors (many have gone all digital) and the risk level has been reduced, the primary function of the requirements of 20.1.5.12.1 is to enclose the projection booth, eliminating it as an exposure threat to the theater audience.

The intent of 20.1.5.12.1 is to protect the audience from the dangers associated with light sources, such as electric arc or xenon. Where incandescent light is used, projection booths are not required in assembly occupancies. Note that the booth is required based on the light source, not on the use of film.

The provisions of 20.1.5.12.2 apply only to projection booths for the use of cellulose acetate or other safety film. Although openings in the booth do not need to be protected, they must be provided with glass or other approved material that will completely close the opening and prevent gas, dust, or radiation from contaminating the audience seating area.

Newer projection equipment has a console that draws air in at the floor and up through the projection machine, thus eliminating the need to provide ducts near the floor.

N **20.1.5.13 Integrated Fire Protection Systems.** Integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***12.7.14; ***101:***13.7.14]

The provision of 20.1.5.13 is new to the 2018 edition of the *Code*. Where fire protection and life safety systems are needed to function together to provide the intended level of protection, they must meet the testing requirements of 13.1.3, which in turn references NFPA 4, *Standard for Integrated Fire Protection and Life Safety System Testing*. The integrated systems test addressed by NFPA 4 verifies and documents the operation and function of all interconnected fire protection and life safety systems, including performance in accordance with applicable codes and standards, sequence of operation, performance in accordance with manufacturers' published instructions, and accuracy of record documents. See the commentary following A.13.1.3 for additional information on integrated fire protection and life safety system testing.

20.2 Educational Occupancies

Section 20.2 provides the life safety features necessary to protect students in an educational setting such as a school. This section applies to educational settings for students in kindergarten through the twelfth grade; it does not apply to college classrooms. The range of student characteristics and self-preservation abilities found in the educational occupancies regulated by Section 20.2 requires that students' fire safety needs be treated differently from those of adults occupying a college classroom.

The protection measures used for educational occupancies recognize the structured environment found in a school. For example, class times, time between classes, and activities during class time are rigidly structured. These factors make it possible to train students to respond to a fire by conducting emergency egress and relocation drills.

Schools also have one of the more assertive schedules for conducting emergency egress drills (see 20.2.4.2). The drills not only provide a structured fire escape plan, they also help to instill fire-safe behavior for long-term use.

20.2.1 Application. New and existing educational occupancies shall comply with Section 20.2 and NFPA *101*.

Educational occupancies include those buildings, or portions of buildings, used for educating six or more students for 4 or more hours per day or more than 12 hours per week, but only through the twelfth grade.

The provisions of 14.1.1.4 and 15.1.1.4 of NFPA *101* recognize that colleges, universities, and similar educational facilities that do not meet the definition of an educational occupancy do not pose the same life safety concerns as elementary and high schools. Because of the maturity of their occupants, college buildings more closely resemble business occupancies.

Paragraphs 14.1.1.4 and 15.1.1.4 of NFPA *101* also identify how to classify an occupancy for other educational uses that do not meet the definition of an educational occupancy. Note that the provisions of 14.1.1.4(1) through (5) and 15.1.1.4(1) through (5) of NFPA *101* apply only where the educational use does not meet the definition of an educational occupancy. For example, 14.1.1.4(3) and 15.1.1.4(3) of NFPA *101* specify that a classroom with an occupant load of 50 or more persons be classified as an assembly occupancy only if such classroom is not an educational occupancy. A classroom occupied by 60 eighth-grade students for more than 12 hours per week is an educational occupancy and not an assembly occupancy, because it meets the definition of an educational occupancy. A classroom occupied by 60 college students is an assembly occupancy in accordance with 14.1.1.4(3) and 15.1.1.4(3) of NFPA *101*, because the definition of an educational occupancy applies through only the twelfth grade. A classroom occupied by 49 college students is a business occupancy in accordance with 14.1.1.4(2) and 15.1.1.4(2) of NFPA *101*, because the definition of an educational occupancy applies through only the twelfth grade.

20.2.2 Flexible Plan and Open Plan Buildings.

20.2.2.1 Flexible plan and open plan buildings shall comply with the requirements of 20.2.2 as modified by 20.2.2.2 through 20.2.2.5. [***101:***14.4.3.1; ***101:***15.4.3.1]

20.2.2.2 Each room occupied by more than 300 persons shall have two or more means of egress entering into separate atmospheres. [***101:***14.4.3.2; ***101:***15.4.3.2]

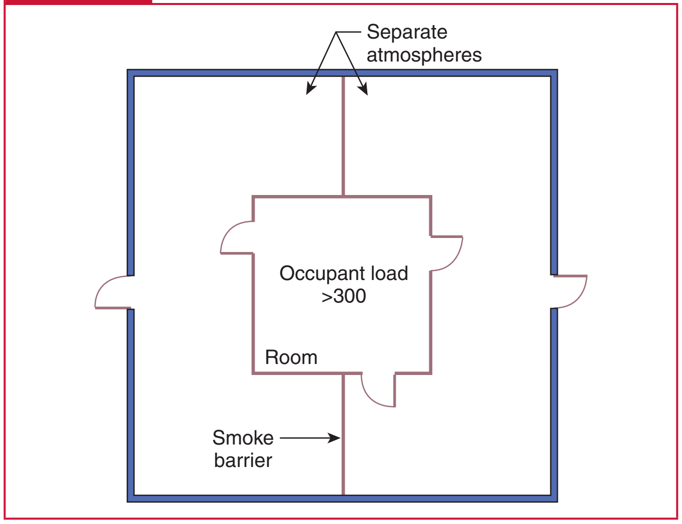
20.2.2.3 Where three or more means of egress are required, the number of means of egress permitted to enter into the same atmosphere shall not exceed two. [***101:***14.4.3.3; ***101:***15.4.3.3]

20.2.2.4 Flexible plan buildings shall be permitted to have walls and partitions rearranged periodically only if revised plans or diagrams have been approved by the AHJ. [***101:***14.4.3.4]

20.2.2.5 Flexible plan buildings shall be evaluated while all folding walls are extended and in use as well as when they are in the retracted position. [***101:***14.4.3.5; ***101:***15.4.3.5]

Flexible plan and open plan buildings are addressed in 20.2.2. Rooms occupied by more than 300 persons require special treatment in flexible plan and open plan schools. To ensure the safety of this large number of persons occupying one room, means of egress must be arranged so that each of the egress paths traverses atmospheres that are separate from each other. If more than two separate means of egress paths are required, not more than two are permitted to pass through the same atmosphere. See the definition of the term *separate atmosphere* in 3.3.27.2 of NFPA *101*. Using this arrangement should prevent a single fire from contaminating or blocking all egress routes in an open plan or flexible plan building.

Exhibit 20.5



Room in open plan building requiring two or more means of egress into separate atmospheres.

Exhibit 20.5 illustrates a room in an open plan building that requires two or more means of egress into separate atmospheres.

In accordance with 20.2.2.4, approval of revised plans or diagrams is necessary to avoid the possibility of circuitous egress paths or other arrangements that do not comply with the intent of the *Code*. Also, flexible plan buildings are required to meet the provisions for corridor protection, as well as those for the subdivision of building spaces, using smoke barriers.

20.2.3 Interior Finish.

20.2.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***14.3.3.1; ***101:***15.3.3.1]

20.2.3.2 Interior Wall and Ceiling Finish. New and existing interior wall and ceiling finish materials complying with Section 12.5 shall be permitted as follows:

(1) Exits — Class A [***101:***14.3.3.2(1); ***101:***15.3.3.2(1)]
(2) In new educational occupancies other than exits — Class A or Class B [***101:***14.3.3.2(2)]
(3) In existing educational occupancies, corridors and lobbies — Class A or Class B [***101:***15.3.3.2(2)]
(4) Low-height partitions not exceeding 60 in. (1525 mm) and used in locations other than exits — Class A, Class B, or Class C [***101:***14.3.3.2(3); ***101:***15.3.3.2(3)]

20.2.3.3 Interior Floor Finish.

20.2.3.3.1 New interior floor finish shall comply with Section 12.5. [***101:***14.3.3.3.1]

20.2.3.3.2 New interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 14.3.6 of NFPA *101* shall be not less than Class II. [***101:***14.3.3.3.2]

20.2.3.3.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***14.3.3.3.3]

20.2.3.3.4 Existing Interior Floor Finish. (Reserved) [***101:***15.3.3.3]

20.2.4 Operating Features.

20.2.4.1 Emergency Action Plan. Emergency action plans shall be provided in accordance with Section 10.8. [***101:***14.7.1; ***101:***15.7.1]

20.2.4.2 Emergency Egress Drills.

20.2.4.2.1* Emergency egress drills shall be conducted in accordance with Section 10.5 and the applicable provisions of 20.2.4.2.3 as otherwise provided in 20.2.4.2.2. [***101:***14.7.2.1; ***101:***15.7.2.1]

A.20.2.4.2.1 The requirements are, of necessity, general in scope, as it is recognized that they apply to all types of educational occupancies as well as conditions of occupancies, such as truant schools; schools for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; and public schools. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements. [***101:***A.14.7.2.1; ***101:***A.15.7.2.1]

20.2.4.2.2 Approved training programs designed for education and training and for the practice of emergency egress to familiarize occupants with the drill procedure, and to establish conduct of the emergency egress as a matter of routine, shall be permitted to receive credit on a one-for-one basis for not more than four of the emergency egress drills required by 20.2.4.2.3, provided that a minimum of four emergency egress drills are completed prior to the conduct of the first such training and practice program. [***101:***14.7.2.2; ***101:***15.7.2.2]

Δ **20.2.4.2.3** Emergency egress drills shall be conducted as follows:

(1) Not less than one emergency egress drill shall be conducted every month the facility is in session, unless both of the following criteria are met:
  (a) In climates where the weather is severe, the monthly emergency egress drills shall be permitted to be deferred.
  (b) The required number of emergency egress drills shall be conducted, and not less than four shall be conducted before the drills are deferred.
(2) All occupants of the building shall participate in the drill.
(3) One additional emergency egress drill, other than for educational occupancies that are open on a year-round basis, shall be required within the first 30 days of operation.

[***101:***14.7.2.3; ***101:***15.7.2.3]

20.2.4.2.4 All emergency drill alarms shall be sounded on the fire alarm system. [***101:***14.7.2.4; ***101:***15.7.2.4]

Emergency egress drills for educational occupancies, particularly those at the grade school level, are essential to ensure an orderly response during a fire. Unfortunately, the predictability of such drills often leads to their ineffectiveness. When an alarm bell sounds and a fire department monitor appears in a corridor, some teachers ignore the bell, assuming that it is a false alarm. If the bell sounds and a fire department monitor is not seen, teachers opt to either evacuate or remain in the building. This decision is made in the hallway. While the bell continues to ring, the students remain in their classrooms. Therefore, when a bell sounds, the primary emphasis should be placed on evacuation, regardless of who is or is not present in the hallways and regardless of whether fire equipment is parked in front of the school. Essentially, the fire department and the school should vary the timing and arrangement of the drills but not the required response, which is orderly evacuation. See also Section 10.5.

The provisions of 20.2.4.2.2 permit emergency egress training programs to substitute for as many as four of the required monthly emergency egress drills. The mixture of training programs and emergency egress drills might elicit student egress behavior that is superior to that instilled by drills alone. However, at least four egress drills need to be conducted prior to the first training program to ensure that the students have walked the egress route and demonstrated other behavior addressed by the emergency plan. The concept behind the requirement that emergency drills be conducted at the start of the school year is that training without the hands-on instruction accomplished by drilling does not guarantee that students will be familiar with the egress routes and able to interact with others during an emergency evacuation or relocation.

20.2.4.3 Inspection.

20.2.4.3.1* It shall be the duty of principals, teachers, or staff to inspect all exit facilities daily to ensure that all stairways, doors, and other exits are in proper condition. [***101:***14.7.3.1; ***101:***15.7.3.1]

A.20.2.4.3.1 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building. [***101:***A.14.7.3.1; ***101:***A.15.7.3.1]

Any condition likely to interfere with safe egress should be corrected immediately, if possible, or otherwise should be reported at once to the appropriate authorities. [***101:***A.14.7.3.1; ***101:***A.15.7.3.1]

20.2.4.3.2 Open plan buildings shall require extra surveillance to ensure that exit paths are maintained clear of obstruction and are obvious. [***101:***14.7.3.2; ***101:***15.7.3.2]

20.2.4.3.3 Inspection of Door Openings. Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***14.7.3.3; ***101:***15.7.3.3]

Compliance with the requirement of 20.2.4.3.1 for daily inspection of the egress system has benefits that far outweigh the time and resources required to conduct such inspections. The provision permits staff other than principals and teachers to make such inspections. The inspection function is often better performed by maintenance personnel who have responsibility for and intimate working knowledge of the many building features and systems.

The provision of 20.2.4.3.3 requires the inspection of door openings in accordance with 7.2.1.15 of NFPA *101*, the criteria of which are formatted to apply only where specifically required by another portion of the *Code*. The inspection requirements apply only to specific doors. This application threshold was chosen to help ensure that the egress doors used under emergency egress or relocation are inspected and tested. Door leaves that are infrequently used, such as those into exit stair enclosures in high-rise buildings, might be misaligned within their frames so as to be difficult to open within the operating forces requirements of 14.5.1.5. The door inspection and testing criteria of 14.5.11 are intended to help identify problems with door openings and ensure that such problems are remedied.

20.2.4.4 Furnishings and Decorations.

20.2.4.4.1 Draperies, curtains, and other similar furnishings and decorations in educational occupancies shall be in accordance with the provisions of 12.6.2. [***101:***14.7.4.1; ***101:***15.7.4.1]

Δ **20.2.4.4.2** Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by one of the following:

(1) This requirement shall not apply to corridors protected by an automatic sprinkler system in accordance with Section 13.3.
(2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with 13.7.1.4.
(3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

[***101:***14.7.4.2; ***101:***15.7.4.2]

Clothing hung on hooks along corridor walls or on racks in school lobbies greatly increases the combustible load and will generally allow flames to spread quickly. Because Section 20.2 regulates the interior wall finish for corridors and lobbies, surfaces covered by combustible clothing that would allow flame to spread more quickly than is permitted by wall surfaces should not be created. The three provisions of 20.2.4.4.2 (control of fire by sprinklers, early warning of incipient-stage fire via smoke detection, or isolation of fuel packages by locating the clothing in metal lockers) help to mitigate the potential for a clothing fire to render the exit access unusable. Exhibit 20.6 shows metal lockers in a corridor.

20.2.4.4.3 Artwork and teaching materials shall be permitted to be attached directly to the walls in accordance with the following:

(1) In new educational occupancies, the artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***14.7.4.3(1)]

Exhibit 20.6

Metal lockers in corridor.

Exhibit 20.7

Sprinklered building classroom with artwork and teaching materials attached to walls.

(2) In existing educational occupancies, the artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***15.7.4.3(1)]

(3) In new educational occupancies, the artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***14.7.4.3(2)]

(4) In existing educational occupancies, the artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***15.7.4.3(2)]

It is advantageous not only to limit the quantity of artwork displayed but also to avoid placing such materials near a room's exit access doors. Because the combustibility of the artwork cannot be effectively controlled, the quantity, in terms of the percentage of wall area covered, is regulated to avoid creating a continuous combustible surface that will spread flame across the room. If the building is protected throughout by automatic sprinklers, the percentage of wall area permitted to be covered with artwork and teaching materials is increased to 50 percent. Exhibit 20.7 shows artwork and teaching materials affixed to walls in a classroom in a sprinklered school building.

NFPA technical staff often hear the criticism that the *Code* is overly restrictive and hampers day-to-day function by limiting the percentage of wall area that can be covered by artwork and teaching materials in educational occupancies. The commenters fail to realize that the wall artwork provision is a relaxation of earlier *Code* provisions, not a more stringent requirement. Prior to the recognition of artwork and teaching materials on up to 20 percent of wall area, such materials were treated like any other interior wall finish material. AHJs routinely prohibited all wall artwork unless there was proof the material met the requisite Class A, B, C interior finish classification requirements based on testing — something that paper and fiberboard cannot meet. The 20 percent criterion was established in accordance with the technical committee's judgment as to a quantity of material that would not spread flame continuously. The 50 percent allowance for sprinklered areas is a further relaxation that the technical committee offered when educators said the 20 percent limit did not meet their educational needs.

20.2.4.5 Unvented Fuel-Fired Heating Equipment. Unvented fuel-fired heating equipment, other than gas space heaters in compliance with NFPA 54 /ANSI Z223.1, *National Fuel Gas Code*, shall be prohibited. [***101:***14.5.2.2; ***101:***15.5.2.2]

It is not in the interest of reasonable life safety to permit unvented fuel-fired equipment in a school building occupied by children; the typical use of such equipment might jeopardize the life safety of the students. Improper venting and potential misuse by students might result in injury to students, especially younger children. Paragraph 20.2.4.5 recognizes a special form of gas space heater that — although not vented in the conventional way — can be used safely.

N **20.2.4.6 Integrated Fire Protection Systems.** In new educational occupancies, integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***14.7.6]

Subsection 13.1.3 is new for the 2018 edition of the *Code*. By reference to this new subsection, new educational occupancies will require that, where two or more fire protection or life safety systems are integrated, the integrated system be tested to verify the proper operation and function of the system in accordance with NFPA 4. See the commentary associated with 13.1.3 for more information.

20.3 Day-Care Occupancies

Section 20.3 addresses not only traditional child day care but also the growing field of adult day care. In both cases, Section 20.3 recognizes that many of the individuals who occupy these facilities are not totally capable of self-preservation. Very young children will require a certain amount of assistance from the day-care staff to help with relocation or evacuation. Likewise, some adults in adult day care will also require staff assistance during a fire emergency. For those reasons, Section 20.3 of this *Code* and Chapters 16 and 17 of NFPA *101* mandate select features that anticipate that these occupants will respond more slowly to a fire than is average. The requirements address a range of protection features, including the physical location of the day-care facility as it relates to the building construction type and the presence of automatic sprinklers (see Table 16.1.6.1 and Table 17.1.6.1 of NFPA *101*).

20.3.1 Application. New and existing day-care occupancies shall comply with Section 20.3 and NFPA *101*.

20.3.1.1 In new day-care occupancies, where a facility houses more than one age group or self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care occupancy or building, as appropriate to a given area, unless the area housing such a group is maintained as a separate fire area. [***101:***16.1.1.6]

20.3.1.2 In existing day-care occupancies, where a facility houses clients of more than one self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care occupancy or building, as appropriate to a given area, unless the area housing such a group is maintained as a separate fire area. [***101:***17.1.1.6]

Δ **20.3.1.3*** Rooms or spaces used for temporary child care, during short-term activities of the child's relative or guardian within the same building, shall not be required to meet the provisions of this chapter. [***101:***16.1.1.7; ***101:***17.1.1.7]

N **A.20.3.1.3** The definition of day-care occupancy is intended to exclude day-care uses that are part of some other occupancy. In such cases, the requirements of the predominant occupancy apply. Examples of excluded facilities include the following:

(1) Rooms located within places of worship used as nurseries or for supervision of children or religious education while services are being held in the building.
(2) Rooms used for temporary child care during short-term recreational activities of the child's relative or guardian, such as within a health club or park district.
(3) Rooms used for temporary child care during short-term activities such as court hearings, medical appointments, libraries, or other similar circumstances.

[***101:***A.16.1.1.7; ***101:***A.17.1.1.7]

Paragraph 20.3.1.3 addresses day care provided within a place of worship while religious services are being held. The parents of the clients of the day-care center would be among those attending a worship service; they and others assembled for the worship service would be expected to assist the day-care staff with any necessary evacuation. The requirements of Section 20.3, therefore, do not apply under such circumstances. On the other hand, if day-care operations are conducted in the same building while religious services are not being conducted — such as during the work week — the day-care provisions of Section 20.3 would apply.

The provisions of 20.3.1.1 and 20.3.1.2 tailor the protection package to the client group with the greatest needs. This concept is similar to that applied by 6.1.14.3 to a multiple occupancy protected as a mixed occupancy. Paragraph 6.1.14.3.2 requires that the most stringent *Code* provisions applicable to any of the occupancies present must be applied throughout the facility, unless separate safeguards are approved.

For example, 16.1.6.2 of NFPA *101* requires smoke partitions in new day-care centers if clients are 30 months old or younger. If any client in a facility is 30 months old or younger, the floors of the building occupied by that client must be provided with smoke partitions. A portion of the facility separated from that occupied by a client who is 30 months old or younger is not required to have smoke partitions. A separated fire area is usually constructed with walls that have a fire resistance rating of 2 hours, as required by Table 6.1.14.4.1(a) or Table 6.1.14.4.1(b), or 1 hour where sprinklers are provided.

Paragraph 20.3.1.3 has been updated for the 2018 edition of the *Code* to expand current *Code* provisions allowing some short-term incidental day-care use, beyond just those child care services at places of worship, to not be classified as a day-care occupancy and thereby not required to apply the provisions of Chapter 16 and Chapter 17 of NFPA *101*. The parents of the clients of the day-care services would be among those attending the activity; they and others at the facility would be expected to assist the day-care staff with any necessary evacuation. The requirements of Chapters 16 and 17 of NFPA *101*, therefore, do not apply under such circumstances. On the other hand, if standalone day-care operations are conducted in the same building while the short-term activities are not being conducted — such as during the work week — the day-care provisions of Chapters 16 and 17 would apply. New A.20.3.1.3 assists in providing examples of those day-care uses that would not be considered a day-care occupancy but rather would fall under the requirements of the predominant occupancy of the building. Some of the areas intended to utilize the provisions of 20.3.1.3 include, but are not limited to, rooms in places of worship that provide care or supervision during religious services, rooms used as temporary care within a health club or recreation club and while parents are located in the same facility, and rooms used for temporary child care during events such as court hearings, medical appointments, library activities, or other similar circumstances.

20.3.1.4 General. Occupancies that include preschools, kindergartens, and other schools whose purpose is primarily educational for children 24 months of age or older, even though the children who attend such schools are of preschool age, shall comply with the provisions of Chapter 14 or Chapter 15 of NFPA *101*, as applicable. [***101:***16.1.2.1;***101:***17.1.2.1]

20.3.1.5 Adult Day-Care Occupancies.

20.3.1.5.1 Adult day-care occupancies shall include any building or portion thereof used for less than 24 hours per day to house more than three adults requiring care, maintenance, and supervision by other than their relative(s). [***101:***16.1.2.2.1; ***101:***17.1.2.2.1]

20.3.1.5.2 Clients in adult day-care occupancies shall be ambulatory or semiambulatory and shall not be bedridden. [***101:***16.1.2.2.2; ***101:***17.1.2.2.2]

20.3.1.5.3 Clients in adult day-care occupancies shall not exhibit behavior that is harmful to themselves or to others. [***101:***16.1.2.2.3; ***101:***17.1.2.2.3]

The specific reference to an adult day-care occupancy in 20.3.1.5 acknowledges that more and more senior citizens are being cared for in day-care centers similar to child day-care centers. The definition of an adult day-care occupancy includes the characteristics of clients who might be cared for in this type of occupancy. Essentially, the capabilities of adult day-care clients clarify that these occupancies are not nursing homes or old-age homes but occupancies used by adults who are capable of self-preservation but who are in need of limited attendance, supervision, or observation.

Earlier editions of the *Code* included several cues for identifying adults who meet the criteria of adult day-care clients as described in the preceding paragraph. However, to avoid the implication that medical training is necessary for assessing such adults, these cues were removed from the *Code*. It might be appropriate, however, to use some of the following guidelines from previous editions to determine the acceptability of a client for adult day care:

1. The client does not require medical injections from staff but might require the administration of oral medication by staff when and as prescribed by a licensed medical examiner.
2. The client might require limited supervision, attendance, or observation.
3. The client exhibits acceptable behavior (not harmful to self or others).

20.3.2 General Requirements.

20.3.2.1 Unvented fuel-fired heating equipment, other than gas space heaters in compliance with NFPA 54/ANSI Z223.1, *National Fuel Gas Code*, shall be prohibited. [***101:***16.5.2.2; ***101:***17.5.2.2]

The interest of reasonable life safety is not served by permitting the use of unvented fuel-fired equipment in buildings occupied by day-care center clients. Thus, 20.3.2.1 prohibits such equipment, with the exception of a special form of gas space heater that can be used safely.

20.3.2.2* Door Latches. Every door latch to closets, storage areas, kitchens, and other similar spaces or areas shall be such that clients can open the door from inside the space or area. [***101:***16.2.2.2.4; ***101:***17.2.2.2.4]

A.20.3.2.2 The purpose of this requirement is to prevent arrangements whereby a client can be trapped in a space or area. It is intended that this provision be broadly interpreted by the AHJ to include equipment such as refrigerators and freezers. [***101:***A.16.2.2.2.4; ***101:***A.17.2.2.2.4]

20.3.2.3 Bathroom Doors. Every bathroom door lock shall be designed to allow opening of the locked door from the outside by an opening device that shall be readily accessible to the staff. [***101:***16.2.2.2.5; ***101:***17.2.2.2.5]

20.3.2.4 Flexible Plan and Open Plan Buildings.

20.3.2.4.1 In new day-care occupancies, flexible plan and open plan buildings shall comply with the requirements of 20.3.2.4 as modified by 20.3.2.4.3 through 20.3.2.4.6. [***101:***16.4.3.1]

20.3.2.4.2 In existing day-care occupancies, flexible plan and open plan buildings shall comply with the requirements of 20.3.2.4 as modified by 20.3.2.4.3 and 20.3.2.4.4. [***101:***17.4.3.1]

20.3.2.4.3 Flexible plan buildings shall be permitted to have walls and partitions rearranged periodically only if revised plans or diagrams have been approved by the AHJ. [***101:***16.4.3.2; ***101:***17.4.3.2]

20.3.2.4.4 Flexible plan buildings shall be evaluated while all folding walls are extended and in use as well as when they are in the retracted position. [***101:***16.4.3.3; ***101:***17.4.3.3]

20.3.2.4.5 Each room occupied by more than 300 persons shall have two or more means of egress entering into separate atmospheres. [***101:***16.4.3.4]

20.3.2.4.6 Where three or more means of egress are required from a single room, the number of means of egress permitted to enter into a common atmosphere shall not exceed two. [***101:***16.4.3.5]

20.3.3 Interior Finish.

20.3.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***16.3.3.1; ***101:***17.3.3.1]

20.3.3.2 New Interior Wall and Ceiling Finish. New interior wall and ceiling finish materials complying with Section 12.5 shall be Class A in stairways, corridors, and lobbies; in all other occupied areas, new interior wall and ceiling finish shall be Class A or Class B. [***101:***16.3.3.2]

20.3.3.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be Class A or Class B throughout. [***101:***17.3.3.2]

20.3.3.4 Interior Floor Finish.

20.3.3.4.1 New interior floor finish shall comply with Section 12.5. [***101:***16.3.3.3.1]

20.3.3.4.2 New interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 14.3.6 of NFPA *101* shall be not less than Class II. [***101:***16.3.3.3.2]

20.3.3.4.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***16.3.3.3.3]

20.3.3.4.4 Existing Interior Floor Finish. (Reserved) [***101:***17.3.3.3]

20.3.4 Day-Care Homes.

20.3.4.1 Classification.

20.3.4.1.1 In new day-care homes, the requirements of 20.3.4 shall apply to day-care homes in which more than 3, but not more than 12, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit. *(See also 16.6.1.4 of NFPA 101.)* [***101:***16.6.1.1.2]

20.3.4.1.2* In existing day-care homes, the requirements of Section 17.6 of NFPA *101* shall apply to existing day-care homes in which more than 3, but not more than 12, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit. An existing day-care home shall be permitted the option of meeting the requirements of Section 16.6 of NFPA *101* in lieu of Section 17.6 of NFPA *101*. Any existing day-care home that meets the requirements of Chapter 16 of NFPA *101* shall be judged as meeting the requirements of this chapter. *(See also 17.6.1.4 of NFPA 101.)* [***101:***17.6.1.1.2]

Δ **A.20.3.4.1.2** Day-care homes do not provide for the full-time maintenance of a client. Day-care occupancies that provide a primary place of residence are addressed in other occupancy chapters. *(See Chapters 24 through 33 of NFPA 101.)* [***101:***A.17.6.1.1.2]

20.3.4.1.3 In new day-care homes, where a facility houses more than one age group or one self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care home or building, as appropriate to a given area, unless the area housing such a group is maintained as a separate fire area. [***101:***16.6.1.1.3]

20.3.4.1.4 In existing day-care homes, where a facility houses clients of more than one self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care home or building, as appropriate to a given area, unless the area housing such a group is maintained as a separate fire area. [***101:***17.6.1.1.3]

20.3.4.1.5 Facilities that supervise clients on a temporary basis with a parent or guardian in close proximity shall not be required to meet the provisions of 20.3.4. [***101:***16.6.1.1.4; ***101:***17.6.1.1.4]

20.3.4.1.6 Places of religious worship shall not be required to meet the provisions of 20.3.4 where operating a day-care home while services are being held in the building. [***101:***16.6.1.1.5; ***101:***17.6.1.1.5]

20.3.4.2 Operating Features.

20.3.4.2.1* Emergency Action Plans. Emergency action plans shall be provided in accordance with Section 10.8. [***101:***16.7.1; ***101:***17.7.1]

Δ **A.20.3.4.2.1** The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; adult day-care; care of infants; and day-care occupancies. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators, through the written fire emergency response plan, to issue supplements to these requirements; however, all supplements should be consistent with these requirements. Additionally, it is recommended that fire safety be a part of the educational programs of the occupancy for clients. [***101:***A.16.7.1; ***101:***A.17.7.1]

Fire emergency response plans need to be written and made available to all employees, including temporary or substitute staff, so that all employees know what is expected of them during a fire emergency. The elements needed in the written plan should be identified in coordination with the AHJ. [***101:***A.16.7.1; ***101:***A.17.7.1]

The facility fire emergency response plan might be a module of a facility disaster plan that covers other emergencies. [***101:***A.16.7.1; ***101:***A.17.7.1]

The proper safeguarding of clients during a fire emergency requires prompt and effective response by the facility employees in accordance with the fire emergency response plan. Duties covered under the plan should be assigned by position rather than by employee name. Such assignment ensures that, in the absence of an employee, the duties of the position will be performed by a substitute or temporary employee assigned to the position. Temporary or substitute employees should be instructed in advance regarding their duties under the plan for the position to which they are assigned. [***101:***A.16.7.1; ***101:***A.17.7.1]

Written fire emergency response plans should include, but should not be limited to, information for employees regarding methods and devices available for alerting occupants of a fire emergency. Employees should know how the fire department is to be alerted. Even where automatic systems are expected to alert the fire department, the written plan should provide for backup alerting procedures by staff. Other responses of employees to a fire emergency should include the following:

(1) Removal of clients in immediate danger to areas of safety, as set forth in the plan
(2) Methods of using building features to confine the fire and its by-products to the room or area of origin
(3) Control of actions and behaviors of clients during removal or evacuation activities and at predetermined safe assembly areas

[***101:***A.16.7.1; ***101:***A.17.7.1]

The written plan should state clearly the facility policy regarding the actions staff are to take or not take to extinguish a fire. It should also incorporate the emergency egress and relocation drill procedures set forth in 20.3.4.2.2. [***101:***A.16.7.1; ***101:***A.17.7.1]

For additional guidance on emergency action plans, see *NFPA 1600*. This standard establishes a common set of criteria for disaster management, emergency management, and business continuity programs. [***101:***A.16.7.1; ***101:***A.17.7.1]

20.3.4.2.2 Emergency Egress and Relocation Drills.

20.3.4.2.2.1* Emergency egress and relocation drills shall be conducted in accordance with Section 10.5 and the applicable provisions of 20.3.4.2.2.2. [***101:***16.7.2.1; ***101:***17.7.2.1]

A.20.3.4.2.2.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; day-care occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements. [***101:***A.16.7.2.1; ***101:***A.17.7.2.1]

Δ **20.3.4.2.2.2** Emergency egress and relocation drills shall be conducted as follows:

(1) Not less than one emergency egress and relocation drill shall be conducted every month the facility is in session, unless both of the following criteria are met:
   (a) In climates where the weather is severe, the monthly emergency egress and relocation drills shall be permitted to be deferred.
   (b) The required number of emergency egress and relocation drills shall be conducted, and not less than four shall be conducted before the drills are deferred.
(2) The monthly frequency specified by 20.3.4.2.2.2(1) shall be permitted to be bimonthly in adult day-care centers.
(3) All occupants of the building shall participate in the drill.
(4) One additional emergency egress and relocation drill, other than for day-care occupancies that are open on a year-round basis, shall be required within the first 30 days of operation.

[***101:***16.7.2.2; ***101:***17.7.2.2]

Emergency egress drills for day-care occupancies are essential to ensure an orderly response of staff and clients during a fire. The day-care facility should vary the timing and arrangement of the drills but not the required response, which is orderly evacuation. See also Section 10.5.

Item (2) of 20.3.4.2.2.2 is new to the 2018 edition of the *Code* and permits the monthly drills as required by 20.3.4.2.2.2(1) to be bimonthly (every other month) in adult day-care centers. It can be seen as excessive to require the same frequency of drills for adult facilities as those facilities caring for small children. Adults don't need to be drilled this much nor does adult day-care staff need to be drilled as frequently. A monthly frequency can be overly burdensome on adult day-care operators without a perceived benefit or increase in the level of safety.

20.3.4.2.3 Inspections.

20.3.4.2.3.1 Fire prevention inspections shall be conducted monthly by a trained senior member of the staff, after which a copy of the latest inspection report shall be posted in a conspicuous place in the day-care facility. [***101:***16.7.3.1; ***101:***17.7.3.1]

20.3.4.2.3.2* It shall be the duty of site administrators and staff members to inspect all exit facilities daily to ensure that all stairways, doors, and other exits are in proper condition. [***101:***16.7.3.2; ***101:***17.7.3.2]

A.20.3.4.2.3.2 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building. [***101:***A.16.7.3.2; ***101:***A.17.7.3.2]

20.3.4.2.3.3 Open plan buildings shall require extra surveillance to ensure that exit paths are maintained clear of obstruction and are obvious. [***101:***16.7.3.3; ***101:***17.7.3.3]

20.3.4.2.3.4 Inspection of Door Openings. Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***16.7.3.4; ***101:***17.7.3.4]

Compliance with the requirement of 20.3.4.2.3.2 for daily inspection of the egress system has benefits that far outweigh the time and resources required to conduct such inspections. Staff members are permitted to conduct such inspections because they are typically well acquainted with the building features and operations of the facility.

The door inspection requirements of 20.3.4.2.3.4 apply to specific doors as detailed in 7.2.1.15 of NFPA *101*. Door leaves that get used frequently are more apt to experience wear that adversely affects operability and leads to failure. Door leaves that are infrequently used might be misaligned within their frames so as to be difficult to open within the operating forces requirements of 14.5.1.5. The door inspection and testing criteria of 7.2.1.15 of NFPA *101* are intended to help identify problems with door openings and ensure that such problems are remedied.

20.3.4.2.3.5 Furnishings and Decorations.

20.3.4.2.3.5.1 Draperies, curtains, and other similar furnishings and decorations in day-care occupancies, other than in day-care homes, shall be in accordance with the provisions of 12.6.2. [***101:***16.7.4.1; ***101:***17.7.4.1]

Δ **20.3.4.2.3.5.2** Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by one of the following:

(1) This requirement shall not apply to corridors protected by an automatic sprinkler system in accordance with Section 13.3.
(2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with Section 13.7.
(3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

[***101:***16.7.4.2; ***101:***17.7.4.2]

See the commentary following 20.2.4.4.2.

20.3.4.2.3.5.3 Artwork and teaching materials shall be permitted to be attached directly to the walls in accordance with the following:

(1) In new day-care homes, the artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***16.7.4.3(1)]
(2) In existing day-care homes, the artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***17.7.4.3(1)]
(3) In new day-care homes, the artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3. [***101:***16.7.4.3(2)]
(4) In existing day-care homes, the artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved automatic sprinkler system in accordance with Section 13.3. [***101:***17.7.4.3(2)]

It is advantageous not only to limit the quantity of artwork displayed but also to avoid placing such materials near a room's exit access doors. Because the combustibility of the artwork cannot be effectively controlled, the quantity, in terms of the percentage of wall area covered, is regulated to avoid creating a continuous combustible surface that will spread flame across the room. If the building is protected throughout by automatic sprinklers, the percentage of wall area permitted to be covered with artwork and teaching materials is increased to 50 percent. See also the commentary following 20.2.4.4.3.

20.3.4.2.3.5.4 The provision of 12.6.3 for cigarette ignition resistance of newly introduced upholstered furniture and mattresses shall not apply to day-care homes. [***101:***16.7.4.4; ***101:***17.7.4.4]

20.3.4.2.3.6* Day-Care Staff. Adequate adult staff shall be on duty and alert at all times where clients are present. [***101:***16.7.5; ***101:***17.7.5]

A.20.3.4.2.3.6 It is the intent that the requirement for adequate adult staff to be awake at all times when clients are present be applied to family day-care and group day-care homes that are operated at night, as well as day-care occupancies. [***101:***A.16.7.5; ***101:***A.17.7.5]

N **20.3.4.2.3.7 Integrated Fire Protection Systems.** In new day care occupancies, integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***16.7.6]

20.4 Health Care Occupancies

Life safety in health care occupancies is so encompassing that it includes nearly the entire gamut of systems, options, and features addressed in the core chapters of NFPA *101*. Unlike most other buildings and use groups addressed by the *Code*, the least desirable emergency action in a health care occupancy is the wholesale relocation or evacuation of patients. For that reason, a defend-in-place strategy is used, whereby patients are relocated to unaffected smoke compartments in the event of a fire.

The defend-in-place strategy is implemented using a total concept approach. As detailed in 18.1.1.3 and 19.1.1.3 of NFPA *101*, the total concept approach provides an assortment of features that are deemed necessary to avoid the movement of patients to the outside during a fire. Of course, those patients who might be perilously close to the effects of the fire are given a range of protection features, such as being moved to an adjacent smoke compartment on the same floor. Exhibit 20.8 shows cross-corridor smoke barrier doors that, when closed, complete the continuity of the smoke barrier, separating one smoke compartment from the adjacent smoke compartment.

Requirements for allowable building construction types, sprinklers, alarm and detection systems, and staff training work in harmony to help ensure that patients can be safely and adequately protected, regardless of where a fire starts.

Staff action is an integral part of the life safety features required in a health care facility. The proper response from staff in terms of availability, actions, and management of a fire can readily influence the outcome of a fire. Health care facility staff members are charged with the responsibility of preserving the safety of their charges, whether that involves informing patients who are not in jeopardy from the fire or helping to relocate those who are.

Staff training, coupled with the traditional built-in systems and features (e.g., construction; compartmentation; interior finish; alarm, detection, and sprinkler systems; and control of contents and furnishings), provides one of the safest environments for one of the most vulnerable population groups addressed by the *Code*.

The health care occupancy environment continues to change as new technology is implemented, especially in

Exhibit 20.8

Cross-corridor smoke barrier doors, which are part of the defend-in-place protection strategy.

hospitals where patient information privacy requirements have made computer screens, mounted on corridor walls and visible to passersby, obsolete. Computers on wheels accompany staff on most interactions with patients. The computers on wheels, when not in use, present challenges to maintaining the corridor clear width required by 18.2.3 and 19.2.3 of NFPA *101*. Exhibit 20.9 shows the ubiquitous computer on wheels.

Health concerns have led to a ban on smoking in health care occupancy buildings and in proximate outdoor areas. Fires caused by smoldering cigarettes trapped in dirty linen were common in years past. Similar incidents are rare today. Exhibit 20.10 shows an outdoor sign, at the main entrance of a hospital, reminding visitors of the smoking ban.

Exhibit 20.9

Computer on wheels.

Exhibit 20.10

Outdoor sign at main entrance of a hospital declaring area to be smoke free.

20.4.1 Application. New and existing health care occupancies shall comply with Section 20.4, NFPA *101*, and NFPA 99.

Health care occupancies are those facilities used on an inpatient basis for the medical care or treatment of four or more persons suffering from physical or mental illness, disease, or infirmity and for the care of infants, convalescents, or infirm aged persons. The health care occupancies addressed in Section 20.4 include the following:

1. Hospitals
2. Nursing homes
3. Limited care facilities

Hospitals, nursing homes, and limited care facilities provide sleeping facilities for occupants incapable of self-preservation due to age, physical or mental disabilities, or security measures not under their control.

Ambulatory health care facilities differ from health care occupancies in that they provide health care services on an outpatient basis; they are addressed separately in Section 20.6.

20.4.2* Operating Features.

A.20.4.2 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside, or even their disturbance caused by moving, is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable. [***101:***A.18.7; ***101:***A.19.7]

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum. [***101:***A.18.7; ***101:***A.19.7]

20.4.2.1 Evacuation and Relocation Plan and Fire Drills.

20.4.2.1.1 The administration of every health care occupancy shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for their evacuation from the building when necessary. [***101:***18.7.1.1; ***101:***19.7.1.1]

20.4.2.1.2 All employees shall be periodically instructed and kept informed with respect to their duties under the plan required by 20.4.2.1.1. [***101:***18.7.1.2; ***101:***19.7.1.2]

20.4.2.1.3 A copy of the plan required by 20.4.2.1.1 shall be readily available at all times in the telephone operator's location or at the security center. [***101:***18.7.1.3; ***101:***19.7.1.3]

20.4.2.1.4 The provisions of Section 10.5 and 20.4.2.1.2 through 20.4.2.2.3 shall apply.

20.4.2.1.5* Fire drills in health care occupancies shall include the transmission of a fire alarm signal and simulation of emergency fire conditions. [***101:***18.7.1.4; ***101:***19.7.1.4]

A.20.4.2.1.5 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency action plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period. [***101:***A.18.7.1.4; ***101:***A.19.7.1.4]

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs. [***101:***A.18.7.1.4; ***101:***A.19.7.1.4]

20.4.2.1.6 Infirm or bedridden patients shall not be required to be moved during drills to safe areas or to the exterior of the building. [***101:***18.7.1.5; ***101:***19.7.1.5]

20.4.2.1.7 Drills shall be conducted quarterly on each shift to familiarize facility personnel (nurses, interns, maintenance engineers, and administrative staff) with the signals and emergency action required under varied conditions. [***101:***18.7.1.6; ***101:***19.7.1.6]

20.4.2.1.8 When drills are conducted between 9:00 p.m. (2100 hours) and 6:00 a.m. (0600 hours), a coded announcement shall be permitted to be used instead of audible alarms. [***101:***18.7.1.7; ***101:***19.7.1.7]

20.4.2.1.9 Employees of health care occupancies shall be instructed in life safety procedures and devices. [***101:***18.7.1.8; ***101:***19.7.1.8]

The life safety provisions applicable to health care occupancies involve more than fixed building features and systems. Life safety in this defend-in-place occupancy relies heavily on staff readiness and action. The evacuation and relocation plan and fire drill provisions of 20.4.2.1 provide the foundation for carrying out the needed staff duties, as detailed in 20.4.2.2.

The former requirement for patient beds to be on wheels or casters was deleted from NFPA *101* in 1991. Ordinary practice in health care occupancies is to move patients through the hospital on narrow beds, on gurneys, on carts, or in wheelchairs. The furniture in patient rooms — chairs, nightstands, food trays/tables, and medical equipment — must be moved out of the way to allow patient beds to be turned and moved out of the room. Moving patients in this way requires extra staff time that is usually unavailable during a fire. Emphasis should be placed on the quick movement of patients who are in the room of fire origin, as well as others who are directly exposed to the fire. Patient movement in fire emergencies is often achieved by dragging occupants on bedding, as opposed to moving beds.

20.4.2.2 Procedure in Case of Fire.

20.4.2.2.1* Protection of Patients.

A.20.4.2.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The recommendations that follow, however, contain many of the elements that should be considered and adapted, as appropriate, to the individual facility. [***101:***A.18.7.2.1; ***101:***A.19.7.2.1]

Upon discovery of fire, personnel should immediately take the following action:

(1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase, which provides for both the immediate aid of any endangered person and the transmission of an alarm.
(2) Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.
(3) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
(4) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
(5) The telephone operator should determine the location of the fire as indicated by the audible signal.
(6) In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
(7) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system and should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
(8) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone, and the operator should then transmit this information to the fire department and alert the building occupants.

[***101:***A.18.7.2.1; ***101:***A.19.7.2.1]

20.4.2.2.1.1 For health care occupancies, the proper protection of patients shall require the prompt and effective response of health care personnel. [***101:***18.7.2.1.1; ***101:***19.7.2.1.1]

Δ **20.4.2.2.1.2** The basic response required of staff shall include the following:

(1) Removal of all occupants directly involved with the fire emergency
(2) Transmission of an appropriate fire alarm signal to warn other building occupants and summon staff
(3) Confinement of the effects of the fire by closing doors to isolate the fire area
(4) Relocation of patients as detailed in the health care occupancy's fire safety plan

[***101:***18.7.2.1.2; ***101:***19.7.2.1.2]

20.4.2.2.2 Fire Safety Plan. A written health care occupancy fire safety plan shall provide for all of the following:

(1) Use of alarms
(2) Transmission of alarms to fire department
(3) Emergency phone call to fire department
(4) Response to alarms

(5) Isolation of fire
(6) Evacuation of immediate area
(7) Evacuation of smoke compartment
(8) Preparation of floors and building for evacuation
(9) Extinguishment of fire
(10) Location and operation of doors disguised with murals as permitted by 18.2.2.2.7 and 19.2.2.2.7 of NFPA *101*.

[***101:***18.7.2.2; ***101:***19.7.2.2]

20.4.2.2.3 Staff Response.

20.4.2.2.3.1 All health care occupancy personnel shall be instructed in the use of and response to fire alarms. [***101:***18.7.2.3.1; ***101:***9.7.2.3.1]

Δ **20.4.2.2.3.2** All health care occupancy personnel shall be instructed in the use of the code phrase to ensure transmission of an alarm under the following conditions:

(1) When the individual who discovers a fire must immediately go to the aid of an endangered person
(2) During a malfunction of the building fire alarm system

[***101:***18.7.2.3.2; ***101:***19.7.2.3.2]

20.4.2.2.3.3 Personnel hearing the code announced shall first activate the building fire alarm using the nearest manual fire alarm box and then shall execute immediately their duties as outlined in the fire safety plan. [***101:***18.7.2.3.3; ***101:***19.7.2.3.3]

In addition to the requirements of 20.4.2.2, evacuation plans should stress that the doors of as many patient rooms as possible be closed to block smoke spreading from a fire and, if possible, to confine the fire in a room. This single action taken by the staff (i.e., manually closing the doors) achieves the level of safety to life mandated by the *Code* in Section 20.4 and Chapters 18 and 19 of NFPA *101*.

In many fatal fires in health care facilities, staff either did not close doors or someone reopened them; the fire spread was sizable, and the loss of life was high. Emphasis must be placed on training staff to sound an alarm, to rescue patients (as needed), and then to close all doors. The closing of doors historically has had the most significant effect on limiting the spread of fire and smoke.

20.4.2.3 Maintenance of Means of Egress.

20.4.2.3.1 Proper maintenance shall be provided to ensure the dependability of the method of evacuation selected. [***101:***18.7.3.1; ***101:***19.7.3.1]

20.4.2.3.2 Health care occupancies that find it necessary to lock means of egress doors shall, at all times, maintain an adequate staff qualified to release locks and direct occupants from the immediate danger area to a place of safety in case of fire or other emergency. [***101:***18.7.3.2; ***101:***19.7.3.2]

20.4.2.3.3* Where required by the AHJ, a floor plan shall be provided to indicate the location of all required means of egress corridors in smoke compartments having spaces not separated from the corridor by partitions. [***101:***18.7.3.3; ***101:***19.7.3.3]

A.20.4.2.3.3 The purpose of this requirement is to provide a means for building designers, occupants, and operators to clearly designate approved egress corridors that can be identified even though physical or other obvious barriers might not be present to indicate their location. Floor plans used to satisfy this requirement might incorporate more than one function and more than one smoke compartment of the building, provided egress corridors are clearly identified where no fixed barriers are present. Such plans should be accessible to the AHJ but should not be required to be posted. [***101:***A.18.7.3.3; ***101:***A.19.7.3.3]

Δ **20.4.2.4* Smoking.** Smoking regulations shall be adopted and shall include not less than the following provisions:

(1) Smoking shall be prohibited in any room, ward, or individual enclosed space where flammable liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and such areas shall be posted with signs that read NO SMOKING or shall be posted with the international symbol for no smoking.
(2) In health care occupancies where smoking is prohibited and signs are prominently placed at all major entrances, secondary signs with language that prohibits smoking shall not be required.
(3) Smoking by patients classified as not responsible shall be prohibited.
(4) The requirement of 20.4.2.4(3) shall not apply where the patient is under direct supervision.
(5) Ashtrays of noncombustible material and safe design shall be provided in all areas where smoking is permitted.
(6) Metal containers with self-closing cover devices into which ashtrays can be emptied shall be readily available to all areas where smoking is permitted.

[***101:***18.7.4; ***101:***19.7.4]

A.20.4.2.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management. [***101:***A.18.7.4; ***101:***A.19.7.4]

The provision of 20.4.2.4(1), related to areas where smoking is prohibited, includes the words "or individual enclosed space." The words help to clarify that smoking is to be regulated on a space-by-space basis. For example, smoking is required to be prohibited from a room where flammable liquids are stored, but is not required to be prohibited from the other rooms within the same smoke compartment where those rooms do not meet the criteria of 20.4.2.4(1) for the prohibition of smoking. The issue is almost moot in that smoking is prohibited widely in and near health care occupancy buildings.

See Section 10.9 for additional information on smoking prohibitions.

20.4.2.5 Furnishings, Mattresses, and Decorations.

20.4.2.5.1* Draperies, curtains, and other loosely hanging fabrics and films serving as furnishings or decorations in health care occupancies shall be in accordance with the provisions of 12.6.2 *(see 18.3.5.10 or 19.3.5.10 of* NFPA *101)*, and the following also shall apply:

(1) Such curtains shall include cubicle curtains.
(2) Such curtains shall not include curtains at showers and baths.
(3) Such draperies and curtains shall not include draperies and curtains at windows in patient sleeping rooms in sprinklered smoke compartments.
(4) Such draperies and curtains shall not include draperies and curtains in other rooms or areas where the draperies and curtains comply with all of the following:
  (a) Individual drapery or curtain panel area does not exceed 48 ft^2 (4.5 m^2).
  (b) Total area of drapery and curtain panels per room or area does not exceed 20 percent of the aggregate area of the wall on which they are located.
  (c) Smoke compartment in which draperies or curtains are located is sprinklered in accordance with 13.3.2.12.

[***101:***19.7.5.1]

A.20.4.2.5.1 In addition to the provisions of 12.6.2, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13. [***101:***A.18.7.5.1; ***101:***A.19.7.5.1]

20.4.2.5.2 Newly introduced upholstered furniture within health care occupancies shall comply with one of the following provisions, unless otherwise provided in 20.4.2.5.3:

(1) The furniture shall meet the criteria specified in 12.6.3.1 and 12.6.3.2.1.
(2) The furniture shall be in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13.

[***101:***18.7.5.2; ***101:***19.7.5.2]

20.4.2.5.3 The requirements of 20.4.2.5.2, 12.6.3.1, and 12.6.3.2.1 shall not apply to upholstered furniture belonging to the patient in sleeping rooms of existing nursing homes where the following criteria are met:

(1) A smoke detector shall be installed where the patient sleeping room is not protected by automatic sprinklers.
(2) Battery-powered single-station smoke detectors shall be permitted.

[***101:***19.7.5.3]

20.4.2.5.4 Newly introduced mattresses within health care occupancies shall comply with one of the following provisions, unless otherwise provided in 20.4.2.5.5:

(1) The mattresses shall meet the criteria specified in 12.6.3.2 and 12.6.3.2.2.
(2) The mattresses shall be in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13.

[***101:***18.7.5.4; ***101:***19.7.5.4]

20.4.2.5.5 The requirements of 12.6.3.2, 12.6.3.2.2, and 20.4.2.5.4 shall not apply to mattresses belonging to the patient in sleeping rooms of existing nursing homes where the following criteria are met:

(1) A smoke detector shall be installed where the patient sleeping room is not protected by automatic sprinklers.
(2) Battery-powered single-station smoke detectors shall be permitted.

[***101:***19.7.5.5]

Δ **20.4.2.5.6** Combustible decorations shall be prohibited in any health care occupancy, unless one of the following criteria is met:

(1) They are flame-retardant or are treated with approved fire-retardant coating that is listed and labeled for application to the material to which it is applied.
(2)* The decorations meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701.

A.20.4.2.5.6(2) The user should verify that the products meet the referenced test methods of NFPA 701, and not the small-scale test procedure that was previously eliminated from NFPA 701. [***101:***A.18.7.5.6(2); ***101:***A.19.7.5.6(2)]

(3) The decorations exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source.
(4)* The decorations, such as photographs, paintings, and other art, are attached directly to the walls, ceiling, and non-fire-rated doors in accordance with the following:
  (a) Decorations on non-fire-rated doors do not interfere with the operation or any required latching of the door and do not exceed the area limitations of 20.4.2.5.6(b), (c), or (d).
  (b) Decorations do not exceed 20 percent of the wall, ceiling, and door areas inside any room or space of a smoke compartment that is not protected throughout by an approved automatic sprinkler system in accordance with Section 13.3.
  (c) Decorations do not exceed 30 percent of the wall, ceiling, and door areas inside any room or space of a smoke compartment that is protected throughout by an approved supervised automatic sprinkler system in accordance with Section 13.3.
  (d) Decorations do not exceed 50 percent of the wall, ceiling, and door areas inside patient sleeping rooms having a capacity not exceeding four persons, in a smoke compartment that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 13.3.

A.20.4.2.5.6(4) The percentage of decorations should be measured against the area of any wall or ceiling, not the aggregate total of walls, ceilings, and doors. The door is considered part of the wall. The decorations must be located such that they do not interfere with the operation of any door, sprinkler, smoke detector, or any other life safety equipment. Other art might include hanging objects or three-dimensional items. [***101:***A.18.7.5.6(4); ***101:***A.19.7.5.6(4)]

(5) In existing health care occupancies, they are decorations, such as photographs or paintings, in such limited quantities that a hazard of fire development or spread is not present.

[***101:***18.7.5.6; ***101:***19.7.5.6]

The provision of 20.4.2.5.1(4) offers some leniency from the fabric testing requirement for small drapery or curtain panels.

Cigarette ignition–resistance testing and rate of heat release testing are required by 20.4.2.5.2 and 20.4.2.5.4 for newly introduced upholstered furniture and newly introduced mattresses in health care occupancies, unless the building is fully sprinklered. However, these requirements would seldom apply in new health care occupancies, because 13.3.2.11.1 requires new health care occupancies to be sprinklered. Unlike new health care occupancies, which are required to be sprinklered, many existing facilities are not sprinklered. Yet government regulations require that patients be permitted to take their own furniture with them to a nursing home, and such movement of existing furniture into the facility mandates the requirement that applies to newly introduced upholstered furniture and newly introduced mattresses. Paragraphs 20.4.2.5.3 and 20.4.2.5.5 offer nonsprinklered existing health care facilities another option — providing smoke detection within the patient room. If early warning is provided to staff, then an incipient-stage fire might be extinguished manually almost as quickly as would occur automatically in a room that is sprinklered.

The provisions of 20.4.2.5.6 permit furnishings that help to make the health care occupancy setting more homelike, especially for nursing home residents. Exhibit 20.11 shows limited decorations on the door to a nursing home resident's room. Note the furniture and furnishings that the resident has interspersed among the institutional-like furniture provided by the facility.

Exhibit 20.11

Limited decorations on nursing home resident's room door.

Δ **20.4.2.5.7** Soiled linen or trash collection receptacles shall not exceed 32 gal (121 L) in capacity and shall meet the following requirements:

(1) The average density of container capacity in a room or space shall not exceed 0.5 gal/ft^2 (20.4 L/m^2).
(2) Mobile soiled linen or trash collection receptacles with capacities greater than 32 gal (121 L) shall be located in a room protected as a hazardous area when not attended.
(3) Container size and density shall not be limited in hazardous areas.

[***101:***18.7.5.7.1; ***101:***19.7.5.7.1]

Δ **20.4.2.5.8*** Containers used solely for recycling clean waste or for patient records awaiting destruction shall be permitted to be excluded from the limitations of 20.4.2.5.7 where all the following conditions are met:

(1) Each container is limited to a capacity of 96 gal (363 L) except as permitted by 20.4.2.5.8(2) or (3).
(2)* Containers with capacities greater than 96 gal (363 L) shall be located in a room protected as a hazardous area when not attended.
(3) Container size shall not be limited in hazardous areas.
(4) Containers for combustibles shall be labeled and listed as meeting the requirements of FM Approval 6921, *Approval Standard for Containers for Combustible Waste*; however, such testing, listing, and labeling shall not be limited to FM Approvals.

[***101:***18.7.5.7.2; ***101:***19.7.5.7.2]

A.20.4.2.5.8 It is the intent that this provision allows recycling for bottles, cans, paper and similar clean items to use larger containers or have several adjacent containers and not be restricted to hazardous areas. Containers for medical records waiting shredding are often larger than 32 gallons. These containers are not to be included in the calculations and limitations of 20.4.2.5.7. There is no limit on the number of these containers as the FM Standard assures that the fire will not spread out of the container.

A.20.4.2.5.8(2) See 20.4.2.5.7(3).

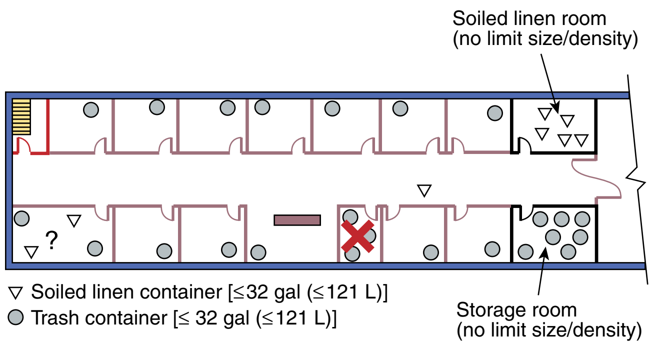
Paragraph 20.4.2.5.7 establishes maximum trash container sizes and placement densities permitted within a room. For the 2018 edition of the *Code*, the criterion that a capacity of 32 gal (121 L) not be exceeded within any 64 ft^2 (6 m^2) area, was deleted. The effect is, for example, that two 32 gal (121 L) containers can be placed side-by-side in a 128 ft^2 (12 m^2) area. Containers larger than those specified or grouped containers exceeding the density per room criterion present a hazard greater than that associated with the normal furnishing of an ambulatory health care center room.

Large, mobile soiled linen or trash receptacles can be moved along the corridor as collections occur but must be attended by staff. If housekeeping staff, for example, must leave the area, the container must be stored in a room designed and maintained as a hazardous area in accordance with 18/19.3.2.1 of NFPA *101*. Exhibit 20.12 shows an aggregation of wheeled trash bins in a

Exhibit 20.12

Wheeled trash bins in room protected as hazardous area.

Exhibit 20.13



Allowable soiled linen or trash collection receptacles.

room protected as a hazardous area. Receptacles positioned at nurses' stations are not to be considered as being attended. Exhibit 20.13 illustrates the requirements of 20.4.2.5.7.

The provisions of 20.4.2.5.8 recognize the need for secure disposal of clean waste, such as paper, that might include patient information. Such waste is typically aggregated in containers larger than the 32 gal (121 L) limitation imposed by 20.4.2.5.7, since it might not be feasible to have such materials removed and shredded as frequently as would be necessitated if smaller containers were used. The maximum 96 gal (363 L) container presents little fire challenge, because the container has been tested for fire performance. The larger clean waste containers typically are outfitted with a tight-fitting lid and narrow slot in order to pass the required fire testing. Exhibit 20.14 illustrates a maximum 96 gal (363 L) container meeting the criteria of 20.4.2.5.8.

Exhibit 20.14

Clean trash or recycling container meeting the requirements of 20.4.2.5.8.

20.4.2.5.9 The provisions of 19.2.1.1 through 19.2.1.2 applicable to soiled linen and trash receptacles shall not apply.

Δ **20.4.2.6 Portable Space-Heating Devices.** Portable space-heating devices shall be prohibited in all health care occupancies, unless both of the following criteria are met:

(1) Such devices are permitted to be used only in nonsleeping staff and employee areas.
(2) The heating elements of such devices do not exceed 212°F (100°C).

[***101:***18.7.8; ***101:***19.7.8]

Δ **20.4.2.7 Integrated Fire Protection Systems.** Integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***18.7.10, 19.7.10]

The provisions of 20.4.2.7 are new to the 2018 edition of the *Code*. For new health care occupancies, integrated fire protection systems must be tested in accordance with 20.4.2.7. The concept is one in which, if two or more fire protection or life safety systems are integrated, the integrated system must be tested to verify the proper operation and function of such system in accordance with NFPA 4. Users should note that for existing health care occupancies, the requirement for compliance with NFPA 4 in accordance with Section 13.1.3 applies only to integrated systems in high-rise buildings, as stated in NFPA *101* Section 19.7.10, which is not reflected by the language of 20.4.2.7.

20.4.3 Interior Finish.

20.4.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***18.3.3.1; ***101:***19.3.3.1]

20.4.3.2 New Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be permitted throughout if Class A, except as indicated in 20.4.3.2.1 or 20.4.3.2.2. [***101:***18.3.3.2]

20.4.3.2.1 New walls and ceilings shall be permitted to have Class A or Class B interior finish in individual rooms having a capacity not exceeding four persons. [***101:***18.3.3.2.1]

20.4.3.2.2 New corridor wall finish not exceeding 48 in. (1220 mm) in height that is restricted to the lower half of the wall shall be permitted to be Class A or Class B. [***101:***18.3.3.2.2]

20.4.3.2.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be permitted to be Class A or Class B. [***101:***19.3.3.2]

20.4.3.3 Interior Floor Finish.

20.4.3.3.1 New interior floor finish shall comply with Section 12.5. [***101:***18.3.3.3.1]

20.4.3.3.2 New interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 18.3.6 of NFPA *101* shall be Class I or Class II. [***101:***18.3.3.3.2]

20.4.3.3.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***18.3.3.3.3]

New interior finishes on walls and ceilings are limited to Class A materials, with the exception of small rooms (see 20.4.3.2.1) and the lower portion of corridor walls (see 20.4.3.2.2). However, if the new interior wall and ceiling finish material is installed in a sprinklered smoke compartment (all new health care occupancies are required to be sprinklered by 13.3.2.11.1), the Class A requirement can be relaxed to Class B per the provisions of 12.5.9.1. Existing interior finish materials are permitted to be Class A or Class B without requiring sprinkler protection.

Paragraph 20.4.3.2.1 permits Class B interior wall and ceiling finish materials in rooms with a capacity of four or fewer persons, but, again, the presence of automatic sprinklers would relax this requirement to permit Class C materials. Paragraph 20.4.3.2.2 permits wall finish in corridors to be of Class B materials where located 48 in. (1220 mm) or less above the floor, but, once again, the presence of automatic sprinklers would relax this requirement to permit Class C materials. This provision recognizes fire research from "Flame Spread in Corridors: Effects of Location and Area of Wall Finish" in *Fire Journal* that has shown the finish on the lower half of the wall to be far less significant in its influence on early fire growth than the finish on the upper half. In the case of textile materials on walls or ceilings, 12.5.5.4 would take precedence and require automatic sprinkler protection in conjunction with Class A materials, or such wall and ceiling materials must be proved safe by specialized fire testing.

Existing interior finishes on walls and ceilings are limited solely on the basis of flame spread. Paragraph 12.5.4.3.1 exempts existing interior finishes from the limitations based on smoke development.

Paragraph 12.5.7.1 provides for the application of approved fire-retardant coatings to existing interior finish materials for the purpose of reducing the flame spread characteristics to an acceptable level. Similarly, 12.5.7.2 permits the surfaces of walls, partitions, columns, and ceilings to be finished with factory-applied fire-retardant-coated products. The commentary following 12.5.7.3 offers additional guidance.

It has been shown that floor coverings will not spread a fire until the fire approaches flashover (see A.12.5.8.3 and associated commentary). Automatic sprinklers will activate well in advance of any significant involvement of a floor covering. Paragraph 20.4.3.2 has the effect of regulating new interior floor finish in exit enclosures and exit access corridors only in nonsprinklered areas, since 12.5.9.2 permits the Class II criterion to be reduced to no rating where sprinkler protection is provided. Existing floor finish materials are permitted to continue to be used.

20.4.3.4 Interior Finish (Nonsprinklered Smoke Compartment Rehabilitation).

20.4.3.4.1 General. Interior finish within the modification area shall be in accordance with Section 12.5. [***101:***18.4.4.6.1]

20.4.3.4.2 Interior Wall and Ceiling Finish. Newly installed interior wall and ceiling finish materials complying with Section 12.5 shall be permitted throughout nonsprinklered smoke compartments if the materials are Class A, except as otherwise permitted in 20.4.3.4.2.1 or 20.4.3.4.2.2. [***101:***18.4.4.6.2]

20.4.3.4.2.1 Walls and ceilings shall be permitted to have Class A or Class B interior finish in individual rooms having a capacity not exceeding four persons. [***101:***18.4.4.6.2.1]

20.4.3.4.2.2 Corridor wall finish not exceeding 48 in. (1220 mm) in height and restricted to the lower half of the wall shall be permitted to be Class A or Class B. [***101:***18.4.4.6.2.2]

20.4.3.5 Interior Floor Finish.

20.4.3.5.1 Newly installed interior floor finish shall comply with Section 12.5. [***101:***18.4.4.6.3.1]

20.4.3.5.2 The requirements for newly installed interior floor finish in exit enclosures and corridors not separated from them by walls complying with 19.3.5.7 of NFPA *101* shall be as follows:

(1) Unrestricted in smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.7 of NFPA *101*

(2) Not less than Class I in smoke compartments not protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.7 of NFPA *101*

[***101:***18.4.4.6.3.2]

20.4.3.5.3 Existing Interior Floor Finish. No restrictions shall apply to existing interior floor finish. [***101:***19.3.3.3]

20.5 Residential Board and Care Occupancies

The primary characteristics that differentiate residential board and care occupancies from other residential occupancies is the assumed ability (or lack thereof) of occupants to evacuate the building in the event of a fire or similar emergency and the availability or level of personal care services. The term *personal care*, as defined in 3.3.209, includes assistance with many of the activities of daily living. Personal care services might include assisting residents with bathing and dressing and helping residents with bill payment and similar household maintenance–related tasks. Personal care does not include nursing home–type care; nor does it include medical care.

Prior to the 2003 edition of the *Code*, application of the requirements for both new and existing residential board and care facilities required the determination of the occupants' evacuation capability — that is, the occupants' ability to move, as a group, to a point of safety in the event of a fire. Evacuation capability was broken down into three subclasses — prompt, slow, and impractical. Ongoing evaluation by the AHJ was required to ensure that the facility was not being used outside the limitations of its design (e.g., a facility designed and constructed using the provisions for slow evacuation capability but actually having an impractical evacuation capability). When tasked with the development of provisions for residential board and care facilities to be included in *NFPA 5000®*, *Building Construction and Safety Code®*, the NFPA Technical Committee on Board and Care Facilities recognized that, because a facility's population is expected to change over time, a facility's evacuation capability will likely change over time as well. It was not, then, practical to simply insert the requirements from this *Code* into *NFPA 5000*. As such, the committee modified the requirements for new board and care facilities so as not to depend on the evacuation capability of the occupants of the facility.

For consistency with *NFPA 5000*, the committee also revised the provisions of Chapter 32 of NFPA *101*, which address new facilities, so they no longer depend on the determination of evacuation capability. Chapter 33 of NFPA *101*, which addresses existing facilities, retains the evacuation capability provisions so as to not unnecessarily place existing facilities out of compliance. Since new board and care facilities might have occupants who do not have the ability to evacuate without assistance, they must be designed and constructed to facilitate the defend-in-place occupant protection strategy, much like health care occupancies. To utilize the defend-in-place strategy, the building must be able to withstand the effects of fire for the time necessary to either evacuate the occupants or relocate them to a safe location within the building.

Section 20.5 classifies residential board and care occupancies based on the number of residents. For that purpose, Section 20.5 is subdivided to address requirements for small (16 or fewer residents) and large (more than 16 residents) facilities. As the number of residents put at risk by fire increases, the requirements become more strict.

Of the determinations that must be made to classify a residential board and care occupancy (i.e., availability of personal care, number of residents, and, in the case of existing facilities, evacuation capability), the most difficult is evacuation capability. Evacuation capability is established on the basis of the occupants' (i.e., residents and staff working together) ability to move to a safe location, such as an enclosed exit stair or a point outside the structure. The term *evacuation capability* is defined in 3.3.81 of NFPA *101*; guidance on classifying evacuation capability is provided in A.3.3.81 of NFPA *101*.

Where an existing facility does not comply with the requirements for new facilities in Chapter 32 of NFPA *101*, Chapter 33 of NFPA *101* requires facility management to furnish the AHJ with an evacuation capability determination conducted using a procedure acceptable to the AHJ. If such documentation is not furnished, the evacuation capability is considered, by default, as impractical.

As in the case of other occupancy chapters that address occupants with limited self-preservation capability, Section 20.5 relies on staff intervention and staff support to assist the residents during fire and similar emergencies. It is the responsibility of the staff to understand and implement the emergency plan for the facility. The plan must include a method for familiarizing residents with the procedures to be followed during a fire. Exhibit 20.15 depicts a typical residential board and care occupancy.

Exhibit 20.15

Typical residential board and care occupancy.

20.5.1 Application. New and existing residential board and care occupancies shall comply with Section 20.5 and NFPA *101*.

20.5.2 Operating Features.

20.5.2.1 Emergency Action Plan.

20.5.2.1.1 The administration of every residential board and care facility shall have, in effect and available to all supervisory personnel, written copies of a plan for protecting all persons in the event of fire, for keeping persons in place, for evacuating persons to areas of refuge, and for evacuating persons from the building when necessary. [***101:***32.7.1.1; ***101:***33.7.1.1]

20.5.2.1.2 The emergency action plan shall include special staff response, including the fire protection procedures needed to ensure the safety of any resident, and shall be amended or revised whenever any resident with unusual needs is admitted to the home. [***101:***32.7.1.2; ***101:***33.7.1.2]

20.5.2.1.3 All employees shall be periodically instructed and kept informed with respect to their duties and responsibilities under the plan, and such instruction shall be reviewed by the staff not less than every 2 months. [***101:***32.7.1.3; ***101:***33.7.1.3]

20.5.2.2 Resident Training.

20.5.2.2.1 All residents participating in the emergency action plan shall be trained in the proper actions to be taken in the event of fire. [***101:***32.7.2.1; ***101:***33.7.2.1]

20.5.2.2.2 The training required by 20.5.2.2.1 shall include actions to be taken if the primary escape route is blocked. [***101:***32.7.2.2; ***101:***33.7.2.2]

20.5.2.2.3 If a resident is given rehabilitation or habilitation training, training in fire prevention and the actions to be taken in the event of a fire shall be a part of the training program. [***101:***32.7.2.3; ***101:***33.7.2.3]

20.5.2.2.4 Residents shall be trained to assist each other in case of fire to the extent that their physical and mental abilities permit them to do so without additional personal risk. [***101:***32.7.2.4; ***101:***33.7.2.4]

20.5.2.3 Emergency Egress and Relocation Drills. Emergency egress and relocation drills shall be conducted in accordance with 20.5.2.3.1 through 20.5.2.3.6. [***101:***32.7.3; ***101:***33.7.3]

20.5.2.3.1 Emergency egress and relocation drills shall be conducted not less than six times per year on a bimonthly basis, with not less than two drills conducted during the night when residents are sleeping, as modified by 20.5.2.3.5 and 20.5.2.3.6. [***101:***32.7.3.1; ***101:***33.7.3.1]

20.5.2.3.2 The emergency drills shall be permitted to be announced to the residents in advance. [***101:***32.7.3.2; ***101:***33.7.3.2]

20.5.2.3.3 The drills shall involve the actual evacuation of all residents to an assembly point, as specified in the emergency action plan, and shall provide residents with experience in egressing through all exits and means of escape required by this *Code*. [***101:***32.7.3.3; ***101:***33.7.3.3]

20.5.2.3.4 Exits and means of escape not used in any drill shall not be credited in meeting the requirements of this *Code* for board and care facilities. [***101:***32.7.3.4; ***101:***33.7.3.4]

20.5.2.3.5 Actual exiting from windows shall not be required to comply with 20.5.2.3; opening the window and signaling for help shall be an acceptable alternative. [***101:***32.7.3.5; ***101:***33.7.3.5]

20.5.2.3.6 Residents who cannot meaningfully assist in their own evacuation or who have special health problems shall not be required to actively participate in the drill. Subsection 20.4.2 shall apply in such instances. [***101:***32.7.3.6; ***101:***33.7.3.6]

20.5.2.4 Smoking.

20.5.2.4.1* Smoking regulations shall be adopted by the administration of board and care occupancies. [***101:***32.7.4.1; ***101:***33.7.4.1]

A.20.5.2.4.1 Smoking regulations should include the following:

(1) Smoking should be prohibited in any room, compartment, or area where flammable or combustible liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and the following also should apply:
    (a) Such areas should be posted with signs that read NO SMOKING or the international symbol for no smoking.
    (b) In residential board and care facilities where smoking is totally prohibited and signs so indicating are placed at all major entrances, secondary signs with language that prohibits smoking are not required.
(2) Smoking by residents classified as not responsible with regard to their ability to safely use and dispose of smoking materials should be prohibited.
(3) Where a resident, as specified in A.20.5.2.4.1(2), is under direct supervision by staff or by a person approved by the administration, smoking might be permitted.
(4) Smoking materials should not be provided to residents or maintained by residents without the approval of the administration.
(5) Areas where smoking is permitted should be clearly identified.
(6) Ashtrays of noncombustible material and safe design should be provided and required to be used in all areas where smoking is permitted.
(7) Self-closing cover devices into which ashtrays can be emptied should be made available to all areas where smoking is permitted and should be required to be used.

[***101:***A.32.7.4.1; ***101:***A.33.7.4.1]

20.5.2.4.2 Where smoking is permitted, noncombustible safety-type ashtrays or receptacles shall be provided in convenient locations. [***101:***32.7.4.2; ***101:***33.7.4.2]

20.5.2.5* Furnishings, Bedding, and Decorations.

A.20.5.2.5 The requirements applicable to draperies/curtains, upholstered furniture, and mattresses apply only to new draperies/curtains, new upholstered furniture, and new mattresses. The word *new* means unused, normally via procurement from the marketplace, either by purchase or donation, of items not previously used.

Many board and care facilities allow residents to bring into the board and care home upholstered furniture items from the resident's previous residence. Such an item is not new and, thus, is not regulated. On the other hand, some of the larger board and care homes purchase contract furniture, as is done in hotels. Such new, unused furniture, whether purchased or received as a donation, is regulated by the requirements of 20.5.2.5.2. By federal law, mattresses manufactured and sold within the United States must pass testing per 16 CFR 1632 (FF4-72), *Standard for the Flammability of Mattresses and Mattress Pads*. [***101:***A.32.7.5; ***101:***A.33.7.5]

20.5.2.5.1 New draperies, curtains, and other similar loosely hanging furnishings and decorations in board and care facilities shall comply with 20.5.2.5.1.1 and 20.5.2.5.1.2. [***101:***32.7.5.1; ***101:***33.7.5.1]

20.5.2.5.1.1 New draperies, curtains, and other similar loosely hanging furnishings and decorations in board and care facilities shall be in accordance with the provisions of 12.6.2, unless otherwise permitted by 20.5.2.5.1.2. [***101:***32.7.5.1.1; ***101:***33.7.5.1.1]

20.5.2.5.1.2 In other than common areas, new draperies, curtains, and other similar loosely hanging furnishings and decorations shall not be required to comply with 20.5.2.5.1.1 where the building is protected throughout by an approved automatic sprinkler system installed in accordance with 13.3.2.21.2 for new small facilities, 13.3.2.21.1 for new large facilities, 13.3.2.22.2 for existing small facilities, or 13.3.2.22.1 for existing large facilities. [***101:***32.7.5.1.2; ***101:***33.7.5.1.2]

20.5.2.5.2* New upholstered furniture within board and care facilities shall comply with 20.5.2.5.2.1 or 20.5.2.5.2.2. [***101:***32.7.5.2; ***101:***33.7.5.2]

A.20.5.2.5.2 New upholstered furniture within board and care homes should be tested for rates of heat release in accordance with 12.6.3.2.1. [***101:***A.32.7.5.2; ***101:***A.33.7.5.2]

20.5.2.5.2.1 New upholstered furniture shall be tested in accordance with the provisions of 12.6.3.1(1) and 12.6.3.2.1. [***101:***32.7.5.2.1; ***101:***33.7.5.2.1]

20.5.2.5.2.2 Upholstered furniture belonging to residents in sleeping rooms shall not be required to be tested, provided that a smoke alarm is installed in such rooms; battery-powered single-station smoke alarms shall be permitted in such rooms. [***101:***32.7.5.2.2; ***101:***33.7.5.2.2]

20.5.2.5.2.3* Newly introduced mattresses within board and care facilities shall comply with 20.5.2.5.2.3.1 or 20.5.2.5.2.3.2. [***101:***32.7.5.3; ***101:***33.7.5.3]

A.20.5.2.5.2.3 New mattresses within board and care homes should be tested for rates of heat release in accordance with 12.6.3.2.2. [***101:***A.32.7.5.3; ***101:***A.33.7.5.3]

20.5.2.5.2.3.1 Newly introduced mattresses shall be tested in accordance with the provisions of 12.6.3.2 and 12.6.3.2.2. [***101:***32.7.5.3.1; ***101:***33.7.5.3.1]

20.5.2.5.2.3.2 Mattresses belonging to residents in sleeping rooms shall not be required to be tested, provided that a smoke alarm is installed in such rooms; battery-powered single-station smoke alarms shall be permitted in such rooms. [***101:***32.7.5.3.2; ***101:***33.7.5.3.2]

The provisions of 20.5.2.5 extend the level of life safety provided to a residential board and care facility by further attempting to prevent room flashover. However, rather than impose these requirements retroactively on existing facilities, they apply to newly introduced draperies, curtains, upholstered furniture, and mattresses. The text of A.20.5.2.5 sufficiently details the meaning of the term *new* in this context.

Draperies must be flame resistant in accordance with 12.6.1, unless they are located in other than common areas (e.g., sleeping rooms) of sprinklered facilities (see 20.5.2.5.1.2). Newly introduced upholstered furniture and mattresses must be resistant to cigarette ignition in accordance with 12.6.3. Newly introduced upholstered furniture and mattresses must have limited rates of heat release in accordance with 12.6.2, unless the building is sprinklered. See the commentary on Section 12.6 for additional details on testing requirements for draperies, curtains, upholstered furniture, and mattresses.

20.5.2.5.3 No stove or combustion heater shall be located to block escape in case of fire caused by the malfunction of the stove or heater. [***101:***32.2.5.2.2; ***101:***33.2.5.2.2]

20.5.2.5.4 Unvented fuel-fired heaters shall not be used in any residential board and care facility. [***101:***32.2.5.2.3; ***101:***33.2.5.2.3]

The provision of 20.5.2.5.3 does not require a kitchen containing a stove to be completely separated by smoke partitions, only that the stove be located so that a malfunction does not result in a blockage of the means of escape. If, in the opinion of the AHJ, the location of the stove would cause the means of escape to be blocked in the event of a malfunction, protection of the area as a hazardous area in accordance with NFPA *101* might be appropriate.

The use of typical kerosene portable heaters, as well as other fuel-fired, unvented heaters, is prohibited by 20.5.2.5.4.

20.5.3 Interior Finish.

20.5.3.1 Small Facilities.

20.5.3.1.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***32.2.3.3.1; ***101:***33.2.3.3.1]

20.5.3.1.2 New Interior Wall and Ceiling Finish. New interior wall and ceiling finish materials complying with Section 12.5 shall be Class A, Class B, or Class C. [***101:***32.2.3.3.2]

20.5.3.1.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be as follows:

(1) Class A or Class B in facilities other than those having prompt evacuation capability
(2) Class A, Class B, or Class C in facilities having prompt evacuation capability

[***101:***33.2.3.3.2]

20.5.3.1.4 Interior Floor Finish.

20.5.3.1.4.1 New interior floor finish shall comply with Section 12.5. [***101:***32.2.3.3.3.1]

20.5.3.1.4.2 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***32.2.3.3.3.2]

20.5.3.1.4.3 Existing Interior Floor Finish. (Reserved) [***101:***33.2.3.3.3]

20.5.3.2 Large Facilities.

20.5.3.2.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***32.3.3.3.1; ***101:***33.3.3.3.1]

20.5.3.2.2 New Interior Wall and Ceiling Finish. New interior wall and ceiling finish materials complying with Section 12.5 shall be in accordance with the following:

(1) Exit enclosures — Class A
(2) Lobbies and corridors — Class B
(3) Rooms and enclosed spaces — Class B

[***101:***32.3.3.3.2]

20.5.3.2.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be Class A or Class B. [***101:***33.3.3.3.2]

20.5.3.2.4 Interior Floor Finish.

20.5.3.2.4.1 New interior floor finish shall comply with Section 12.5. [***101:***32.3.3.3.3.1]

20.5.3.2.4.2 New interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 32.3.3.6 of NFPA *101* shall be not less than Class II. [***101:***32.3.3.3.3.2]

20.5.3.2.4.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***32.3.3.3.3.3]

20.5.3.2.4.4 Existing Interior Floor Finish. Existing interior floor finish, other than approved existing floor coverings, shall be Class I or Class II in corridors or exits. [***101:***33.3.3.3.3]

20.5.3.3 Apartment Buildings Housing Board and Care Occupancies.

20.5.3.3.1 New Interior Finish.

20.5.3.3.1.1 The requirements of 20.9.3 shall apply only to the parts of means of egress serving the apartment(s) used as a residential board and care occupancy, as modified by 20.5.3.3.1.2. [***101:***32.4.3.1.1]

20.5.3.3.1.2 If a new board and care occupancy is created in an existing apartment building, the requirements of 31.3.3 of NFPA *101* shall apply to the parts of the means of egress serving the apartment(s) used as a residential board and care occupancy. [***101:***32.4.3.1.2]

20.5.3.3.2 Existing Interior Finish. The requirements of 20.9.3 shall apply only to the parts of means of egress serving the apartment(s) used as a residential board and care occupancy. [***101:***33.4.3.1]

20.6 Ambulatory Health Care Centers

Section 20.6 addresses the needs of occupants of facilities that provide medical treatment on an outpatient basis. The patient treatment is not merely a routine medical visit, such as to a doctor's office, but rather a treatment that renders the patient incapable of self-preservation, a treatment that requires anesthesia that renders the patient incapable of self-preservation, or a treatment for patients who, due to the nature of their injury or illness, are incapable of self-preservation when they arrive at the ambulatory health care facility. Although these descriptions might seem to resemble a situation typically associated with a hospital, the major difference is that an ambulatory health care facility does not provide care for any individual for 24 hours or more. Rather, a patient receives treatment and then leaves the facility. Patients suffering complications that would prevent them from leaving the ambulatory health care facility would typically be transported and admitted to a hospital that provides care on a 24-hour basis. Patients requiring rehabilitation following a procedure or treatment would be admitted to a 24-hour rehabilitation facility.

There is also an important distinction concerning the number of occupants required to constitute classification as an ambulatory health care occupancy — that number being four or more (see the definition of the term *ambulatory health care occupancy* in 3.3.192.1). The Centers for Medicare and Medicaid Services (CMS) play an important role in the government financing of health care services in the United States. CMS applies a stricter definition of an ambulatory health care occupancy than NFPA by requiring surgical centers and some other outpatient services facilities for one or more patients to be classified as an ambulatory health care occupancy. NFPA's four-person criterion applies to all forms of ambulatory health care occupancies.

The provisions of Section 20.6 for ambulatory health care occupancies were drawn from those applicable to hospitals and those applicable to business occupancies. If an outpatient medical facility does not meet the definition of the term *ambulatory health care occupancy*, it generally needs to be classified as, and comply with the requirements for, a business occupancy.

Commentary Table 20.1 differentiates among health care, ambulatory health care, and business occupancies on the basis of the patient load and care provided. Incapability of self-preservation might be the result of the use of general anesthesia, a treatment such as dialysis, or an injury or illness that brings the patient to the ambulatory health care facility for treatment. Based on the information in Commentary Table 20.1, if a dentist administers general anesthesia to not more than three patients simultaneously, the dentist's office would be classified as a business occupancy. If the dentist expands the simultaneous administration of general anesthesia to a fourth patient, the more stringent requirements for ambulatory health care occupancies would apply.

COMMENTARY TABLE 20.1 *Occupancy Classification Comparison*

Factor	Section 20.4 and Chapters 18 and 19 of NFPA 101 Health Care Occupancies	Section 20.6 and Chapters 20 and 21 of NFPA 101 Ambulatory Health Care Occupancies	Section 20.13 and Chapters 38 and 39 of NFPA 101 Business Occupancies
Number of patients rendered incapable of self-preservation	4 or more*,†	4 or more*,†	3 or fewer
Care provided on a 24-hour basis?	Yes	No	No

*Incapability of self-preservation might exist prior to admission and be unrelated to the treatment provided.

†Incapability of self-preservation might not exist prior to admission but be related to the treatment provided.

20.6.1 Application. New and existing ambulatory health care centers shall comply with Section 20.6 and NFPA *101*.

Ambulatory health care facilities exhibit some of the occupancy characteristics of business occupancies and some of the characteristics of health care occupancies. Section 20.6 prescribes a level of life safety from fire that is greater than that typically specified for business occupancies but less than that typically found in hospitals, nursing homes, and limited care facilities.

20.6.2* Operating Features.

A.20.6.2 Ambulatory health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside, or even their disturbance caused by moving, is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable. [***101:***A.20.7; ***101:***A.21.7]

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in ambulatory health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum. [***101:***A.20.7; ***101:***A.21.7]

20.6.2.1 Evacuation and Relocation Plan and Fire Drills.

20.6.2.1.1 The administration of every ambulatory health care facility shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for their evacuation from the building when necessary. [***101:***20.7.1.1; ***101:***21.7.1.2]

20.6.2.1.2 All employees shall be periodically instructed and kept informed with respect to their duties under the plan required by 20.6.2.1.1. [***101:***20.7.1.2; ***101:***21.7.1.2]

20.6.2.1.3 A copy of the plan required by 20.6.2.1.1 shall be readily available at all times when the facility is open. [***101:***20.7.1.3; ***101:***21.7.1.3]

20.6.2.1.4 The provisions of Section 10.6 and 20.6.2.1.5 through 20.6.2.2.3 shall apply.

20.6.2.1.5* Fire drills in ambulatory health care facilities shall include the simulation of emergency fire conditions. [***101:***20.7.1.4; ***101:***21.7.1.4]

A.20.6.2.1.5 Many ambulatory health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors in the vicinity prior to the initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in ambulatory health care facilities are drilled not less than once in each 3-month period. [***101:***A.20.7.1.4; ***101:***A.21.7.1.4]

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs. [***101:***A.20.7.1.4; ***101:***A.21.7.1.4]

20.6.2.1.6 Patients shall not be required to be moved during drills to safe areas or to the exterior of the building. [***101:***20.7.1.5; ***101:***21.7.1.5]

20.6.2.1.7 Drills shall be conducted quarterly on each shift to familiarize facility personnel (including but not limited to nurses, interns, maintenance engineers, and administrative staff) with the emergency action required under varied conditions. [***101:***20.7.1.6; ***101:***21.7.1.6]

20.6.2.1.8 Employees of ambulatory health care facilities shall be instructed in life safety procedures and devices. [***101:***20.7.1.7; ***101:***21.7.1.7]

20.6.2.2 Procedure in Case of Fire.

20.6.2.2.1* Protection of Patients.

A.20.6.2.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The recommendations that follow, however, contain many of the elements that should be considered and adapted, as appropriate, to the individual facility. [***101:***A.20.7.2.1; ***101:***A.21.7.2.1]

Upon discovery of fire, personnel should immediately take the following action:

(1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase, which provides for both the immediate aid of any endangered person and the transmission of an alarm.
(2) Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.
(3) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
(4) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
(5) The telephone operator should determine the location of the fire as indicated by the audible signal.
(6) In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
(7) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system and should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
(8) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone, and the operator should then transmit this information to the fire department and alert the building occupants.

[***101:***A.20.7.2.1; ***101:***A.21.7.2.1]

20.6.2.2.1.1 For ambulatory health care facilities, the proper protection of patients shall require the prompt and effective response of ambulatory health care personnel. [***101:***20.7.2.1.1; ***101:***21.7.2.1.1]

Δ **20.6.2.2.1.2** The basic response required of staff shall include the following:

(1) Removal of all occupants directly involved with the fire emergency
(2) Transmission of an appropriate fire alarm signal to warn other building occupants and summon staff
(3) Confinement of the effects of the fire by closing doors to isolate the fire area
(4) Relocation of patients as detailed in the facility's fire safety plan

[***101:***20.7.2.1.2; ***101:***21.7.2.1.2]

Δ **20.6.2.2.2 Fire Safety Plan.** A written fire safety plan shall provide for all of the following:

(1) Use of alarms
(2) Transmission of alarms to fire department
(3) Response to alarms
(4) Isolation of fire
(5) Evacuation of immediate area
(6) Evacuation of smoke compartment
(7) Preparation of floors and building for evacuation
(8) Extinguishment of fire

[***101:***20.7.2.2; ***101:***21.7.2.2]

The AHJ should require a fire safety plan to be put in place to ensure that the staff of the ambulatory health care occupancy has been trained on their duties. This plan should include occasional review by all staff members.

20.6.2.2.3 Staff Response.

20.6.2.2.3.1 All personnel shall be instructed in the use of and response to fire alarms. [***101:***20.7.2.3.1; ***101:***21.7.2.3.1]

20.6.2.2.3.2 All personnel shall be instructed in the use of the code phrase to ensure transmission of an alarm under either of the following conditions:

(1) When the individual who discovers a fire must immediately go to the aid of an endangered person
(2) During a malfunction of the building fire alarm system

[***101:***20.7.2.3.2; ***101:***21.7.2.3.2]

20.6.2.2.3.3 Personnel hearing the code announced shall first activate the building fire alarm using the nearest fire alarm box and then shall execute immediately their duties as outlined in the fire safety plan. [***101:***20.7.2.3.3; ***101:***21.7.2.3.3]

20.6.2.3 Maintenance of Exits.

20.6.2.3.1 Proper maintenance shall be provided to ensure the dependability of the method of evacuation selected. [***101:***20.7.3.1; ***101:***21.7.3.1]

20.6.2.3.2 Ambulatory health care occupancies that find it necessary to lock exits shall, at all times, maintain an adequate staff qualified to release locks and direct occupants from the immediate danger area to a place of safety in case of fire or other emergency. [***101:***20.7.3.2; ***101:***21.7.3.2]

Δ **20.6.2.4* Smoking.** Smoking regulations shall be adopted and shall include not less than the following provisions:

(1) Smoking shall be prohibited in any room, ward, or compartment where flammable liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and such areas shall be posted with signs that read NO SMOKING or shall be posted with the international symbol for no smoking.
(2) In ambulatory health care facilities where smoking is prohibited and signs are placed at all major entrances, secondary signs with language that prohibits smoking shall not be required.
(3) Smoking by patients classified as not responsible shall be prohibited.
(4) The requirement of 20.6.2.4(3) shall not apply where the patient is under direct supervision.
(5) Ashtrays of noncombustible material and safe design shall be provided in all areas where smoking is permitted.
(6) Metal containers with self-closing cover devices into which ashtrays can be emptied shall be readily available to all areas where smoking is permitted.

[***101:***20.7.4; ***101:***21.7.4]

A.20.6.2.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management. [***101:***A.20.7.4; ***101:***A.21.7.4]

20.6.2.5 Furnishings, Mattresses, and Decorations.

Δ **20.6.2.5.1*** Draperies, curtains, and other loosely hanging fabrics and films serving as furnishings or decorations in ambulatory health care occupancies shall be in accordance with the provisions of 12.6.2, and the following also shall apply:

(1) Such curtains shall include cubicle curtains.
(2) Such curtains shall not include curtains at showers.
[***101:***20.7.5.1; ***101:***21.7.5.1]

A.20.6.2.5.1 In addition to the provisions of 12.6.2, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13. [***101:***A.20.7.5.1; ***101:***A.21.7.5.1]

Δ **20.6.2.5.2** Newly introduced upholstered furniture shall comply with 12.6.3.1 and one of the following provisions:

(1) The furniture shall meet the criteria specified in 12.6.3.2.1.
(2) The furniture shall be in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13.
[***101:***20.7.5.2; ***101:***21.7.5.2]

Δ **20.6.2.5.3** Newly introduced mattresses shall comply with 12.6.3.2 and one of the following provisions:

(1) The mattresses shall meet the criteria specified in 12.6.3.2.2.
(2) The mattresses shall be in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with NFPA 13.
[***101:***20.7.5.3; ***101:***21.7.5.3]

Δ **20.6.2.5.4** Combustible decorations shall be prohibited, unless one of the following criteria is met:

(1) They are flame-retardant.
(2) The decorations meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701.
(3) The decorations exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source.
(4)* The decorations, such as photographs, paintings, and other art, are attached directly to the walls, ceiling, and non-fire-rated doors in accordance with the following:
   (a) Decorations on non-fire-rated doors do not interfere with the operation or any required latching of the door and do not exceed the area limitations of 20.6.2.5.4(4)(b) or (c).
   (b) Decorations do not exceed 20 percent of the wall, ceiling, and door areas inside any room or space of a smoke compartment that is not protected throughout by an approved automatic sprinkler system in accordance with Section 13.3.
   (c) Decorations do not exceed 30 percent of the wall, ceiling, and door areas inside any room or space of a smoke compartment that is protected throughout by an approved supervised automatic sprinkler system in accordance with Section 13.3.

[***101:***20.7.5.4; ***101:***21.7.5.4]

A.20.6.2.5.4(4) The percentage of decorations should be measured against the area of any wall or ceiling, not the aggregate total of walls, ceilings, and doors. The door is considered part of the wall. The decorations must be located such that they do not interfere with the operation of any door, sprinkler, smoke detector, or any other life safety equipment. Other art might include hanging objects or three-dimensional items. [***101:***A.20.7.5.4(4); ***101:***A.21.7.5.4(4)]

20.6.2.5.5 Soiled Linen and Trash Receptacles.

Δ **20.6.2.5.5.1** Soiled linen or trash collection receptacles shall not exceed 32 gal (121 L) in capacity, and all of the following also shall apply:

(1) The average density of container capacity in a room or space shall not exceed 0.5 gal/ft^2 (20.4 L/m^2).
(2) Mobile soiled linen or trash collection receptacles with capacities greater than 32 gal (121 L) shall be located in a room protected as a hazardous area when not attended.
(3) Container size and density shall not be limited in hazardous areas.
[***101:***20.7.5.5.1; ***101:***21.7.5.5.1]

20.6.2.5.5.2* Containers used solely for recycling clean waste or for patient records awaiting destruction shall be permitted to be excluded from the requirements of 20.6.2.5.5.1 where all the following conditions are met:

(1) Each container shall be limited to a maximum capacity of 96 gal (363 L), except as permitted by 20.6.2.5.5.2(2) or (3).
(2) Containers with capacities greater than 96 gal (363 L) shall be located in a room protected as a hazardous area when not attended.
(3) Container size shall not be limited in hazardous areas.
(4) Containers for combustibles shall be labeled and listed as meeting the requirements of FM Approval 6921, *Approval Standard for Containers for Combustible Waste*; however, such testing, listing, and labeling shall not be limited to FM Approvals.
[***101:***20.7.5.5.2; ***101:***21.7.5.5.2]

A.20.6.2.5.5.2 It is the intent that this provision permits recycling of bottles, cans, paper and similar clean items that do not contain grease, oil, flammable liquids, or significant plastic materials using larger containers or several adjacent containers and not require locating such containers in a room protected as a hazardous area.

Containers for medical records awaiting shredding are often larger than 32 gal (121 L). These containers are not to be included in the calculations and limitations of 20.6.2.5.5.1. There is no limit on the number of these containers, as FM Approval Standard 6921, *Containers for Combustible Waste*, ensures that the fire will not spread outside of the container. FM approval standards are written for use with FM Approvals. The tests can be conducted by any approved laboratory. The portions of the standard referring to FM Approvals are not included in this reference. [***101:***A.20.7.5.5.2; ***101:***A.21.7.5.5.2]

20.6.2.5.5.3 The provisions of 19.2.1.1 through 19.2.1.2 applicable to soiled linen and trash receptacles shall not apply.

Cigarette ignition–resistance testing for newly introduced upholstered furniture and mattresses is required for ambulatory health care occupancies. Further, rate of heat release testing, as detailed in 12.6.3.1 and 12.6.3.2, is required by 20.6.2.5.2 and 20.6.2.5.3 for newly introduced upholstered furniture and newly introduced mattresses in ambulatory health care occupancies, unless the building is sprinklered throughout.

Paragraph 20.6.2.5.5.1 establishes maximum trash container sizes and placement densities permitted within a room. For the 2018 edition of the *Code*, the criterion that a capacity of 32 gal (121 L) not be exceeded within any 64 ft^2 (6 m^2) area was deleted. The effect is, for example, that two 32 gal (121 L) containers can be placed side-by-side in a 128 ft^2 (12 m^2) area. Containers larger than those specified or grouped containers exceeding the density per room criterion present a hazard greater than that associated with the normal furnishing of an ambulatory health care center room.

Large, mobile soiled linen or trash receptacles can be moved along the corridor as collections occur but must be attended by staff. If housekeeping staff, for example, must leave the area, the container must be stored in a room designed and maintained as a hazardous area in accordance with 20/21.3.2 of NFPA *101*. Exhibit 20.13 illustrates the requirements of 20.6.2.5.5.

The provisions of 20.6.2.5.5.2 recognize the need for secure disposal of clean waste, such as paper, that might include patient information. Such waste is typically aggregated in containers larger than the 32 gal (121 L) limitation imposed by 20.6.2.5.5.1, since it might not be feasible to have such materials removed and shredded as frequently as would be necessitated if smaller containers were used. The maximum 96 gal (363 L) container presents little fire challenge, because the container has been tested for fire performance. The larger, clean waste containers typically are outfitted with a tight-fitting lid and narrow slot in order to pass the required fire testing. Exhibit 20.14 illustrates a maximum 96 gal (363 L) container meeting the criteria of 20.6.2.5.5.2.

Δ **20.6.2.6 Portable Space-Heating Devices.** Portable space-heating devices shall be prohibited in all ambulatory health care occupancies, unless both of the following criteria are met:

(1) Such devices are used only in nonsleeping staff and employee areas.
(2) The heating elements of such devices do not exceed 212°F (100°C).

[***101:***20.7.8; ***101:***21.7.8]

N **20.6.2.7 Integrated Fire Protection Systems.** Integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***20.7.10, ***101:***21.7.10]

The provisions of 20.6.2.7 are new to the 2018 edition of the *Code*. For new ambulatory health care occupancies, integrated fire protection systems must be tested in accordance with 13.1.3. The concept is one in which if two or more fire protection or life safety systems are integrated, the integrated system must be tested to verify the proper operation and function of such system in accordance with NFPA 4. For existing ambulatory health care occupancies, the requirement for compliance with NFPA 4 applies only to integrated systems in high-rise buildings.

20.6.3 Interior Finish.

Δ **20.6.3.1 General.** Interior finish shall be in accordance with Section 12.5. [***101:***20.3.3.1; ***101:***21.3.3.1]

20.6.3.2 Interior Wall and Ceiling Finish.

Δ **20.6.3.2.1** Interior wall and ceiling finish material complying with Section 12.5 shall be Class A or Class B in exits and in exit access corridors. [***101:***20.3.3.2.1; ***101:***21.3.3.2.1]

20.6.3.2.2 Interior wall and ceiling finishes shall be Class A, Class B, or Class C in areas other than those specified in 20.6.3.2.1. [***101:***20.3.3.2.2; ***101:***21.3.3.2.2]

20.6.3.3 New Interior Floor Finish.

20.6.3.3.1 New interior floor finish shall comply with Section 12.5. [***101:***20.3.3.3.1]

20.6.3.3.2 New interior floor finish in exit enclosures shall be Class I or Class II. [***101:***20.3.3.3.2]

20.6.3.3.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***20.3.3.3.3]

The provision of 20.6.3.3.2, applicable to new floor finish materials, requires that the interior floor finish be Class I or Class II only in exit enclosures, such as enclosed exit stairs. The intent is that the interior floor finish materials used in exits are to resist the spread of fire if exposed to the radiant energy from a fully developed room fire by means of an open door. It should be noted that the reference to 12.5.9.1 and 12.5.9.2 in 20.6.3.3.3 should be to 12.5.8.1 and 12.5.8.2 of this *Code*. The provision of 12.5.9.2 permits a reduction of one class of interior floor finish (i.e., from Class I to Class II or from Class II to no classification required) in sprinklered buildings.

In all cases, regardless of sprinkler protection, new carpet and carpet-like floor finishes must comply with ASTM D2859, *Standard Test Method for Ignition Characteristics of Finished Textile Floor Covering Materials*, as referenced in 12.5.8.1. New floor finish materials, other than carpet, must resist a minimum critical radiant flux of 0.1 W/cm^2 per 12.5.8.2 per the testing requirements described in 12.5.8.3.

20.6.3.4 Existing Interior Floor Finish. (Reserved) [***101:*** 21.3.3.3]

20.7 Detention and Correctional Occupancies

Detention and correctional occupancies apply the total concept approach to life safety — complete with a defend-in-place strategy — much as is done for health care occupancies. Unlike people in health care occupancies, whose incapability of self-preservation is due to medical conditions, those in detention and correctional occupancies are incapable of self-preservation because of security restrictions. Security restrictions prevent, to a large extent, free and customary movement and access to other areas of a building. In general, many of the normal features needed in a detention facility are nearly the exact opposite of what the *Code* attempts to provide for other occupancies. The use of locked doors, often with key-operated locks (see 22/23.2.11.1.2 and 22/23.2.11.1.3 of NFPA *101*); egress components for which use is restricted or traffic flow is constricted, such as a sally port (see 22.2.5.4 and 23.2.5.4 of NFPA *101*); and discharge of exits onto other than public ways (see 22.2.7.1 and 23.2.7.1 of NFPA *101*) are features not usually permitted in other occupancies.

Chapters 22 and 23 of NFPA *101* impose limitations on the degree of locking that can be used. These limits form a classification scheme based on the appropriate use condition. In general, the amount of restriction (e.g., Use Condition I is free egress and Use Condition V is contained; see 22.1.2.1 and 23.1.2.1 of NFPA *101*) in the detention and correctional facility dictates the use of acceptable locking methods and means of egress features not permitted in other occupancies. As in a health care facility, those unique features necessary to protect the occupants in place include construction, compartmentation, alarm and detection, and staff facilitation to help lead or direct occupants to safe areas within the premises of the detention facility campus.

Subsection 20.7.2 provides routine operating requirements, such as 24-hour staffing; means for resident notification of staff in an emergency; preparation and maintenance of evacuation plans; staff training in the use of portable fire extinguishers; storage of combustible personal property; presence of heat-producing appliances; control of flammability of draperies, curtains, mattresses, and upholstered furniture; and visual and tactile identification of keys necessary for unlocking doors within the means of egress. Because locking doors — which is necessary for the intended function of the facility — is contrary to the basic *Code* tenet that the means of egress system is under the control of building occupants, the presence of properly trained staff is paramount to providing a level of life safety equivalent to that provided in other occupancies. Subsection 20.7.2 requires the necessary staffing and training that — where combined with the requirements of NFPA *101* — achieve the necessary level of life safety. Exhibit 20.16 shows the front entrance of Lubbock County Detention Center, Lubbock, Texas.

20.7.1 Application. New and existing detention and correctional occupancies shall comply with Section 20.7 and NFPA *101*.

Exhibit 20.16

Detention facility front entrance.

20.7.2 Operating Features.

20.7.2.1 Attendants, Evacuation Plan, Fire Drills.

20.7.2.1.1 Detention and correctional facilities, or those portions of facilities having such occupancy, shall be provided with 24-hour staffing, and the following requirements also shall apply:

(1) Staff shall be within three floors or a 300 ft (91 m) horizontal distance of the access door of each resident housing area.
(2) For Use Condition III, Use Condition IV, and Use Condition V, the arrangement shall be such that the staff involved starts the release of locks necessary for emergency evacuation or rescue and initiates other necessary emergency actions within 2 minutes of alarm.
(3) The following shall apply to areas in which all locks are unlocked remotely in compliance with 22.2.11.8 or 23.2.11.8 of NFPA *101*.
    (a) Staff shall not be required to be within three floors or 300 ft (91 m) of the access door.
    (b) The 10-lock, manual key exemption of 22.2.11.8.2 or 23.2.11.8.2 of NFPA *101* shall not be permitted to be used in conjunction with the alternative requirement of 20.7.2.1.1(3)(a).

[***101:***22.7.1.1; ***101:***23.7.1.1]

Paragraph 20.7.2.1.1 requires 24-hour staffing, which is typically accomplished from control rooms where the staff has visibility of large spaces or multiple areas, including those on more than one level. Such control rooms are often walled-in glass or other glazing material. Exhibit 20.17 shows a glass-enclosed control room.

20.7.2.1.2* Provisions shall be made so that residents in Use Condition III, Use Condition IV, and Use Condition V shall be able to notify staff of an emergency. [***101:***22.7.1.2; ***101:***23.7.1.2]

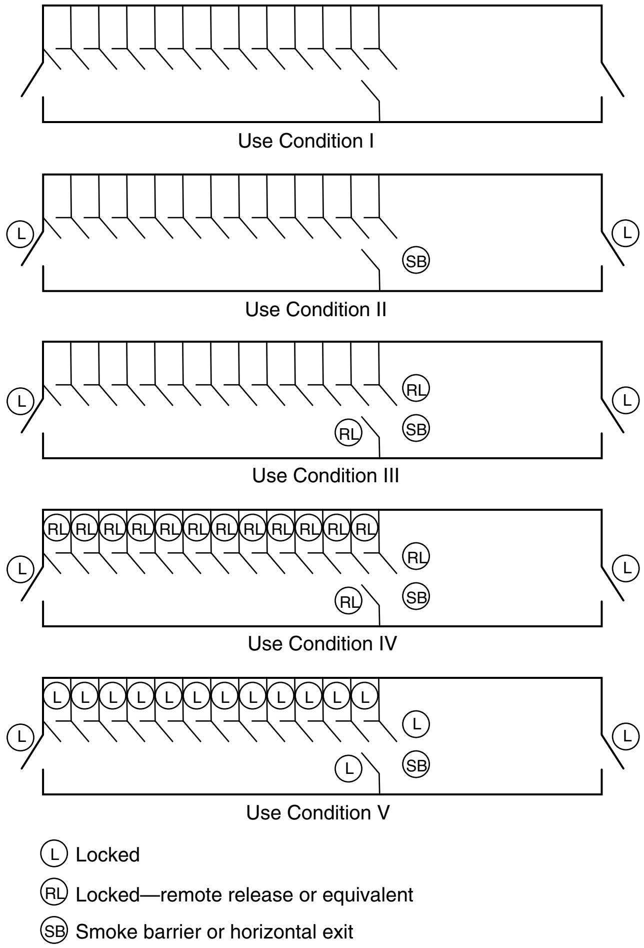
A.20.7.2.1.2 This requirement is permitted to be met by electronic or oral monitoring systems, visual monitoring, call signals, or other means. [***101:***A.22.7.1.2; ***101:***A.23.7.1.2]

20.7.2.1.3* The administration of every detention or correctional facility shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons

Exhibit 20.17

Glass-enclosed control rooms.

Exhibit 20.18



Detention and correctional use conditions.

in the event of fire, for their evacuation to areas of refuge, and for evacuation from the building when necessary. [***101:***22.7.1.3; ***101:***23.7.1.3]

A.20.7.2.1.3 Periodic, coordinated training should be conducted and should involve detention and correctional facility personnel and personnel of the fire department legally committed to serving the facility. [***101:***A.22.7.1.3; ***101:***A.23.7.1.3]

Paragraph 20.7.2.1.2 requires that residents in Use Condition III, Use Condition IV, and Use Condition V facilities be able to notify staff of an emergency. Use Condition IV and Use Condition V facilities rely on staff action to release locks to allow residents to leave their rooms; Use Condition III, Use Condition IV, and Use Condition V facilities rely on staff action to release locks to allow residents to move to an adjacent smoke compartment. The staff needs to be made aware of fire conditions early in a fire. Thus, in case residents discover a fire before automatic detection devices are initiated, they need a means of notifying staff. Exhibit 20.18 illustrates the five use conditions.

A properly designed and well-tested fire emergency plan, as required by 20.7.2.1.3, is important in detention and correctional occupancies where residents depend heavily on staff performance for safety under fire conditions.

20.7.2.1.3.1 All employees shall be instructed and drilled with respect to their duties under the plan. [***101:***22.7.1.3.1; ***101:***23.7.1.3.1]

20.7.2.1.3.2 The plan shall be coordinated with, and reviewed by, the fire department legally committed to serve the facility. [***101:***22.7.1.3.2; ***101:***23.7.1.3.2]

20.7.2.1.4 Employees of detention and correctional occupancies shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment. [***101:***22.7.1.4; ***101:***23.7.1.4]

20.7.2.1.4.1 The training specified in 20.7.2.1.4 shall be provided to new staff promptly upon commencement of duty. [***101:***22.7.1.4.1; ***101:***23.7.1.4.1]

20.7.2.1.4.2 Refresher training shall be provided to existing staff at not less than annual intervals. [***101:***22.7.1.4.2; ***101:***23.7.1.4.2]

20.7.2.2* Combustible Personal Property. Books, clothing, and other combustible personal property allowed in sleeping rooms shall be stored in closable metal lockers or an approved fire-resistant container. [***101:***22.7.2; ***101:***23.7.2]

A.20.7.2.2 Personal property provides combustible contents for fire development. Therefore, adequate controls are needed to limit the quantity and combustibility of the fuels available to burn to reduce the probability of room flashover. The provisions of 20.7.2.4 will not, by themselves, prevent room flashover if personal property controls are not provided. [***101:***A.22.7.2; ***101:***A.23.7.2]

20.7.2.3 Heat-Producing Appliances. The number of heat-producing appliances, such as toasters and hot plates, and the overall use of electrical power within a sleeping room shall be controlled by facility administration. [***101:***22.7.3; ***101:***23.7.3]

20.7.2.4* Furnishings, Bedding, and Decorations.

A.20.7.2.4 The type, quantity, and arrangement of furniture and other combustibles are important factors in determining how fast the fire will develop. Furnishings, including upholstered items and wood items, such as wardrobes, desks, and bookshelves, might provide sufficient fuel to result in room flashover, which is the full fire involvement of all combustibles within a room once sufficient heat has been built up within the room. [***101:***A.22.7.4; ***101:***A.23.7.4]

20.7.2.4.1 Draperies and curtains, including privacy curtains, in detention and correctional occupancies shall be in accordance with the provisions of 12.6.2. [***101:***22.7.4.1; ***101:***23.7.4.1]

20.7.2.4.2 Newly introduced upholstered furniture within detention and correctional occupancies shall be tested in accordance with the provisions in 12.6.3.1(2) and 12.6.3.2.1. [***101:***23.7.4.2]

20.7.2.4.3* Newly introduced mattresses within detention and correctional occupancies shall be tested in accordance with the provisions in 12.6.3.2 and 12.6.3.2.2. [***101:***23.7.4.3]

A.20.7.2.4.3 Mattresses used in detention and correctional facilities should be evaluated with regard to the fire hazards of the environment. The potential for vandalism and excessive wear and tear also should be taken into account when evaluating the fire performance of the mattress. ASTM F1870, *Standard Guide for Selection of Fire Test Methods for the Assessment of Upholstered Furnishings in Detention and Correctional Facilities* provides guidance for this purpose. [***101:***A.23.7.4.3]

20.7.2.4.4 Combustible decorations shall be prohibited in any detention or correctional occupancy unless they are flame-retardant and approved. [***101:***22.7.4.4; ***101:***23.7.4.4]

20.7.2.4.5 Wastebaskets and other waste containers shall be of noncombustible or other approved materials. Waste containers with a capacity exceeding 20 gal (76 L) shall be provided with a noncombustible lid or lid of other approved material. [***101:***22.7.4.5; ***101:***23.7.4.5]

The provisions of 20.7.2.4 make use of the menu of provisions in Section 12.6 that apply to furnishings and contents, particularly those that address upholstered furniture and mattresses. Nevertheless, the control of combustible personal property is needed to limit fire development in sprinklered facilities and prevent the occurrence of room flashover in nonsprinklered facilities. Paragraph 20.7.2.2 provides staff with the authority to regulate the quantities of personal property in sleeping rooms.

The provisions of 20.7.2.4.1 through 20.7.2.4.5 are the most rigorous regulations of contents and furnishings provided by this *Code*. It is appropriate that these provisions be applied to detention and correctional occupancies in consideration of the protect-in-place strategy required of these occupancies by the *Code* and the reluctance of staff to unlock doors to allow residents to move to the outside.

Draperies and curtains must be flame resistant in accordance with 12.6.1, which requires flame propagation performance criteria in accordance with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*.

Paragraphs 20.7.2.4.2 and 20.7.2.4.3 require newly introduced upholstered furniture and mattresses to be resistant to cigarette ignition, regardless of whether the facility is sprinklered. Paragraphs 20.7.2.4.2 and 20.7.2.4.3 also have the effect of limiting the rate of heat release for newly introduced upholstered furniture and mattresses in existing, nonsprinklered detention and correctional facilities.

20.7.2.5 Keys. All keys necessary for unlocking doors installed in a means of egress shall be individually identified by both touch and sight. [***101:***22.7.5; ***101:***23.7.5]

20.7.2.6 Portable Space-Heating Devices. Portable space-heating devices shall be prohibited in all detention and correctional occupancies. [***101:***22.7.6; ***101:***23.7.6]

20.7.2.7 Door Inspection. Doors and door hardware in means of egress shall be inspected annually by an appropriately trained person. The inspection shall be documented. [***101:***22.7.7; ***101:***23.7.7]

The provision of 20.7.2.7 recognizes that detention and correctional occupancies make extensive use of doors — especially locked doors — for security reasons and that such doors need inspection. The regular inspection of doors and door hardware in these occupancies is particularly important.

N **20.7.2.8 Integrated Fire Protection Systems.** Integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***22.7.8; ***101:***23.7.7]

The provisions of 20.7.2.8 are new to the 2018 edition of the *Code*. Where fire protection and life safety systems are needed to function together to provide the intended level of protection, they must meet the testing requirements of 13.1.3, which in turn references NFPA 4. The integrated systems test addressed by NFPA 4 verifies and documents the operation and function of all interconnected fire protection and life safety systems, including performance in accordance with applicable codes and standards, sequence of operation, performance in accordance with manufacturers' published instructions, and accuracy of record documents. See the commentary following A.13.1.3 for additional information on integrated fire protection and life safety system testing.

20.7.3 Interior Finish.

20.7.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***22.3.3.1; ***101:***23.3.3.1]

20.7.3.2 New Interior Wall and Ceiling Finish. New interior wall and ceiling finish materials complying with Section 12.5 shall be Class A or Class B in corridors, in exits, and in any space not separated from corridors and exits by partitions capable of retarding the passage of smoke; and Class A, Class B, or Class C in all other areas. The provisions of 12.5.9.1 shall not apply to new detention and correctional occupancies. [***101:***22.3.3.2]

20.7.3.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be Class A or Class B in corridors, in exits, and in any space not separated from corridors and exits by partitions capable of retarding the passage of smoke; and Class A, Class B, or Class C in all other areas. [***101:***23.3.3.2]

20.7.3.4 New Interior Floor Finish.

20.7.3.4.1 New interior floor finish shall comply with Section 12.5. [***101:***22.3.3.3.1]

20.7.3.4.2 Interior floor finish in exit enclosures and exit access corridors shall be not less than Class II. The provisions of 12.5.9.2 shall not apply to new detention and correctional occupancies. [***101:***22.3.3.3.2]

20.7.3.4.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***22.3.3.3.3]

Compliance with the interior wall and ceiling finish provisions within resident rooms is typically easily accomplished given the construction materials and finishes used for security reasons. Painted masonry often meets the requirements for Class A interior wall and ceiling finish. *Code*-compliant interior wall and ceiling finish in resident rooms might be compromised by combustible decorations applied to the walls and ceiling, and that issue is addressed by 20.7.2.4.4. Exhibit 20.19 shows a resident room after construction and before resident occupancy. The interior wall and ceiling finishes appear not to pose a flame spread problem.

Exhibit 20.19

Resident room with interior wall and ceiling finishes that do not pose a fire spread problem.

Paragraph 20.7.3.3 imposes stricter interior wall and ceiling finish requirements in exits, corridors, and spaces not separated from the corridor than it does in other use areas. To apply the less stringent requirements within the use areas, the required separation need be only a partition capable of retarding the passage of smoke. The partition must be of substantial construction but is not required to have a fire resistance rating.

Paragraph 20.7.3.5.2 recognizes existing interior floor finish materials that have been tested in accordance with the test procedures specified in 12.5.4.3 for wall and ceiling finish materials (i.e., ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials,* or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*) as an exemption to the requirement of 12.5.8 that testing of floor finish materials be performed per NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, or ASTM E648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*. ASTM E84 and ANSI/UL 723 contain the flame spread and smoke development measurement method currently used to evaluate interior wall and ceiling finish materials in accordance with the requirements of Section 12.5. Prior to the 1981 edition of the *Code*, floor finish was tested in accordance with ASTM E84. Paragraph 20.7.3.5.2 permits material that was tested and approved by this method to remain in use.

20.7.3.5 Existing Interior Floor Finish.

20.7.3.5.1 Existing interior floor finish complying with Section 12.5 shall be Class I or Class II in corridors and exits. [***101:***23.3.3.3.1]

20.7.3.5.2 Existing floor finish material of Class A or Class B in nonsprinklered smoke compartments and Class A, Class B, or Class C in sprinklered smoke compartments shall be permitted to be continued to be used, provided that it has been evaluated based on tests performed in accordance with 12.5.4. [***101:***23.3.3.3.2]

20.7.3.6 Interior Finish (Nonsprinklered Existing Building Renovations).

20.7.3.6.1 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be Class A in corridors, in exits, and in any space not separated from corridors and exits by partitions capable of retarding the passage of smoke; and Class A, Class B, or Class C in all other areas. [***101:***22.4.4.8.1]

20.7.3.6.2 Interior Floor Finish.

20.7.3.6.2.1 Interior floor finish shall comply with Section 12.5. [***101:***22.4.4.8.2.1]

20.7.3.6.2.2 New interior floor finish in exit enclosures and exit access corridors shall be not less than Class I. [***101:***22.4.4.8.2.2]

20.7.3.6.2.3 Interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***22.4.4.8.2.3]

20.8 Hotels and Dormitories

Section 20.8 addresses residential occupancies that are primarily transient in nature. Hotel and motel accommodations that are mainly used for stays of relatively short duration fit into this category. Dormitory occupancies, although typically used for up to nine months of near-continuous occupancy in the case of a college or university dormitory, are also regulated by this section.

The hotel and dormitory classification is one of five residential occupancy types addressed by the *Code*. Other residential occupancies include one- and two-family dwellings (Section 20.11 and Chapter 24 of NFPA *101*); lodging or rooming houses (Section 20.10 and Chapter 26 of NFPA *101*); apartment buildings (Section 20.9 and Chapters 30 and 31 of NFPA *101*); and residential board and care occupancies (Section 20.5 and Chapters 32 and 33 of NFPA *101*).

The common principle of life safety that is applied to all residential occupancies addressed by Chapters 24 through 33 of NFPA *101* is highlighted by 6.1.8.1, which states that residential occupancies are those occupancies in which sleeping accommodations are provided for purposes other than health care or detention and correction. The presence of sleeping occupants is central to the provisions of Chapters 24 through 33 of NFPA *101*, because occupants who are asleep will be unaware of a developing fire and, when awakened to be alerted to the emergency, might be somewhat confused. The definition of the term *residential occupancy* in 6.1.8.1 also differentiates between sleeping occupants in residential occupancies and those in health care or detention and correctional occupancies, which are also characterized by the occupants' incapability of self-preservation. The provisions of Chapters 24 through 33 of NFPA *101* are also based on the presence of hazards (such as cooking and heating equipment) in residential occupancies and the degree to which occupants are familiar with their living space. Occupants might have little or no familiarity with the building, as in the case of the transient residents of hotels, or they might have the total familiarity that is common to residents of single-family dwellings.

Unfamiliar surroundings and the possibility of being asleep when a fire occurs are factors that jeopardize the safety of hotel guests in particular. Hotels pose an additional problem, because typical hotel building configurations often require escaping guests to traverse an interior corridor, which subsequently might expose them to the heat and smoke of corridor and room fires. In recognition of these potential hazards, the *Code* requires most new hotels and dormitories to be protected throughout by approved, supervised automatic sprinkler systems.

In recent years, hotels and motels have experienced a steady reduction in the number of fires, civilian casualties, and civilian injuries. Part of the explanation for these reductions is the increasing percentage of hotels that are provided with smoke detection and automatic sprinkler systems. From 2009 to 2013, hotels and motels averaged 3520 structure fires per year, as reported to fire departments across the United States. These fires resulted in a yearly average of 9 civilian deaths and 120 civilian injuries. These numbers are approximately equivalent to, or slightly down from, the previous 4-year averages for which statistics were available (2007 to 2013) of 3600 structure fires, 11 civilian deaths, and 139 civilian injuries per year.

Exhibit 20.20

The former MGM Grand Hotel and Casino, site of the November 1980 fire in which 85 occupants perished.

Exhibit 20.20 depicts Bally's Resort and Casino, formerly the MGM Grand Hotel and Casino in Las Vegas, Nevada, as it appears today. On the morning of November 21, 1980, a fire at the MGM Grand resulted in the deaths of 85 occupants. Because of this fire, and several others in the 1980s, nearly all new hotels and many existing hotels are protected with automatic sprinkler systems.

20.8.1 Application. New and existing hotels and dormitories shall comply with Section 20.8 and NFPA *101*.

Section 20.8 applies to various operations that do not specifically use the term *hotel* but are considered such by definition. The terms *dormitory* and *hotel* are defined in 3.3.192.9 and 3.3.192.14, respectively. In some cases, Section 20.8 applies even if the identification of the occupancy suggests the application of a different section. For example, a rooming house that accommodates more than 16 people is classified as a hotel.

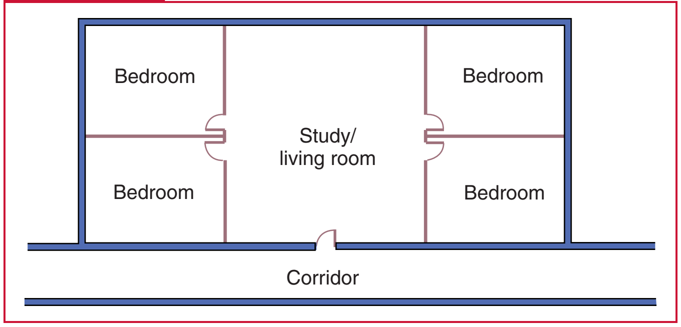
Conversely, some operations that one might expect to be covered by Chapters 28 and 29 of NFPA *101* are not. For example, 28.1.1.4 and 29.1.1.4 of NFPA *101* recognize that the common dormitory design in which a group of bedrooms opens into a study or living room duplicates a typical apartment design in which several bedrooms open into a living room or kitchen. Because the design and the risk of fire are similar, the *Code* treats this arrangement as an apartment building, despite the lack of individual kitchens. Exhibit 20.21 illustrates the arrangement of a dormitory suite that would be treated as an apartment.

20.8.2 Operating Features.

20.8.2.1 Hotel Emergency Organization.

20.8.2.1.1* Employees of hotels shall be instructed and drilled in the duties they are to perform in the event of fire, panic, or other emergency. [***101:***28.7.1.1; ***101:***29.7.1.1]

Exhibit 20.21



Dormitory suite apartment.

A.20.8.2.1.1 Employers are obligated to determine the degree to which employees are to participate in emergency activities. Regulations of the U.S. Department of Labor (OSHA) govern these activities and provide options for employers, from total evacuation to aggressive structural fire fighting by employee brigades. *(For additional information, see 29 CFR 1910, E and L, "OSHA Regulations for Emergency Procedures and Fire Brigades.")* [***101:***A.28.7.1.1; ***101:***A.29.7.1.1]

The AHJ should put a plan in place to ensure that the staff of the hotel or dormitory occupancy has been trained in their duties. Staff training for those supervising students in dormitories should be conducted annually at the beginning of each school year, and refresher training should be provided in the second semester.

20.8.2.1.2* Drills of the emergency organization shall be held at quarterly intervals and shall cover such points as the operation and maintenance of the available first aid fire appliances, the testing of devices to alert guests, and a study of instructions for emergency duties. [***101:***28.7.1.2; ***101:***29.7.1.2]

A.20.8.2.1.2 Emergencies should be assumed to have arisen at various locations in the occupancy in order to train employees in logical procedures. [***101:***A.28.7.1.2; ***101:***A.29.7.1.2]

One of the leading problems within college dormitories is tampering with smoke alarms and using portable fire extinguishers for non–fire suppression activities. The local AHJ needs to have a plan in place to verify that the devices are in working order. It is also vitally important to teach students the reasons for not tampering with fire safety equipment and the ramifications that tampering can have if an emergency should occur. A sound philosophy is one that includes prevention (teaching students how to avoid the occurrence of fire); detection (early detection and sounding the alarm); and suppression (preferably through the activation of the building's automatic fire sprinkler system).

Δ **20.8.2.2 Emergency Duties.** Upon discovery of a fire, employees shall carry out all of the following duties:

(1) Activation of the facility fire protection signaling system, if provided
(2) Notification of the public fire department
(3) Other action as previously instructed

[***101:***28.7.2; ***101:***29.7.2]

20.8.2.3 Drills in Dormitories. Emergency egress and relocation drills in accordance with Section 10.5 shall be held with sufficient frequency to familiarize occupants with all types of hazards and to establish conduct of the drill as a matter of routine. Drills shall be conducted during peak occupancy periods and shall include suitable procedures to ensure that all persons subject to the drill participate. [***101:***28.7.3; ***101:***29.7.3]

The requirements for fire drills in hotels and dormitories differ. In hotels, employees must be trained in and practice the duties they are expected to perform in the event of a fire. The *Code* specifically does not require hotel guests to take part in fire drills so as to not contribute to complacency with regard to fire alarms. In dormitories, the provisions of 20.8.2.3 require all occupants to participate in drills, because occupants of dormitories tend to be less transient than those of hotels. Dormitory occupants typically live in the building for several weeks or months at a time (or longer), making them semipermanent residents. As such, they require a high degree of familiarization with the actions they should take in the event of a fire or similar emergency.

20.8.2.4 Emergency Instructions for Residents or Guests.

20.8.2.4.1* A floor diagram reflecting the actual floor arrangement, exit locations, and room identification shall be posted in a location and manner acceptable to the AHJ on, or immediately adjacent to, every guest room door in hotels and in every resident room in dormitories. [***101:***28.7.4.1; ***101:***29.7.4.1]

A.20.8.2.4.1 Floor diagrams should reflect the actual floor arrangement and should be oriented with the actual direction to the exits. [***101:***A.28.7.4.1; ***101:***A.29.7.4.1]

The manner in which the information specified in 20.8.2.4.1 is to be posted and the nature of its contents are at the discretion of the AHJ and depend on the building, its layout, and the protection provided.

20.8.2.4.2* Fire safety information shall be provided to allow guests to make the decision to evacuate to the outside, to evacuate to an area of refuge, to remain in place, or to employ any combination of the three options. [***101:***28.7.4.2; ***101:***29.7.4.2]

A.20.8.2.4.2 Factors for developing the fire safety information include such items as construction type, suppression systems, alarm and detection systems, building layout, and building HVAC systems. [***101:***A.28.7.4.2; ***101:***A.29.7.4.2]

20.8.2.4.3 Emergency Action Plans. Emergency action plans in accordance with Section 10.8 shall be provided. [***101:***28.7.5]

20.8.2.5 Contents and Furnishings.

Δ **20.8.2.5.1** New draperies, curtains, and other similar loosely hanging furnishings and decorations shall meet the flame propagation performance criteria contained in Test Method 1 or Test Method 2, as appropriate, of NFPA 701. [***101:***28.7.6.1; ***101:***29.7.6.1]

20.8.2.5.2 Upholstered Furniture and Mattresses.

20.8.2.5.2.1 Newly introduced upholstered furniture shall meet the criteria specified in 12.6.3.1 and 12.6.3.2.2. [***101:***28.7.6.2.1; ***101:***29.7.6.2.1]

20.8.2.5.2.2 Newly introduced mattresses shall meet the criteria specified in 12.6.3.2 and 12.6.3.2.2. [***101:***28.7.6.2.2]

20.8.2.5.3 Furnishings or decorations of an explosive or highly flammable character shall not be used. [***101:***28.7.6.3; ***101:***29.7.6.3]

20.8.2.5.4 Fire-retardant coatings shall be maintained to retain the effectiveness of the treatment under service conditions encountered in actual use. [***101:***28.7.6.4; ***101:***29.7.6.4]

20.8.2.6 Fuel-Fired Heaters. Unvented fuel-fired heaters, other than gas space heaters in compliance with NFPA 54 shall not be used. [***101:***28.5.2.2; ***101:***29.5.2.2]

Unvented fuel-fired heaters can produce dangerous levels of CO. The danger from CO cannot be stressed enough. Depending on the concentrations of CO within a space, a person can quickly be disabled and suffer fatal injuries.

N **20.8.2.7 Integrated Fire Protection Systems.** In new hotels and dormitories, integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***28.7.8]

The provision of 20.8.2.7 is new to the 2018 edition of the *Code*. Where fire protection and life safety systems are needed to function together to provide the intended level of protection, they must meet the testing requirements of 13.1.3, which in turn references NFPA 4. The integrated systems test addressed by NFPA 4 verifies and documents the operation and function of all interconnected fire protection and life safety systems, including performance in accordance with applicable codes and standards, sequence of operation, performance in accordance with manufacturers' published instructions, and accuracy of record documents. See the commentary following A.13.1.3 for additional information on integrated fire protection and life safety system testing.

20.8.3 Interior Finish.

20.8.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***28.3.3.1; ***101:***29.3.3.1]

20.8.3.2 New Interior Wall and Ceiling Finish. New interior wall and ceiling finish materials complying with Section 12.5 shall be permitted as follows:

(1) Exit enclosures — Class A
(2) Lobbies and corridors — Class A or Class B
(3) Other spaces — Class A, Class B, or Class C
[***101:***28.3.3.2]

20.8.3.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be permitted as follows:

(1) Exit enclosures — Class A or Class B
(2) Lobbies and corridors — Class A or Class B
(3) Other spaces — Class A, Class B, or Class C
[***101:***29.3.3.2]

20.8.3.4 New Interior Floor Finish.

20.8.3.4.1 New interior floor finish shall comply with Section 12.5. [***101:***28.3.3.3.1]

20.8.3.4.2 New interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 28.3.6.1 of NFPA *101* shall be not less than Class II. [***101:***28.3.3.3.2]

20.8.3.4.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***28.3.3.3.3]

20.8.3.5 Interior Floor Finish (Existing Nonsprinklered Buildings). In nonsprinklered buildings, newly installed interior floor finish in exits and exit access corridors shall be not less than Class II in accordance with 12.5.9. [***101:***29.3.3.3]

20.9 Apartment Buildings

The apartment building classification is one of five residential occupancy types addressed by NFPA *101*. Other residential occupancies include one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and residential board and care occupancies.

The common principle of life safety that is applied to all residential occupancies addressed by Chapters 24 through 33 of NFPA *101* is highlighted by 6.1.8.1, which states that residential occupancies are those occupancies in which sleeping accommodations are provided for purposes other than health care or detention and correction. The presence of sleeping occupants is central to the provisions of Chapters 24 through 33 of NFPA *101*, because occupants who are asleep will be unaware of a developing fire and, when awakened to be alerted to the emergency, might be somewhat confused. The definition of the term *residential occupancy* in 6.1.8.1 also differentiates between sleeping occupants in residential occupancies and those in health care or detention and correctional occupancies, which are also characterized by the occupants' incapability of self-preservation. The provisions of Chapters 24 through 33 of NFPA *101* are also based on the presence of hazards (such as cooking and heating equipment) in residential occupancies and the degree to which occupants are familiar with their living space. Occupants might have little or no familiarity, as in the case of the transient residents of hotels, or they might have the total familiarity that is common to residents of single-family dwellings.

Apartment buildings pose a problem from a life safety perspective, because the typical building configuration often requires an escaping resident to traverse an interior corridor, which subsequently might expose the resident to the heat and smoke of a corridor or dwelling unit fire. In recognition of these potential hazards, the *Code* requires most new apartment buildings to be protected throughout by an approved, supervised automatic sprinkler system.

From 2011 to 2015, apartment buildings accounted for an average of 95,900 structure fires per year, as reported to U.S. fire departments (up from 93,700 for the previous 5-year period of 2008 to 2012). This number represents approximately 26 percent of the 367,500 total home fires per year on average for the period (down from 30 percent for the period 2008 to 2012). Apartment building fires resulted in an average of 385 civilian deaths per year (15 percent of all home fire deaths), which is about consistent with the period 2008 to 2012, and 3840 civilian injuries per year (31 percent of all home fire injuries), which is about consistent with the period 2008 to 2012.

The causes of apartment building fires differ significantly from those of one- and two-family dwelling fires in building equipment areas. Data from 2010 through 2014 indicate heating and electrical equipment accounted for 31 percent of the fires in one- and two-family dwellings, while accounting for only 10 percent of the fires in apartment buildings. This difference is most likely due to the centralized arrangement of the heating and electrical systems typical of most apartment buildings. Equipment fires are usually the result of poor maintenance or human error. Heating and electrical systems tend to be more closely regulated, maintained, and supervised in apartment buildings, which results in a reduced chance of equipment malfunction.

The number of fires caused by occupants (e.g., those due to cooking and smoking) is high in both categories of home structures.

These data demonstrate the importance of applying the *Code* to apartment buildings to help ensure fire safety, but they also demonstrate the continuing need for public education regarding the causes and prevention of home fires.

20.9.1 Application. New and existing apartment buildings shall comply with Section 20.9 and NFPA *101*.

Due to the disproportionate percentage of deaths associated with residential occupancies, this *Code* and NFPA *101* mandate sprinkler protection in new apartment buildings with no exceptions. For existing apartment buildings, NFPA *101* provides four alternative protection packages referred to as options.

The options specify the varying degrees to which an apartment building is protected by fire detection or fire suppression systems as follows:

1. Option 1 — no suppression or detection systems
2. Option 2 — total automatic fire detection and notification (although 31.3.4.5.1 of NFPA *101* requires single-station smoke alarms within each apartment unit, such smoke alarms are not part of a system and are not located in all areas of the building; therefore, their presence does not signify an Option 2 apartment building)
3. Option 3 — partial sprinkler protection (mainly corridor sprinklers — see 31.3.5.9 of NFPA *101*)
4. Option 4 — protection throughout by means of an automatic sprinkler system (see 31.3.5.10 of NFPA *101*)

In recognition of the life safety benefits associated with a properly installed and maintained sprinkler system, an Option 4 apartment building is exempted from selected NFPA *101* provisions required of Option 1 through Option 3 apartment buildings. The benefits of such exemptions include the following:

1. Increased travel distance allowances
2. Reduction in required corridor fire resistance ratings
3. Less restrictive interior finish requirements
4. Exemption from the smoke compartmentation requirement

The protection requirements of NFPA *101* for new apartment buildings are equivalent to Option 4.

Commentary Table 20.2 summarizes the different protection packages required, depending on whether an existing apartment building is provided with the protection features required for Option 1, Option 2, Option 3, or Option 4.

This comprehensive approach is an attempt to codify system design. Although a total system would consist of many alternatives, the systems detailed in Options 1 through 4 are more limited, because only four options are available. However, the user can identify the most appropriate option, based on the existing building's size, height, and arrangement. The options provide an opportunity to coordinate the safety approach that best fits a building, rather than adapting a building to a single codified set of criteria.

20.9.2 Operating Features.

20.9.2.1 Emergency Instructions for Residents of Apartment Buildings. Emergency instructions shall be provided annually to each dwelling unit to indicate the location of alarms, egress paths, and actions to be taken, both in response to a fire in the dwelling unit and in response to the sounding of the alarm system. [***101:***30.7.1; ***101:***31.7.1]

The manner in which the information required by 20.9.2.1 is provided to the residents and the nature of its contents are at the discretion of the AHJ and depend on the building, its layout, and the protection provided. For example, the instructions could be provided to residents when they sign their lease and move into their apartment and every year thereafter when the lease is renewed. The building's management should review the instructions periodically so they can be updated with any needed revisions resulting from changes to the building's configuration or protection systems.

20.9.2.2 Fuel-Fired Heaters. Unvented fuel-fired heaters, other than gas space heaters in compliance with NFPA 54, shall not be used. [***101:***30.5.2.2; ***101:***31.5.2.2]

Unvented fuel-fired heaters can produce dangerous levels of CO. The danger from CO cannot be stressed enough. Depending on the concentrations of CO within a space, a person can quickly become disabled and suffer fatal injuries.

N **20.9.2.3 Inspection of Door Openings.** Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***30.7.3; ***101:***31.7.3]

The provision of 20.9.2.3 requires the annual inspection of certain means of egress door openings in accordance with 7.2.1.15 of NFPA *101* to ensure they operate correctly in the event of an

COMMENTARY TABLE 20.2 *Alternative Requirements for Existing Apartment Buildings According to Protection Provided*

Feature	*No Suppression or Detection System Option 1*	*Complete Automatic Fire Detection Option 2*	*Automatic Sprinkler Protection in Selected Areas Option 3*	*Automatic Sprinkler Protection Throughout per NFPA 13 (with exceptions) Option 4*

emergency. Doors subject to the required annual inspection include doors equipped with panic hardware or fire exit hardware, doors serving exit enclosures, electrically controlled egress doors, and door assemblies with special locking arrangements in accordance with 14.5.3. The annual inspection must be documented to permit verification of compliance by the AHJ.

N **20.9.2.4 Integrated Fire Protection Systems.** In new high-rise apartment buildings, integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***30.7.4]

20.9.3 Interior Finish.

20.9.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***30.3.3.1; ***101:***31.3.3.1]

20.9.3.2 New Interior Wall and Ceiling Finish. New interior wall and ceiling finish materials complying with Section 12.5 shall be permitted as follows:

(1) Exit enclosures — Class A
(2) Lobbies and corridors — Class A or Class B
(3) Other spaces — Class A, Class B, or Class C
[***101:***30.3.3.2]

20.9.3.3 Existing Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 12.5 shall be permitted as follows:

(1) Exit enclosures — Class A or Class B
(2) Lobbies and corridors — Class A or Class B
(3) Other spaces — Class A, Class B, or Class C
[***101:***31.3.3.2]

20.9.3.4 New Interior Floor Finish.

20.9.3.4.1 New interior floor finish shall comply with Section 12.5. [***101:***30.3.3.3.1]

20.9.3.4.2 New interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 30.3.6 of NFPA *101* shall be not less than Class II. [***101:***30.3.3.3.2]

20.9.3.4.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***30.3.3.3.3]

20.9.3.5 Existing Interior Floor Finish. In buildings utilizing Option 1 or Option 2, as defined in 31.1.1.1 of NFPA *101*, newly installed interior floor finish in exits and exit access corridors shall be not less than Class II in accordance with 12.5.9. [***101:***31.3.3.3]

20.9.4 Contents and Furnishings.

20.9.4.1 Contents and furnishings shall not be required to comply with Section 12.6. [***101:***30.7.2.1; ***101:***31.7.2.1]

20.9.4.2 Furnishings or decorations of an explosive or highly flammable character shall not be used outside of dwelling units. [***101:***30.7.2.2; ***101:***31.7.2.2]

20.9.4.3 Fire-retardant coatings shall be maintained to retain the effectiveness of the treatment under service conditions encountered in actual use. [***101:***30.7.2.3; ***101:***31.7.2.3]

20.10 Lodging or Rooming Houses

Section 20.10 addresses the requirements for both new and existing lodging or rooming houses. These facilities provide sleeping accommodations for 16 or fewer occupants on a transient basis. While some users of the *Code* might confuse lodging or rooming facilities with a hotel occupancy — or a board and care facility — the primary differences among the occupancies center on the total number of occupants served and the nature of any personal care that is provided. While some of these facilities might provide what appear to be longer-term, daily living accommodations, other facilities, such as a bed-and-breakfast facility, might provide accommodations on a short-term basis. If a bed-and-breakfast facility serves more than 16 occupants, it would be appropriate to use Section 20.8 for hotels and dormitories to evaluate the requisite life safety features.

Commentary Table 20.3 is a guide to the appropriate occupancy chapter for multi-tenant residential occupancies.

20.10.1 Application. New and existing lodging or rooming houses shall comply with Section 20.10 and NFPA *101*.

COMMENTARY TABLE 20.3 *Comparative Factors for Classification of Residential Occupancies*

Factor	*Section 20.10 and Chapter 26 of NFPA 101 Lodging or Rooming Houses*	*Section 20.8 and Chapters 28 and 29 of NFPA 101 Hotels and Dormitories*	*Section 20.9 and Chapters 30 and 31 of NFPA 101 Apartment Buildings*	*Section 20.5 and Chapters 32 and 33 of NFPA 101 Residential Board and Care*
Occupants of a transient nature?	Yes	Yes	No	No
Number of occupants in facility?	16 or fewer	More than 16	As few as 3; application based on presence of 3 or more independent dwelling units	4 or more
Personal care services provided?	No	No	No	Yes

20.10.2 Fuel-Fired Heaters. Unvented fuel-fired heaters, other than gas space heaters in compliance with NFPA 54, shall not be used. [***101:***26.5.2.2]

Unvented fuel-fired heaters can produce dangerous CO levels. The danger from CO cannot be stressed enough. Depending on the concentrations of CO within a space, a person can quickly become disabled and suffer fatal injuries.

20.10.3 Interior Finish.

20.10.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***26.3.3.1]

20.10.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be Class A, Class B, or Class C. [***101:***26.3.3.2]

20.10.3.3 Interior Floor Finish.

20.10.3.3.1 Newly installed interior floor finish shall comply with Section 12.5. [***101:***26.3.3.3.1]

20.10.3.3.2 Newly installed interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***26.3.3.3.2]

20.10.4 Contents and furnishings shall not be required to comply with Section 12.6. [***101:***26.7.1.1]

20.10.4.1 Furnishings or decorations of an explosive or highly flammable character shall not be used. [***101:***26.7.1.2]

20.10.4.2 Fire-retardant coatings shall be maintained to retain the effectiveness of the treatment under service conditions encountered in actual use. [***101:***26.7.1.3]

20.11 One- and Two-Family Dwellings and Manufactured Housing

Although most people feel safest in their homes, fire deaths in the home account for some 80 percent of all fatalities attributable to fire in the United States. Section 20.11 and Chapter 24 of NFPA *101* highlight a number of factors that significantly mitigate the fire problem. A key and unique component that is addressed in Chapter 24 of NFPA *101* and that is selectively applied to the other residential chapters is means of escape (see Section 24.2 of NFPA *101*). The concept of means of escape focuses on providing a second way out of an occupied room or space within a living unit, regardless of whether it is a single-family home or a dwelling unit within an apartment building. Means of escape features do not need to meet the high standards and criteria that apply to the means of egress. In short, means of escape is an important yet broadly applied concept that is intended to reduce the chance of occupants becoming trapped in a room or space if the primary egress route is unavailable.

Recognizing that the greatest number of fire fatalities occur in what has historically been the least regulated occupancy, the *Code* has required, since the 2006 edition, all new one- and two-family dwellings to be protected by automatic sprinkler systems. Residential sprinkler systems have a phenomenal record of success in preventing fire deaths and injuries. Although residential sprinkler systems are designed exclusively to protect life and not necessarily property, many homes and personal possessions have, in fact, been saved from the devastating effects of fire thanks to their installation.

20.11.1 Application. New and existing one- and two-family dwellings shall comply with Section 20.11 and NFPA *101*.

Considerable debate has centered on the term *family*. The intent of 24.1.1.2 of NFPA *101* is not to define the term; however, A.24.1.1.2 of NFPA *101* provides assistance in determining where the term is inappropriate and another chapter of the *Code* should be used. If more than three outsiders are accommodated in rented rooms within a dwelling unit, the occupancy should be classified as a lodging or rooming house and should meet the requirements of Section 20.10 and Chapter 26 of NFPA *101*. The reasoning behind this classification guideline is that outsiders do not tend to keep each other as informed as family members do with regard to conditions within the building. In addition, when occupying their rooms, they keep their room doors closed more often than do family members. The lack of communication and reduced openness and awareness justify the additional alarm system, vertical opening, and corridor wall and door requirements that apply to lodging or rooming houses.

20.11.2 Fuel-Fired Heaters. Unvented fuel-fired heaters shall not be used, unless they are listed and approved. [***101:***24.5.1.2]

Unvented fuel-fired heaters can produce dangerous CO levels. The danger from CO cannot be stressed enough. Depending on the concentrations of CO within a space, a person can quickly become disabled and suffer fatal injuries.

20.11.3 Interior Finish.

20.11.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***24.3.3.1]

20.11.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be Class A, Class B, or Class C. [***101:***24.3.3.2]

20.11.3.3 Interior Floor Finish. (Reserved) [***101:***24.3.3.3]

20.11.4 Fire Protection of Floors. In new construction, floor assemblies shall be provided with a continuous membrane of gypsum wallboard having a nominal thickness of not less than ½ in. (13 mm), or equivalent, to protect the floor framing members from a fire exposure from below.

20.11.4.1 Protection in accordance with 20.11.4 shall not be required where the building is protected by an approved automatic sprinkler system installed in accordance with 13.3.1.2.

20.11.4.2 Protection in accordance with 20.11.4 shall not be required for floor assemblies located directly over a crawl space not intended for storage or fuel-fired equipment.

20.11.4.3 Portions of floor assemblies shall be permitted to be unprotected where the aggregate area of the unprotected portions does not exceed 80 ft^2 (7.4 m^2) per story and where fire blocking is installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.

20.11.4.4* Protection in accordance with 20.11.4 shall not be required in floor assemblies using wood joists with nominal dimensions not less than 2 in. (51 mm) in thickness by 10 in. (254 mm) in width, or other approved floor assemblies providing equivalent performance.

A.20.11.4.4 Materials such as wood I-Joist, wood or steel trusses, or cold formed steel would not typically be considered equivalent.

20.11.4.5 Protection in accordance with 20.11.4 shall not be required in floor assemblies using wood joist structural composite lumber that are compliant with ASTM D5456 and that have dimensions not less than 1½ in. (38 mm) in thickness by 9¼ in. (235 mm) in width.

20.11.4.6 Penetrations by mechanical, plumbing, fire protection, and electrical systems through the membrane protection required by 20.11.4 shall not be required to be protected.

The intent of the requirements of 20.11.4 is to provide for a minimal degree of structural fire resistance for floors in new nonsprinklered one- and two-family dwellings to permit for fire department search and rescue operations. It is not uncommon for the room of fire origin to be fully involved by the time the fire department arrives on the scene; in many cases, the fire has extended beyond the room of origin. With no sprinkler system to keep the fire in check, the fire intensity can significantly affect the structural stability of floor construction and increase the risk to search and rescue crews.

While it is noted that the *Code* requires all new one- and two-family dwellings to be protected by automatic sprinkler systems (see 13.3.2.20.1), it is recognized that not all jurisdictions will include such requirement in their *Code* adoptions. For this reason, the *Code* includes the requirements of 20.11.4 for new, nonsprinklered one- and two-family dwellings.

Δ **20.11.5 Manufactured Housing.** New manufactured housing shall comply with Section 20.11 and NFPA 501.

NFPA 501, *Standard on Manufactured Housing*, covers all the equipment and installations used in the design, construction, transportation, fire safety, plumbing, heat-producing, and electrical systems of manufactured homes that are designed to be used as dwelling units.

20.12 Mercantile Occupancies

Mercantile occupancies include stores, markets, and other rooms, buildings, or structures used for the display and sale of merchandise. This occupancy classification includes, but is not limited to, the following:

1. Supermarkets
2. Convenience stores
3. Department stores
4. Hardware stores
5. Video sales/rental stores
6. Pharmacies
7. Rental equipment centers
8. Automobile sales showrooms
9. Flea markets and craft centers
10. Building materials/supplies centers
11. Shopping centers/malls
12. Office supply stores
13. Computer and electronics stores
14. Sporting goods stores
15. Warehouse club stores

Minor merchandising operations in buildings that house other predominant occupancies, such as a newsstand in an office building, are typically classified as incidental uses and must, therefore, meet the *Code* requirements of the predominant occupancy (see 6.1.14.1.3).

The life safety provisions for mercantile occupancies are based on their characteristic of displaying merchandise for sales purposes, which introduces significant quantities of fuel in sales areas occupied by persons who are mostly unfamiliar with the building. Mercantile occupancies are also characterized by the use of layouts of merchandise displays and store fixtures that can confuse the egress path. Fires in department stores, mall buildings, and similar mercantile occupancies that once resulted in occupant fatalities have been practically unheard of in the United States over the past two decades. Although some serious fires have occurred in such properties, the established *Code* provisions have served the life safety needs of the occupants very well.

As marketing techniques change to meet consumer demands — beginning in the 1960s, when the first covered shopping malls were built — store design and layout also change. Consumers are offered choices that include everything from one-stop shopping to unique specialty stores. As the big-box store concept became popular in the early 1980s, the general public found itself shopping in warehouse-type surroundings. The *Code* provisions that apply to mercantile occupancies have recognized these challenges to providing adequate life safety via a combination of flexible general requirements and specialized provisions, such as those contained in 36.4.4 and 37.4.4 of NFPA *101* for mall buildings and 36.4.5 and 37.4.5 of NFPA *101* for bulk merchandising retail buildings.

The features of a mercantile occupancy that determine the needed protection include the items for sale, the location of the areas occupied by the public with respect to the level of exit discharge, and the size (i.e., gross area) of the facility. Guidance on establishing the appropriate subclassification for mercantile occupancies is provided by 36.1.2.2 and 37.1.2.2 of NFPA *101*.

Establishing and controlling the widths of aisles that lead to exits is an important consideration. For example, 36.2.5.5 and 37.2.5.5 of NFPA *101* establish minimum widths, which are based on the clear width, to prevent boxed or loose merchandise from obstructing the egress path. In certain larger stores, minimum 60 in. (1525 mm) aisles might be the norm to accommodate shopping carts as well as large numbers of occupants. Automatic sprinkler protection and a manual fire alarm system complement the major features of the protection package for the larger Class A stores.

The requirements for bulk merchandising retail buildings found in 36.4.5 and 37.4.5 of NFPA *101* establish criteria that meet the special needs of such stores. The typical bulk merchandising retail store includes display and storage racks that are often more than 20 ft (6100 mm) high. Display merchandise is typically maintained at the lower levels, while the excess inventory of merchandise is stored on the upper tiers of the rack systems. In such cases, the range of materials in the occupancies is extensive and can include building materials, paint, electrical equipment, and indoor/outdoor power equipment and appliances. In some cases, the store inventory might consist of foodstuffs as well as household goods. Due to the crossover nature of such occupancies — which are part warehouse and part retail store — 36/37.4.5.2 and 36/37.4.5.3 of NFPA *101* establish requirements for providing the egress measures needed for an occupancy with a large occupant load and the fire protection measures needed for a warehouse.

20.12.1 Application. New and existing mercantile occupancies shall comply with Section 20.12 and NFPA *101*.

20.12.2 Operating Features.

20.12.2.1 Emergency Plans. Emergency action plans complying with Section 10.8 shall be provided in high-rise buildings. [***101:***36.7.1; ***101:***37.7.1]

The AHJ should require that a plan be put in place to ensure that the staff of the mercantile occupancy has been trained in their duties as specified by the emergency plan.

20.12.2.2 Drills. In every Class A or Class B mercantile occupancy, employees shall be periodically trained in accordance with Section 10.5. [***101:***36.7.2; ***101:***37.7.2]

20.12.2.3 Extinguisher Training. Employees of mercantile occupancies shall be periodically instructed in the use of portable fire extinguishers. [***101:***36.7.3; ***101:***37.7.3]

The AHJ determines the extent of the extinguisher training required by 20.12.2.3 (e.g., instruction only or instruction and hands-on use).

20.12.2.4 Food Service Operations. Food service operations shall comply with Chapter 50. [***101:***36.7.4; ***101:***37.7.4]

N **20.12.2.5 Inspection of Door Openings.** Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***36.7.7; ***101:***37.7.7]

N **20.12.2.6 Integrated Fire Protection Systems.** In new apartment buildings, integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***36.7.8; ***101:***37.7.8]

20.12.3 Interior Finish.

20.12.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***36.3.3.1; ***101:***37.3.3.1]

20.12.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be Class A, Class B, or Class C. [***101:***36.3.3.2; ***101:***37.3.3.2]

20.12.3.3 Interior Floor Finish.

20.12.3.3.1 New interior floor finish shall comply with Section 12.5. [***101:***36.3.3.3.1]

20.12.3.3.2 New interior floor finish in exit enclosures shall be Class I or Class II. [***101:***36.3.3.3.2]

20.12.3.3.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***36.3.3.3.3]

20.12.3.3.4 Existing Interior Floor Finish. (Reserved) [***101:***37.3.3.3]

20.13 Business Occupancies

Business occupancies, such as the one shown in Exhibit 20.22, are typically occupied by persons who are awake and ready to begin emergency egress or relocation, with little or no staff assistance, as soon as they become aware of a fire. Exhibit 20.22 depicts a typical business occupancy building.

Historical evidence validates that the package of life safety features imposed on business occupancies by the *Code* does not need to be extensive. Nonetheless, several notable multiple-death fires have occurred in business occupancies in the United States in recent years. (For the purposes of fire data analysis, the term *multiple-death* means three or more fatalities.)

On October 17, 2003, a fire broke out on the twelfth floor of the 37-story, nonsprinklered Cook County Administration Building in Chicago, Illinois. Six occupants perished after becoming trapped in an exit stair. On February 9, 2000, a fire took place in a 3-story (with a basement), partially sprinklered building in Newton, Massachusetts, and resulted in five deaths. The fire, of

Exhibit 20.22

Typical business occupancy building.

undetermined cause, started in a second-floor nonsprinklered office. Smoke spread quickly throughout the building, making escape impossible for those victims who perished. Another fire resulting in five deaths took place in an Atlanta, Georgia, high-rise office building in 1989. One of the fire victims was intimate with the fire source in an electrical vault; the other four victims were occupying their areas on the same floor when the fire began. This was the first office building fire in 17 years to result in more than three fatalities.

The life safety features in Section 20.13 and Chapters 38 and 39 of NFPA *101* center on arrangement of the means of egress as well as alarm and occupant notification provisions. The travel distance and common path of travel allowances are generous. Fire resistance–rated corridor walls or other mitigating features, such as sprinkler protection, are required in an effort to keep the means of egress system usable.

20.13.1 Application. New and existing business occupancies shall comply with Section 20.13 and NFPA *101*.

20.13.2 Operating Features.

20.13.2.1 Emergency Plans. Emergency action plans complying with Section 10.8 shall be provided in high-rise buildings. [***101:***38.7.1; ***101:***39.7.1]

Emergency action plans must be provided for both new and existing high-rise business occupancies per 20.13.2.1. This requirement, along with the companion requirements of Section 10.8 and the associated Annex A material, were developed and revised, respectively, in response to recommendations by the NFPA High Rise Building Safety Advisory Committee, which was appointed following the collapse of the World Trade Center towers on September 11, 2001. See Section 10.8 and its associated commentary for details on the contents of the required emergency action plan.

20.13.2.2 Drills. In all business occupancy buildings occupied by more than 500 persons, or by more than 100 persons above or below the street level, employees and supervisory personnel shall be periodically instructed in accordance with Section 10.5 and shall hold drills periodically where practicable. [***101:***38.7.2; ***101:***39.7.2]

The AHJ should ensure that business occupancies conduct evacuation drills in accordance with 20.13.2.2. The term *periodically* is not defined, but, at a minimum, there should be one full drill per year and quarterly instruction provided to both new and existing staff.

20.13.2.3 Extinguisher Training. Designated employees of business occupancies shall be periodically instructed in the use of portable fire extinguishers. [***101:***38.7.3; ***101:***39.7.3]

The AHJ determines the extent of the portable fire extinguisher training required by 20.13.2.3 (e.g., instruction only, or instruction and hands-on use).

20.13.2.4 Food Service Operations. Food service operations shall comply with Chapter 50. [***101:***38.7.4; ***101:***39.7.4]

N **20.13.2.5 Inspection of Door Openings.** Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***38.7.7; ***101:***39.7.7]

Added in the 2015 edition of the *Code*, 20.13.2.5 mandates the annual inspection of egress doors equipped with panic hardware or fire exit hardware, doors in exit enclosures, electrically controlled egress doors, and doors with special locking arrangements, via the reference to 7.2.1.15 of NFPA *101*, which is also included in this *Code* as Section 14.5.11 The intent is to ensure that such doors, which might not be used routinely, operate properly in an emergency. See 7.2.1.15 of NFPA *101* or 14.5.11 of this *Code* and its associated commentary for additional details on the required inspection.

20.13.3 Interior Finish.

20.13.3.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***38.3.3.1; ***101:***39.3.3.1]

20.13.3.2 Interior Wall and Ceiling Finish.

20.13.3.2.1 Interior wall and ceiling finish material complying with Section 12.5 shall be Class A or Class B in exits and in exit access corridors. [***101:***38.3.3.2.1; ***101:***39.3.3.2.1]

20.13.3.2.2 Interior wall and ceiling finishes shall be Class A, Class B, or Class C in areas other than those specified in 20.13.3.2.1. [***101:***38.3.3.2.2; ***101:***39.3.3.2.2]

20.13.3.3 Interior Floor Finish.

20.13.3.3.1 New interior floor finish shall comply with Section 12.5. [***101:***38.3.3.3.1]

20.13.3.3.2 New interior floor finish in exit enclosures shall be Class I or Class II. [***101:***38.3.3.3.2]

20.13.3.3.3 New interior floor finish shall comply with 12.5.9.1 or 12.5.9.2, as applicable. [***101:***38.3.3.3.3]

20.13.3.3.4 Existing Interior Floor Finish. (Reserved) [***101:***39.3.3.3]

20.14 Industrial Occupancies

The industrial occupancy classification is broad in its scope and application. For examples of industrial occupancies, see A.6.1.12.1.

The range of facilities that are classified as industrial occupancies is diverse. Industrial occupancies comprise a wide variety of building configurations, uses, and equipment types. Some industrial occupancies might be considered innocuous with respect to the threat of fire hazard, such as a factory that manufactures concrete blocks. An industrial occupancy subject to the threat of serious fire hazard might be a petroleum processing and refining plant, where the threat of explosion is always present. The subclassification system used in 40.1.2.1 of NFPA *101* is intended to assist the user in establishing the level of hazard to the occupants of an industrial occupancy.

One of the major features to be considered in the design of an industrial occupancy's life safety system is the use of automatic sprinkler protection. Originally developed for industrial property protection, automatic sprinkler systems have also been largely responsible for an excellent life safety record in industrial occupancies — limiting the size of a fire by means of sprinklers provides sufficient time for the safe evacuation of occupants. This record has been recognized by the fire protection community, as evidenced by the widespread use of automatic sprinkler systems in buildings with significant hazards to life. The contribution of the automatic sprinkler to safety to life can be fully appreciated only when the wide range of fire risks associated with the many processes used in an industrial facility are recognized.

Employees and other occupants of industrial buildings are generally ambulatory and capable of quick response to fires. They are also able to exit rapidly once properly alerted. To capitalize on this employee capability, many industrial facilities include life safety measures in their emergency preplanning. A well-conceived plan provides a valuable tool in preventing loss of life. Provisions that should be part of the emergency pre-plan include the following:

1. Measures for alerting employees
2. Identification and posting of exit access routes
3. Establishment of group assembly areas for occupants once they have evacuated the building
4. Procedures for determining that all employees have safely evacuated

Responsibilities are usually established and assigned in the pre-plan to ensure that the tasks necessary to facilitate safe evacuation of the building are performed. The pre-plan should routinely be evaluated through simulated fire exercises and drills. Only through the execution of such drills can flaws in the pre-plan be recognized and modified.

Although the life safety record in industrial occupancies has been good, the trend toward constructing large industrial plants that house hazardous operations might prove problematic. The introduction of combustible materials, such as extensive quantities of plastics, has increased the need for additional measures to help protect workers from fire. Compared with the industrial buildings of the early twentieth century, the modern industrial complex has placed a larger number of employees in a more complex and increasingly hazardous environment. This trend has increased the need for facility managers to concentrate on life safety principles, not only during the design stage but also during day-to-day plant operations.

As part of their employee training programs, most industrial firms include education in the use of first aid fire-fighting equipment, such as in-plant standpipes, hose, and portable fire extinguishers. Although first aid fire-fighting measures are primarily a property protection measure, they also provide a significant life safety benefit when utilized correctly by trained individuals. Industrial training of this type, where fully utilized, has resulted in a major reduction in loss of property and life.

20.14.1 Application. New and existing industrial occupancies shall comply with Section 20.14 and NFPA *101*.

20.14.2 Permits. Permits, where required, shall comply with Section 1.12.

N **20.14.3 Operating Features.**

N **20.14.3.1 Inspection of Door Openings.** Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*.[***101:***40.7.3]

Paragraph 20.14.3.1 mandates the annual inspection of egress doors equipped with panic hardware or fire exit hardware, doors in exit enclosures, electrically controlled egress doors, and doors with special locking arrangements, via the reference to 7.2.1.15, also included in this *Code* as 14.5.11. The intent is to ensure that such doors, which might not be used routinely, operate properly in an emergency. See 7.2.1.15 of NFPA *101* or 14.5.11 of this *Code* and its associated commentary for additional details on the required inspection.

N **20.14.3.2 Integrated Fire Protection Systems.** Integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***40.7.4]

Subsection 13.1.3 is new to the 2018 edition of the *Code*. By reference to this new subsection, all industrial occupancies will require that, where two or more fire protection or life safety systems are integrated, the integrated system be tested to verify the proper operation and function of the system in accordance with NFPA 4. See the commentary associated with 13.1.3 for more information.

20.14.4 Interior Finish.

20.14.4.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***40.3.3.1]

20.14.4.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 12.5 shall be Class A, Class B, or Class C in operating areas and shall be as required by 7.1.4 of NFPA *101* in exit enclosures. [***101:***40.3.3.2]

20.14.4.3 Interior Floor Finish.

20.14.4.3.1 Interior floor finish in exit enclosures and in exit access corridors shall be Class I or Class II in accordance with 12.5.9.4. [***101:***40.3.3.3.1]

20.14.4.3.2 Interior floor finish in areas other than those specified in 20.14.4.3.1 shall not be required to comply with 12.5.9. [***101:***40.3.3.3.2]

20.15 Storage Occupancies

Storage occupancies include all buildings or structures used primarily for the storage or sheltering of goods, merchandise, products, or vehicles. For examples of storage occupancies, see A.6.1.13.1.

Section 20.15 and Chapter 42 of NFPA *101* cover a range of facilities used for storage of a wide variety of commodities. While the same life safety philosophy that prevails in the other occupancy chapters applies to storage occupancies, the protection scheme is less complicated, given the relatively small number of people who characteristically occupy a storage occupancy. Although some warehouse facilities are substantially larger than buildings housing other occupancies, few people typically occupy them.

Once the basic characteristics of a given storage occupancy are determined, the general protection measures of Sections 42.2 and 42.3 of NFPA *101* can be applied. In addition to these measures, the supplementary provisions that are specific to a particular type of storage occupancy can be applied. These provisions include those for aircraft storage hangars (Section 21.1), grain and other bulk storage elevators (20.15.5), and parking structures (Chapter 29).

20.15.1 Application. New and existing storage occupancies shall comply with NFPA *101*, Chapter 34, appropriate codes or standards referenced in Chapter 2, and Section 20.15.

20.15.2 Permits. Permits, where required, shall comply with Section 1.12.

N **20.15.3 Operating Features.**

N **20.15.3.1 Inspection of Door Openings.** Door openings shall be inspected in accordance with 7.2.1.15 of NFPA *101*. [***101:***42.9.3]

Paragraph 20.15.3.1 mandates the annual inspection of egress doors equipped with panic hardware or fire exit hardware, doors in exit enclosures, electrically controlled egress doors, and doors with special locking arrangements, via the reference to 7.2.1.15, and also included in this *Code* as 14.5.11. The intent is to ensure that such doors, which might not be used routinely, operate properly in an emergency. See 7.2.1.15 of NFPA *101* or 14.5.11 of this *Code* and its associated commentary for additional details on the required inspection.

N **20.15.3.2 Integrated Fire Protection Systems.** Integrated fire protection systems shall be tested in accordance with 13.1.3. [***101:***42.9.4]

Subsection 13.1.3 is new to the 2018 edition of the *Code*. By reference to this new subsection, storage occupancies require that, where two or more fire protection or life safety systems are integrated, the integrated system be tested to verify the proper operation and function of the system in accordance with NFPA 4. See the commentary associated with 13.1.3 for more information.

20.15.4 Interior Finish.

20.15.4.1 General. Interior finish shall be in accordance with Section 12.5. [***101:***42.3.3.1]

20.15.4.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials shall be Class A, Class B, or Class C in accordance with 12.5 in storage areas and shall be as required by 7.1.4 of NFPA *101* in exit enclosures. [***101:***42.3.3.2]

20.15.4.3 Interior Floor Finish.

20.15.4.3.1 Interior floor finish in exit enclosures and in exit access corridors shall be Class I or Class II. [***101:***42.3.3.3.1]

20.15.4.3.2 Interior floor finish in areas other than those specified in 20.15.4.3.1 shall not be required to comply with 12.5.9. [***101:***42.3.3.3.2]

Δ **20.15.5 Bulk Storage Elevators.** Bulk storage elevators shall comply with 20.15.5 and NFPA 61.

Δ **20.15.5.1* Application.** The requirements of 20.15.5 shall apply to all of the following:

(1) All facilities that receive, handle, process, dry, blend, use, mill, package, store, or ship dry agricultural bulk materials, their by-products, or dusts that include grains, oilseeds, agricultural seeds, legumes, sugar, flour, spices, feeds, dry dairy/food powders, and other related materials
(2) All facilities designed for manufacturing and handling starch, including drying, grinding, conveying, processing, packaging, and storing dry or modified starch, and dry products and dusts generated from these processes
(3) Those seed preparation and meal-handling systems of oilseed processing plants not covered by NFPA 36

[**61:**1.3.1]

A.20.15.5.1 Examples of facilities covered by NFPA 61 include, but are not limited to, bakeries, grain elevators, feed mills, flour mills, milling, corn milling (dry and wet), rice milling, dry milk products, mix plants, soybean and other oilseed preparation operations, cereal processing, snack food processing, tortilla plants, chocolate processing, pet food processing, cake mix processing, sugar refining and processing, and seed plants. [**61:**A.1.3.1]

20.15.5.2 Subsection 20.15.5 shall not apply to oilseed extraction processes that are covered by NFPA 36. [**61:**1.3.2]

20.15.5.3 Applicability.

20.15.5.3.1 Unless otherwise noted, the provisions of 20.15.5 on bulk storage elevators shall not be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of this *Code*, except in those cases where it is determined by the AHJ that the existing situation involves a distinct hazard to life or adjacent property.

20.15.5.3.2 The requirements of Chapter 11 of NFPA 61 shall apply to all facilities.

20.15.6 Record Storage.

Δ **20.15.6.1** Records protection equipment, facilities, and records-handling techniques that provide protection from the hazards of fire shall comply with 20.15.6 and NFPA 232.

NFPA 232, *Standard for the Protection of Records*, provides requirements for records protection equipment and facilities and records-handling techniques that provide protection from the hazards of fire. NFPA 232 does not consider forcible entry. NFPA 232 covers the following four categories of records storage environments and corresponding levels of risk tolerance:

1. Records vaults — provide the highest level of protection
2. File rooms — provide an intermediate level of protection for active and semiactive records
3. Archival storage — provides a high level of protection for permanently valuable records
4. Records centers — provide an intermediate level of protection for temporary records

NFPA 232 does not cover the storage and handling of useful records. For the storage and handling of cellulose nitrate motion picture film records, see 20.15.7.

20.15.6.2* Because of the volume of records, 20.15.6.1 shall not cover large archives or records storage buildings.

Δ **A.20.15.6.2** See NFPA 232 where large archives or records storage buildings are involved.

20.15.7 Cellulose Nitrate Motion Picture Film Storage.

Δ **20.15.7.1 Application.** The storage and handling of cellulose nitrate film records shall comply with 20.15.7 and NFPA 40.

20.15.7.2 Permits. Permits, where required, shall comply with Section 1.12.

NFPA 40 applies to all facilities that are involved with the storage and handling of cellulose nitrate–based film. NFPA 40 does not apply to the storage and handling of film having a base other than cellulose nitrate. NFPA 40 includes general provisions regarding the storage and handling of cellulose nitrate film and special provisions for such occupancies as motion picture projection booths, nitrate film vaults, and laboratories handling nitrate film. These special provisions apply in addition to any and all applicable general provisions.

20.15.8 High-Piled Storage.

20.15.8.1 Application. Buildings containing high-piled storage shall comply with Chapter 13, Chapter 34, and 20.15.8.

20.15.8.2 Permits. Permits, where required, shall comply with Section 1.12.

20.15.8.3 Fire Department Hose Connections.

20.15.8.3.1 When any portion of the high-piled combustible storage area is greater than 200 ft (61 m) from a fire department access door, Class I standpipe outlets connected to a system sized to deliver 250 gpm (946.4 L/min) at the most hydraulically remote outlet shall be provided in accordance with 20.15.8.3.

20.15.8.3.2 The outlet shall be permitted to be supplied from the sprinkler system and shall be hydraulically calculated.

20.15.8.3.3 Standpipe outlets shall be provided at each of the following locations:

(1) In each exit passageway at the entrance from the storage areas into the passageway
(2) At each intermediate landing between floor levels in every required exit stairway serving the storage area
(3) At exterior entrances into the storage

20.16 Special Structures and High-Rise Buildings

The facilities to which Section 20.16 provisions might be applied range from a refinery petroleum-cracking plant to an air traffic control tower. While the life safety and functional use considerations of such properties might, at times, seem to conflict, this section and Chapter 11 of NFPA *101* provide the necessary guidance to make them safe as well as functional.

Examples of usual occupancies housed in unusual surroundings or special structures include a large convention center located on a pier where the facility is surrounded by water on three sides, or a storage facility located completely below grade level. Exhibit 20.23 depicts an air traffic control tower, which is an example of a usual occupancy in an unusual structure.

Exhibit 20.23

Air traffic control tower at Denver International Airport. (Courtesy of Denver International Airport)

The AHJ should ensure that any engineered solutions to the special structure's inherent egress deficiencies provide an overall level of life safety equivalent to that specified by the requirements of the NFPA *101* occupancy chapter that applies to the structure's use. In some cases, a structure might be so unusual that the only practical option is a complete performance-based design in accordance with Chapter 5.

Section 20.16 of this *Code* and Chapter 11 of NFPA *101* also regulate water-surrounded structures, vehicles and vessels, and limited-access (referred to as *windowless* prior to the 2003 edition of NFPA *101*) and underground structures. These provisions apply regardless of the occupancy classification. For example, a permanently moored ship that is used as a hotel with restaurants and other entertainment facilities must comply with Section 20.1 of this *Code* and Chapter 12 or Chapter 13 of NFPA *101*, for assembly occupancies, and Section 20.8 of this *Code* and Chapter 28 or Chapter 29 of NFPA *101*, for hotels and dormitories, as appropriate, by virtue of the language in 11.6.2 of NFPA *101*. The Queen Mary, which has been permanently moored in Long Beach, California, since 1967, is an example of such an occupancy. See Exhibit 20.24.

Section 11.8 of NFPA *101* presents a series of unique provisions applicable to high-rise buildings. Sections 11.9 through 11.11 of NFPA *101* provide a series of requirements applicable to membrane structures and tents. See Chapter 25 for additional guidance on this subject.

Exhibit 20.24

The Queen Mary in Long Beach, CA. (Courtesy of the Queen Mary, Long Beach, CA)

20.16.1 Application.

20.16.1.1 New and existing special structures and high-rise buildings shall comply with NFPA *101*.

20.16.1.2 Motion picture and television production studio soundstages and approved production facilities shall comply with Chapter 32.

20.17 Historic Buildings and Cultural Resources

Historic buildings pose unique fire and life safety problems. Historic structures are irreplaceable artifacts of history and culture with immeasurable, intangible value. Special consideration is necessary to design fire and life safety into such structures without sacrificing historic integrity. The AHJ must have latitude in applying the *Code* to historic structures, because strict compliance, in most cases, cannot be achieved without considerable expense and usually provides little or no gain in safety.

The provisions of NFPA 909, *Code for the Protection of Cultural Resource Properties — Museums, Libraries, and Places of Worship*, and NFPA 914, *Code for Fire Protection of Historic Structures*, as referenced in Section 20.17, offer alternative approaches to providing for fire protection in historic buildings and cultural resource properties. A fundamental tenet of these codes involves bringing together all interested stakeholders at the start of a project, rather than at the project's conclusion, to ensure that the necessary level of fire and life safety is provided without destroying the building's historic fabric or cultural significance. Strict application of *Code* requirements without due consideration of their impact on a building's historic or cultural significance can be nearly as destructive as a fire.

Δ **20.17.1** Historic buildings shall comply with this *Code* or with the provisions of NFPA 914.

Subsection 20.17.1 applies to buildings that are designated as historic buildings by a local, regional, or national jurisdiction. Conditions created by deviating from full *Code* compliance should not constitute a serious life safety hazard.

NFPA 914 describes fire safety requirements for the protection of historic structures and for those who operate, use, or visit them. It covers ongoing operations, renovation, and restoration and acknowledges the need to preserve historic character. NFPA 914 addresses those construction, protection, operational, and occupancy features that are necessary to minimize danger to life, structures, and contents from the effects of fire, including smoke, heat, and fumes. NFPA 914 identifies the minimum fire safety criteria to allow prompt escape of the building occupants to a safe area and to minimize the impact of fire and fire protection on the structure, contents, or features associated with the historic character. For library and museum collections, see 20.17.2.

Δ **20.17.2** Buildings that store or display cultural resources, including museum or library collections, or spaces within other buildings used for such culturally significant purposes, shall comply with this *Code* or with the provisions of NFPA 909.

NFPA 909 describes principles and practices of fire safety for cultural resource properties (museums, libraries, and places of worship) and for those who operate, use, or visit them.

NFPA 909 covers ongoing operations and rehabilitation and acknowledges the need to preserve culturally significant and character-defining building features and sensitive, often irreplaceable, collections and to provide continuity of operations. NFPA 909 prescribes minimum requirements for the protection of cultural resource properties and their contents from fire through a comprehensive fire protection program.

20.17.3 The provisions of this *Code* relating to the construction, repair, alteration, enlargement, restoration, and moving of buildings or structures shall not be mandatory for the following:

(1) Existing buildings or structures identified and classified by the state or local government authority as historic buildings where such buildings comply with NFPA 914

(2)* Buildings or spaces within buildings that store or display cultural resources and comply with the provisions of NFPA 909

Δ **A.20.17.3(2)** See also NFPA 914.

Airports and Heliports

21

Chapter 21 addresses airport and heliport hangars and terminals. Aircraft refueling is covered in Section 42.10.

Δ 21.1 Hangars

The construction and protection of aircraft hangars from fire shall comply with this section; NFPA 409, NFPA 410, and Sections 40.6 and 42.6 of NFPA *101*.

NFPA 409, *Standard on Aircraft Hangars*, defines the term *aircraft hangar* as a "building or other structure inside any part of which aircraft are housed." NFPA 409 contains the minimum requirements for the proper construction of aircraft hangars and for their protection from fire.

NFPA 410, *Standard on Aircraft Maintenance*, covers the minimum requirements for fire safety to be followed during aircraft maintenance and does not include the health and safety requirements for personnel involved in aircraft maintenance. The operations include maintenance of electrical systems; maintenance of oxygen systems; fuel tank repair, cleaning, painting, and paint removal; welding operations in hangars; interior cleaning; and refurbishing operations. NFPA 410 also covers requirements for fire protection of aircraft ramp areas.

NFPA *101*®, *Life Safety Code*®, also deals with aircraft hangars: Section 40.6 covers aircraft servicing hangars, and Section 42.6 covers aircraft storage hangars.

21.1.1 Permits. Permits, where required, shall comply with Section 1.12.

21.1.2 Fire Department Access. Fire department access roads shall be provided and maintained in accordance with Section 18.2 for all aircraft hangars.

21.1.3 Smoking.

21.1.3.1 Smoking shall be prohibited in aircraft hangars.

21.1.3.2 Smoking shall be in accordance with Section 10.9.

21.1.4* Means of Egress Provisions for Aircraft Servicing Hangars.

Δ **A.21.1.4** For further information on aircraft hangars, see NFPA 409. [***101:***A.40.6]

21.1.4.1 The requirements of Sections 40.1 through 40.5 of NFPA *101* shall be met, except as modified by 21.1.4.2 through 21.1.4.4. [***101:***40.6.1]

21.1.4.2 The requirements for exits from aircraft servicing areas shall comply with 21.1.4.2.1 through 21.1.4.2.4. [***101:***40.6.2]

NFPA 409 defines an *aircraft storage and servicing area* as "that part of a hangar normally used for the storage and servicing of one or more aircraft, not including any adjacent or contiguous areas or structures, such as shops, storage areas, and offices."

21.1.4.2.1 There shall be not less than two means of egress from each aircraft servicing area. [***101:***40.6.2.1]

21.1.4.2.2 Exits from aircraft servicing areas shall be provided at intervals not exceeding 150 ft (46 m) on all exterior walls. [***101:***40.6.2.2]

21.1.4.2.3 Where horizontal exits are provided, doors shall be provided in the horizontal exit fire barrier at intervals not exceeding 100 ft (30 m). [***101:***40.6.2.3]

21.1.4.2.4 Where dwarf, or "smash," doors are provided in doors that accommodate aircraft, such doors shall be permitted for compliance with 21.1.4.2.1 through 21.1.4.2.3. [***101:***40.6.2.4]

21.1.4.3 Means of egress from mezzanine floors in aircraft servicing areas shall be arranged so that the travel distance to the nearest exit from any point on the mezzanine does not exceed 75 ft (23 m), and such means of egress shall lead directly to a properly enclosed stair discharging directly to the exterior, to a suitable cutoff area, or to outside stairs. [***101:***40.6.3]

21.1.4.4 Dead ends shall not exceed 50 ft (15 m) for other than high hazard contents areas and shall not be permitted for high hazard contents areas. [***101:***40.6.4]

21.1.5* Means of Egress Provisions for Aircraft Storage Hangars.

Δ **A.21.1.5** For further information on aircraft hangars, see NFPA 409. [***101:***A.42.6]

21.1.5.1 The requirements of Sections 42.1 through 42.5 of NFPA *101* shall be met, except as modified by 21.1.5.1.1 through 21.1.5.1.3. [***101:***42.6.1]

21.1.5.1.1 There shall be not less than two means of egress from each aircraft storage area. [***101:***42.6.1.1]

21.1.5.1.2 Exits from aircraft storage areas shall be provided at intervals not exceeding 150 ft (46 m) on all exterior walls. [***101:***42.6.1.2]

21.1.5.1.3 Where horizontal exits are provided, doors shall be provided in the horizontal exit fire barrier at intervals not exceeding 100 ft (30 m). [***101:***42.6.1.3]

21.1.5.1.4 Where dwarf, or "smash," doors are provided in doors that accommodate aircraft, such doors shall be permitted for compliance with 21.1.5.1.1, 21.1.5.1.2, and 21.1.5.1.3. [***101:***42.6.1.4]

21.1.5.2 Means of egress from mezzanine floors in aircraft storage areas shall be arranged so that the travel distance to the nearest exit from any point on the mezzanine does not exceed 75 ft (23 m), and such means of egress shall lead directly to a properly enclosed stair discharging directly to the exterior, to a suitable cutoff area, or to outside stairs. [***101:***42.6.2]

21.1.5.3 Dead ends shall not exceed 50 ft (15 m) for other than high hazard contents areas and shall not be permitted for high hazard contents areas. [***101:***42.6.3]

For provisions that apply to aircraft servicing hangars, see Section 40.6 of NFPA *101*.

Section 21.1.5 specifies two alternative methods of providing egress from aircraft storage hangars. Where egress is possible through the outside wall, a distance of 150 ft (46 m) between exit doors is adequate. In larger hangars, the storage bay might have offices and other rooms located along one or more sides, with the walls constructed of fire resistance–rated assemblies. In those cases where the wall has a fire resistance rating so as to qualify as a horizontal exit, exit door spacing of up to 100 ft (30 m) is specified. If the wall is nonrated, access to the outside is required. During inclement weather, when large hangar doors typically are closed, a common design method is to provide small access doors for personnel in the larger aircraft hangar door. The small doors can be considered normal means of egress from an aircraft hangar. If possible, the door should swing in the direction of egress; however, this might not be possible due to the design of the aircraft hangar door. A typical aircraft storage hangar is depicted in Exhibit 21.1.

Exhibit 21.1

Typical aircraft storage hangar.

21.2 Terminals

Δ **21.2.1 Application.** Airport terminal buildings shall comply with the requirements of Section 21.2 and NFPA 415.

The term *airport terminal building* is defined in 3.3.29.1 as "a structure used primarily for air passenger enplaning or deplaning, including ticket sales, flight information, baggage handling, and other necessary functions in connection with air transport operations. This term includes any extensions and satellite buildings used for passenger handling or aircraft flight service functions. Aircraft loading walkways and 'mobile lounges' are excluded." NFPA 415, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*, specifies the minimum fire protection requirements for the construction and protection of airport terminal buildings. In addition, the minimum requirements for the design, construction, and fire protection of aircraft loading walkways between the terminal building and aircraft are covered.

The term *terminal* is sometimes applied to airport facilities other than those serving passengers, such as cargo and freight facilities and fuel-handling facilities, which are covered by NFPA 30, *Flammable and Combustible Liquids Code*, and not by this chapter. See Chapters 20, 42, 60, and 66 for additional guidance.

Airport control towers are not considered part of the terminal building. See Section 20.16, which references NFPA *101* for requirements for these special structures.

The minimum requirements for the design and maintenance of the drainage system of an aircraft fueling ramp are specified to control the flow of fuel that can be spilled on a ramp and to minimize the resulting possible danger. Ramp drainage systems are intended to limit the fire and exposure hazard from fuel spillage. The requirements control the spread of a fuel spill to limit exposure to buildings, aircraft loading walkways, concourses, or elevated structures in order to prevent the fuel's liquid or vapors from reaching a source of ignition or accumulating within structures and thus limiting the spread of the fuel spill over the ramp surface. They also prevent the transmission of vapors by the drainage system from exposing aircraft or other equipment parked or operating on the ramp. NFPA 415 also specifies the minimum criteria for fire protection of aircraft loading walkways that can serve as an egress route from an aircraft in the event of a flammable liquid spill fire on the airport ramp that could expose the walkway and the aircraft.

21.2.2 General.

21.2.2.1 Permits. Permits, where required, shall comply with Section 1.12.

21.2.2.2 Fire Department Access. Fire department access roads for all airport terminal buildings shall be provided and maintained in accordance with Section 18.2.

21.2.3 Smoking.

21.2.3.1 Smoking shall be prohibited in fuel ramp areas and loading walkways.

21.2.3.2 Smoking shall be in accordance with Section 10.9.

21.2.4 General.

Δ **21.2.4.1** Airport terminal buildings shall be of Type I, Type II, or Type IV construction, as defined in NFPA 220.

See Section 12.2 and its associated commentary for descriptions of construction types as defined in NFPA 220, *Standard on Types of Building Construction*.

21.2.4.2* Interior finish materials shall be limited to Class A or Class B regardless of the occupant load. [**415:**4.1.2]

Δ **A.21.2.4.2** Furniture, floor and wall coverings, and other furnishings in airport terminal occupancies, including passenger holding lounges, waiting areas, restaurant dining rooms, bars, and retail stores, should not be made of materials that have high combustibility, smoke-development characteristics, or both, for example, some plastic foams, latex-rubber foam, some plastics, and some synthetic fibers. Such materials have a tendency to release combustible gases at relatively low temperatures, making them easily ignitible. When burning, these materials also release high amounts of heat energy at rapid rates, thereby contributing greatly to fire propagation. [**415:**A.4.1.2]

Interior finish Class A and Class B are described in NFPA *101*. [**415:**A.4.1.2]

See Section 12.5 for additional guidance on interior finish classifications.

Δ **21.2.4.3** Aircraft fueling facilities and ramps shall be designed in accordance with NFPA 407, and Chapter 5 of NFPA 415. [**415:**4.1.3]

Δ **21.2.4.4** Belowgrade areas and blind spaces in airport terminal buildings shall be protected against flammable fuel and vapor penetration or shall be mechanically ventilated to provide at least four complete air changes per hour. The mechanical ventilation system shall be installed in accordance with NFPA 91. [**415:**4.1.4]

Where operationally feasible, openings to areas of terminals that are belowgrade should not be located on the ramp side of the building, in order to minimize the probability of flammable fuel or vapors entering such areas.

21.2.4.5 Glazing Material–Covered Openings Facing the Ramp.

21.2.4.5.1 Openings covered with glazing material that have the lowest part of the glazing material not less than 7 ft (2.1 m) above each finished floor level shall not be required to comply with 21.2.4.5.3. [**415:**4.1.5.1]

21.2.4.5.2 Openings covered with glazing material listed for use in a fire barrier and installed in accordance with the listing shall not be required to comply with 21.2.4.5.3. [**415:**4.1.5.2]

21.2.4.5.3 Where potential fuel spill points are located less than 100 ft (30.5 m) horizontally from glazing material–covered openings in airport terminal building walls facing the airport ramp, they shall be provided with an automatically activated water spray system in accordance with 21.2.4.5.3.1 or an automatically activated, listed fire shutter system in accordance with 21.2.4.5.3.2. *(See Annex C of NFPA 415.)* [**415:**4.1.5.3]

Δ **21.2.4.5.3.1** Where an automatically activated water spray system(s) is provided, it shall be installed in accordance with NFPA 15. [**415:**4.1.5.3.1]

21.2.4.5.3.1.1 The system shall be designed to provide a density of at least 0.25 gpm/ft^2 [10.2 (L/min)/m^2] over the exterior surface area of the glazing material. [**415:**4.1.5.3.1.1]

21.2.4.5.3.1.2 Where multiple water spray systems are used, the water supply shall be capable of supplying all systems that could be expected to operate as a result of one fire incident. [**415:**4.1.5.3.1.2]

When the flow rate for the water supply is being determined, all heads must be included in the demand calculation. One method for performing this calculation is addressed in NFPA 13, *Standard for the Installation of Sprinkler Systems*, where the flow is calculated by multiplying the K-factor of the head by the square root of the pressure. In these calculations, the friction loss for the pipe, fittings, and elevation must be considered in the evaluation.

21.2.4.5.3.1.3 The detection system design analysis for the water spray system shall include consideration of false alarms and detector response time. [**415:**4.1.5.3.1.3]

21.2.4.5.3.2 Where an automatically activated, listed fire shutter is provided, it shall be installed in accordance with its listing. [**415:**4.1.5.3.2]

21.2.5 Heating, Ventilating, and Air Conditioning.

21.2.5.1 Heating, ventilating, and air-conditioning systems shall be installed in accordance with Section 11.2 and Section 11.5, as applicable.

21.2.5.2* Air supply intake and exhaust openings for air-conditioning or ventilating equipment serving the terminal building, if located on the ramp side, shall be not less than 10 ft (3 m) above the grade level of the ramp and shall be at least 50 ft (15 m) from any point of flammable vapor release. [**415:**4.2.2]

A.21.2.5.2 Examples of points of flammable vapor release are fuel tank vent openings and fuel hydrant pits. Air supply intake and exhaust openings for air-conditioning or ventilating equipment serving the terminal building should not be located on the ramp side of an airport terminal building. Fixed air-conditioning and ventilating equipment serving only aircraft should be in a room that has no openings communicating with the remainder of the terminal building. [**415:**A.4.2.2]

21.2.5.3* Openings to rooms that contain coal-, gas-, or oil-fired equipment or any other open-flame device and that face the ramp side of the terminal shall be above ramp grade and 50 ft (15 m) from any point of flammable vapor release. [**415:**4.2.3]

A.21.2.5.3 Rooms that contain coal-, gas-, or oil-fired equipment or any other open-flame device should not have openings on the ramp side of the building. Combustion and ventilation air should be supplied from the street side or the roof of the building or through a gravity louver from a nonhazardous area in the building. [**415:**A.4.2.3]

21.2.5.4 Stacks or chimneys from a boiler, heater, or incinerator shall terminate at least 20 ft (6.1 m) above ramp grade and above the roof of the building. Stacks or chimneys from boilers or heaters that use solid fuel or from any incinerator shall be fitted with double screening to control fly ash and sparks. Such stacks or chimneys shall be located so the outlet is at least 100 ft (30.5 m) horizontally from any aircraft position or point of flammable vapor release. [**415:**4.2.4]

Δ **21.2.5.5** Incinerators shall conform to the requirements of Chapter 4 of NFPA 82. [**415:**4.2.5]

21.2.5.6 Exhaust hood ventilation systems for restaurant and flight kitchens shall conform to the applicable portions of Chapter 50. [**415:**4.2.6]

See Chapter 50 and its associated commentary for additional guidance on the protection of commercial cooking operations.

21.2.6 Exits.

Δ **21.2.6.1** Airport terminal building means of egress shall conform to the requirements of NFPA *101*. [**415:**4.3.1]

21.2.6.2* In addition to the exit signage requirements specified in NFPA *101*, doors serving as exits that discharge onto an airport ramp and are provided solely for the purpose of meeting emergency egress requirements from public areas shall be placarded "Emergency Exit Only" in letters at least 2 in. (50 mm) high. [**415:**4.3.2]

A.21.2.6.2 The hazards to persons from jet intakes and blast, noise, propellers, and so forth, on the ramp should be taken into consideration in locating emergency exit points leading to ramps from the airport terminal building. A means of notification of unauthorized usage (such as an alarm system) of these emergency exits may be desirable. [**415:**A.4.3.2]

21.2.7* Fire Protection — Sprinkler Systems.

A.21.2.7 The assembly portion of the terminal building can include areas such as the concourse waiting areas, baggage claim areas, and restaurants. The assembly portion should exclude kitchens, toilets, small office areas, and other areas not normally accessible to the public. [**415:**A.4.5.1]

21.2.7.1 An airport terminal building with more than 12,000 ft² (1115 m²) total floor area for the assembly portion of the occupancy shall be provided with an automatic sprinkler system installed in accordance with Section 13.3. [**415:**4.5.1.1]

21.2.7.2 Terminal buildings with less than 12,000 ft² (1115 m²) total floor area for the assembly portion of the occupancy shall not be required to be provided with an automatic sprinkler system. [**415:**4.5.1.2]

21.2.7.3 Passenger-handling areas shall be classified as Ordinary Hazard Group 1 Occupancy, as defined in NFPA 13, for the purpose of sprinkler system design. [**415:**4.5.1.3]

21.2.7.4 Baggage, package, and mail-handling areas shall be classified as Ordinary Hazard Group 2 Occupancy, as defined in NFPA 13, for the purpose of sprinkler system design. [**415:**4.5.1.4]

21.2.7.5* Other areas of the airport terminal building shall be classified in accordance with Chapter 5 of NFPA 13, based on the occupancy of the area. [**415:**4.5.1.5]

A.21.2.7.5 The exposure to the airport terminal building from the airport ramp is significant. The number of building sprinklers operating from the exposure fire could be greater than the number of building sprinklers operating from an internal ignition source. [**415:**A.4.5.1.5]

Δ **21.2.7.6 Covered Plane-Loading Positions.** Airport terminal buildings having canopy areas or roofed-over recesses at aircraft loading positions that, in effect, place the aircraft totally or substantially under such canopies or roofs shall have the canopies or roofs protected by automatic sprinkler systems in accordance with NFPA 409. [**415:**4.5.1.6]

21.2.8 Fire Alarm and Communications Systems. A fire alarm and communications system shall be installed as required by 13.7.2.1. [**415:**4.5.2]

21.2.8.1 Means to alert the public fire department or the airport fire station shall be available through manual fire alarm pull stations. Manual fire alarm services shall be installed in accordance with *NFPA 72*. [**415:**4.5.2.1]

21.2.8.2* Annunciation for all building fire alarm signals shall be provided near the front entrance of the building. [**415:**4.5.2.2]

A.21.2.8.2 If the public fire department is responding to the "street" side of the airport terminal building, timely access to the normal alarm receiving point might be limited by emergency conditions or distance. Planned radio communication with a constantly attended alarm-receiving point can assist in a more efficient response by the public fire department. The remote annunciator on the street side of the terminal building can provide building condition information not otherwise available. [**415:**A.4.5.2.2]

21.2.8.3 If the public fire department has two-way voice communication with a constantly attended location, 21.2.8.2 shall not apply. [**415:**4.5.2.3]

21.2.9 Fire Hydrants. Fire hydrants shall be provided on both the ramp and the street sides of airport terminal buildings. Such hydrants shall be located so that no portion of the terminal building is more than 500 ft (152.4 m) from a hydrant. [**415:**4.5.3]

When the location of hydrants is being determined, the direction of approach for fire apparatus should be considered. Hydrants should be accessible to the fire department as it approaches the terminal. Consideration should also be given to traffic flow in front of the terminal, so that hose lines from the hydrant to the normal position where a pumper sets up or to a sprinkler or standpipe connection do not restrict traffic movement to the point that response by other apparatus is hampered. See Chapter 18 for additional fire flow and fire hydrant requirements.

21.2.10 Standpipe and Hose Systems. Standpipe and hose systems shall be provided for all airport terminal buildings in excess of two stories [35 ft (10.7 m)] in height or 100 ft (30.5 m) in shortest horizontal dimension. Standpipe and hose systems shall be installed in accordance with Section 13.2. [**415:**4.5.4]

21.2.10.1 Class I standpipe systems shall be provided in buildings protected throughout by an approved automatic sprinkler system. Each 2½ in. (63.5 mm) hose connection shall be equipped with a 2½ in. × 1½ in. (63.5 mm × 38 mm) reducer and cap. [**415:**4.5.4.1]

21.2.10.2 Class III standpipe systems shall be provided in nonsprinklered buildings. Paragraphs 5.3.3.1 and 5.3.3.2 of NFPA 14 for Class III systems shall be applicable to this requirement. [**415:**4.5.4.2]

21.2.11 Portable Fire Extinguishers. Portable fire extinguishers shall be provided throughout the airport terminal building in accordance with Section 13.6. [**415:**4.5.6]

21.3 Rooftop Heliport Construction and Protection

Δ **21.3.1 Application.** Rooftop heliport construction and protection shall comply with Section 21.3 and NFPA 418.

NFPA 418, *Standard for Heliports*, specifies the minimum requirements for fire protection for heliports and rooftop hangars and establishes minimum fire safety requirements for operation at heliports for the protection of persons, aircraft, and other property. NFPA 418 does not apply to ground-level helicopter hangars, temporary landing sites, and emergency evacuation facilities.

To identify specifically where the requirements for a rooftop heliport are to be applied, NFPA 418 includes two definitions that are relevant. The term *heliport* is defined as "an identifiable area located on land, on water, or on a structure that also includes any existing building or facilities thereon, used or intended to be used for the landing and takeoff of helicopters." (The term *heliport* applies to all sites used or intended to be used for the landing and takeoff of helicopters.) The term *rooftop landing pad* is defined as "the entire load-bearing surface intended for the touchdown and liftoff (TLOF) of helicopters." The requirements for helicopter landing sites are not intended to apply to entire roof areas or the building's structure beyond the landing area.

Note that NFPA 418 is not intended to apply to military aircraft with onboard armaments.

21.3.1.1 Section 21.3 shall not apply to ground level helicopter hangars. All hangars not covered by this section shall comply with NFPA 409.

21.3.1.2 Temporary landing sites and emergency evacuation facilities shall not be required to comply with Section 21.3.

21.3.2 General.

21.3.2.1 Permits. Permits, where required, shall comply with Section 1.12.

21.3.2.2 Fire Department Access. Fire department access roads for all buildings with a rooftop heliport shall be provided and maintained in accordance with Section 18.2.

21.3.2.3 Smoking.

21.3.2.3.1 Smoking shall be prohibited at rooftop heliports.

21.3.2.3.2 Smoking shall be in accordance with Section 10.9.

21.3.3 General Requirements — Land-Based Facilities.

21.3.3.1* Plans.

A.21.3.3.1 FAA AC 150/5390-2C, *Heliport Design Advisory Circular*, contains design and construction information on heliports. This advisory circular provides for adequate clearance between operating aircraft and buildings or structures located at the heliport. The FAA advisory circular should be consulted to ensure that adequate safe practice and facilities are maintained. [**418:**A.4.2]

21.3.3.1.1 The design drawings for the construction and protection of the heliport shall be approved by the AHJ. [**418:**4.2.1]

21.3.3.1.2 The design of the heliport, including all the aeronautical components, shall be in accordance with FAA AC 150/5390-2C, *Heliport Design Advisory Circular*. [**418:**4.2.2]

21.3.3.1.3 The final approach and takeoff (FATO) area, the approach/departure path, and the touchdown and liftoff (TLOF) area shall be designated on the design drawings. [**418:**4.2.3]

21.3.3.2 Tank and Equipment Locations.

21.3.3.2.1 Storage, handling, and use of flammable and combustible liquids shall be in accordance with Chapter 66. [**418:**4.3.1]

Δ **21.3.3.2.2** Oxygen and other medical gases shall be stored and used in accordance with NFPA 99. [**418:**4.3.2]

21.3.3.2.3 Aboveground flammable liquid storage tanks, compressed gas storage tanks, fuel storage tanks, and liquefied gas storage tanks shall be laterally located at least 50 ft (15.2 m) from the edge of the final approach and takeoff (FATO) area as defined in FAA AC 150/5390-2C, *Heliport Design Advisory Circular*. [**418:**4.3.3]

21.3.3.3 Fire-Fighting Access.

21.3.3.3.1 The heliport shall have at least two access points for fire-fighting/rescue personnel. The access points shall be located at least 90 degrees from each other as measured from the center of the landing pad (TLOF). [**418:**4.4.1]

21.3.3.3.2 Fences shall not prevent access by fire-fighting/rescue personnel. [**418:**4.4.2]

21.3.3.4 Fuel Spill Control. The landing pad shall be designed so that fuel spills are directed away from access/egress points and passenger holding areas. [**418:**4.5]

See the commentary following 21.3.4.2.

21.3.3.5 No Smoking.

For additional guidance on smoking restrictions, see Section 10.9.

21.3.3.5.1 No smoking shall be permitted within 50 ft (15.2 m) of the landing pad edge. [**418:**4.6.1]

21.3.3.5.2 NO SMOKING signs shall be erected at access/egress points to the heliport. [**418:**4.6.2]

21.3.3.6 Fueling System. Fueling systems shall be designed in accordance with Section 42.10. [**418:**4.7]

21.3.3.6.1 Fueling equipment shall not hinder or obstruct access to exits or fire-fighting equipment. [**418:**4.7.1]

21.3.3.6.2 Fueling equipment shall be located a minimum of 25 ft (7.6 m) from hangars and fixed fire protection equipment. [**418:**4.7.2]

21.3.3.6.3 Fuel servicing equipment shall be designed to not penetrate the FATO and safety area obstruction clearance requirements in FAA AC 150/5390-2C, *Heliport Design Advisory Circular*. [**418:**4.7.3]

21.3.3.7* Means of Egress. At least two means of egress that lead to a public way shall be provided from the landing pad. [**418:**4.8]

A.21.3.3.7 The two means of egress can also be used for access to the landing pad for fire-fighting and/or rescue operations. Where doors accessing the interior of the building are locked, an approved means should be provided for entry of emergency responders. [**418:**A.4.8]

21.3.3.7.1* The egress points shall be located at least 90 degrees from each other as measured from the center of the landing pad (TLOF). [**418:**4.8.1]

A.21.3.3.7.1 Figure A.21.3.3.7.1(a) and Figure A.21.3.3.7.1(b) are examples of acceptable configurations of egress points on landing pads. The geometry of the landing pad in Figure A.21.3.3.7.1(b) is such that it has no sides and does not comply with 21.3.3.7.3; however, it does comply with the 90-degree rule in 21.3.3.7.1. Figure A.21.3.3.7.1(c) is an example of an unacceptable configuration, due to both egress points being on the same side of the landing pad. [**418:**A.4.8.1]

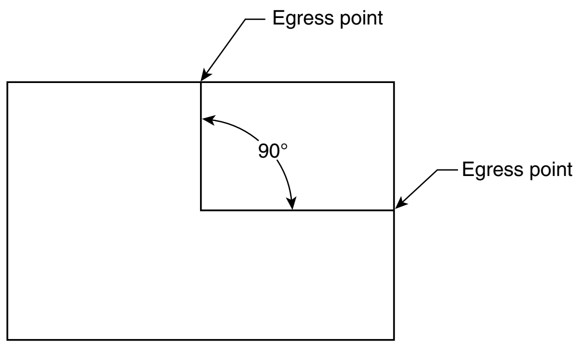

*FIGURE A.21.3.3.7.1(a) Example of an Acceptable Configuration of Egress Points on a Landing Pad. [**418:**Figure A.4.8.1(a)]*

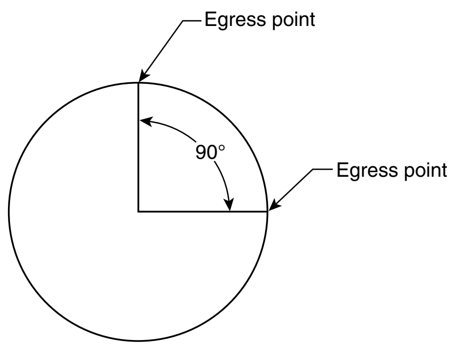

*FIGURE A.21.3.3.7.1(b) Example of an Acceptable Configuration of Egress Points on a Landing Pad with No Sides. [**418:**Figure A.4.8.1(b)]*

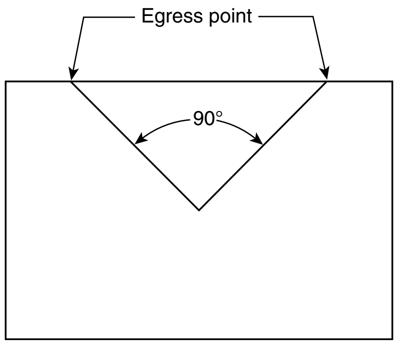

*FIGURE A.21.3.3.7.1(c) Example of an Unacceptable Configuration of Egress Points on a Landing Pad. [**418:**Figure A.4.8.1(c)]*

21.3.3.7.2 The egress points shall be located remotely from each other, not less than 30 ft (9.1 m) apart. [**418:**4.8.2]

21.3.3.7.3 No two egress points shall be located on the same side of the landing pad. [**418:**4.8.3]

21.3.4 Rooftop Landing Facilities.

21.3.4.1* Structural Support. Main structural support members that could be exposed to a fuel spill shall be made fire resistant using listed materials and methods to provide a fire-resistance rating of not less than 2 hours. [**418:**5.2]

A.21.3.4.1 Where the landing pad is nonporous, fuel-tight, and provided with a proper drainage system, and where fuel cannot flow to support members, the main structural support members would not need to be fire rated. [**418:**A.5.2]

21.3.4.2 Landing Pad Pitch. The rooftop landing pad shall be pitched to provide drainage at a slope of 0.5 percent to 2 percent. [**418:**5.3]

To reduce fuel leak–related hazards, 21.3.4.2 requires that the pitch of the landing area be directed away from locations where people might be waiting or where the fuel could enter a building.

The requirement for handling fuel drainage, including water-oil separators, is addressed by federal and state regulations. This commentary also applies to 21.3.3.4.

21.3.4.2.1 The pitch of the pad shall be designed to protect, at a minimum, the primary egress path, passenger holding area, rooftop hangar, and fire protection activation systems. [**418:**5.3.1]

21.3.4.2.2 Drainage flow shall not penetrate alternate egress points, stairways, ramps, hatches, and other openings not designed for drainage. [**418:**5.3.2]

21.3.4.2.3 The pitch of the pad shall not be required where the pad consists of a passive fire protection grid surface designed and listed for fuel catchment and containment. [**418:**5.3.3]

21.3.4.3 Landing Pad Construction Materials.

21.3.4.3.1 The rooftop landing pad surface shall be constructed of approved noncombustible, nonporous materials. [**418:**5.4.1]

21.3.4.3.2 The contiguous building roof covering within 50 ft (15.2 m) of the landing pad edge shall have a Class A fire resistance rating for exterior fire exposure, and shall be tested according to FM 4470, *Approval for Class 1 Roof Covers;* ANSI/UL 790, *Standard Test Methods for Fire Tests of Roof Covering;* or ASTM E108, *Standard Test Methods for Fire Tests of Roof Coverings*. [**418:**5.4.2]

21.3.4.4* Means of Egress. Two means of egress from the rooftop landing pad to the building's egress system shall be provided. [**418:**5.5]

A.21.3.4.4 Design of the means of egress from a rooftop landing pad might involve a compromise among several different code requirements. Rooftop landing pads bring with them an inherent risk. The means of egress must be provided for safety to human life. Strict compliance with a code's requirement for rated stairways off the landing pad is not the intent of this standard. The intent of this standard is to provide a minimum safeguard to provide a reasonable degree of safety to all persons on the roof. The building's egress system is dictated by the adopted building code. Once those persons enter the building's egress system, they are away from the FATO area. [**418:**A.5.5]

The purpose of 21.3.4.4 requiring landing pads to have two remotely located means of egress from the pad edge is to allow passengers and crew to exit the pad area quickly in an emergency and to allow emergency personnel to reach the area from more than one direction. For example, see Exhibit 21.2, which shows a landing pad on a hospital roof with one means of egress leading directly to the hospital building and another means to the roof area.

21.3.4.4.1* The egress points shall be located at least 90 degrees from each other as measured from the center of the landing pad (TLOF). [**418:**5.5.1]

A.21.3.4.4.1 See Figure A.21.3.3.7.1(a) through Figure A.21.3.3.7.1(c) for examples of acceptable configurations of egress points on landing pads. The geometry of the landing pad in Figure A.21.3.3.7.1(b) is such that it has no sides and cannot comply with 21.3.4.4.3; however, it does comply with the 90-degree rule in 21.3.4.4.1. Figure A.21.3.3.7.1(c) is not an acceptable configuration due to both egress points being on the same side of the landing pad. [**418:**A.5.5.1]

Exhibit 21.2

Landing pad on a hospital roof. (Dave Greenberg/Dreamstime.com)

21.3.4.4.2 The egress points shall be remotely located from each other, not less than 30 ft (9.1 m) apart. [**418:**5.5.2]

21.3.4.4.3 No two egress points shall be located on the same side of the rooftop landing pad. [**418:**5.5.3]

21.3.4.4.4* Means of egress from the landing pad shall not obstruct flight operations. [**418:**5.5.4]

A.21.3.4.4.4 When considering the means of egress from the landing pad and for the rooftop, obstructions to the FATO need to be avoided since they can create unsafe flight conditions that have been shown to cause aircraft accidents. Exterior, open stairways leading to the building's egress system should not encroach into the FATO. [**418:**A.5.5.4]

21.3.4.5 Fire-Fighting Access. (Reserved)

21.3.4.6 Fire Protection.

N **21.3.4.6.1 General.** A foam fire-extinguishing system with either a fixed discharge outlet(s) in accordance with 21.3.4.6.2.1 or a hose line(s) in accordance with 21.3.4.6.3.1 shall be designed and installed to protect the rooftop landing pad, unless otherwise permitted by the following:

(1) A foam fire-extinguishing system shall not be required for heliports located on open parking structures or buildings that are not normally occupied.
(2) For H-1 heliports, two portable foam extinguishers, each having a rating of 20-A:160-B, shall be permitted to be used to satisfy the requirement of 21.3.4.6.

[**418:**5.7.1]

21.3.4.6.1.1 Where trained personnel are not available, fixed fire protection outlet(s) shall be provided. [**418:**5.7.1.1]

21.3.4.6.1.2* The foam discharge rate for the fire-extinguishing system shall be 0.10 gpm/ft^2 (4.1 L/min·m^2) for aqueous film forming foam (AFFF). [**418:**5.7.1.2]

A.21.3.4.6.1.2 Currently, the qualified products listed for MIL-F-24385 do not contain any fluoroprotein or protein foam products. [**418:**A.5.7.1.2]

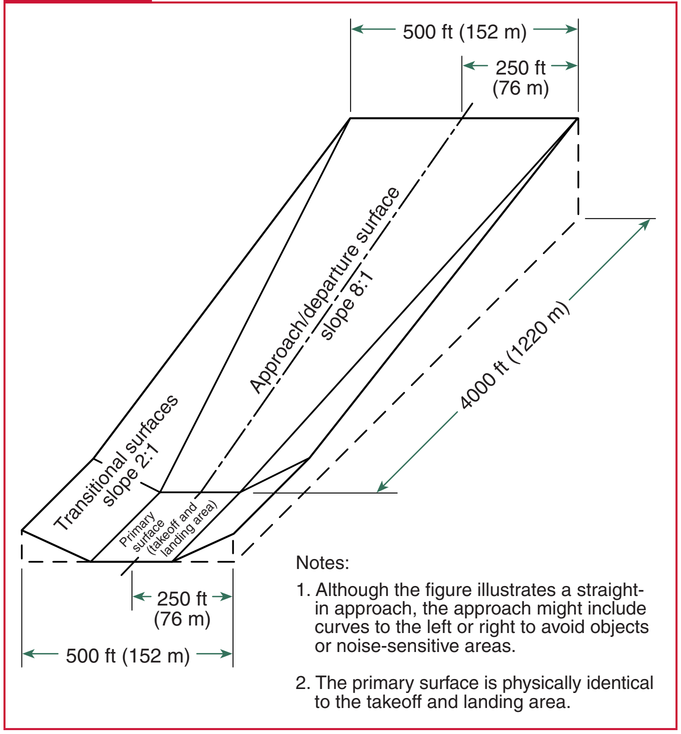
N **21.3.4.6.1.3** Where freezing is possible, freeze protection shall be provided. [**418:**5.7.1.3]

N **21.3.4.6.1.4** The foam components shall be installed in an area of the heliport and shall not penetrate the approach takeoff surface, transitional surfaces, and safety area as defined in FAA AC 150/5390-2C, *Heliport Design Advisory Circular*. [**418:**5.7.1.4]

Paragraph 21.3.4.6.1.4 is important because foam equipment and piping must be kept clear of the primary surface and must remain outside the approach/departure surface and the transitional surface. Penetration into these imaginary surfaces increases the risk that an aircraft could impact the fire protection system, causing it to be inoperative when it is needed.

The contents of FAA A/C 150/5390-2B, *Heliport Design Advisory Circular*, are too extensive to repeat here. They address the normal design of the heliport approach and departure surfaces and the required clearances to the designated landing area. The clearance has three components: the primary surface, the approach/departure surface, and the transitional surface. These three surfaces, illustrated in Exhibit 21.3, are defined as follows:

Exhibit 21.3



Heliport imaginary surfaces.

1. Primary surface. An area of a size and shape that coincides with the designated takeoff and landing area of a heliport. This surface is a horizontal plane with an elevation equivalent to the established heliport elevation.
2. Approach/departure surface. An imaginary surface that begins at the end of the heliport primary surface. It has the same width as the primary surface and extends outward and upward horizontally to a distance of 4000 ft (1220 m), where its width is 500 ft (152 m). The slope of the approach/departure surface is 8 to 1 for civil heliports.
3. Transitional surface. An imaginary surface that extends outward and upward from the lateral boundaries of the heliport primary surface and from the approach surface at a slope of 2 to 1 for a distance of 250 ft (76 m), measured horizontally from the centerline of the primary and approach surfaces.

21.3.4.6.2 Fixed Foam Fire-Extinguishing Systems.

N **21.3.4.6.2.1** Fixed foam fire-extinguishing systems shall be designed and installed in accordance with NFPA 11, NFPA 16, or an equivalent standard, as appropriate, except as modified by Chapter 5 of NFPA 418. [**418:**5.7.2.1]

21.3.4.6.2.2* The area of application of foam discharge for fixed discharge outlet systems shall be the entire rooftop landing pad. [**418:**5.7.2.2]

A.21.3.4.6.2.2 Consideration should be given to the environmental conditions of the rooftop landing pad in the design of the system, including wind, exhaust fans, and other factors that affect the distribution of the foam on the rooftop landing pad. [**418:**A.5.7.2.2]

21.3.4.6.2.3 The duration of foam discharge for the fixed discharge outlet system shall be 10 minutes. [**418:**5.7.2.3]

N **21.3.4.6.2.4** A fixed nozzle discharge outlet system shall be one of the following: fixed stationary nozzles around the perimeter, two or more oscillating monitors/nozzles, or in-deck nozzles within the perimeter of the deck. [**418:** 5.7.2.4]

N **21.3.4.6.2.5** Where fixed foam systems utilizing fixed deck nozzles or oscillating foam turrets, or both, are installed, system components shall be listed or approved. [**418:**5.7.2.5]

N **21.3.4.6.2.6 Activation of Systems.**

N **21.3.4.6.2.6.1*** The fixed discharge outlet system shall be activated manually. [**418:**5.7.2.6.1]

N **A.21.3.4.6.2.6.1** Training on the operation of the fire protection system should be in accordance with Annex B of NFPA 418. [**418:**A.5.7.2.6.1]

N **21.3.4.6.2.6.2*** Manual actuation stations shall be located at each egress point from the rooftop landing pad and at an approved location inside the building from which the rooftop landing pad can be viewed. [**418:**5.7.2.6.2]

N **A.21.3.4.6.2.6.2** It is acceptable for the rooftop landing pad to be viewed using video or other acceptable means. [**418:**A.5.7.2.6.2]

N **21.3.4.6.2.6.3** Manual foam activation stations shall be clearly labeled or identified as to the purpose and hazard protected. [**418:**5.7.2.6.3]

N **21.3.4.6.2.7** Where buildings are provided with a fire alarm system, the activation of the foam system shall be monitored by the building fire alarm system in accordance with *NFPA 72*. [**418:**5.7.2.6.4]

N **21.3.4.6.2.8** An approved manual control for foam system shutdown shall be accessible at all times, including the time of fire and system operation. [**418:**5.7.2.6.5]

21.3.4.6.3 Manual Fire-Fighting Equipment.

21.3.4.6.3.1* The area of application of foam discharge for hose line systems shall be the practical critical fire area for the category of the helicopter landing facility in accordance with Table 21.3.4.6.3.1. [**418:**5.7.3.1]

TABLE 21.3.4.6.3.1 *Practical Critical Fire Areas for Hose Line Systems Only*

Heliport Category	Helicopter Overall Length*	Practical Critical Fire Area ft²	m²
H-1	Less than 50 ft (15.2 m)	375	34.8
H-2	50 ft (15.2 m) up to but not including 80 ft (24.4 m)	840	78.0
H-3	80 ft (24.4 m) up to but not including 120 ft (36.6 m)	1440	133.8

*Helicopter length, including the tail boom and the rotors.
[**418:** Table 5.7.3.1]

The minimum required foam discharge rate, as specified in 21.3.4.6.1.2, is based on the rate developed by the NFPA Technical Committee on Aircraft Rescue and Fire Fighting, which determined the amount of foam required to control aviation fuel fires. See Annex C of NFPA 418 for information on establishing extinguishing agent quantities and discharge rates for helicopters.

A.21.3.4.6.3.1 The area of application and the duration where using a hose line system is reduced because foam is applied efficiently and directly on the fire by trained personnel. [**418:**A.5.7.3.1]

The concept of *critical fire area* referenced in 21.3.4.6.4.3.1 was initially developed for fixed-wing aircraft. Critical fire area is the area equal to the length of the fuselage multiplied by the width of the wing. The formula was used to determine the amount of foam needed for application in the event of a crash. In a study of 106 fixed-wing aircraft fires, the quantities of agents used were less than those recommended by the theoretical critical fire area calculations in 99 of 106 fires. As a result, a practical critical area (PCA) of fixed-wing aircraft was determined to be approximately two-thirds of the theoretical area.

21.3.4.6.3.2 The duration of foam discharge for the hose line systems shall be 2 minutes. [**418:**5.7.3.2]

N **21.3.4.6.4** Standpipes and hose stations, if used, shall be installed in accordance with Section 13.4. [**418:**5.7.4]

21.3.4.6.5 Water Supply.

N **21.3.4.6.5.1** The water supply for the foam system shall be from a source approved by the AHJ. [**418:**5.7.5.1]

21.3.4.6.5.2 Fire pumps, if used, shall be installed in accordance with Section 13.4. [**418:**5.7.5.2]

N **21.3.4.6.6 Foam Concentrate Supply.**

N **21.3.4.6.6.1** The supply of foam concentrate shall be sufficient to supply the largest system. [**418:**5.7.6.1]

Δ **21.3.4.6.7** The foam concentrate for the fixed system or manual fire-fighting equipment shall be listed in accordance with UL 162, *Standard for Foam Equipment and Liquid Concentrates*, and shall be on the qualified products list for MIL-F-24385, or equivalent. [**418:**5.7.6.2]

21.3.4.6.8 Fire Alarm. A means of communication shall be provided from the roof area to notify the fire department of emergencies. [**418:**5.7.7.1]

21.3.4.6.8.1 Where buildings are provided with a fire alarm system, a manual pull station shall be provided for each designated means of egress from the roof. *(See 21.3.4.4.)* [**418:**5.7.7.2]

N **21.3.4.6.9 Acceptance Testing.**

N **21.3.4.6.9.1 Fixed Foam Fire-Extinguishing Systems.** The fixed foam discharge outlet system shall be tested with foam to determine the coverage of the rooftop landing pad. [**418:**5.7.8.1]

N **21.3.4.6.9.1.1** The system shall cover 95 percent of the rooftop landing pad during the test. [**418:**5.7.8.1.1]

N **21.3.4.6.9.1.2** The access points for firefighting and for egress shall be covered. [**418:**5.7.8.1.2]

N **21.3.4.6.9.2 Manual Fire-Fighting Equipment.** The hose handlines shall be flow tested to demonstrate that the design objectives are met. [**418:**5.7.8.2]

N **21.3.4.6.10 Inspection, Testing, and Maintenance.**

N **21.3.4.6.10.1** Fire protection systems installed in accordance with NFPA 14 or NFPA 16 shall be inspected, tested, and maintained in accordance with NFPA 25. [**418:**5.7.9.1]

N **21.3.4.6.10.2** Foam systems installed in accordance with NFPA 11 shall be maintained in accordance with NFPA 11. [**418:**5.7.9.2]

21.3.5 Portable Fire Extinguishers.

21.3.5.1 Minimum Requirement. At least one portable fire extinguisher as specified in Table 21.3.5.1 shall be provided for each takeoff and landing area, parking area, and fuel storage area. [**418:**9.2]

TABLE 21.3.5.1 *Minimum Ratings of Portable Fire Extinguishers for Heliport Categories*

Heliport Category	Helicopter Overall Length*	Minimum Rating
H-1	Less than 50 ft (15.2 m)	4-A:80-B
H-2	50 ft (15.2 m) up to but not including 80 ft (24.4 m)	10-A:120-B
H-3	80 ft (24.4 m) up to but not including 120 ft (36.6 m)	30-A:240-B

*Helicopter length, including the tail boom and the rotors.
[**418:** Table 9.2]

21.3.5.2 Extinguishers Subject to Damage, Theft, or Tampering. Where the portable extinguisher cannot be maintained and safeguarded against damage, theft, or tampering, the portable fire extinguisher shall be omitted with the approval of the AHJ. [**418:**9.3]

22 Automobile Wrecking Yards

Chapter 22 covers automobile wrecking yards, which pose a wide variety of hazards, including hot work and the handling and storage of fuels and fluids, tires, plastics, combustibles, and hazardous materials. Automobile wrecking yards also pose general housekeeping issues. The nature of operations conducted at automobile wrecking yards presents many possibilities for fire hazards and hazardous materials incidents.

22.1 General

Automobile wrecking yards shall be in accordance with this chapter.

22.2 Permits

Permits, where required, shall comply with Section 1.12.

In addition to a permit to operate an automobile wrecking yard, Section 1.12 might require other permits. Other permits could cover, for example, storage of flammable and combustible liquids, hot work operations, burning, and storage of hazardous materials. See Section 1.12 for additional information on required permits.

22.3 Fire Department Access Roads

Fire department access roads shall be in accordance with Section 18.2.

22.4 Welding and Cutting

Welding and cutting operations shall be in accordance with Chapter 41.

22.5 Housekeeping

The yard shall be kept free of vegetation, debris, and any other material that is not necessary to the proper operation of the facility.

Housekeeping is a typical problem at automobile wrecking yards. All materials not necessary for the operation of the facility should be removed as soon as practicable to reduce unnecessary accumulations of combustible materials. Additionally, weeds and other vegetation should be kept clear to prevent a fire from spreading out of the automobile wrecking yard or to another adjacent area or into the facility. See 10.13.10 for additional guidance on managing combustible vegetation.

22.6 Fire Extinguishers

Fire extinguishers shall be placed and sized in accordance with Section 13.6.

22.7 Tire Storage

The storage of tires shall be in accordance with Chapters 33 and 34.

22.8 Burning Operations

Burning operations shall be in accordance with Section 10.10.

22.9 Motor Vehicle Fluids and Hazardous Materials

22.9.1 General. The storage, use, and handling of motor vehicle fluids and hazardous materials shall be in accordance with Chapters 60 and 66.

22.9.2 Motor Vehicle Fluids.

22.9.2.1 Motor vehicle fluids shall be drained from salvage vehicles when such fluids are leaking.

Leaking fluids from vehicles pose fire, health, and environmental concerns. When a vehicle is found to be leaking fluids, 22.9.2.1 requires that the fluids be drained completely from the vehicle. Paragraph 22.9.1 requires the storage of such fluids to comply with Chapters 60 and 66. A good practice is to drain all fluids from the vehicles upon entry to the yard, thus eliminating the potential for leaks due to handling or deterioration of vehicle components.

22.9.2.2 Storage and handling of motor vehicle fluids shall be done in an approved manner.

22.9.2.3 Flammable and combustible liquids shall be stored and handled in accordance with Chapter 66.

22.9.3 Mitigation for Vehicle Fluid Leaks.

22.9.3.1 Supplies or equipment capable of mitigating leaks from fuel tanks, crankcases, brake systems, and transmissions shall be kept available on site.

Vehicle fluid leaks are common at automobile wrecking yards. Appropriate means must be provided on site for immediate containment and cleanup of such leaks.

22.9.3.2 Single-use plugging, diking, and absorbent materials shall be disposed of as hazardous waste and removed from the site in a manner approved by federal, state, and local requirements.

Materials used to control and contain vehicle fluid leaks should be disposed of after use in an appropriate manner and in compliance with applicable environmental regulations.

22.9.4 Air Bag Systems. Removed air bag systems shall be handled and stored in accordance with Chapter 60.

Air bag systems contain sodium azide (NaN_3), which reacts with potassium nitrate (KNO_3) to produce nitrogen gas to inflate the air bags. Sodium azide is not only highly explosive but also extremely toxic. Care should be taken when working with, removing, or handling air bags, including attention to the bumper area and side area where activation can occur. Vehicle manufacturers should be contacted for information on the best way to handle air bag systems.

22.9.5 Lead-Acid Batteries.

Much like draining motor vehicle fluids, a best practice might be to remove all batteries from vehicles upon their arrival at the automobile wrecking yard. This practice prevents damage to batteries during operations and eliminates the need to mitigate battery acid leaks as well as possible electrical faults, which could start fires.

22.9.5.1 Lead-acid batteries shall be removed from salvage vehicles when such batteries are leaking.

22.9.5.2 Lead-acid batteries that have been removed from vehicles shall be stored in an approved manner.

23 Cleanrooms

Cleanrooms in semiconductor fabrication facilities and other comparable fabrication facilities are addressed by Chapter 23. Also see Chapter 60 for additional requirements for hazardous materials used in the fabrication of semiconductors or semiconductor research and development.

Δ 23.1 General

All semiconductor facilities containing a cleanroom or a clean zone, or both, shall comply with this chapter and NFPA 318.

The loss potential in a semiconductor manufacturing plant can be enormous. Typical plants cost more than $100 million to construct and $1 billion to equip. Add to this figure the value of completed and in-process semiconductor wafers, which are very susceptible to damage from fire and smoke, and the cost of the potential disruption of production schedules, product distribution, and business, and the loss could be staggering.

NFPA 318, *Standard for the Protection of Semiconductor Fabrication Facilities*, applies to semiconductor fabrication facilities and comparable research and development areas in which hazardous chemicals are used, stored, and handled and that contain a *cleanroom,* a *clean zone,* or both (see 3.3.48 and 3.3.49). The purpose of NFPA 318 is to provide reasonable safeguards for the protection of facilities containing cleanrooms from fire and related hazards. Those safeguards are intended to provide protection against injury, loss of life, and property damage.

Semiconductor fabrication facilities are defined in NFPA 318 as "buildings or portions thereof used for the fabrication of semiconductors and related research containing quantities of hazardous materials exceeding the maximum allowable quantities of Level 5 contents permitted in a control area."

NFPA 318 covers the following topics:

1. Chapter 4 addresses building construction and related services.
2. Chapter 5 addresses hazardous materials.
3. Chapter 6 addresses liquid chemical storage and handling.
4. Chapter 7 addresses gas storage and handling.
5. Chapter 8 addresses production and support equipment.
6. Chapter 9 addresses exhaust systems.
7. Chapter 10 addresses waste treatment.
8. Chapter 11 addresses fire protection.
9. Chapter 12 addresses general safety precautions.

23.2 Applicability

Unless otherwise noted in NFPA 318, the provisions of NFPA 318 shall not be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of this *Code*, except in those cases where it is determined by the AHJ that the existing situation involves a distinct hazard to life or adjacent property.

23.3 Permits

Permits, where required, shall comply with Section 1.12.

National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 318, *Standard for the Protection of Semiconductor Fabrication Facilities*, 2018 edition.

Drycleaning

24

24.1 General

Δ **24.1.1** Drycleaning plants shall comply with this chapter and NFPA 32.

NFPA 32, *Standard for Drycleaning Facilities*, prescribes safeguards intended to prevent fires and explosions involving drycleaning processes and to minimize the personal injury and property damage consequences of such incidents. NFPA 32 does not include requirements for disposal of any hazardous chemicals or materials.

The term *drycleaning* is defined in NFPA 32 as "the process of removing dirt, grease, paints, and other stains from such items as apparel, textiles, fabrics, and rugs by the use of nonaqueous liquids." Methods of drycleaning include the following:

1. Immersion and agitation with solvent in closed machines
2. Spotting with cleaning solvents
3. Dual-phase processing

NFPA 32 addresses five types of drycleaning plants or systems, as follows:

1. Type I. Systems employing Class I [flash point below 73°F (22.8°C)] solvents, which are prohibited by this *Code*, in accordance with 4.2.1 of NFPA 32 [e.g., 50°F (10°C) flash point naphtha]
2. Type II. Systems employing Class II solvents and complying with the requirements of Chapters 4, 5, 6, and 7 of NFPA 32 (e.g., Stoddard solvent)
3. Type IIIA. Systems employing Class IIIA solvents and complying with the requirements of Chapters 4, 5, 6, and 8 of NFPA 32 [e.g., 140°F (60°C) flash point solvent]
4. Type IIIB. Systems employing Class IIIB liquids and complying with the requirements of Chapters 4, 5, 6, and 8 of NFPA 32 (e.g., specially compounded oils)
5. Type IV. Systems employing Class IV (nonflammable) solvents and complying with the requirements of Chapters 4, 5, 6, and 9 of NFPA 32 (e.g., perchloroethylene, also known as "perc")

NFPA 32 recognizes the use of nonflammable liquefied gases, such as liquefied carbon dioxide, for drycleaning. Such use must comply with the requirements for Type IV plants, with additional requirements for the unique hazards of this solvent.

24.1.2 Drycleaning plants or systems using solvents that have a flash point below 100°F (37.8°C) shall be prohibited.

24.2 Permits

Permits, where required, shall comply with Section 1.12.

National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 32, *Standard for Drycleaning Facilities*, 2016 edition.

Grandstands and Bleachers, Folding and Telescopic Seating, Tents, and Membrane Structures

25

Chapter 25 addresses the construction, location, protection, and maintenance of grandstands and bleachers, folding and telescopic seating, tents, and membrane structures. Exhibit 25.1 depicts the terminal building at Denver International Airport, which is an example of a membrane structure.

25.1 General

Δ **25.1.1** The construction, location, protection, and maintenance of grandstands and bleachers, folding and telescopic seating, tents, and membrane structures shall meet the requirements of this chapter. Seating facilities located in the open air or within enclosed or semi-enclosed structures, such as tents, membrane structures, and stadium complexes, shall comply with this chapter, NFPA *101*, and NFPA 102.

25.1.2 Permits. Permits, where required, shall comply with Section 1.12.

25.1.3 Means of Egress.

25.1.3.1 Means of egress shall comply with the requirements of Chapter 14.

25.1.3.2 No guy wire or guy rope shall cross any means of egress at a height of less than 7 ft (2.1 m).

The 7 ft (2.1 m) height for guy wires required by 25.1.3.2 prevents people from walking or running into the guy wire. Tent stakes also present a tripping hazard. Stakes located near a means of egress or walkway must be protected and identified so that people will not trip over or fall on them. A recommended practice is to locate a fence, where possible, to prevent people from coming into contact with stakes and guy wires.

Exhibit 25.1

Membrane structure. (Courtesy of Denver International Airport)

25.1.3.3 Tent stakes adjacent to any means of egress from any tent open to the public shall be railed off, capped, or covered so as not to present a hazard to the public.

25.1.3.4 New facilities shall comply with the means of egress provisions of NFPA *101* for the applicable occupancies.

25.1.3.5 Existing facilities shall comply with the means of egress provisions of NFPA *101* for the applicable occupancies.

25.1.4 Flammable Liquids and Gases.

Δ **25.1.4.1** Where required by the provisions of Chapters 11 through 43 in NFPA *101*, occupancies with storage and handling of hazardous materials shall comply with the following codes unless otherwise modified by other provisions of NFPA *101:* Chapter 66 for flammable and combustible liquids, NFPA 54, Chapter 66 for compressed gases and cryogenic fluids, Chapter 69 for liquefied petroleum gases and liquefied natural gases, NFPA 400, and NFPA 495. [***101:***8.7.3.1]

25.1.4.2* No storage, use, or handling of hazardous materials shall be permitted in any location where such storage, use, or handling would jeopardize egress from the structure, unless otherwise permitted by a document listed in 25.1.4.1. [***101:***8.7.3.2]

A.25.1.4.2 NFPA 58 permits the use of portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by a maximum of two 10 oz (0.28 kg) LP-Gas capacity, nonrefillable butane containers with a water capacity not in excess of 1.08 lb (0.4 kg) per container. Containers are required to be directly connected to the appliance, and manifolding of containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance–rated barrier. *(See 4.1.3 of NFPA 101 and Annex C of NFPA 101 for referenced documents on hazardous materials.)* [***101:***A.8.7.3.2]

Subsection 25.1.4 has been updated for the 2018 edition of the *Code* to provide a more comprehensive approach to hazardous materials as well as to bridge a gap between NFPA *101®, Life Safety Code®,* and the other NFPA codes and standards addressing hazardous materials.

Generators, heaters, propane cylinders, and similar items should not be in proximity to the means of egress. If problems occur with the functioning of these types of equipment, the means of egress could be blocked, preventing or delaying egress.

Equipment using flammable liquids should be located outside the structure, at a safe distance from the structure, and in an area that will not directly affect any other structures or operations. Where fuel-fired equipment is permitted to be used indoors, refueling should take place outside at a safe distance from the structure.

25.1.4.3 Refueling of equipment with liquids having flash points below 100°F (38°C) shall not be permitted within the structure.

25.1.5 Fire Hazards.

25.1.5.1 The finished ground level enclosed by the structure, and the surrounding finished ground level not less than 10 ft (3050 mm) outside of the structure, shall be cleared of all flammable or combustible material and vegetation. [**5000:**32.3.5.1.1]

Care should be taken when erecting structures in open fields to ensure that dried vegetation is not a fuel source. Many times, tents or temporary membrane structures are set up in fields. The field or other setup areas should be mowed to remove excessive and tall combustible vegetation from the site. If the tent or membrane structure will be in place for an extended period of time, additional cuttings might be necessary to keep the combustible vegetation to a minimum.

25.1.5.2 Where prohibited by the AHJ, smoking shall not be permitted in any temporary membrane structure. [***101:***11.10.2.2]

See Section 10.9 for additional smoking prohibitions.

25.1.5.3 Hay, straw, shavings, or similar combustible materials that have not been treated to make them flame retardant to a degree acceptable to the AHJ shall not be permitted within any structure used as an assembly occupancy.

Exception: Animal bedding and fodders in quantities approved by the AHJ.

The quantity of combustible materials in an assembly occupancy addressed by Chapter 25 should be limited. Where combustible materials are permitted, they must be treated to make them flame retardant. However, bedding materials used for animals are exempt from treatment because the flame retardant could cause irritation. Depending on the type and amount of materials present, the authority having jurisdiction (AHJ) might require additional protection, standby personnel, or both. (See 1.7.17 for additional information on standby fire personnel.)

25.1.5.4 Open Flame Devices and Pyrotechnics. Use of open flame devices and pyrotechnics shall comply with 20.1.5.3.

25.1.6 Extinguishment Requirements.

Δ **25.1.6.1** Enclosed stadiums, arenas, and similar structures shall be protected throughout by an approved, electrically supervised automatic sprinkler system in accordance with Section 13.3, unless otherwise permitted by the following:

(1) Where the ceiling or roof, whichever is lower, of the playing/activity area is more than 55 ft (16.7 m) above the floor, sprinklers shall not be required above the playing/activity area where permitted by the AHJ.
(2) Sprinklers shall not be required above seating areas that view the playing/activity area.

[**5000:**32.3.5.2]

25.1.6.2 An enclosed area shall be protected by an approved sprinkler system in accordance with Section 13.3, unless such an area is one of the following:

(1) Enclosed stadiums, arenas, and similar structures
(2) Press boxes of less than 1000 ft^2 (93 m^2)
(3) Storage facilities of less than 1000 ft^2 (93 m^2), if enclosed with minimum 1-hour fire resistance–rated construction
(4) Enclosed areas underneath grandstands or bleachers that comply with 16.4.9.5 of *NFPA 5000*

[**5000:**32.3.5.3]

Enclosed areas are required to be provided with automatic sprinkler protection unless they are small in area, as outlined in 25.1.6.2. A fire in an enclosed area can grow unnoticed for an extended period of time. Such fires can adversely affect occupant response and the functioning of various protection features, such as means of egress routes and structural integrity.

Additional automatic sprinkler protection might be required where combustible materials are used. Exhibit 25.2 shows sprinklers installed under a grandstand with wooden structural elements.

Exhibit 25.2

Sprinklers installed under a grandstand.

25.1.6.3 Portable fire extinguishers shall be installed in assembly occupancies in accordance with Section 13.6, unless otherwise permitted by one of the following:

(1) The requirement of 25.1.6.3 shall not apply to seating areas.
(2) The requirement of 25.1.6.3 shall not apply to floor areas used for contests, performances, or entertainment.
(3) The requirement of 25.1.6.3 shall not apply to outside assembly occupancy areas.
(4) Portable extinguishers shall be permitted to be located in secure locations accessible to staff.

[**5000:**16.3.5.3]

25.1.6.4 Fire-extinguishing equipment shall be maintained in accordance with Section 13.6.

25.1.6.5 Employees shall be trained to operate fire-extinguishing equipment and shall be required to exhibit their skill when requested by the AHJ.

25.1.7 Detection, Alarm, and Communications Systems. Detection, alarm, and communications systems shall comply with Section 13.7 where required by 13.7.2.1 or 13.7.2.2.

New assembly occupancies having an occupant load of more than 300 must be provided with a fire alarm system, regardless of the type of structure in which the assembly occupancy is located. Where the AHJ determines the installation of a complete fire alarm in accordance with *NFPA 72®, National Fire Alarm and Signaling Code®,* is impracticable, an alternative arrangement to provide notification of an emergency to occupants might be permitted using the provisions for equivalency in Section 1.4.

25.1.8* Fire Detail. See 1.7.17 for fire detail requirements.

A.25.1.8 Because of the variety of types of places of assembly covered by this *Code*, no general requirement for patrols or fire watchers has been included. The committee fully recognizes the importance of this feature of fire protection, however, and believes that a system of well-trained patrols or fire watchers should be maintained in every place of assembly where fire hazards might develop. Such locations would include, among others, the spaces underneath grandstands and the areas inside and outside tents and air-supported structures. The fire watchers serve to detect incipient fires and to prevent an accumulation of materials that will carry fire. The number of such watchers required will, of course, vary for the different types of assembly occupancies, depending upon the combustibility of the construction and the number of persons accommodated. Provided with an adequate supply of portable fire-extinguishing equipment located at readily accessible points, such a fire watch or detail should be able to prevent small fires from reaching serious proportions.

Standby personnel are often required due to the size of a structure, the types of hazards present, or the large numbers of occupants.

25.1.9 Electrical Installations.

Because electrical wiring might require a complicated system or array involving many specifications and design details, the *Code* does not repeat them; rather, it references *NFPA 70®, National Electrical Code®* for design and installation requirements.

The requirements for emergency lighting addressed by Section 7.9 of NFPA *101*, particularly by 7.9.2.3, with respect to independence of the emergency lighting source and distribution network, are more stringent than the more general requirements of *NFPA 70*. See the commentary throughout Section 7.9 of NFPA *101*.

25.1.9.1 Electrical Systems. Electrical wiring and equipment shall be in accordance with Section 11.1, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101:***9.1.2]

25.1.9.2 The electrical system shall be installed, maintained, and operated in a safe and professional manner. When in use, portable electrical systems shall be inspected daily by a qualified person representing the owner, and any defects found shall be corrected before the public is admitted.

25.1.9.3 The electrical system and equipment shall be isolated from the public by proper elevation or guarding, and all electrical fuses and switches shall be enclosed in approved enclosures. Cables on the ground in areas traversed by the public shall be placed in trenches or protected by approved covers.

Electrical wires and installations should be placed beyond the normal travel routes and away from immediate public access. Wires that cross paths of travel should be suspended overhead at a minimum height of 7 ft (2.1 m), as shown in Exhibit 25.3, and higher if the path of travel is used as a fire department access road (see 18.2.3). Another option is to place electrical wires under an approved device. Exhibit 25.4 shows an incorrect installation of electrical wiring across a path of travel.

25.1.10 Heating Devices.

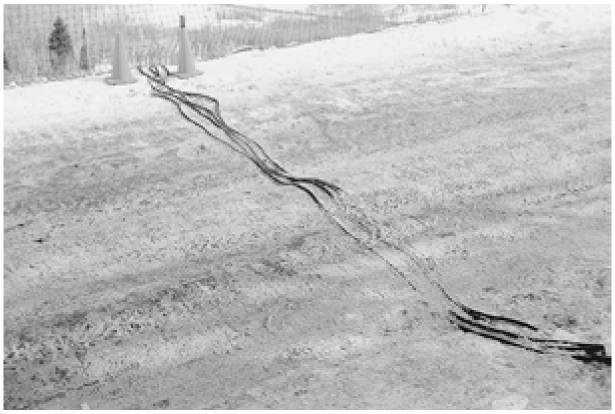
25.1.10.1 Fired Heaters.

25.1.10.1.1 Heating devices shall comply with Sections 11.2 and 11.5.

Exhibit 25.3

Elevated electrical system.

Exhibit 25.4



Incorrect electrical system installation in a roadway.

25.1.10.1.2 Only labeled heating devices shall be used. [***101:***11.9.5.1.1]

25.1.10.1.3 Fuel-fired heaters and their installation shall be approved by the AHJ. [***101:***11.9.5.1.2]

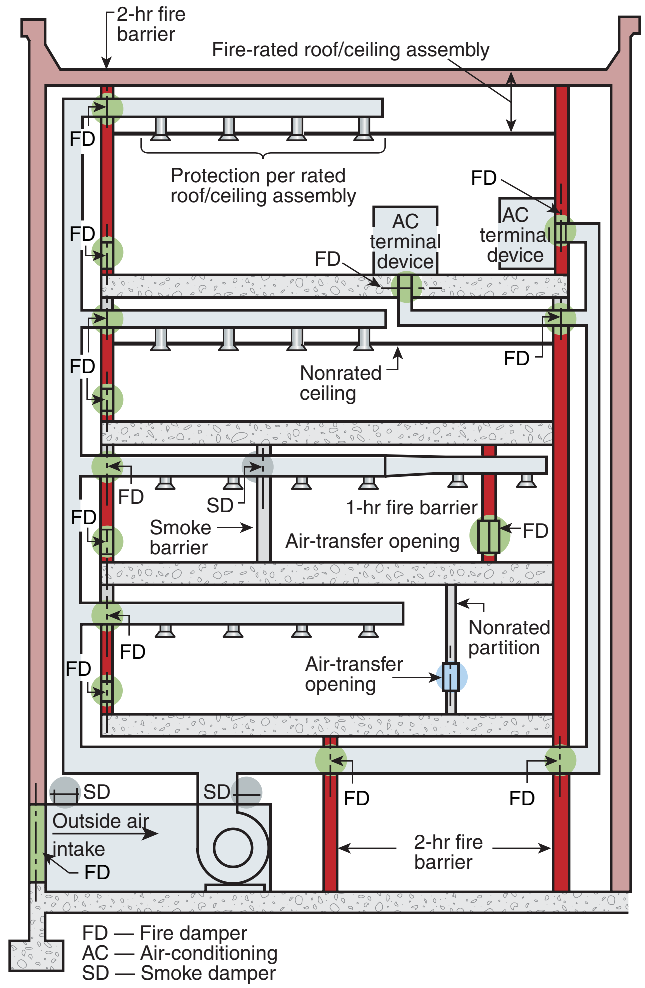
Portable heaters can be placed within tents and membrane structures. All other heaters should be placed outside and ducted into the structure, unless otherwise approved by the AHJ. Exhibit 25.5 depicts portable heaters located outside a membrane structure. Although the *Code* does not require carbon monoxide (CO) detection in assembly occupancies, its installation — to ensure that CO levels are within an acceptable range — would be beneficial.

25.1.10.1.4 Air-Conditioning, Heating, Ventilating Ductwork, and Related Equipment. Air-conditioning, heating, ventilating ductwork, and related equipment shall be in accordance with 11.2.1, as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101:***9.2.1]

Exhibit 25.5

Portable heaters placed outside membrane structure.

Exhibit 25.6



Partition and fire barrier penetration protection.

For the proper installation of HVAC systems, 25.1.10.1.4 refers the *Code* user to NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems.* For occupancies with small overall volumes, such as one- and two-family dwellings, the *Code* refers the user to NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems.*

For example, NFPA 90A addresses fire damper requirements for both ductwork and air-transfer grilles that penetrate fire barriers. NFPA 90A also prohibits means of egress corridors in health care, detention and correctional, and residential occupancies from being used as a portion of a supply-, return-, or exhaust-air system serving adjoining areas. Exhibit 25.6 identifies some of the areas where fire dampers and smoke dampers would be required by NFPA 90A.

25.1.10.1.5 Ventilating or Heat-Producing Equipment. Ventilating or heat-producing equipment shall be in accordance with 11.2.2, as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101:***9.2.2]

25.1.10.1.6 Containers for liquefied petroleum gases shall be installed not less than 5 ft (1.5 m) from any tent or temporary membrane structure and shall be in accordance with the provisions of Chapter 69.

25.1.10.1.7 Tanks shall be secured in the upright position and protected from vehicular traffic.

Fuel tanks must be secured in accordance with 25.1.10.1.7 to prevent them from tipping over. If a fuel tank tips over while in use, liquid fuel, instead of vapors, will be introduced into the heating unit, resulting in a larger flame in the heater.

25.1.10.2 Electric Heaters.

25.1.10.2.1 Electric heaters shall comply with 25.1.10.2 and Section 11.5.

25.1.10.2.2 Only labeled heaters shall be permitted. [***101:*** 11.9.5.2.1]

25.1.10.2.3 Electric heaters, their placement, and their installation shall be approved by the AHJ. [***101:***11.9.5.2.2]

25.1.10.2.4 Heaters shall be connected to electricity by electric cable that is suitable for outside use and is of sufficient size to handle the electrical load. [***101:***11.9.5.2.3]

25.1.11 Cooking. Cooking operations shall comply with Chapter 50.

25.1.12 Generators.

25.1.12.1 Generators and other internal combustion power sources shall be separated from temporary membrane structures and tents by a minimum of 5 ft (1.5 m) and shall be protected from contact by fencing, enclosure, or other approved means.

Due to the location and temporary nature of tents and membrane structures, generators are often used to provide electrical power. Generators and other combustion engines must be placed a minimum of 5 ft (1.5 m) from such structures. Generators should be located away from public access. Based on the size of the generating unit, the 5 ft (1.5 m) distance requirement of 25.1.12.1 might need to be increased to prevent exhaust gas containing CO from entering the structure. Fencing or other approved means should be placed around the generator and other heat-producing appliances to prevent unauthorized access and inadvertent contact with electrical connections and hot surfaces. The AHJ should discuss with the operator the precautions to be taken when refueling the generators. The generator should not be refueled during events or while the structure is occupied by the public.

25.1.12.2 Fueling. Fuel tanks shall be of adequate capacity to permit uninterrupted operation during normal operating hours. Refueling shall be conducted only when not in use.

25.1.12.3 Fire Extinguishers. A minimum of one portable fire extinguisher with a rating of not less than 2-A:10-B:C shall be provided.

25.2 Tents

A tent is considered a temporary structure composed of a pliable covering material that achieves its support by mechanical means, such as beams, columns, poles, or arches, or by rope or cables, or both. A tent could also include a temporary tensioned-membrane structure.

25.2.1 General.

25.2.1.1 Tents shall be permitted only on a temporary basis. [***101:***11.11.1.2]

Tents are intended to remain in place for a period of 180 consecutive days or less. Tents must comply with Chapter 25 of this *Code*; NFPA *101*; NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*; and the applicable requirements of *NFPA 5000®*, *Building Construction and Safety Code®*.

An application for use of a tent should include not less than the following information:

1. Start and finish dates of the event/activity.
2. Venue name, address, and telephone number.
3. Applicant's mailing address and telephone number.
4. Size of the tent and the area that it will cover on the premises. (See 25.2.1.2.)
5. Description of the activities that will take place within the tent (e.g., use of the tent as a place of assembly for a circus, carnival, show, theater, skating rink, dance hall, concert or for dining or other place of assembly in or under which persons gather for any purpose).
6. Dates of the use period (dates tent is erected and dismantled).
7. Construction documents that show the structural design loads, flame resistance of the fabric material (25.2.2), electrical installation needs (25.1.9), and heating appliances if used (25.1.10).
8. Documentation from a licensed structural engineer regarding structural stability. Tents and their appurtenances must be adequately roped, braced, and anchored to withstand the elements of weather and prevent unintentional collapse.
9. Certificate executed by an approved testing laboratory certifying that the tent(s) and its appurtenances, sidewalls, canopies, tarpaulins, floor coverings, bunting, combustible decorative materials, and effects are as follows:
   a. Composed of flame-resistant material or treated with a flame retardant in an approved manner
   b. Meet the requirements for flame resistance as determined in accordance with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*
   c. Flame resistance in accordance with NFPA 701 is effective for the use period of the tent (tents required to have a permanently affixed label bearing the identification of size and fabric or material type, per 25.2.2

10. Certification of the flame resistance of the tent fabric material, including names and addresses of the owners of the structure, date the fabric was last treated with flame-resistant solution, trade name or type of chemical used in treatment, name of person or firm treating the material, and name of testing agency and test standard by which the fabric was tested. (See 25.2.2.2.)
11. Detailed site and floor plan for each tent that identifies the means of egress facilities, seating capacity, seating arrangement, location and type of heating equipment, and location and type of electrical equipment. Seating arrangements are among the most common reasons for rejection of tent applications. The AHJ should be given the opportunity to review the plan early in the application process. (See 25.1.3 and Chapter 14. Also see Section 1.12 and Section 10.14.)

The applicant must also do the following:

1. Indicate to the AHJ whether any connecting corridors will be provided between the tents. If tents are to be joined together by means of corridors, exit doors should be provided at the end of each such corridor. The appropriate size of openings, as required by NFPA *101*, must be provided. (See 25.1.3, 25.2.3, and Chapter 14.)
2. Indicate to the AHJ the placement of tents. The placement of tents relative to other structures is at the discretion of the AHJ. Care must be taken by the AHJ to ensure that tents are not located too close to lot lines, buildings, other structures and tents, parked vehicles, or internal combustion engines. (See Exhibit 25.7.) The AHJ must also consider the required distances and separation requirements for support ropes and guy wires. (See 25.1.3.2, 25.1.4, 25.1.12, and 25.2.3.)
3. Indicate to the AHJ whether any outside fireworks display will take place, such that appropriate measures and precautions can be put in place. Tents must not be placed within the fallout zone of fireworks or any other pyrotechnic displays. (See 25.1.5.4.)
4. Indicate to the AHJ whether any spot or effect lighting will be provided. Spot and/or effect lighting, as shown in Exhibit 25.8, must be powered by electricity, and all combustible construction must be located away from such equipment and be protected with approved noncombustible insulation in accordance with *NFPA 70*. (See 25.1.9.)
5. Provide portable fire extinguishers in all tent structures in accordance with Section 13.6. (See 25.1.6.3, 25.1.6.4, 25.1.6.5, and 25.2.5.)
6. Ensure that the required means of egress widths for exits, aisles, and other means are maintained at all times. Care must be taken to ensure that wires, ropes, and other support members do not obstruct the means of egress. The means of egress must be maintained clear and free of any obstructions at all times. (See Section 14.4 and 25.1.3.2.)
7. Ensure that adequate means of egress illumination and markings are provided and visible from all areas within the structure.

The AHJ, owner, and fire department should consider the following factors when reviewing a permit application for an inspection:

1. The permit applicant, owner, or agent must inspect the tent at regular intervals to determine that the installation is maintained in accordance with Chapter 25 and the permit approval conditions.
2. Fire and other emergency vehicles must be able to reach a point no greater than 150 ft (46 m) from any portion of the exterior wall of any structure. Emergency access roads must have an unobstructed width of 20 ft (6 m) and an unobstructed vertical clearance of 13 ft 6 in. (4 m). The AHJ must determine turning radius minimums due to varying equipment needs. Dead-end roadways having lengths greater than 150 ft (46 m) require AHJ approval and verification of acceptable turning provisions. (See 18.2.3.)
3. The ground enclosed by any structure and the ground outside the structure for a reasonable distance, but not less

Exhibit 25.7

Placement of membrane structure near fire department access.

Exhibit 25.8

Effect lighting inside a tent. (Brett Pellitier/Dreamstime.com) than 10 ft (3 m) from each structure, must be kept clear of all flammable and combustible materials or combustible vegetation. Care must also be given to guy ropes or other obstructions that are needed to maintain all sides of the tent. (See 25.1.3.2 and 25.1.5.)

4. Combustible materials should not be permitted under stands or seats at any time. Combustible trash must be removed at least daily from the structure during the period the tent is occupied by the public. (See 25.1.5.)
5. Special precautions should be taken for tents used for cooking. Care must be taken when locating cooking tents next to other buildings, temporary structures, other tents, parked vehicles, or internal combustion engines. (See 25.1.11 and 25.1.12.)
6. Smoking should be prohibited in and around all tents. The AHJ should verify that the appropriate number of No Smoking signs are located throughout and around the tent area. (See Section 10.10 and 25.1.5.2.)
7. The AHJ should not approve any type of open flame device or any other type of device that emits a flame. Flammable or combustible liquids, gas, charcoal, or any other unapproved devices should not be allowed by the AHJ inside or outside the tent, within a reasonable distance, while open to the public, unless approved by the AHJ. Any type of open flame or device capable of igniting combustibles cannot be used without obtaining a hot work permit from the AHJ. (See Section 1.12 and 25.1.4.2.)
8. Exit signs, such as the one shown in Exhibit 25.9, must be installed at required exit doorways and where otherwise necessary to indicate clearly the direction of egress, as required by NFPA *101*. Exit signs can be self-luminous or supplied from a power source as required by NFPA *101*. Fixtures provided for means of egress illumination must be supplied with power in accordance with NFPA *101*. (See Sections 14.12, 14.13, and 14.14.)
9. Heating equipment, tanks, piping, hose, fittings, valves, tubing, and other related components must be installed as specified by NFPA 54, *National Fuel Gas Code*; NFPA 58, *Liquefied Petroleum Gas Code*; and the applicable mechanical code. Gas, liquid, and solid fuel–burning equipment designed to be vented must be vented to the outside air, with vents equipped with approved spark arresters where required by the AHJ. (See 25.1.4, 25.1.9, 25.1.10, and 25.1.12.)
10. Liquefied petroleum gas (LP-Gas) equipment, such as tanks, piping, hoses, fittings, valves, tubing, and other related components, must be approved by the AHJ and in accordance with NFPA 58. LP-Gas containers must be located outside the structure. Safety release valves must be pointed away from the tent. Portable LP-Gas containers must be separated from the container and tent structure in accordance with NFPA 58. Portable LP-Gas containers, piping, valves, and fittings that are located outside and that are being used to fuel equipment inside the tent must be protected to prevent tampering, damage by vehicles, or other hazards and must be placed in a location approved by the AHJ. Portable LP-Gas containers must be securely fastened in place to prevent unauthorized movement. (See 25.1.4 and 25.1.10.)
11. Cooking and heating equipment must not be located near exits or combustible materials. Tents in which cooking is performed must be separated from other tents and structures. Outdoor cooking that produces sparks or grease-laden vapors must not be performed next to tents or other structures. Operations such as warming of foods, cooking demonstrations, and similar operations that use devices using solid flammable fuel, butane, or other similar devices that do not pose an ignition hazard must be approved by the AHJ. Electrical heating and cooking equipment must comply with *NFPA 70*. (See 25.1.6.3, 25.1.9, and 25.1.11.)
12. Flammable liquid–fueled equipment should not be used inside tents. Flammable and combustible liquids must be stored outside in a manner approved by the AHJ. Storage must be in accordance with NFPA 30, *Flammable and Combustible Liquids Code*. Refueling must be performed outside the tent at a location approved by the AHJ. (See 25.1.4.)
13. Standby personnel might be required due to the number of occupants present when potentially hazardous conditions or a reduction in a life safety feature exists because of the type of performance, display, exhibit, occupancy, or contest or activity. The AHJ might also require crowd managers in accordance with NFPA *101*. The owner, agent, or lessee must employ one or more qualified persons, as required and approved by the AHJ, for such purpose. (See 1.7.17 and 25.1.8.)

Exhibit 25.9

Exit sign inside a tent.

25.2.1.2 Tents shall be erected to cover not more than 75 percent of the premises, unless otherwise approved by the AHJ. [***101:***11.11.1.3]

25.2.2 Flame Propagation Performance.

Δ **25.2.2.1** All tent fabric shall meet the flame propagation performance criteria contained in Test Method 2 of NFPA 701. [***101:***11.11.2.1]

Δ **25.2.2.2** One of the following shall serve as evidence that the tent fabric materials have the required flame propagation performance:

(1) The AHJ shall require a certificate or other evidence of acceptance by an organization acceptable to the AHJ.
(2) The AHJ shall require a report of tests made by other inspection authorities or organizations acceptable to the AHJ.

[***101:***11.11.2.2]

25.2.2.3 Where required by the AHJ, confirmatory field tests shall be conducted using test specimens from the original material, which shall have been affixed at the time of manufacture to the exterior of the tent. [***101:***11.11.2.3]

Refer to NFPA 705, *Recommended Practice for a Field Flame Test for Textiles and Films*, for guidance to enforcement officials for the field application of an open flame to textiles and films for which reliable laboratory data are not available.

25.2.3 Location and Spacing.

25.2.3.1 There shall be a minimum of 10 ft (3050 mm) between stake lines. [***101:***11.11.3.1]

25.2.3.2 Adjacent tents shall be spaced to provide an area to be used as a means of emergency egress. Where 10 ft (3050 mm) between stake lines does not meet the requirements for means of egress, the distance necessary for means of egress shall govern. [***101:***11.11.3.2]

The specified minimum distances between stake lines and adjacent tents ensure adequate egress routes for occupants while exiting. In tents with larger numbers of occupants, the specified 10 ft (3050 mm) minimum distance might need to be increased, based on calculations similar to those for determining the minimum width of an aisle. (See 14.8.3.4.)

25.2.3.3 Tents not occupied by the public and not used for the storage of combustible material shall be permitted to be erected less than 10 ft (3050 mm) from other structures where the AHJ deems such close spacing to be safe from hazard to the public. [***101:***11.11.3.3]

25.2.3.4 Tents, each not exceeding 1200 ft^2 (112 m^2) in finished ground level area and located in fairgrounds or similar open spaces, shall not be required to be separated from each other, provided that safety precautions meet the approval of the AHJ. [***101:***11.11.3.4]

25.2.3.5 The placement of tents relative to other structures shall be at the discretion of the AHJ, with consideration given to occupancy, use, opening, exposure, and other similar factors. [***101:***11.11.3.5]

25.2.4 Fire Hazards.

25.2.4.1 The finished ground level enclosed by any tent, and the finished ground level for a reasonable distance, but for not less than 10 ft (3050 mm) outside of such a tent, shall be cleared of all flammable or combustible material or vegetation that is not used for necessary support equipment. The clearing work shall be accomplished to the satisfaction of the AHJ prior to the erection of such a tent. The premises shall be kept free from such flammable or combustible materials during the period for which the premises are used by the public. [***101:***11.11.4.1]

See the commentary following 25.1.5.1 for further details on fire hazards.

25.2.4.2 Smoking.

See Section 10.9 for additional prohibitions on smoking.

25.2.4.2.1 Smoking shall not be permitted in any tent, unless approved by the AHJ. [***101:***11.11.4.2.1]

25.2.4.2.2 In rooms or areas where smoking is prohibited, plainly visible signs shall be posted that read as follows:

NO SMOKING

[***101:***11.11.4.2.2]

25.2.5 Fire-Extinguishing Equipment. Portable fire-extinguishing equipment of approved types shall be furnished and maintained in tents in such quantity and in such locations as directed by the AHJ. [***101:***11.11.5]

See Section 13.6 for additional requirements concerning portable fire extinguishers.

25.3 Grandstands

Grandstands are structures that provide tiered or stepped seating. Exhibit 25.10 shows an example of a temporary grandstand. Temporary grandstands can pose many challenges to the AHJ. These challenges include providing proper distances for seating, proper dimensions for the rise and run of stair treads, and the required means of egress. Temporary grandstands must conform to the requirements of Section 25.3, along with the requirements of NFPA *101*. Exhibit 25.11 shows the back view of a temporary grandstand with enclosed spaces above.

25.3.1 Seating.

25.3.1.1 Where grandstand seating without backs is used indoors, rows of seats shall be spaced not less than 22 in. (560 mm) back-to-back. [***101:***12.4.9.2.1]

Exhibit 25.10

Large temporary grandstand.

Exhibit 25.11

Temporary grandstand with enclosed spaces above.

25.3.1.2 The depth of footboards and seat boards in grandstands shall be not less than 9 in. (230 mm); where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided. [***101:***12.4.9.2.2]

25.3.1.3 Seats and footrests of grandstands shall be supported securely and fastened in such a manner that they cannot be displaced inadvertently. [***101:***12.4.9.2.3]

25.3.1.4 Individual seats or chairs shall be permitted only if secured in rows in an approved manner, unless seats do not exceed 16 in number and are located on level floors and within railed-in enclosures, such as boxes. [***101:***12.4.9.2.4]

The requirements of 25.3.1.4 are intended to ensure that individual chairs do not become an impediment to egress during an emergency. The requirement that chairs be secured in rows can be accomplished by fastening the chairs to the floor or by fastening them together in groups of not fewer than three.

25.3.1.5 The maximum number of seats permitted between the farthest seat in an aisle in grandstands and bleachers shall not exceed that shown in Table 25.3.1.5. [***101:***12.4.9.2.5]

TABLE 25.3.1.5 *Maximum Number of Seats Between Farthest Seat and an Aisle*

Application	Outdoors	Indoors
Grandstands	11	6
Bleachers *[See 12.2.5.6.1.2 of NFPA 101]*	20	9

[***101:***Table 12.4.9.2.5]

25.3.2 Special Requirements — Wood Grandstands.

Δ **25.3.2.1** An outdoor wood grandstand shall be erected within not less than two-thirds of its height and, in no case, within not less than 10 ft (3050 mm) of a building, unless otherwise permitted by one of the following:

(1) The distance requirement shall not apply to buildings having minimum 1-hour fire resistance–rated construction with openings protected against the fire exposure hazard created by the grandstand.
(2) The distance requirement shall not apply where a wall having minimum 1-hour fire resistance–rated construction separates the grandstand from the building.

[***101:***12.4.9.3.1]

Δ **25.3.2.2** An outdoor wood grandstand unit shall not exceed 10,000 ft^2 (929 m^2) in finished ground level area or 200 ft (61 m) in length, and all of the following requirements also shall apply:

(1) Grandstand units of the maximum size shall be placed not less than 20 ft (6100 mm) apart or shall be separated by walls having a minimum 1-hour fire resistance rating.
(2) The number of grandstand units erected in any one group shall not exceed three.
(3) Each group of grandstand units shall be separated from any other group by a wall having minimum 2-hour fire resistance–rated construction extending 24 in. (610 mm) above the seat platforms or by an open space of not less than 50 ft (15 m).

[***101:***12.4.9.3.2]

Δ **25.3.2.3** The finished ground level area or length required by 25.3.2.2 shall be permitted to be doubled where one of the following criteria is met:

(1) Where the grandstand is constructed entirely of labeled fire-retardant-treated wood that has passed the standard rain test, ASTM D2898, *Standard Test Methods for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*
(2) Where the grandstand is constructed of members conforming to dimensions for heavy timber construction [Type IV (2HH)]

[***101:***12.4.9.3.3]

25.3.2.4 The highest level of seat platforms above the finished ground level or the surface at the front of any wood grandstand shall not exceed 20 ft (6100 mm). [***101:***12.4.9.3.4]

25.3.2.5 The highest level of seat platforms above the finished ground level, or the surface at the front of a portable grandstand within a tent or membrane structure, shall not exceed 12 ft (3660 mm). [***101:***12.4.9.3.5]

25.3.2.6 The height requirements specified in 25.3.2.4 and 25.3.2.5 shall be permitted to be doubled where constructed entirely of labeled fire-retardant-treated wood that has passed the standard rain test, ASTM D2898, or where constructed of members conforming to dimensions for heavy timber construction [Type IV (2HH)]. [***101:***12.4.9.3.6]

25.3.3 Special Requirements — Portable Grandstands.

25.3.3.1 Portable grandstands shall conform to the requirements of Section 25.3 for grandstands and the requirements of 25.3.3.2 through 25.3.3.7. [***101:***12.4.9.4.1]

25.3.3.2 Portable grandstands shall be self-contained and shall have within them all necessary parts to withstand and restrain all forces that might be developed during human occupancy. [***101:***12.4.9.4.2]

25.3.3.3 Portable grandstands shall be designed and manufactured so that, if any structural members essential to the strength and stability of the structure have been omitted during erection, the presence of unused connection fittings shall make the omissions self-evident. [***101:***12.4.9.4.3]

25.3.3.4 Portable grandstand construction shall be skillfully accomplished to produce the strength required by the design. [***101:***12.4.9.4.4]

25.3.3.5 Portable grandstands shall be provided with base plates, sills, floor runners, or sleepers of such area that the permitted bearing capacity of the supporting material is not exceeded. [***101:***12.4.9.4.5]

25.3.3.6 Where portable grandstands rest directly on a base of such character that it is incapable of supporting the load without appreciable settlement, mud sills of suitable material, having sufficient area to prevent undue or dangerous settlement, shall be installed under base plates, runners, or sleepers. [***101:***12.4.9.4.6]

25.3.3.7 All bearing surfaces of portable grandstands shall be in contact with each other. [***101:***12.4.9.4.7]

Δ **25.3.4 Spaces Underneath Grandstands.** Spaces underneath a grandstand shall be kept free of flammable or combustible materials, unless protected by an approved, supervised automatic sprinkler system in accordance with Section 13.3 or unless otherwise permitted by one of the following:

(1) This requirement shall not apply to accessory uses of 300 ft^2 (28 m^2) or less, such as ticket booths, toilet facilities, or concession booths where constructed of noncombustible or fire-resistive construction in otherwise nonsprinklered facilities.
(2) This requirement shall not apply to rooms that are enclosed in not less than 1-hour fire resistance–rated construction and are less than 1000 ft^2 (93 m^2) in otherwise nonsprinklered facilities.

[***101:***12.4.9.5]

Paragraph 25.3.4 recognizes the dangers associated with dried vegetation, combustible debris, or both, located underneath grandstands. This situation is of particular concern where the ground beneath the grandstand is not level but has a slope that is parallel to the slope of seating, causing the accumulation of trash at one point. Many large fire incidents have occurred in which combustible materials under a grandstand have ignited and burned down the grandstands and injured many people.

The requirement to separate or sprinkler enclosed spaces under grandstands is similar to those required in 25.1.6.2. When a fire occurs in an enclosed area, the fire can grow unnoticed for an extended period of time. Such fires can adversely affect occupant response and the functioning of various protection features, such as means of egress routes and structural integrity.

25.3.5 Guards and Railings.

25.3.5.1 Railings or guards not less than 42 in. (1065 mm) above the aisle surface or footrest or not less than 36 in. (915 mm) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all grandstands where the seats are more than 48 in. (1220 mm) above the floor or the finished ground level. [***101:***12.4.9.6.1]

25.3.5.2 The requirement of 25.3.5.1 shall not apply where an adjacent wall or fence affords equivalent safeguard. [***101:***12.4.9.6.2]

25.3.5.3 Where the front footrest of any grandstand is more than 24 in. (610 mm) above the floor, railings or guards not less than 33 in. (825 mm) above such footrests shall be provided. [***101:***12.4.9.6.3]

25.3.5.4 The railings required by 25.3.5.3 shall be permitted to be not less than 26 in. (660 mm) high in grandstands or where the front row of seats includes backrests. [***101:***12.4.9.6.4]

25.3.5.5 Cross aisles located within the seating area shall be provided with rails not less than 26 in. (660 mm) high along the front edge of the cross aisle. [***101:***12.4.9.6.5]

25.3.5.6 The railings specified by 25.3.5.5 shall not be required where the backs of the seats in front of the cross aisle project 24 in. (610 mm) or more above the surface of the cross aisle. [***101:***12.4.9.6.6]

25.3.5.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [***101:***12.4.9.6.7]

25.3.5.8 An opening between the seat board and footboard located more than 30 in. (760 mm) above the finished ground level shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [***101:***12.4.9.6.8]

25.3.6 Maintenance of Outdoor Grandstands.

25.3.6.1 The owner shall provide for not less than annual inspection and required maintenance of each outdoor grandstand to ensure safe conditions. [***101:***12.7.10.1]

The owner is responsible for having an inspection of the outdoor grandstands conducted annually in accordance with 25.3.6.1. These inspections should ensure that outdoor grandstands are structurally sound and meet the provisions of Section 25.3.

25.3.6.2 At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer. [***101:***12.7.10.2]

The owner is responsible for having outdoor grandstands inspected every other year by a professional engineer, a registered architect, or a person certified by the manufacturer. This inspection and subsequent report ensure that the grandstand is structurally sound, meets the requirements of Section 25.3, and is safe for continued use. Copies of the report should be made available when requested by the AHJ.

25.3.6.3 Where required by the AHJ, the owner shall provide a copy of the inspection report and certification that the inspection required by 25.3.6.2 has been performed. [***101:***12.7.10.3]

25.4 Folding and Telescopic Seating

Folding and telescopic seating is usually found in multipurpose rooms in schools and other buildings. The seating is pulled out to allow for seating at events, such as basketball games or concerts, and then pushed back in for storage to provide additional floor space during normal use of the space.

25.4.1 Seating.

Δ **25.4.1.1** The horizontal distance of seats, measured back-to-back, shall be not less than 22 in. (560 mm) for seats without backs, and all of the following requirements shall also apply:

(1) There shall be a space of not less than 12 in. (305 mm) between the back of each seat and the front of each seat immediately behind it.
(2) If seats are of the chair type, the 12 in. (305 mm) dimension shall be measured to the front edge of the rear seat in its normal unoccupied position.
(3) All measurements shall be taken between plumb lines.

[***101:***12.4.10.2.1]

25.4.1.2 The depth of footboards (footrests) and seat boards in folding and telescopic seating shall be not less than 9 in. (230 mm). [***101:***12.4.10.2.2]

25.4.1.3 Where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided. [***101:***12.4.10.2.3]

25.4.1.4 Individual chair-type seats shall be permitted in folding and telescopic seating only if firmly secured in groups of not less than three. [***101:***12.4.10.2.4]

25.4.1.5 The maximum number of seats permitted between the farthest seat in an aisle in folding and telescopic seating shall not exceed that shown in Table 25.3.1.5. [***101:***12.4.10.2.5]

25.4.2 Guards and Railings.

25.4.2.1 Railings or guards not less than 42 in. (1065 mm) above the aisle surface or footrest or not less than 36 in. (915 mm) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all folding and telescopic seating where the seats are more than 48 in. (1220 mm) above the floor or the finished ground level. [***101:***12.4.10.3.1]

25.4.2.2 The requirement of 25.4.2.1 shall not apply where an adjacent wall or fence affords equivalent safeguard. [***101:***12.4.10.3.2]

25.4.2.3 Where the front footrest of folding or telescopic seating is more than 24 in. (610 mm) above the floor, railings or guards not less than 33 in. (825 mm) above such footrests shall be provided. [***101:***12.4.10.3.3]

25.4.2.4 The railings required by 25.4.2.3 shall be permitted to be not less than 26 in. (660 mm) high where the front row of seats includes backrests. [***101:***12.4.10.3.4]

25.4.2.5 Cross aisles located within the seating area shall be provided with rails not less than 26 in. (660 mm) high along the front edge of the cross aisle. [***101:***12.4.10.3.5]

25.4.2.6 The railings specified by 25.4.2.5 shall not be required where the backs of the seats in front of the cross aisle project 24 in. (610 mm) or more above the surface of the cross aisle. [***101:***12.4.10.3.6]

25.4.2.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [***101:***12.4.10.3.7]

25.4.2.8 An opening between the seat board and footboard located more than 30 in. (760 mm) above the finished ground level shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [***101:***12.4.10.3.8]

25.4.3 Maintenance and Operation of Folding and Telescopic Seating.

25.4.3.1 Instructions in both maintenance and operation shall be transmitted to the owner by the manufacturer of the seating or his or her representative. [***101:***12.7.11.1]

Δ **25.4.3.2** Maintenance and operation of folding and telescopic seating shall be the responsibility of the owner or his or her duly authorized representative and shall include all of the following:

(1) During operation of the folding and telescopic seats, the opening and closing shall be supervised by responsible personnel who shall ensure that the operation is in accordance with the manufacturer's instructions.
(2) Only attachments specifically approved by the manufacturer for the specific installation shall be attached to the seating.
(3) An annual inspection and required maintenance of each grandstand shall be performed to ensure safe conditions.
(4) At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

[***101:***12.7.11.2]

Maintenance and inspection of folding and telescopic seating is important to ensure that such seating is safe for use. Folding and telescopic seating is set up and taken down many times during the year, placing additional wear on the structure and parts. Persons responsible for folding and telescopic seating should know the required frequency of maintenance and inspection and correct setup and takedown procedures.

The owner is responsible for having an inspection of the folding and telescopic seating conducted annually. This inspection should ensure that the seating is structurally sound and meets the provisions of Section 25.4. Copies of the inspection report should be made available when requested by the AHJ.

25.5 Permanent Membrane Structures

Permanent membrane structures are those that are intended to remain in place for more than 180 consecutive days. Membrane structures include buildings or portions of buildings incorporating air-inflated, air-supported, tensioned-membrane structures; membrane roofs; or membrane-covered rigid frames. (See Exhibit 25.1.) The most common use of a membrane structure incorporates a membrane-covered rigid frame or membrane roof to provide weather protection for an occupied rooftop or exterior patios, tennis courts, or athletic fields during inclement weather.

25.5.1 Application.

Δ **25.5.1.1 Use of Membrane Roofs.** Membrane roofs shall be used in accordance with the following:

(1) Membrane materials shall not be used where fire resistance ratings are required for walls or roofs.
(2) Where every part of the roof, including the roof membrane, is not less than 20 ft (6100 mm) above any floor, balcony, or gallery, a noncombustible or limited-combustible membrane shall be permitted to be used as the roof in any construction type.
(3) With approval of the AHJ, membrane materials shall be permitted to be used where every part of the roof membrane is sufficiently above every significant fire potential, such that the imposed temperature cannot exceed the capability of the membrane, including seams, to maintain its structural integrity.

[***101:***11.9.1.2]

25.5.1.2 Testing. Testing of membrane materials for compliance with the requirements of Section 25.5 for use of the categories of noncombustible and limited-combustible materials shall be performed on weathered-membrane material as defined in 3.3.171.5 of NFPA *101*. [***101:***11.9.1.3]

25.5.1.3 Flame Spread Index. The flame spread index of all membrane materials exposed within the structure shall be Class A in accordance with Section 12.5. [***101:***11.9.1.4]

25.5.1.4 Roof Covering Classification. Roof membranes shall have a roof covering classification, as required by the applicable building codes, when tested in accordance with ASTM E108, *Standard Test Methods for Fire Tests of Roof Coverings*; or ANSI/UL 790, *Test Methods for Fire Tests of Roof Coverings*. [***101:***11.9.1.5]

25.5.1.5 Flame Propagation Performance.

Δ **25.5.1.5.1** All membrane structure fabric shall meet the flame propagation performance criteria contained in Test Method 2 of NFPA 701. [***101:***11.9.1.6.1]

Δ **25.5.1.5.2** One of the following shall serve as evidence that the fabric materials have the required flame propagation performance:

(1) The AHJ shall require a certificate or other evidence of acceptance by an organization acceptable to the AHJ.
(2) The AHJ shall require a report of tests made by other inspection authorities or organizations acceptable to the AHJ.

[***101:***11.9.1.6.2]

25.5.1.5.3 Where required by the AHJ, confirmatory field tests shall be conducted using test specimens from the original material, which shall have been affixed at the time of manufacture to the exterior of the structure. [***101:***11.9.1.6.3]

25.5.2 Tensioned-Membrane Structures.

A tensioned-membrane structure incorporates a membrane and a structural support system of arches, columns and cables, or beams whereby the stress developed in the tensioned membrane interacts with the stresses in the structural support so that the entire assembly acts together to resist the applied loads.

25.5.2.1 The design, materials, and construction of the building shall be based on plans and specifications prepared by a licensed architect or engineer knowledgeable in tensioned-membrane construction. [***101:***11.9.2.1]

25.5.2.2 Material loads and strength shall be based on physical properties of the materials verified and certified by an approved testing laboratory. [***101:***11.9.2.2]

25.5.2.3 The membrane roof for structures in climates subject to freezing temperatures and ice buildup shall be composed of two layers separated by an air space through which heated air can be moved to guard against ice accumulation. As an alternative to the two layers, other approved methods that protect against ice accumulation shall be permitted. [***101:***11.9.2.3]

25.5.2.4 Roof drains shall be equipped with electrical elements to protect against ice buildup that can prevent the drains from functioning. Such heating elements shall be served by on-site standby electrical power in addition to the normal public service. As an alternative to such electrical elements, other approved methods that protect against ice accumulation shall be permitted. [***101:***11.9.2.4]

25.5.3 Air-Supported and Air-Inflated Structures.

An air-inflated structure differs from an air-supported structure. The shape of an air-inflated structure is maintained by air pressure within cells or tubes forming the enclosure, and the occupants are not within the pressurized areas used to support the structure. The shape of an air-supported structure is maintained by air pressure, and the occupants are within the elevated pressure area. Exhibit 25.12 depicts an air-supported structure.

25.5.3.1 General. In addition to the general provisions of 25.5.1, the requirements of 25.5.3 shall apply to air-supported and air-inflated structures. [***101:***11.9.3.1]

Δ **25.5.3.2 Pressurization (Inflation) System.** The pressurization system shall consist of one or more operating blower units. The

Exhibit 25.12

Air-supported structure.

system shall include automatic control of auxiliary blower units to maintain the required operating pressure. Such equipment shall meet the following requirements:

(1) Blowers shall be powered by continuous-rated motors at the maximum power required.
(2) Blowers shall have personnel protection, such as inlet screens and belt guards.
(3) Blower systems shall be weather protected.
(4) Blower systems shall be equipped with backdraft check dampers.
(5) Not less than two blower units shall be provided, each of which has capacity to maintain full inflation pressure with normal leakage.
(6) The blowers shall be designed to be incapable of overpressurization.
(7) The auxiliary blower unit(s) shall operate automatically if there is any loss of internal pressure or if an operating blower unit becomes inoperative.
(8) The design inflation pressure and the capacity of each blower system shall be certified by a professional engineer.

[***101:***11.9.3.2]

25.5.3.3 Standby Power System.

25.5.3.3.1* A fully automatic standby power system shall be provided. The system shall be either an auxiliary engine generator set capable of running the blower system or a supplementary blower unit that is sized for 1 times the normal operating capacity and is powered by an internal combustion engine. [***101:***11.9.3.3.1]

Δ **A.25.5.3.3.1** The requirements of 25.5.3.3.1 can be considered as a Class 4, Type 60 system per NFPA 110. [***101:***A.11.9.3.3.1]

25.5.3.3.2 The standby power system shall be fully automatic to ensure continuous inflation in the event of any failure of the primary power. The system shall be capable of operating continuously for a minimum of 4 hours. [***101:***11.9.3.3.2]

25.5.3.3.3 The sizing and capacity of the standby power system shall be certified by a professional engineer. [***101:***11.9.3.3.3]

25.5.4 Maintenance and Operation.

25.5.4.1 Instructions in both operation and maintenance shall be transmitted to the owner by the manufacturer of the tensioned-membrane, air-supported, or air-inflated structure. [***101:***11.9.4.1]

25.5.4.2 Annual inspection and required maintenance of each structure shall be performed to ensure safety conditions. At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer. [***101:***11.9.4.2]

The owner is responsible for having an inspection of tensioned-membrane, air-supported, or air-inflated structures conducted annually. These inspections should ensure that such structures are structurally sound and meet the provisions of Section 25.5. The owner is responsible for having the tensioned-membrane, air-supported, or air-inflated structure inspected every other year by a professional engineer, a registered architect, or a person certified by the manufacturer. This inspection and subsequent report should ensure that the structure is structurally sound, meets the requirements of Section 25.5, and is safe for continued use. Copies of the inspection report should be made available when requested by the AHJ.

25.6 Temporary Membrane Structures

25.6.1 Application.

25.6.1.1 Required Approval. Membrane structures designed to meet all the requirements of Section 25.6 shall be permitted to be used as temporary buildings subject to the approval of the AHJ. [***101:***11.10.1.2]

25.6.1.2 Alternative Requirements. Temporary tensioned-membrane structures shall be permitted to comply with Section 25.2 instead of Section 25.6. [***101:***11.10.1.3]

25.6.1.3 Roof Covering Classification. Roof membranes shall have a roof covering classification, as required by the applicable building codes, when tested in accordance with ASTM E108 or ANSI/UL 790. [***101:***11.10.1.4]

25.6.1.4 Flame Propagation Performance.

Δ **25.6.1.4.1** All membrane structure fabric shall meet the flame propagation performance criteria contained in Test Method 2 of NFPA 701. [***101:***11.10.1.5.1]

Δ **25.6.1.4.2** One of the following shall serve as evidence that the fabric materials have the required flame propagation performance:

(1) The AHJ shall require a certificate or other evidence of acceptance by an organization acceptable to the AHJ.
(2) The AHJ shall require a report of tests made by other inspection authorities or organizations acceptable to the AHJ.

[***101:***11.10.1.5.2]

25.6.1.4.3 Where required by the AHJ, confirmatory field tests shall be conducted using test specimens from the original material, which shall have been affixed at the time of manufacture to the exterior of the structure. [***101:***11.10.1.5.3]

25.6.2 Fire Hazards.

25.6.2.1 The finished ground level enclosed by any temporary membrane structure, and the finished ground level for a reasonable distance but for not less than 10 ft (3050 mm) outside of such a structure, shall be cleared of all flammable or combustible material or vegetation that is not used for necessary support equipment. The clearing work shall be accomplished to the satisfaction of the AHJ prior to the erection of such a structure. The premises shall be kept free from such flammable or combustible materials during the period for which the premises are used by the public. [***101:***11.10.2.1]

For a discussion of fire hazards, see the commentary following 25.1.5.1.

25.6.2.2 Where prohibited by the AHJ, smoking shall not be permitted in any temporary membrane structure. [***101:***11.10.2.2]

See Section 10.9 for additional prohibitions on smoking.

25.6.3 Fire-Extinguishing Equipment. Portable fire-extinguishing equipment of approved types shall be furnished and maintained in temporary membrane structures in such quantity and in such locations as directed by the AHJ. [***101:***11.10.3]

See Section 13.6 for requirements concerning portable fire extinguishers.

25.6.4 Tensioned-Membrane Structures.

A tensioned-membrane structure incorporates a membrane and a structural support system of arches, columns and cables, or beams whereby the stress developed in the tensioned membrane interacts with the stresses in the structural support so that the entire assembly acts together to resist the applied loads.

25.6.4.1 The design, materials, and construction of the building shall be based on plans and specifications prepared by a licensed architect or engineer knowledgeable in tensioned-membrane construction. [***101:***11.10.4.1]

25.6.4.2 Material loads and strength shall be based on physical properties of the materials verified and certified by an approved testing laboratory. [***101:***11.10.4.2]

25.6.4.3 The membrane roof for structures in climates subject to freezing temperatures and ice buildup shall be composed of two layers separated by an air space through which heated air can be moved to guard against ice accumulation. As an alternative to the two layers, other approved methods that protect against ice accumulation shall be permitted. [***101:***11.10.4.3]

25.6.4.4 Roof drains shall be equipped with electrical elements to protect against ice buildup that can prevent the drains from functioning. Such heating elements shall be served by on-site standby electrical power in addition to the normal public service. As an alternative to such electrical elements, other approved methods that protect against ice accumulation shall be permitted. [***101:***11.10.4.4]

25.6.5 Air-Supported and Air-Inflated Structures.

25.6.5.1 General. In addition to the general provisions of 25.6.1, the requirements of 25.6.5 shall apply to air-supported and air-inflated structures. [***101:***11.10.5.1]

Δ **25.6.5.2 Pressurization (Inflation) System.** The pressurization system shall consist of one or more operating blower units. The system shall include automatic control of auxiliary blower units to maintain the required operating pressure. Such equipment shall meet the following requirements:

(1) Blowers shall be powered by continuous-rated motors at the maximum power required.
(2) Blowers shall have personnel protection, such as inlet screens and belt guards.
(3) Blower systems shall be weather protected.
(4) Blower systems shall be equipped with backdraft check dampers.
(5) Not less than two blower units shall be provided, each of which has capacity to maintain full inflation pressure with normal leakage.
(6) The blowers shall be designed to be incapable of overpressurization.
(7) The auxiliary blower unit(s) shall operate automatically if there is any loss of internal pressure or if an operating blower unit becomes inoperative.
(8) The design inflation pressure and the capacity of each blower system shall be certified by a professional engineer.

[***101:***11.10.5.2]

25.6.5.3 Standby Power System.

25.6.5.3.1 A fully automatic standby power system shall be provided. The system shall be either an auxiliary engine generator set capable of running the blower system or a supplementary blower unit that is sized for 1 times the normal operating capacity and is powered by an internal combustion engine. [***101:***11.10.5.3.1]

25.6.5.3.2 The standby power system shall be fully automatic to ensure continuous inflation in the event of any failure of the primary power. The system shall be capable of operating continuously for a minimum of 4 hours. [***101:***11.10.5.3.2]

25.6.5.3.3 The sizing and capacity of the standby power system shall be certified by a professional engineer. [***101:***11.10.5.3.3]

25.6.6 Maintenance and Operation.

25.6.6.1 Instructions in both operation and maintenance shall be transmitted to the owner by the manufacturer of the tensioned-membrane, air-supported, or air-inflated structure. [***101:***11.10.6.1]

25.6.6.2 Annual inspection and required maintenance of each structure shall be performed to ensure safety conditions. At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer. [***101:***11.10.6.2]

The owner is responsible for having an inspection of each tensioned-membrane, air-supported, or air-inflated structure conducted annually. These inspections should ensure that the structures are structurally sound and meet the provisions of Section 25.6. The owner is responsible for having the structure inspected every other year by a professional engineer, a registered architect, or a person certified by the manufacturer. This inspection and subsequent report should ensure that the structure is structurally sound, meets the requirements of Section 25.6, and is safe for continued use. Copies of the inspection report should be made available when requested by the AHJ.

26 Laboratories Using Chemicals

Chapter 26 contains general requirements for laboratories using chemicals. These types of laboratories pose a variety of hazards. In addition to ordinary hazards found in laboratories, such as crowded research space, other hazards are present, such as flammable and combustible liquids storage, handling and use of hazardous chemicals, compressed and liquefied gases, radiological hazards, and biological hazards. Risk management involves the systematic identification, evaluation, and control of hazards that can result in loss of life and property damage. Risk management of laboratories requires recognizing possible risks, evaluating their frequency and the magnitude of their consequences, and determining appropriate measures for preventing or reducing such risks from a cost-benefit viewpoint.

Critical to risk management of laboratories using chemicals are design and construction, fire protection, explosion hazard protection, ventilation, and safe storage and handling of chemicals and compressed and liquefied gases. Each laboratory is unique in its operation, risks, and associated needs and should be evaluated as such.

26.1 General

Δ **26.1.1** The handling or storage of chemicals in laboratory buildings, laboratory units, and laboratory work areas whether located above or below grade shall comply with this chapter. Construction and protection of new laboratories shall also comply with NFPA 45.

The purpose of NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, is to provide basic requirements for the protection of life and property through prevention and control of fires and explosions involving the use of chemicals in laboratory-scale operations. NFPA 45 is designed to control hazards and protect personnel from the toxic, corrosive, or other harmful effects of chemicals to which they might be exposed as a result of fire or explosion. The goal is to achieve a comprehensive laboratory fire prevention and protection program by limiting injury to the occupants at the point of fire origin, limiting injury to emergency response personnel, and limiting property loss to a maximum of a single laboratory unit. NFPA 45 does not intend to address financial losses such as business interruption or property loss when the loss of a laboratory unit is unacceptable.

The provisions of NFPA 45 are necessary to provide a reasonable level of protection from loss of life and property from fires and explosions in laboratories using chemicals. The provisions of NFPA 45, unless otherwise noted, are not intended to be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of NFPA 45, except in those cases where the authority having jurisdiction (AHJ) has determined that the existing situation involves a distinct hazard to life or property.

Exhibit 26.1 provides guidance for applying NFPA 45 to a laboratory setting.

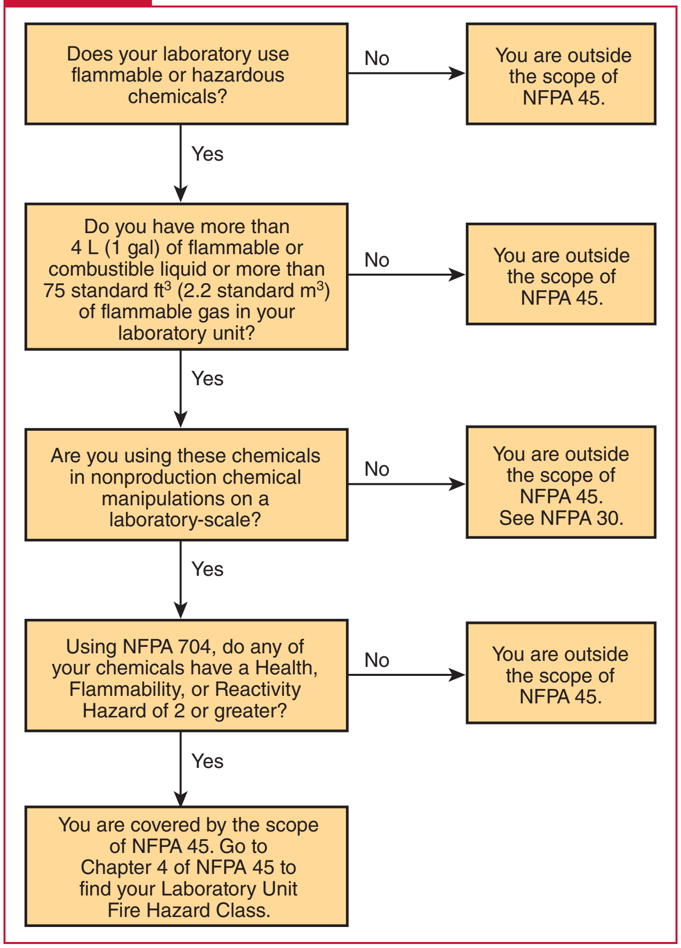
26.1.2 Chapter 26 shall apply to laboratory buildings, laboratory units, and laboratory work areas whether located above or below grade in which chemicals, as defined in NFPA 704 with one or more of the following hazard ratings are handled or stored: health — 2, 3, or 4; flammability — 2, 3, or 4; or instability — 2, 3, or 4. *(See also Section B.2 of NFPA 45.).* [**45:**1.1.1]

N **26.1.3** Chapter 26 shall apply to all educational laboratory units and instructional laboratory units in which any quantity of chemicals, as defined in NFPA 704 with one or more of the following hazard ratings, is handled or stored: health — 2, 3, or 4: flammability — 2, 3, 4; or instability — 2, 3, 4. *(See also Section B.2 of NFPA 45).* [**45:**1.1.2]

The 2015 edition of NFPA 45, referenced in this edition of the *Code*, added a statement to its scope to clarify that it applies to all educational laboratories and instructional laboratories, regardless of the quantity of chemicals that are handled or stored. Educational laboratory units and instructional laboratory units are defined in NFPA 45 as follows:

> ***Educational Laboratory Unit.*** A laboratory unit that is under direct supervision of an instructor and used for educational purposes for students through the twelfth grade.
> ***Instructional Laboratory Unit.*** A laboratory unit under the direct supervision of an instructor that is used for purposes of instruction for students beyond the twelfth grade.

Exhibit 26.1



Determining the applicability of NFPA 45 to a laboratory setting.

Δ **26.1.4** With the exception of 26.1.3, Chapter 26 shall not apply to the following:

(1)* Laboratories for which the following conditions apply:
 (a) Laboratory units that contain less than or equal to 1 gal (4 L) of flammable or combustible liquid
 (b) Laboratory units that contain less than 75 scf (2.2 standard m^3) of flammable gas, not including piped-in low-pressure utility gas installed in accordance with NFPA 54

Δ **A.26.1.4(1)** Either condition of 26.1.4(1) meeting the minimum quantity will bring the lab within the scope of Chapter 26. A school lab with a low pressure natural gas system supplying Bunsen burners (with less than the minimum quantities of combustible or flammable liquids and less than the minimum quantities of other flammable gases) is an example of a lab outside the scope of Chapter 26. [**45:**A.1.1.3(1)]

Note that the quantities of hazardous materials cited in either of the conditions in 26.1.4(1)(a) or (b) are minimum quantities of flammable and combustible liquid or flammable gas that would qualify the lab for coverage under NFPA 45. The minimum quantity of flammable gas does not include low pressure utility gas installed in accordance with NFPA 54, *National Fuel Gas Code*.

(2)* Pilot plants

A.26.1.4(2) The hazards of pilot plants are primarily based on the process, the chemistry, and the equipment, not the laboratory environment. [**45:**A.1.1.3(2)]

(3) Laboratories that handle only chemicals with a hazard rating of 0 or 1 for all of the following: health, flammability, and instability, as defined by NFPA 704
(4) Laboratories that are primarily manufacturing plants
(5) Incidental testing facilities
(6) Physical, electronic, instrument, laser, or similar laboratories that use chemicals only for incidental purposes, such as cleaning
(7)* Hazards associated with radioactive materials, as covered by NFPA 801

Δ **A.26.1.4(7)** NFPA 801 provides direction for controlling hazards associated with radioactive materials. NFPA 801 should be used only for issues related to radioactive materials in a laboratory. All other nonradioactive, laboratory issues are covered by NFPA 45. [**45:**A.1.1.3(7)]

(8) Laboratories that work only with explosive material, as covered by NFPA 495
(9) A laboratory work area containing an explosion hazard great enough to cause property damage outside that laboratory work area or injury outside that laboratory work area requiring medical treatment beyond first aid

[**45:**1.1.3]

Δ **26.1.5** Chapter 26 contains requirements, but not all-inclusive requirements, for handling and storage of chemicals where laboratory-scale operations are conducted and shall not cover the following:

(1) The special fire protection required when handling explosive materials *(See NFPA 495.)*
(2) The special fire protection required when handling radioactive materials

[**45:**1.1.6]

26.1.6 Plans and Procedures.

26.1.6.1* Fire prevention, maintenance, and emergency action plans and procedures shall be established.

A.26.1.6.1 Laboratory buildings, laboratory units, and laboratory work areas need to have clearly developed plans for fire prevention, maintenance, and emergency procedures. Guidance of the development of these plans and procedures can be found in NFPA 45.

26.2 Permits

Permits, where required, shall comply with Section 1.12.

Table 1.12.8(a) requires a permit for construction, alteration, or operation of laboratories.

Additional permits might be required for certain operations involving flammable gases, flammable or combustible liquids, or industrial ovens. Other hazardous materials, including the following, would require permits as called for by this *Code* (see 1.12.8):

1. Compressed gases
2. Cryogens
3. Flammable and combustible liquids
4. Hazardous materials
5. Industrial ovens
6. Laboratories
7. Liquefied petroleum gases (LP-Gas)
8. Organic peroxide formulations
9. Oxidizers

Manufactured Home and Recreational Vehicle Sites

27

Chapter 27 prescribes minimum fire safety requirements for manufactured home sites and recreational vehicle parks and campgrounds by providing mandatory references to NFPA 501A, *Standard for Fire Safety Criteria for Manufactured Home Installations, Sites, and Communities*, and NFPA 1194, *Standard for Recreational Vehicle Parks and Campgrounds*. NFPA 501A addresses site fuel supply requirements, electrical systems, life safety/fire safety requirements for manufactured home sites, community buildings and accessory buildings, and site access roads. NFPA 1194 contains similar requirements for recreational vehicle parks and campgrounds and also includes provisions for environmental health and sanitation.

27.1 General

27.1.1 Manufactured home and recreational vehicle sites shall meet the requirements of this chapter.

Δ **27.1.2** This chapter shall not apply to recreational vehicles as defined in NFPA 1192 or to park trailers as defined in RVIA/ANSI A.119.5, *Park Model Recreational Vehicle Standard*.

27.1.3 This chapter shall not cover the design of recreational vehicles or other forms of camping units or the operational and maintenance practices of recreational vehicle parks and campgrounds.

Δ 27.2 Manufactured Home Sites

The fire safety requirements for the installation of manufactured homes and manufactured home sites, including accessory buildings, structures, and communities, shall comply with NFPA 501A.

NFPA 501A does not apply to recreational vehicles as defined in NFPA 1192, *Standard on Recreational Vehicles*, or to park trailers as defined in RVIA/ANSI A.119.5, *Park Model Recreational Vehicle Standard*.

In 1.3.1.1 of NFPA 501A *manufactured homes* are described as follows: "A structure, transportable in one or more sections, that in the traveling mode is 8 body-ft (2.4 m) or more in width or 40 body-ft (12.2 m) or more in length or that on site is 320 ft^2 (29.7 m^2) or more, is built on a permanent chassis, is designed to be used as a dwelling with or without a permanent foundation, whether or not connected to the utilities, and includes plumbing, heating, air-conditioning, and electrical systems contained therein. Such terms shall include any structure that meets all the requirements of this paragraph except the size requirements and with respect to which the manufacturer voluntarily files a certification required by the regulatory agency. Calculations used to determine the number of square feet (square meters) in a structure are based on the structure's exterior dimensions, include all expandable rooms, cabinets, and other projections containing interior space, but do not include bay windows."

NFPA 501A goes on to define *manufactured home site* as a "parcel of land for the accommodation of one manufactured home, its accessory building or structures, and accessory equipment for the exclusive use of the occupants."

Δ 27.3 Recreational Vehicle Parks and Campgrounds

The construction of recreational vehicle parks and campgrounds that offer temporary living sites for use by recreational vehicles and camping units shall comply with NFPA 1194.

NFPA 1194 does not cover the design of recreational vehicles, recreational park trailers, other forms of camping units, or operational and maintenance practices for recreational vehicle parks and campgrounds. NFPA 1192 is a companion standard on which the provisions of NFPA 1194 are largely based.

NFPA 1194 was developed to serve as a basis for regulation by authorities having jurisdiction (AHJs) over the facilities provided in new recreational vehicle parks and campgrounds and additions to existing facilities only. Facilities provided in existing recreational vehicle parks and campgrounds are permitted to be continued in use, provided that such facilities do not constitute a recognized health or safety hazard.

Marinas, Boatyards, Marine Terminals, Piers, and Wharves

28

Chapter 28 covers marinas, boatyards, yacht clubs, boat condominiums, docking facilities associated with residential condominiums, multiple-docking facilities at multiple-family residences, and all associated piers, docks, and floats. This chapter also addresses construction and fire protection at marine terminals, piers, and wharves.

28.1 Marinas, Boatyards, and Other Recreational Marine Facilities

28.1.1 Scope. The construction and operation of marinas, boatyards, yacht clubs, boat condominiums, docking facilities associated with residential condominiums, multiple-docking facilities at multiple-family residences, and all associated piers, docks, and floats shall comply with NFPA 303 and Section 28.1. [**303:**1.1]

Jurisdictions might have other regulatory requirements that can be imposed on marinas and boatyards, including environmental regulations or zoning ordinances. NFPA 303, *Fire Protection Standard for Marinas and Boatyards*, and all applicable federal, state, and local regulations should be followed. The specified chapters of NFPA 303 cover the following:

1. Chapter 4 provides direction to the marina facility management on basic fire safety practices and procedures.
2. Chapter 5 covers marina electrical wiring and equipment.
3. Chapter 6 addresses fire protection within the marina and boatyard, including portable and fixed extinguishing systems.
4. Chapter 7 covers boat berthing and storage for wet, dry, and rack arrangements.
5. Chapter 8 addresses operational hazards, such as fueling and vessel maintenance involving paints, solvents, and various hot work processes.

In addition to safe practices for fueling boats, the provisions for the fueling facility within a marina or boatyard can be found in NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*, and Section 42.9 of this *Code*.

Unless otherwise noted, the provisions of NFPA 303 are not intended to be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of the document, except in those cases where the authority having jurisdiction (AHJ) determines that the existing situation involves a distinct hazard to life or adjacent property.

N **28.1.1.1** Section 28.1 also applies to support facilities and structures used for construction, repair, storage, hauling and launching, or fueling of vessels if fire on a pier would pose an immediate threat to these facilities, or if a fire at a referenced facility would pose an immediate threat to a docking facility. [**303:**1.1.1]

N **28.1.1.2** Section 28.1 applies to marinas and facilities servicing small recreational and commercial craft, yachts, and other craft of not more than 300 gross tons. [**303:**1.1.2]

N **28.1.1.3** Section 28.1 shall not apply to private, non-commercial docking facility constructed or occupied for the use of the owners or residents of an associated single-family dwelling. [**303:**1.1.3]

28.1.1.4 No requirement in this chapter is to be construed as reducing applicable building, fire, and electrical codes. [**303:**1.1.4]

• **28.1.2 Fire Protection.**

28.1.2.1 Portable Fire Extinguishers.

28.1.2.1.1 Placement.

28.1.2.1.1.1 Placement of portable fire extinguishers shall be in accordance with Chapter 5 of NFPA 10 unless otherwise permitted by 28.1.2.1.1.1.1, 28.1.2.1.1.1.2, or 28.1.2.1.1.1.3. [**303:**6.2.1.1.1]

Δ **28.1.2.1.1.1.1** Placement of portable fire extinguishers on piers and along bulkheads where vessels are moored or are permitted to be moored shall meet the following criteria:

(1) Extinguishers listed for Class A, Class B, and Class C fires shall be installed at the pier/land intersection on a pier that exceeds 25 ft (7.62 m) in length.
(2) Additional fire extinguishers shall be placed such that the maximum travel distance to an extinguisher does not exceed 75 ft (22.86 m).
(3) Extinguishers shall be protected from environmental exposures to prevent damage and lack of operability.

[**303:**6.2.1.1.1.1]

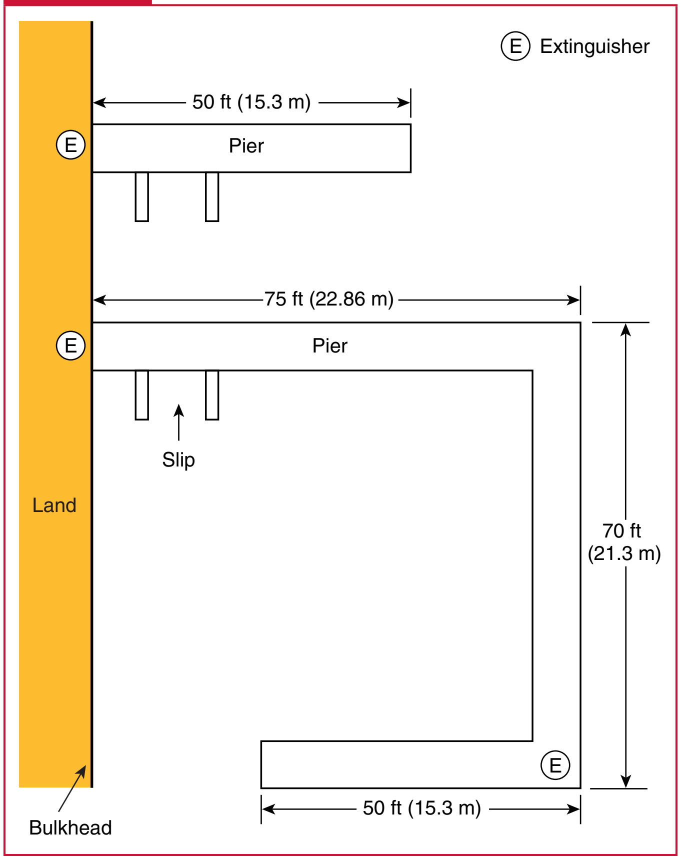
The pier/land intersection has been established as a reference point from which to define the minimum requirements for portable fire extinguishers. Paragraph 28.1.2.1.1.1.1 requires a portable fire extinguisher at the pier/land intersection for those piers greater than 25 ft (7.62 m) in length. If the pier structure running parallel to the land has finger piers extending perpendicular from that structure, each finger pier could be required to have a portable fire extinguisher at the pier/land intersection, depending on the travel distance to extinguishers. Enough portable fire extinguishers will be required to be positioned so that the travel distance from any point on the pier to a fire extinguisher does not exceed 75 ft (22.86 m). See Section 13.6 of this *Code* and NFPA 10, *Standard for Portable Fire Extinguishers*, for additional information on requirements for the selection and locations of portable fire extinguishers.

Exhibit 28.1 illustrates extinguisher requirements on a finger pier. The top portion of the exhibit shows the extinguisher at the pier/land intersection because the pier is greater than 25 ft (7.62 m) in length. The bottom portion shows additional extinguishers on the pier to keep the travel distance to an extinguisher no greater than 75 ft (22.86 m).

28.1.2.1.1.1.2 Fuel-Dispensing Areas.

(A) Portable fire extinguishers that meet the minimum requirements of Chapter 5 of NFPA 10 for extra (high) hazard type shall be installed on two sides of a fuel-dispensing area. [**303:**6.1.1.1.2.1]

Exhibit 28.1



Extinguisher requirements on finger pier.

(B) On piers or bulkheads where long fueling hoses are installed for fueling vessels, additional extinguishers installed on piers or bulkheads shall meet the requirements of Chapter 5 of NFPA 10 for extra (high) hazard type and 28.1.2.1.1.1.1. [**303:**6.1.1.1.2.2]

28.1.2.1.1.1.3 All extinguishers installed on piers shall meet the rating requirements set forth in Chapter 5 of NFPA 10 for ordinary (moderate) hazard type. [**303:**6.1.1.1.3]

Δ **28.1.2.1.2 Visibility and Identification.** All portable fire extinguishers shall be clearly visible and marked. [**303:**6.2.2]

28.1.2.2* Fixed Fire-Extinguishing Systems.

A.28.1.2.2 Where fixed fire-extinguishing system components are installed in areas subjecting these components to corrosion or other atmospheric damage, special considerations might be necessary. Corrosion-resistant types of pipe, fittings, and hangers or protective corrosion-resistant coatings should be used where corrosive conditions exist. [**303:**A.6.2]

28.1.2.2.1 Buildings on Piers.

28.1.2.2.1.1 Buildings in excess of 500 ft² (46 m²) that are constructed on piers shall be protected by an approved automatic fire-extinguishing system unless otherwise permitted by 28.1.2.2.1.2 or 28.1.2.2.1.3. [**303:**6.2.1.1]

Δ **28.1.2.2.1.2** Buildings of Type I or Type II construction, as specified in NFPA 220 and without combustible contents shall not be required to be protected by an automatic fire-extinguishing system. [**303:**6.2.1.2]

28.1.2.2.1.3* Existing facilities shall not be required to be protected by an automatic fire-extinguishing system where acceptable to the AHJ. [**303:**6.2.1.3]

A.28.1.2.2.1.3 Where clearly impractical for economic or physical reasons, the AHJ could permit the omission of an automatic fire-extinguishing system when considering water supply availability and adequacy and size of facility. [**303:**A.6.2.1.3]

28.1.2.2.2* Buildings Exceeding 5000 ft² (465 m²).

A.28.1.2.2.2 It is not the intent of this paragraph to limit the types of fire protection systems to automatic sprinklers in order to comply with the requirements of 28.1.2.2.2. Other types of automatic fire-extinguishing systems, such as foam/water, expanded foam, or clean agents, can be used for compliance provided that the system is applicable to the hazard present; automatically provides for the detection, control, and extinguishment of fires involving the hazards that might be present in the building; and is acceptable to the AHJ. The combustibility of the boats in storage should be considered in determining the hazard classification for appropriate sprinkler system design. [**303:**A.6.2.2]

28.1.2.2.2.1 Marina and boatyard buildings in excess of 5000 ft² (465 m²) in total area shall be protected by an approved automatic fire-extinguishing system unless otherwise permitted by 28.1.2.2.2.2. [**303:**6.2.2.1]

28.1.2.2.2.2* Existing facilities shall not be required to be protected by an automatic fire-extinguishing system where acceptable to the AHJ. [**303:**6.2.2.2]

A.28.1.2.2.2.2 See A.28.1.2.2.1.3. [**303:**A.6.3.2.2]

28.1.2.2.3 Combustible Piers and Substructures.

Δ **28.1.2.2.3.1** Combustible piers and substructures in excess of 25 ft (7.62 m) in width or in excess of 5000 ft^2 (465 m^2) in area, or within 30 ft (9.14 m) of other structures or superstructures required to be so protected, shall be protected in accordance with Section 4.3 of NFPA 307 unless otherwise permitted by 28.1.2.2.3.2, 28.1.2.2.3.3, or 28.1.2.2.3.4. [**303:**6.2.3.1]

Paragraph 28.1.2.2.3.1 differentiates between the types of facilities covered by NFPA 303 and those intended for coverage by NFPA 307, *Standard for the Construction and Fire Protection of Marine Terminals, Piers, and Wharves*. NFPA 307 provides much more extensive treatment of the actual construction requirements for the piers and substructures more commonly associated with commercial cargo operations at marine terminals, piers, and wharves.

28.1.2.2.3.2 Fixed piers shall not be required to be protected as specified in 28.1.2.2.3.1 where the vertical distance from the surface of mean high water level to the underside of the pier surface does not exceed 36 in. (914 mm). [**303:**6.2.3.2]

28.1.2.2.3.3 Floating piers shall not be required to be protected as specified in 28.1.2.2.3.1 where the vertical distance from the surface of the water to the underside of the pier surface does not exceed 36 in. (914 mm). [**303:**6.2.3.3]

28.1.2.2.3.4* Existing facilities shall not be required to be protected by an automatic fire-extinguishing system where acceptable to the AHJ. [**303:**6.2.3.4]

A.28.1.2.2.3.4 See A.28.1.2.2.1.3. [**303:**A.6.3.3.4]

28.1.2.2.4 Indoor Rack Storage.

See the commentary following 28.1.3.2.3.2(4).

28.1.2.2.4.1* Where boats are stored on multilevel racks in buildings, an approved automatic fire-extinguishing system shall be installed throughout the building unless otherwise permitted by 28.1.2.2.4.2 or 28.1.2.2.4.3. [**303:**6.2.4.1]

A.28.1.2.2.4.1 Compliance with the requirements of Chapter 12 of NFPA 13 for the protection of Group A plastics stored on solid shelves should be considered for the design and installation of automatic sprinkler systems provided for the protection of buildings housing boats stored on multilevel racks. The combustibility of the boats in storage should be considered in determining hazard classifications. Plan view configuration of the boats in storage should be reviewed to determine whether in-rack sprinklers are needed and to aid in the proper design of the in-rack portion of the sprinkler system. Sound engineering judgment is necessary in selecting sprinkler spacing, placement, and design criteria. [**303:**A.6.2.4.1]

Δ **28.1.2.2.4.2** An automatic fire-extinguishing system shall not be required for buildings less than 5000 ft^2 (465 m^2) having multilevel racks where provided with one of the following:

(1) An automatic fire detection and alarm system supervised by a central station complying with *NFPA 72*
(2) An automatic fire detection and alarm system supervised by a local protective signaling system complying with *NFPA 72*, if the provisions of 28.1.2.2.4.2(1) are not technically feasible
(3) A full-time watch service if the provisions of 28.1.2.2.4.2(1) are not technically feasible

[**303:**6.2.4.2]

28.1.2.2.4.3* Existing facilities shall not be required to be protected by an automatic fire-extinguishing system where acceptable to the AHJ. [**303:**6.2.4.3]

A.28.1.2.2.4.3 See A.28.1.2.2.1.3. [**303:**A.6.2.4.3]

28.1.2.2.5* An approved water supply shall be provided within 100 ft (30 m) of the pier/land intersection or fire department connection serving fire protection systems. [**303:**6.2.5]

A.28.1.2.2.5 To comply with this requirement, water supplies can consist of a hydrant that is part of an approved water supply system, drafting hydrant, or drafting site. [**303:**A.6.2.5]

28.1.2.2.6 Access between water supplies and pier/land intersections or fire department connections shall be by roadway acceptable to the AHJ. [**303:**6.2.6]

28.1.2.3* Fire Standpipe Systems.

A.28.1.2.3 Where standpipe system components are installed in areas subjecting these components to corrosion or other atmospheric damage, special considerations might be necessary. Corrosion-resistant types of pipe, fittings, and hangers or protective corrosion-resistant coatings should be used where corrosive conditions exist. [**303:**A.6.43]

Paragraph 28.1.2.3 addresses the requirements for standpipe systems. Standpipe systems are required to be installed wherever access to piers, bulkheads, or buildings is limited. If the distance from fire apparatus to any of these structures exceeds 150 ft (45.8 m), a Class I standpipe system is required to ensure that adequate fire-fighting water is easily accessible and available in the event of a fire in these structures.

These requirements represent efforts to balance the fire protection and the practical limitations associated with the weight of the piping on piers or docks. Many piers or docks float and might not support the weight of the standpipe system piping. These requirements include options to use flexible connections and nonferrous piping, subject to approval by the AHJ and their listing. Because of vandalism and potential misuse by marina residents, hose racks, hoses, and standpipe cabinets are not required to be located on the piers or bulkheads. See Section 13.2 and NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, for additional information on standpipe systems.

28.1.2.3.1 Class I standpipe systems shall be provided for piers, bulkheads, and buildings where the hose lay distance from the fire apparatus exceeds 150 ft (45 m). [**303:**6.3.1]

28.1.2.3.2 Class I standpipes shall be provided in all buildings used for the rack storage of boats. [**303:**6.4.2]

Δ **28.1.2.3.3** Standpipe systems, where installed, shall be in accordance with NFPA 14, except for the provisions identified in 28.1.2.3.4 through 28.1.2.3.7. [**303:**6.3.3]

28.1.2.3.4 Hose racks, hoses, and standpipe cabinets shall not be required on piers and bulkheads. [**303:**6.3.4]

28.1.2.3.5 Supply piping for standpipes on piers and bulkheads shall be sized for the minimum flow rate of 300 gpm (1136 L/min). [**303:**6.3.5]

Paragraph 28.1.2.3.5 requires that the standpipe system be sized for Class II flow rate due to weight considerations on the pier structure. Essentially the standard is requiring a Class II system with a permanently attached water supply and no hose.

28.1.2.3.6 Manual dry standpipes shall be permitted. [**303:**6.3.6]

28.1.2.3.7 Flexible connections shall be permitted on floating piers where acceptable to the AHJ. [**303:**6.3.7]

28.1.2.4 In-Out Dry Storage and Rack Storage. Water supply and hoses or portable fire extinguishers and wheeled cart assemblies equipped with discharge nozzles capable of reaching all boats on the highest racks shall be provided. [**303:**6.4]

Δ **28.1.2.5 Hydrants and Water Supplies.** Hydrants and water supplies for fire protection in marinas and boatyards shall be provided in accordance with NFPA 13, NFPA 14, and NFPA 24. [**303:**6.5]

28.1.2.6 Fire Detectors.

Δ **28.1.2.6.1** Fire detection devices and installation shall be in accordance with *NFPA 72*. [**303:**6.9.1]

Δ **28.1.2.6.2** Fire detectors shall be installed in the following interior or covered locations unless those locations are protected by a fixed automatic sprinkler system installed in accordance with NFPA 13:

(1) Rooms containing combustible storage or goods
(2) Rooms containing flammable liquid storage or use
(3) Rooms containing battery storage or maintenance
(4) Rooms containing paint and solvent storage or use
(5) Areas used for enclosed or covered storage of vessels
(6) Areas used for enclosed or covered maintenance of vessels
(7) Areas used for public assembly, dining, or lodging
(8) Kitchens and food preparation areas
(9) Dust bins and collectors
(10) Inside trash storage areas
(11) Rooms used for storing janitor supplies or linens
(12) Laundry rooms
(13) Furnace rooms

[**303:**6.9.2]

28.1.3 Berthing and Storage.

28.1.3.1 Wet Storage and Berthing.

28.1.3.1.1 Each berth shall be arranged such that a boat occupying the berth can be removed in an emergency without the necessity of moving other boats. [**303:**7.1.1]

28.1.3.1.2 Access to all piers, floats, and wharves shall be provided for municipal fire-fighting equipment. [**303:**7.1.2]

28.1.3.1.3* Electrical lighting shall be provided to ensure adequate illumination of all exterior areas, piers, and floats. [**303:**7.1.3]

A.28.1.3.1.3 It is recommended that an auxiliary power supply be provided to ensure lighting in the event of a power failure. [**303:**A.7.1.3]

28.1.3.1.4 Electrical lighting shall not interfere with navigation or aids to navigation. [**303:**7.1.4]

28.1.3.1.5 Only listed 120/240 V ac electrical equipment shall be operated unattended. [**303:**7.1.5]

28.1.3.2 Dry Storage.

28.1.3.2.1 General.

28.1.3.2.1.1 Heaters.

28.1.3.2.1.1.1 The use of portable heaters in boat storage areas shall be prohibited except where necessary to accomplish repairs. [**303:**7.2.1.1.1]

28.1.3.2.1.1.2 Portable heaters used in accordance with 28.1.3.2.1.1.1 shall be used only when personnel are in attendance. [**303:**7.2.1.1.2]

28.1.3.2.1.1.3 Open flame heaters shall not be used in boat storage areas. [**303:**7.2.1.1.3]

28.1.3.2.1.2 Ladders long enough to reach the deck of any stored boat shall be provided and readily available. [**303:**7.2.1.2]

28.1.3.2.1.3 The use of blow torches or flammable paint remover shall be prohibited unless permitted by 8.7.1 of NFPA 303. [**303:**7.2.1.3]

28.1.3.2.1.4 The use of gasoline or other flammable solvents for cleaning purposes shall be prohibited. [**303:**7.2.1.4]

Δ **28.1.3.2.1.5** Where a boat is to be dry-stored for the season or stored indoors for an extended period of time, such as while awaiting repairs, the following precautions shall be taken:

(1) The vessel shall be inspected for any hazardous materials or conditions that could exist, and corrective action shall be taken.
(2) Liquefied petroleum gas (LPG) and compressed natural gas (CNG) cylinders, reserve supplies of stove alcohol or kerosene, and charcoal shall be removed from the premises or stored in a separate, designated safe area.

(3) All portable fuel tanks shall be removed from the premises or emptied and, if emptied, the cap shall be removed and the tank left open to the atmosphere.
(4)* Permanently installed fuel tanks shall be stored at least 95 percent full.

[**303:**7.2.1.5]

Paragraph 28.1.3.2.1.5 addresses necessary precautions for boat storage — either dry-stored for the season or while awaiting repairs. An inspection of the marina or boatyard storage area should be conducted to identify the presence of any auxiliary fuel sources (LP-Gas or CNG cylinders, charcoal, or stove fuels like kerosene or alcohol) and primary fuel in either portable or permanently installed fuel tanks. Where a boat has a permanently installed fuel tank, the boat must be stored with the tank approximately 95 percent full, which is often not apparent. This condition causes the vapor space in the tank to be above the upper flammable limit (UFL). The tank contents would be in a too-rich condition and, therefore, not capable of being ignited. If stored with less fuel, the vapor space that exists in the tank might be within the flammable range and thus be ignitable.

Δ **A.28.1.3.2.1.5(4)** Where fuel tanks and fuel systems are susceptible to damage by certain fuel additives or fuel blends, special considerations might be required to prevent damage to tanks and fuel systems that could lead to fuel leaks. Such considerations might include, but are not limited to, completely emptying and purging the fuel tank and/or more frequent inspections to detect damage and leakage from the fuel tank and fuel system that are stored at least 95 percent full in accordance with NFPA 303. [**303:**A.7.2.1.5(4)]

28.1.3.2.1.6 No unattended electrical equipment shall be in use aboard boats. [**303:**7.2.1.6]

Paragraph 28.1.3.2.1.6 addresses unattended equipment, which is not permitted to be in use aboard boats while in storage. Unattended electrical equipment can produce sources of ignition that might cause a fire to move beyond the incipient stage in a stored boat until detected by a fire detection system (where provided) or a watch service on scheduled rounds that might notice the fire.

28.1.3.2.1.7 All storage areas shall be routinely raked, swept, or otherwise policed to prevent the accumulation of rubbish. [**303:**7.2.1.7]

28.1.3.2.1.8 Fire Department Access.

28.1.3.2.1.8.1 Access to boats stored outside shall be such that the hose-lay distance from the fire apparatus to any portion of the boat shall not exceed 150 ft (45 m). [**303:**7.2.1.8.1]

28.1.3.2.1.8.2 Access to buildings in which boats are stored shall be such that the hose-lay distance from the fire apparatus to all exterior portions of the building shall not exceed 150 ft (45 m). [**303:**7.2.1.8.2]

28.1.3.2.1.8.3 Wet standpipe systems shall be permitted to be used to meet the requirement in 28.1.3.2.1.8.1 or 28.1.3.2.1.8.2. [**303:**7.2.1.8.3]

Paragraphs 28.1.3.2.1.8.1 and 28.1.7.2.1.8.2 emphasize the importance of ensuring that access for emergency response is provided for both outside storage (where boats are frequently stored in cradles) and for storage in buildings. To have adequate fire protection, fire apparatus needs to readily reach and operate in all parts of the marina or boatyard. The land approach to the marina or boatyard needs to be by way of an improved road. For outside storage, the arrangement of aisles is an important consideration. For buildings, the use of fire department access lanes around the building should be considered to facilitate fire apparatus access as close to the building as possible. In each instance, wet standpipe systems can be used to meet the minimum requirements. Access to and from land to piers and floats needs to be arranged and maintained to permit municipal or other fire-fighting equipment to be located where the hose lines can be extended to the full length of the pier or floats. See 18.2.3 for additional requirements and information regarding fire department access roads.

28.1.3.2.2 Indoors.

28.1.3.2.2.1 When work is being carried out onboard a vessel in an unsprinklered storage building, management shall require an inspection of the vessel at the end of the day to ensure that no hazards resulting from the day's work are present. [**303:**7.2.2.1]

28.1.3.2.2.2 If a guard is employed, vessels addressed in 28.1.3.2.2.1 shall be included in the regular rounds. [**303:**7.2.2.2]

28.1.3.2.2.3 Class I flammable liquids shall not be stored in an indoor boat storage area. [**303:**7.2.2.3]

28.1.3.2.2.4 Work performed on boats stored indoors shall be performed by qualified personnel. [**303:**7.2.2.4]

28.1.3.2.2.5 Facility management shall maintain control over all personnel access to storage facilities and boats stored indoors. [**303:**7.2.2.5]

28.1.3.2.3 In-Out Dry Storage and Rack Storage.

28.1.3.2.3.1 Where boats are stored either inside or outside in single- or multiple-level racks, those boats shall have unimpeded vehicular access at one end, and equipment shall be available to remove any stored boat. [**303:**7.2.3.1]

Δ **28.1.3.2.3.2** Where boats are stored in multilevel racks, either inside or outside, for seasonal storage or for in-out operation, the following precautions shall be taken:

(1) Drain plugs shall be removed (in sprinklered buildings).
(2) Batteries shall be disconnected or the master battery switch turned off.
(3) Fuel tank valves shall be closed.
(4) For seasonal storage, the requirements of 28.1.3.2.1 shall apply.

[**303:**7.2.3.2]

Exhibit 28.2

Rack storage of boats without protection. (Courtesy of Brewer Onset Bay Marina)

Paragraph 28.1.3.2.3.2 addresses the fire prevention provisions for multilevel rack storage of boats, such as those shown in Exhibit 28.2. For the fire protection requirements for boats stored in multilevel racks in buildings, refer to 28.1.2.2.4 for the specific requirements for sprinkler protection for indoor rack storage. See NFPA 13, *Standard for the Installation of Sprinkler Systems*, for additional information on determining hazard classification for sprinkler system design, installation, and maintenance. Design of automatic sprinkler protection based on NFPA 13 is needed, because testing of protection strategies for rack storage of boats is under development but has not yet been determined. See 28.1.2.2.4.2 for the acceptable alternative provisions addressing the use of automated fire detection or the use of a full-time watch service.

Multilevel rack storage of boats is no longer just a seasonal activity. Today, multilevel rack storage is used year round as an additional means of storing boats awaiting use. Boats in this situation are ready to use and include all the items associated with boats tied to slips or docks, such as fuel, combustible storage, and electronics. In order to get a boat out of multilevel rack storage, the marina must be notified that the boat is needed at a specific time. The marina will remove the boat from the rack and put it in the water. Upon return, the marina will place the boat back in the rack.

28.1.3.2.3.3 Repairs to boats that are on racks or that are inside an in-out dry storage building shall be prohibited. [**303:**7.2.3.3]

28.1.3.2.3.4 Portable power lines, such as drop cords, shall be prohibited from use on boats in an in-out dry storage building. [**303:**7.2.3.4]

28.1.3.2.3.5 The charging of batteries shall be prohibited in the in-out dry storage building. [**303:**7.2.3.5]

Δ **28.1.3.2.4* Battery Storage.** Where due to size and weight the removal of batteries for storage or charging is impractical, batteries shall be permitted to remain onboard provided the following conditions are met:

(1) The battery compartment is arranged to provide adequate ventilation.
(2) A listed battery charger is used to provide a suitable charge.
(3) The power connection to the charger consists of a three-wire cord of not less than No. 14 AWG conductors connected to a source of 110 V to 125 V single-phase current, with a control switch and approved circuit protection device designed to trip at not more than 125 percent of the rated amperage of the charger.
(4) There is no connection on the load side of the charger to any other device except the battery, and the boat battery switch is turned off.
(5) The battery is properly connected to the charger, and the grounding conductor effectively grounds the charger enclosure.
(6) Unattended battery chargers are checked at intervals not exceeding 8 hours while in operation.

[**303:**7.2.4]

A.28.1.3.2.4 Batteries should be removed for storage and charging wherever practical. [**303:**A.7.2.4]

28.1.4 Operational Hazards.

28.1.4.1* Conditions on Individual Boats.

Δ **A.28.1.4.1** Marinas and boatyard owners and operators are encouraged to be familiar with the requirements of NFPA 302. It is recommended that marina and boatyard owners and operators encourage vessel owners and occupants to practice proper fire prevention aboard moored and stored vessels. [**303:**A.8.1]

28.1.4.1.1 The management shall have an inspection made of each boat received for major repair or storage as soon as practicable after arrival of a boat and before commencement of any work aboard. [**303:**8.1.1]

Δ **28.1.4.1.2** The inspection required in 28.1.4.1.1 shall include the following determinations:

(1) Presence of combustible vapors in any compartment
(2) General maintenance and cleanliness, and location of any combustible materials that require removal or protection for the safe accomplishment of the particular work involved
(3) Quantity, type, and apparent condition of fire-extinguishing equipment onboard
(4) Listed and appropriate shore power inlet(s) and ship-to-shore cable(s), when present

[**303:**8.1.2]

28.1.4.1.3 The management shall, as a condition to accepting a boat received for major repair or storage, require the owner to correct any inadequacies found in 28.1.4.1.2 or to authorize management to do so. [**303:**8.1.3]

28.1.4.2 General Precautions.

28.1.4.2.1 Smoking in the working area shall be prohibited. [**303:**8.2.1]

See Section 10.9 for additional requirements related to smoking.

28.1.4.2.2 Loose combustibles in the area of any hazardous work shall be removed. [**303:**8.2.2]

28.1.4.2.3 Unprotected battery terminals shall be covered to prevent inadvertent shorting from dropped tools or otherwise, and the ungrounded battery lead shall be disconnected. [**303:**8.2.3]

28.1.4.2.4 Personnel employed in the removal or installation of storage batteries shall be qualified. [**303:**8.2.4]

28.1.4.2.5 Where electric service is provided to boats in storage, the receptacle providing the power shall be protected with a ground-fault circuit-interrupter. [**303:**8.2.5]

28.1.4.2.6 The marina or boatyard operator shall post in a prominent location, or provide to boat operators using a marina or boatyard for mooring, repair, servicing, or storage, a list of safe operating procedures containing at least the following information:

(1) A prohibition against the use of any form of hibachis, charcoal, wood, or gas-type portable cooking equipment, except in specifically authorized areas that are not on the docks, on boats in the berthing area, or near flammables
(2) Procedures for disposal of trash
(3) Designation of nonsmoking areas
(4) Location of fire extinguishers and hoses
(5) Procedures for turning in a fire alarm
(6) Fueling procedures
(7)* Emergency contact information and marina address for notifying emergency services to respond to an incident

[**303:**8.2.6]

A.28.1.4.2.6(7) For the purpose of this requirement, the emergency contact information should only include the means to contact the fire department or emergency services and the marina or boatyard address. [**303:**A.8.2.6(7)]

An inspection is required for boats that are accepted for storage or major repair in accordance with 28.1.4.1.1. Many marina and boatyard operators use 28.1.4.2.6 as the basis for preparing a checklist of "dos and don'ts" while boats are in their facilities. A number of fires have been caused by the use of hibachis or portable charcoal cooking equipment on individual boats. A boat sitting at the dock can become unstable due to the wakes of other boats passing by within or near the marina. This action can cause portable cooking equipment to overturn and ignite the boat and, in some instances, boats in adjacent berths. Boats that use the marina for permanent berthing or mooring or transient overnight docking need to observe these safe operating procedures as well.

Δ **28.1.4.2.7** The information on fueling procedures referred to in 28.1.4.2.6(6) shall include at least the following information:

(1) Procedures before fueling
  (a) Stop all engines and auxiliaries
  (b) Shut off all electricity, open flames, and heat sources
  (c) Check bilges for fuel vapors
  (d) Extinguish all smoking materials
  (e) Close access fittings and openings that could allow fuel vapors to enter the boat›s enclosed spaces
  (f) Remove all personnel from the boat except the person handling the fueling hose
(2) Procedures during fueling
  (a) Maintain nozzle contact with fill pipe
  (b) Attend fuel-filling nozzle at all times
  (c) Wipe up spills immediately
  (d) Avoid overfilling
(3) Procedures after fueling and before starting engine
  (a) Inspect bilges for leakage or fuel odors
  (b) Ventilate until odors are removed

[**303:**8.2.7]

Fueling or refueling continues to be one of the most dangerous activities associated with the operation of a pleasure boat. Paragraph 28.1.4.2.7 provides the steps that all boaters and marina operators should follow before, during, and after fueling. Marina operators should consider posting safety information near the fueling area to reinforce the steps for boaters and marina and boatyard personnel.

28.2 Marine Terminals, Piers, and Wharves

28.2.1 Section 28.2 shall apply to marine terminals as defined herein. Special use piers and wharf structures that are not marine terminals, such as public assembly, residential, business, or recreational occupancies that differ in design and construction from cargo handling piers, require special consideration. The general principles of NFPA 307 for the construction and fire protection of piers and wharves shall be applicable to such structures and shall comply with NFPA 307 and Section 28.2.

The provisions of NFPA 307 are essential to provide a reasonable level of protection from loss of life and property from fire and explosion in marine terminals, piers, and wharves. NFPA 307 covers the following:

1. Chapter 4 addresses pier and wharf construction, automatic sprinkler protection, and other fire protection requirements based on the construction materials of the pier or wharf.
2. Chapter 5 addresses the construction and protection of terminal buildings.
3. Chapter 6 addresses the safe operation of the terminal yards.
4. Chapter 7 addresses the water supply for fire protection.
5. Chapter 8 addresses hazardous materials storage.
6. Chapter 9 addresses general terminal operations, which cover fire organization, fire safety plans, vessels, and shipboard and terminal cargo handling and storage.
7. Chapter 10 addresses miscellaneous installations and operations, such as tractors, lift trucks, cranes, and other material-handling equipment; automotive and railroad equipment; electrical installations; heating equipment;

processes; fumigation; pallets and dunnage; packaging and recoopering; incinerators; maintenance; repairs and housekeeping; and hot work.

Unless otherwise noted, the provisions of NFPA 307 are not intended to be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of the document, except in those cases where the AHJ determines that the existing situation involves a distinct hazard to life or adjacent property.

28.2.1.1 Marine terminals, piers, and wharves shall comply with 28.1.4.2.7.

Bunkering (fueling) of vessels at a marine terminal must be done in accordance with all applicable laws, ordinances, and regulations, and the authority having jurisdiction as stated in NFPA 307, Section 9.4.5.

Paragraph 28.2.1.1 applies specifically to the transfer of fuel to or from a marine vessel at a marine terminal. When the transfer of fuel or any hazardous material is being carried out, the vessel operator and the terminal operator must, at a minimum, comply with applicable regulations, which include 33 CFR 156, "Oil and Hazardous Material Transfer Operations," and any local requirements established by the AHJ.

28.2.2* Section 28.2 shall not apply to marinas and boatyards. *(See Section 28.1.)* [**307:**1.3.2]

Δ **A.28.2.2** See NFPA 303. [**307:**A.1.3.2]

Δ **28.2.3** Section 28.2 shall not apply to the handling of the following:

(1)* Flammable or combustible liquids in bulk (*See Chapter 66.*)
(2)* Liquefied gases in bulk *(See Chapter 69.)*
[**307:**1.3.3]

Δ **A.28.2.3(1)** See NFPA 30. [**307:**A.1.3.3(1)]

Δ **A.28.2.3(2)** See NFPA 59A or NFPA 58. [**307:**A.1.3.3(2)]

28.2.4 Nothing in Section 28.2 shall supersede any of the regulations of governmental or other regulatory authority. [**307:**1.1.2]

28.3 Construction, Conversion, Repair, and Lay-Up of Vessels

28.3.1* The construction, conversion, repair, or lay-up of vessels shall comply with NFPA 312 and Section 28.3.

A.28.3.1 Many vessels undergoing construction, conversion, or repairs, and vessels laid up in a shipyard or elsewhere are readily vulnerable to fire, due to the quantity and character of combustible materials used in building. Long passageways, unenclosed stairways, hatches, and hoistways facilitate the rapid spread of fire throughout the vessel. Often the location of the vessel is isolated so that private protection is the main source of fire-fighting services. Even where major municipal protection is available, material damage or complete destruction before effective means of extinguishment are brought into action often results from the following:

(1) Possible delayed response, due either to late discovery of the fire or to the absence of means for quick notification
(2) Lack of special equipment in many municipal fire departments for combating shipboard fires
(3) An unfamiliarity with ship construction due to the transitory nature of the risk

[**312:**A.1.2]

Unless otherwise noted, the provisions of NFPA 312, *Standard for Fire Protection of Vessels During Construction, Conversion, Repair, and Lay-Up*, are not intended to be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of the document, except in those cases where the AHJ determines that the existing situation involves a distinct hazard to life or adjacent property.

NFPA 306, *Standard for the Control of Gas Hazards on Vessels*, contains additional relevant safeguards to be applied during construction, conversion, repair, lay-up, and shipbreaking.

28.3.2 Nothing in Section 28.3 shall be construed as prohibiting the immediate dry-docking of a vessel whose safety is imperiled, as by being in a sinking condition or by being seriously damaged. [**312:**1.2.2]

28.3.3 In such cases, all necessary precautionary measures shall be taken as soon as practicable. [**312:**1.2.3]

Δ **28.3.4** Section 28.3 shall not apply to situations where it is in conflict with or superseded by requirements of any government regulatory agency. [**312:**1.1.2]

29

Parking Garages

Chapter 29 covers parking garages and structures that include buildings, structures, or portions thereof used for the parking or storage, or both, of motor vehicles. A parking structure is permitted to be enclosed or open, to use ramps, and to use mechanical control push button–type elevators to transfer vehicles from one floor to another. Motor vehicles are permitted to be parked by the driver or an attendant and are permitted to be parked mechanically in automatic facilities. Where automatic parking is provided, the operator of such a facility is permitted either to remain at the entry level or to travel to another level. No specific requirements are included for mechanical parking structures where cars are moved to parking places by lifts or other devices instead of being driven. A typical open parking structure is shown in Exhibit 29.1.

29.1 General

29.1.1 The protection of new and existing parking garages, as well as the control of hazards in open parking structures, enclosed parking structures, and basement and underground parking structures shall comply with this chapter and Section 42.8 of NFPA *101*.

The provisions of Section 42.8 of NFPA *101*®, *Life Safety Code*®, which address life safety requirements for parking structures, must be met, in addition to those found in NFPA 88A, *Standard for Parking Structures*. NFPA 88A covers the construction and protection of, as well as the control of hazards in, open and enclosed parking structures. NFPA 88A does not apply to one- and two-family dwellings. NFPA 88A covers the following topics:

1. Chapter 4 addresses means of egress.
2. Chapter 5 addresses construction requirements.

Exhibit 29.1

Parking structure. (Eric Krouse/Dreamstime.com)

3. Chapter 6 covers building service and fire protection, including lighting and power; heating; ventilation; sprinkler systems; standpipes; and detection, alarm, and communications systems.
4. Chapter 7 addresses special hazard protection, including storage, use, handling, and dispensing of fuels and lubricants.
5. Chapter 8 addresses housekeeping.
6. Chapter 9 addresses special structures, including automated-type parking structures.

Unless otherwise noted within NFPA 88A, the provisions of NFPA 88A are not intended to be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of the document, except where the authority having jurisdiction (AHJ) determines that the existing situation involves a distinct hazard to life or adjacent property.

Δ **29.1.2** Construction and protection of new parking garages shall also comply with NFPA 88A.

N **29.1.3** The storage of self-propelled vehicles powered by GH_2 or LH_2 shall be in accordance with NFPA 2.

29.1.4 Chapter 29 shall not apply to parking garages in one- and two-family dwellings.

Motor Fuel Dispensing Facilities and Repair Garages

30

Chapter 30 applies to motor fuel dispensing facilities, marine/motor fuel dispensing facilities, and motor fuel dispensing facilities located inside buildings. This chapter also applies to motor vehicle repair garages. Chapter 30 does not apply, however, to those motor fuel dispensing facilities where only liquefied natural gas (LNG), liquefied petroleum gas (LP-Gas), or compressed natural gas (CNG) is dispensed as motor fuel.

Facilities that dispense only hydrogen are covered directly by NFPA 2, *Hydrogen Technologies Code.* Facilities that dispense only LNG or CNG are covered directly by NFPA 52, *Vehicular Natural Gas Fuel Systems Code*. Facilities that dispense only LP-Gas are covered directly by NFPA 58, *Liquefied Petroleum Gas Code*. However, the NFPA Standards Council has given the Technical Committee on Automotive and Marine Service Stations responsibility for developing appropriate requirements for refueling vehicles with alternative gaseous fuels where these are dispensed along with liquid fuels. Facilities that dispense both gaseous and liquid fuels are, therefore, covered by NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*. Most of the requirements for the use of gaseous fuels at mixed fuel facilities are addressed by referencing the primary document for the fuel, such as NFPA 2 for hydrogen and NFPA 52 LNG, and CNG.

The 2018 edition of NFPA 1, *Fire Code*, derives its extracted text from the 2018 edition of NFPA 30A.

30.1 Motor Fuel Dispensing Facilities

30.1.1 Application.

30.1.1.1 Motor fuel dispensing facilities, marine/motor fuel dispensing facilities, motor fuel dispensing facilities located inside buildings, and fleet vehicle motor fuel dispensing facilities shall comply with Sections 30.1 and 30.3 and NFPA 30A. Hydrogen fueling facilities shall comply with NFPA 2.

The following terms are defined in NFPA 30A:

- *Motor Fuel Dispensing Facility* — That portion of a property where motor fuels are stored and dispensed from fixed equipment into the fuel tanks of motor vehicles or marine craft or into approved containers, including all equipment used in connection therewith.
- *Fleet Vehicle Motor Fuel Dispensing Facility* — A motor fuel dispensing facility at a commercial, industrial, governmental, or manufacturing property where motor fuels are dispensed into the fuel tanks of motor vehicles that are used in connection with the business or operation of that property by persons within the employ of such business or operation.
- *Marine Motor Fuel Dispensing Facility* — A motor fuel dispensing facility at or adjacent to shore, a pier, a wharf, or a floating dock where motor fuels are dispensed into the fuel tanks of marine craft.
- *Motor Fuel Dispensing Facility Located Inside a Building* — That portion of a motor fuel dispensing facility located within the perimeter of a building or building structure that also contains other occupancies.

30.1.1.2 This chapter shall not apply to refueling operations. *(For refueling operations, see Chapter 42.)*

30.1.1.3 Permits. Permits, where required, shall comply with Section 1.12.

30.1.2 Occupancy Classification. The occupancy classification of a motor fuel dispensing facility that is located inside a building or structure shall be a special purpose industrial occupancy as defined in NFPA *101* or as determined in accordance with the adopted building code. [**30A:**7.3.1]

For the 2012 edition of the *Code*, the technical committee responsible for NFPA 30A clarified 30.1.2 by deleting *low hazard* and replacing it with *special purpose* to correlate 30.1.3 on means of egress with the occupancy classification and means of egress for repair garages under 30.2.2 and 30.2.4. The intent of the committee was always to provide the proper occupancy classifications for motor fuel dispensing facilities and repair garages that correlate with the appropriate requirements in NFPA *101*®, *Life Safety Code*®, as well as *NFPA 5000*®, *Building Construction and Safety Code*®.

30.1.3 Means of Egress. In a motor fuel dispensing facility that is located inside a building or structure, the required number, location, and construction of means of egress shall meet all applicable requirements for special purpose industrial occupancies, as set forth in NFPA *101* or as determined in accordance with the adopted building code. [**30A:**7.3.3]

30.1.4 Drainage. Where Class I or Class II liquids are dispensed, provisions shall be made to prevent spilled liquids from flowing into the interior of buildings. Such provisions shall be made by grading driveways, raising door sills, or other equally effective means. [**30A:**7.3.4]

30.1.5 Fixed Fire Protection.

30.1.5.1* For an unattended, self-serve, motor fuel dispensing facility, additional fire protection shall be provided where required by the AHJ. [**30A:**7.3.5.1]

A.30.1.5.1 Additional fire protection considerations can include items such as fixed suppression systems, automatic fire detection, manual fire alarm stations, transmission of alarms to off-site locations, and limiting volume delivered per transaction. [**30A:**A.7.3.5.1]

Paragraph 30.1.5.1 allows the authority having jurisdiction (AHJ) to require other fire protection systems or features as a condition of approval of an unattended self-service station. The additional provisions, if any, might vary considerably, depending on the specific installation.

30.1.5.2 Where required, an automatic fire suppression system shall be installed in accordance with the appropriate NFPA standard, manufacturers' instructions, and the listing requirements of the systems. [**30A:**7.3.5.2]

See Section 13.8 for additional guidance on fire protection systems other than automatic sprinkler systems.

30.1.6 Fuel Dispensing Areas Inside Buildings.

Subsection 30.1.6 applies to the unusual fire hazards posed by the presence of a fuel dispensing operation inside a building. NFPA 30A requires that the dispensing operation be completely cut off from the rest of the building (see 30.1.6.1, 30.1.6.3, and 30.1.6.4), that it be relatively close to the entrance (see 30.1.6.5), and that the dispensing operation be limited in size (see 30.1.6.6).

30.1.6.1 The fuel dispensing area shall be separated from all other portions of the building by walls, partitions, floors, and floor–ceiling assemblies having a fire resistance rating of not less than 2 hours. [**30A:**7.3.6.1]

30.1.6.2 Interior finish shall be of noncombustible materials or of approved limited-combustible materials, as defined in this *Code* and NFPA 220. [**30A:**7.3.6.2]

30.1.6.3 Door and window openings in fire-rated interior walls shall be provided with listed fire doors having a fire protection rating of not less than 1½ hours. Doors shall be self-closing. They shall be permitted to remain open during normal operations if they are designed to close automatically in a fire emergency by means of listed closure devices. Fire doors shall be installed in accordance with NFPA 80. They shall be kept unobstructed at all times. [**30A:**7.3.6.3]

30.1.6.4 Openings for ducts in fire-rated interior partitions and walls shall be protected by listed fire dampers. Openings for ducts in fire-rated floor or floor–ceiling assemblies shall be protected with enclosed shafts. Enclosure of shafts shall be with wall or partition assemblies having a fire resistance rating of not less than 2 hours. Openings for ducts into enclosed shafts shall be protected with listed fire dampers. [**30A:**7.3.6.4]

30.1.6.5 The fuel dispensing area shall be located at street level, with no dispenser located more than 50 ft (15 m) from the vehicle exit to, or entrance from, the outside of the building. [**30A:**7.3.6.5]

30.1.6.6 The fuel dispensing area shall be limited to that required to serve not more than four vehicles at one time.

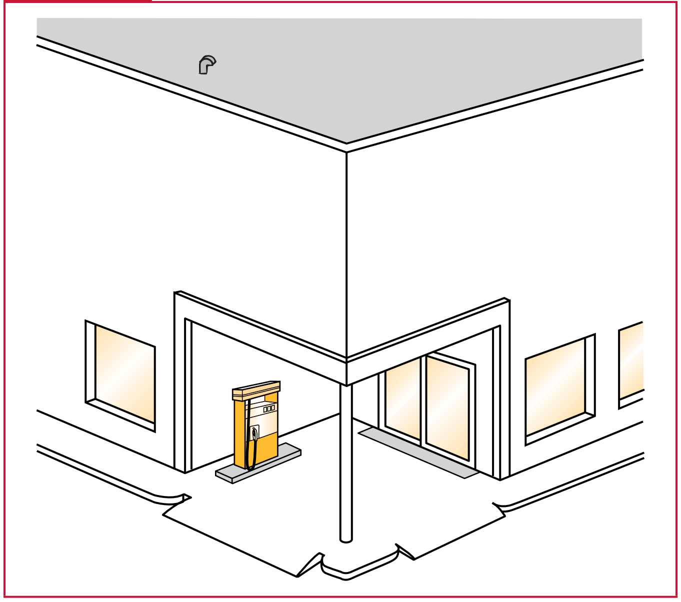
*Exception: At a fleet vehicle motor fuel dispensing facility inside a building, where only Class II and Class III liquids are dispensed, the number of vehicles serviced at any one time shall be permitted to be increased to 12. [**30A:**7.3.6.6]*

Some large fleet service and refueling buildings can have up to 12 interior refueling lanes to accommodate the large number of vehicles being served. The Technical Committee on Automotive and Marine Service Stations agreed that this number was reasonable for this special type of operation, because the general public does not have access.

30.1.6.7* A mechanical exhaust system that serves only the fuel dispensing area shall be provided. This system shall meet all of the following requirements:

(1) The system shall be interlocked with the dispensing system so that airflow is established before any dispensing device can operate. Failure of airflow shall automatically shut down the dispensing system.
(2) The exhaust system shall be designed to provide air movement across all portions of the floor of the fuel dispensing area and to prevent the flowing of ignitible vapors beyond the dispensing area.
(3) Exhaust inlet ducts shall not be less than 3 in. (76 mm) or more than 12 in. (305 mm) above the floor. Exhaust ducts shall not be located in floors or penetrate the floor of the dispensing area. Exhaust ducts shall discharge to a safe location outside the building.
(4) The exhaust system shall provide ventilation at a rate of not less than 1 $ft^3/min/ft^2$ (0.3 $m^3/min/m^2$) of floor area, based on the fuel dispensing area.
(5) The exhaust system shall meet all applicable requirements of NFPA 91.

Exhibit 30.1



Motor fuel dispensing area located in the portico of a building.

*Exception: The provisions of 30.1.6.7 shall not apply to a fuel dispensing area located inside a building if two or more sides of the dispensing area are open to the building exterior. [**30A:**7.3.6.7]*

A.30.1.6.7 Natural ventilation can normally be expected to dissipate any fuel vapors before they reach ignitible concentrations if at least two sides of the dispensing area are open to the building exterior. [**30A:**A.7.3.6.7]

The intent of 30.1.6.7 is to provide a sweep of clean air across the floor of the dispensing area to pick up any fugitive vapors and carry them to the exterior of the building. The exception waives the ventilation requirement for dispensing areas that are basically outside the building but within its footprint, such as the situation depicted in Exhibit 30.1.

30.1.6.8 The floor of the dispensing area shall be liquidtight. Where Class I liquids are dispensed, provisions shall be made to prevent spilled liquids from flowing out of the fuel dispensing area and into other areas of the building by means of curbs, scuppers, special drainage systems, or other means acceptable to the AHJ. [**30A:**7.3.6.8]

30.1.6.9* Oil drainage systems shall be equipped with approved oil/water traps or separators if they connect to public sewers or discharge into public waterways. [**30A:**7.3.6.9]

A.30.1.6.9 Oil/water separators might not be designed to remove or separate flammable or combustible liquids other than oil. [**30A:**A.7.3.6.9]

30.2 Repair Garages

30.2.1 Application. The construction and protection of, as well as the control of hazards in, garages used for major repair and maintenance of motorized vehicles and any sales and servicing facilities associated therewith shall comply with Sections 30.2 and 30.3 and NFPA 30A.

NFPA 30A separates repair garages into two categories:

1. The term *major repair garage* is defined as "a building or portions of a building where major repairs, such as engine overhauls, painting, body and fender work, and repairs that require draining of the motor vehicle fuel tank are performed on motor vehicles, including associated floor space used for offices, parking, or showrooms."
2. The term *minor repair garage* is defined as "a building or portions of a building used for lubrication, inspection, and minor automotive maintenance work, such as engine tune-ups, replacement of parts, fluid changes (e.g., oil, antifreeze, transmission fluid, brake fluid, air conditioning refrigerants, etc.), brake system repairs, tire rotation, and similar routine maintenance work, including associated floor space used for offices, parking, or showrooms."

N **30.2.1.1** Repair garages servicing self-propelled vehicles powered by GH_2 or LH_2 shall comply with NFPA 2.

30.2.1.2 Permits. Permits, where required, shall comply with Section 1.12.

30.2.2 Occupancy Classification. The occupancy classification of a repair garage shall be a special purpose industrial occupancy as defined in NFPA *101*, or as determined in accordance with the adopted building code. [**30A:**7.4.1]

NFPA *101* defines the term *special-purpose industrial occupancy* as "an industrial occupancy in which ordinary and low hazard industrial operations are conducted in buildings designed for, and suitable only for, particular types of operations, characterized by a relatively low density of employee population, with much of the area occupied by machinery or equipment."

30.2.3 General Construction Requirements. In major repair garages, where CNG-fueled vehicles, hydrogen-fueled vehicles, LNG-fueled vehicles, or LP-Gas-fueled vehicles are repaired, all applicable requirements of NFPA 2, NFPA 52, or NFPA 58, whichever is applicable, shall be met. [**30A:**7.4.2]

30.2.4 Means of Egress. In a repair garage, the required number, location, and construction of means of egress shall meet all applicable requirements for special purpose industrial occupancies, as set forth in NFPA *101*, or as determined in accordance with the adopted building code. [**30A:**7.4.3]

30.2.5 Drainage. In areas of repair garages used for repair or servicing of vehicles, floor assemblies shall be constructed of noncombustible materials or, if combustible materials are used in the assembly, they shall be surfaced with approved, nonabsorbent, noncombustible material, except as indicated in 30.2.5.1. [**30A:**7.4.4]

N **30.2.5.1** Slip-resistant, nonabsorbent, interior floor finishes having a critical radiant flux not more than 9.87 Btu/in.^{2} (0.45 W/cm^2), as determined by NFPA 253, shall be permitted. [**30A:**7.4.4.1]

30.2.5.2 Floors shall be liquidtight to prevent the leakage or seepage of liquids and shall be sloped to facilitate the movement of water, fuel, or other liquids to floor drains. [**30A:**7.4.4.2]

30.2.5.3 In areas of repair garages where vehicles are serviced, any floor drains shall be properly trapped and shall discharge through an oil/water separator to the sewer or to an outside vented sump. [**30A:**7.4.4.3]

Note that 30.2.5.2 and 30.2.5.3 do not mandate installation of floor drains; they only establish certain provisions to be followed where floor drains are present. The requirement to install floor drains would be the purview of the applicable plumbing code.

30.2.6 Pits, Belowgrade Work Areas, and Subfloor Work Areas.

Subsection 30.2.6 addresses the lower-level work areas of quick-lube service stations and similar facilities. Due to the number of vehicles capable of being serviced on a daily basis by these facilities, servicing the vehicles from the lower-level area is more efficient and actually safer than raising the vehicle on a lift. Service pits, subfloor work areas, and belowgrade work areas are below the level of the surface on which the vehicle to be serviced is located.

The difference between a service pit or subfloor work area and a belowgrade work area is that a service pit or subfloor work area is generally much smaller, usually extending only under the vehicle being serviced, while a belowgrade work area tends to be the same size as the building's footprint. The belowgrade work area, in addition to being larger, usually is subject to the same building code requirements as a floor or story of a building, including requirements for fixed lighting, ventilation, minimum headroom, and alternative means of egress. Exhibit 30.2 depicts a belowgrade work area.

Exhibit 30.2

Belowgrade work area of a lube-only facility. (Courtesy of Jiffy-Lube)

30.2.6.1 Pits, belowgrade work areas, and subfloor work areas used for lubrication, inspection, and minor automotive maintenance work shall comply with the provisions of this chapter, in addition to other applicable requirements of NFPA 30A. [**30A:**7.4.5.1]

30.2.6.2 Walls, floors, and structural supports shall be constructed of masonry, concrete, steel, or other approved noncombustible materials. [**30A:**7.4.5.2]

All structural elements of pits, belowgrade work areas, and subfloor work areas must be of noncombustible material. Floor and wall surfaces should be capable of being easily cleaned and should not absorb spills. Floor surfaces should provide adequate traction to minimize personnel injuries from slipping and falls. This requirement is not intended to restrict the use of interior finishes or floor finishes that meet the requirements of NFPA *101*, such as approved rubberized nonslip floor finishes over a concrete floor. (For further information, see also 30.2.5.1.)

30.2.6.3 In pits, belowgrade work areas, and subfloor work areas, the required number, location, and construction of means of egress shall meet the requirements for special purpose industrial occupancies in Chapter 40 of NFPA *101*, or in accordance with the adopted building code. [**30A:**7.4.5.3]

Means of egress from belowgrade and subfloor work areas must comply with the provisions for special-purpose industrial occupancies, as set forth in 40.1.2.1.2 of NFPA *101*. A special-purpose industrial occupancy is characterized as being of low or ordinary hazard and having few employees. The number of means of egress required from these areas is based on the total travel distance to an exit. If the total travel distance does not exceed 50 ft (15 m), only one means of egress is required, as allowed by 40.2.4.1.2 of NFPA *101*. Most quick-lube operations have vehicles located over unprotected floor openings. Subsection 40.3.1(1) of NFPA *101* requires that at least one of the exits from the lower level be an enclosed stairway or similar type of exit that is protected against obstruction by fire or smoke that could enter the lower level from the open service bays.

30.2.6.4 Pits, belowgrade work areas, and subfloor work areas shall be provided with exhaust ventilation at a rate of not less than 1 ft^3/min/ft^2 (0.3 m^3/min/m^2) of floor area at all times that the building is occupied or when vehicles are parked in or over these areas. Exhaust air shall be taken from a point within 12 in. (0.3 m) of the floor. [**30A:**7.4.5.4]

Paragraph 30.2.6.4 addresses ventilation of pits, belowgrade work areas, and subfloor work areas. Experience with these facilities shows that a vehicle seldom has a leak in its fuel system or fuel tank. When a leak is present, the odor of the fuel is obvious and the vehicle will be removed from the building. The Technical Committee on Automotive and Marine Service Stations reviewed ventilation rates required by NFPA 30, *Flammable and Combustible Liquids Code*; NFPA 88B, *Standard for Repair Garages* (which was incorporated into the 2000 edition of NFPA 30A); and *NFPA 70®*, *National Electrical Code®*, as well as several mechanical codes. The committee also reviewed the calculation procedure to determine dilution rates, which are described in *NFPA's Fire Protection Handbook*®. Using this method, a spill of about 1 pt (about ½ L) of gasoline would require 800 ft^3 to 1050 ft^3 (23 m^3 to 30 m^3) of air to dilute the mixture to 25 percent of the lower flammable limit (LFL), the point that is traditionally considered minimally safe. Based on this result, it was determined that the traditionally accepted ventilation rate required by NFPA 30 and other codes — 1 ft^3 per minute per ft^2 (0.3 m^3 per minute per m^2) of floor area — would be more than adequate. This ventilation rate provides at least six air changes per hour, based on an assumed ceiling height of 10 ft (3 m), without causing excessive heat loss in the winter months.

Make-up air supplied in excess of that which is actually exhausted should be avoided, because any flammable vapors that are released might be driven above the exhaust duct inlets and into overhead electrical fixtures. Usually, sufficient make-up air is provided by normal leakage around service bay doors.

The user is cautioned that the ventilation rate specified is adequate for small spills only. A larger spill would require much more ventilation capacity; for example, 6300 ft^3 to 8400 ft^3 per minute per ft^2 (180 m^3 to 240 m^3 per minute per m^2) for a 1 gal (3.8 L) spill. Therefore, compliance with Chapter 9 of NFPA 30A is just as important for these facilities as it is for traditional service stations.

Δ **30.2.7 Fixed Fire Protection.** Automatic sprinkler protection installed in accordance with the requirements of Section 13.3 shall be provided throughout all buildings containing major repair garages, as herein defined, when any one of the following conditions exist:

(1) The building housing the major repair garage is two or more stories, including basements, and the aggregate area of the major repair garage exceeds 10,000 ft^2 (930 m^2).
(2) The major repair garage is one story and exceeds 12,000 ft^2 (1115 m^2).
(3) The major repair garage is servicing vehicles parked in the basement of the building.

[**30A:**7.4.6]

30.2.8 Gas Detection System. Repair garages used for repair of vehicle engine fuel systems fueled by nonodorized gases shall be provided with an approved flammable gas detection system. Gas detection systems in repair garages for hydrogen vehicles shall be in accordance with NFPA 2. [**30A:**7.4.7]

Certain gaseous fuels cannot be odorized because the mercaptans typically used as odorants damage the system in which the fuel is to be used. For example, mercaptans can poison the platinum catalysts used in hydrogen fuel cells.

Detectors should be located to account for both the buoyancy of the gas and the possibility that it can disperse into spaces that might be enclosed or partially enclosed. These types of spaces would be of particular concern because of the possibility of gas accumulating sufficiently to reach concentrations in the flammable range.

30.2.8.1 System Design. The flammable gas detection system shall be calibrated to the types of fuels or gases used by vehicles to be repaired. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammable limit (LFL). Gas detection shall also be provided in lubrication or chassis repair pits of repair garages used for repairing non-odorized LNG/CNG-fueled vehicles. [**30A:**7.4.7.1]

Δ **30.2.8.2 Operation.** Activation of the gas detection system shall result in all of the following:

(1) Initiation of distinct audible and visual alarm signals in the repair garage
(2) Deactivation of all heating systems located in the repair garage
(3) Activation of the mechanical ventilation system, when the system is interlocked with gas detection

[**30A:**7.4.7.2]

30.2.8.3 Failure of the Gas Detection System. Failure of the gas detection system shall result in the deactivation of the heating system and activation of the mechanical ventilation system and, where the ventilation system is interlocked with gas detection, shall cause a trouble signal to sound in an approved location. [**30A:**7.4.7.3]

30.2.8.4 System Integrity. The circuits of the detection system required by 30.2.8 shall be monitored for integrity in accordance with *NFPA 72*. [**30A:**7.4.7.4]

Circuits required by 30.2.8 must be monitored for integrity. Given the fact that the gas detection system is a safety system, integrity monitoring in accordance with *NFPA 72*®, *National Fire Alarm and Signaling Code*®, is justified. If a fault is on the circuit wiring, a trouble signal will be generated at the protected premises.

30.2.9* Heating, Ventilating, and Air-Conditioning.

A.30.2.9 The ventilation requirements contained in this section do not consider exhaust emissions from motor vehicle engines. An appropriate professional should be consulted to determine precautions necessary to protect against this health hazard. [**30A:**A.7.5]

30.2.9.1* Forced air heating, air-conditioning, and ventilating systems serving a fuel dispensing area inside a building or a repair garage shall not be interconnected with any such systems serving other occupancies in the building. Such systems shall be installed in accordance with NFPA 90A. [**30A:**7.5.1]

A.30.2.9.1 Manual control switches for supply and exhaust ventilating systems should be located close to the entrance to the area served. In buildings protected by automatic sprinklers or fire alarm systems, it is recommended that the necessary interlocks be provided to shut down supply and exhaust fans when the sprinklers or fire alarms operate. For service facilities for CNG-fueled vehicles and LNG-fueled vehicles, see NFPA 52. [**30A:**A.7.5.1]

The requirement in 30.2.9.1 eliminates the possibility of vapors from a fuel spill being dispersed to adjacent spaces of the building.

30.2.9.2 Return air openings in areas of repair garages used for the repair or servicing of vehicles or in a fuel dispensing area shall be not less than 18 in. (455 mm) above floor level measured to the bottom of the openings. [**30A:**7.5.2]

30.2.9.3 Combined ventilation and heating systems shall not recirculate air from areas that are below grade level. [**30A:**7.5.3]

Because such a system serves the combined purposes of conditioning the space and removing fugitive vapors from it, this requirement is needed to ensure that the system does not allow buildup of vapors.

30.2.9.4* Exhaust duct openings shall be located so that they effectively remove vapor accumulations at floor level from all parts of the floor area. Where lighter-than-air gaseous fuel vehicles are repaired, exhaust duct openings shall be located so that they effectively remove vapor accumulations at the ceiling level. [**30A:**7.5.4]

N **A.30.2.9.4** Lighter-than-air fuels include fuels such as hydrogen and natural gas, but not LPG. [**30A:**A.7.5.4]

30.2.10 Heat-Producing Appliances.

30.2.10.1 Heat-producing appliances shall be installed in accordance with the requirements of 30.2.10. They shall be permitted to be installed in the conventional manner except as provided in 30.2.10. [**30A:**7.6.1

30.2.10.2 Heat-producing appliances shall be of an approved type. Solid fuel stoves, improvised furnaces, salamanders, or space heaters shall not be permitted in areas of repair garages used for repairing or servicing of vehicles or in a fuel dispensing area.

Exception No. 1: Unit heaters, when installed in accordance with Chapter 7 of NFPA 30A, need not meet this requirement.

*Exception No. 2: Heat-producing equipment for any lubrication room or service room where there is no dispensing or transferring of Class I or Class II liquids or LP-Gas, when installed in accordance with Chapter 7 of NFPA 30A, need not meet this requirement. [**30A:**7.6.2]*

Salamanders, space heaters, and similar types of heaters are often found in repair garages. Misuse of these heaters is an increasing concern for fire inspectors. The use of unapproved heaters in garage settings can result in the ignition of flammable and combustible liquids from spilled or open containers or in the ignition of the flammable or combustible vapors created by the repair work itself.

30.2.10.3 Heat-producing appliances shall be permitted to be installed in a special room that is separated from areas that are classified as Division 1 or Division 2, in accordance with Chapter 8 of NFPA 30A, by walls that are constructed to prevent the transmission of vapors, that have a fire resistance rating of at least 1 hour, and that have no openings in the walls that lead to a classified area within 8 ft (2.4 m) of the floor. Specific small openings through the wall, such as for piping and electrical conduit, shall be permitted, provided the gaps and voids are filled with a fire-resistant material to resist transmission of vapors. All air for combustion purposes shall be taken from outside the building. This room shall not be used for storage of combustible materials, except for fuel storage as permitted by the standards referenced in 30.2.10.9. [**30A:**7.6.3]

30.2.10.4 Heat-producing appliances using gas or oil fuel shall be permitted to be installed in a lubrication or service room where there is no dispensing or transferring of Class I liquids, including the open draining of automotive gasoline tanks, provided the bottom of the combustion chamber is at least 18 in. (455 mm) above the floor and the appliances are protected from physical damage. [**30A:**7.6.4]

30.2.10.5 Heat-producing appliances using gas or oil fuel listed for use in garages shall be permitted to be installed in lubrication rooms, service rooms, or fuel dispensing areas where Class I liquids are dispensed or transferred, provided the equipment is installed at least 8 ft (2.4 m) above the floor. [**30A:**7.6.5]

30.2.10.6* Where major repairs are conducted on lighter-than-air-fueled vehicles, open flame heaters or heating equipment with exposed surfaces having a temperature in excess of 750°F (399°C) shall not be permitted in areas subject to ignitible concentrations of gas. [**30A:**7.6.6]

A.30.2.10.6 Enclosed rooms or spaces storing CNG- or LNG-fueled vehicles should prohibit the transmission of gases to other areas of the building. Other areas outside of the enclosure, if not used for repairing or storing CNG- or LNG-fueled vehicles, can use other heating methods. Note that, according to A.1.1 of NFPA 52, CNG weighs about two-thirds as much as air and, therefore, as a gas, will rise in a room. LNG at a temperature of less than or equal to –170°F (–112°C) is heavier than ambient air [at 60°F (15°C)], but as the LNG's temperature rises, the gas becomes lighter than air. Determination of the potential for gas accumulation should be based on an engineering analysis. (Guidance for classification of hazardous locations is available in NFPA 497.) [**30A:**A.7.6.6]

30.2.10.7 Electrical heat-producing appliances shall meet the requirements of Chapter 8 of NFPA 30A. [**30A:**7.6.7]

30.2.10.8 Fuels used shall be of the type and quality specified by the manufacturer of the heating appliance. Crankcase drainings shall not be used in oil-fired appliances, unless the appliances are specifically approved for such use. [**30A:**7.6.8]

See Section 11.5 for additional requirements for heating appliances.

Δ **30.2.10.9** Heat-producing appliances shall be installed to meet the requirements of NFPA 31, NFPA 54, NFPA 82, NFPA 90A, and NFPA 211 as applicable, except as hereinafter specifically provided. [**30A:**7.6.9]

30.3 Operational Requirements

Operations conducted in motor fuel dispensing facilities and repair garages shall comply with Section 42.7.

Forest Products and Biomass Feedstocks

31

Chapter 31 contains provisions for the storage, manufacturing, and processing of timber, lumber, plywood, veneers, biomass feedstock, and by-products of forest products. Fires in these types of facilities pose special problems for fire-fighting operations.

Δ 31.1* General

The storage, manufacturing, and processing of timber, lumber, plywood, veneers, biomass feedstock, and by-products shall be in accordance with this chapter and NFPA 664.

A.31.1 Each individual property has its own special conditions of stock handling, exposure, and topography. For this reason, only basic fire protection principles are discussed herein and are intended to be applied with due consideration of all local factors involved. The AHJ should be consulted.

NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*, establishes the minimum requirements for fire and explosion prevention and protection of industrial, commercial, or institutional facilities that process wood or manufacture wood products; that use wood or other cellulosic fiber as a substitute for, or additive to, wood fiber; and that process wood, creating wood chips, particles, or dust. Woodworking and wood processing facilities include, but are not limited to, wood flour plants, industrial woodworking plants, furniture plants, plywood plants, composite board plants, lumber mills, and production-type woodworking shops and carpentry shops that are incidental to facilities that would not otherwise fall within the scope of NFPA 664. NFPA 664 applies to woodworking operations that occupy areas of more than 5000 ft^2 (465 m^2) or where dust-producing equipment requires an aggregate dust collection flow rate of more than 1500 ft^3/min (2549 m^3/hr).

31.2 Permits

Permits, where required, shall comply with Section 1.12.

Table 1.12.8(a) requires a permit for the storage of lumber exceeding 100,000 board feet. A permit is also required to store chips, hogged material, lumber, or plywood in excess of 200 ft^3 (5.7 m^3) in accordance with Table 1.12.8(a).

31.3 Protection of Storage of Forest Products

The outdoor storage of forest products involves many arrangements of storage, from retail lumber outlets to the large cold decks found at wood processing facilities. Storage also involves a wide range of products, from wood chips and plywood to large tree logs for logging operations. If any of these types of storage goes unchecked, a fire could mean large product losses for the company and vast amounts of resources expended by the responding fire department. Therefore, the requirements for the outdoor storage of forest products are aimed at minimizing the likelihood of fire, controlling a fire if one occurs, and ensuring rapid fire department access to the site should a fire occur.

The fire department, authorities having jurisdiction (AHJs), and users should be familiar with the site and pre-plan for fire incidents involving various scenarios. Some of the requirements among the different types of storage are common; therefore, review of all the outdoor forest products storage commentary is recommended.

31.3.1 Application.

31.3.1.1 The requirements of this chapter shall apply to the outside storage of the following:

(1) Lumber and wood panel products at retail and wholesale lumber storage yards
(2) Lumber and wood panel products at other than retail and wholesale storage yards
(3) Ties, poles, piles, posts, and other similar forest products at pressure-treating plant yards
(4) Outside storage of wood chips, hogged material, and wood by-products
(5) Logs
(6) Outside storage of biomass feedstocks

Indoor storage areas should comply with NFPA 664 and Chapter 34 of this *Code*.

For the 2018 edition of this Code, Chapter 31 has been updated to include the outside storage of biomass feedstocks in its application. See the commentary on 31.3.10 for more information on the protection of biomass feedstocks.

Δ **31.3.1.2** The requirements of this chapter shall not apply to forest products stored on piers and wharves as addressed in NFPA 307.

31.3.2 General Fire Protection. The requirements in this subsection shall apply to all facilities regulated by 31.3.3 through 31.3.8 except as modified by those subsections.

31.3.2.1 Operational Fire Prevention.

31.3.2.1.1* Combustible waste materials such as bark, sawdust, chips, and other debris shall not be permitted to accumulate in a quantity or location that constitutes an undue fire hazard.

A.31.3.2.1.1 Good housekeeping should be maintained at all times, including regular and frequent cleaning of materials-handling equipment.

If combustible materials are allowed to accumulate around lumber piles or in equipment, a fire could quickly spread beyond the fire-fighting capabilities of the responding fire department. Combustible waste materials generally are more easily ignited than whole pieces of lumber or logs.

Good housekeeping also includes dealing with weeds throughout storage areas. The precautions identified in A.31.3.2.1.1, 31.3.2.2.2, and 10.13.10 should be applied to all forest product storage areas. Processing by-products should be removed at regular intervals to prevent buildup. The by-products should be stored in approved areas with the appropriate protection. (See 31.3.6.)

31.3.2.1.2 Smoking shall be prohibited except in specified safe locations approved by the AHJ.

See Section 10.9 for additional requirements related to smoking.

31.3.2.1.2.1 Signs that read "No Smoking" shall be posted in those areas where smoking is prohibited.

31.3.2.1.2.2 Signs indicating areas designated as safe for smoking shall be posted in those locations where smoking is permitted.

31.3.2.1.2.3 Smoking areas shall be provided with approved, noncombustible ash receptacles.

31.3.2.1.2.4 Smoking shall be specifically prohibited in and around railroad cars.

A cigarette carelessly disposed among forest products could smolder for an extended period of time before igniting a fire. Railroad cars could transport an incipient fire to some other location before the occurrence of flaming ignition. The careless disposal of cigarettes is one of the major causes of fires in lumberyards. For additional requirements related to smoking, see Section 10.9.

31.3.2.1.3 Access into yard areas by unauthorized persons shall be prohibited.

31.3.2.1.4 Storage areas shall be enclosed with a fence equipped with effective gates located as necessary to allow the entry of fire department apparatus.

A fence is perhaps the best means of preventing unauthorized access to a site. In accordance with Chapter 18, gates should be provided at the main entrance and at other locations around the perimeter to permit fire department apparatus to gain immediate access to all areas.

The outdoor storage of forest products typically involves large quantities of combustibles visible from the street, making such storage areas the targets of arson and requiring appropriate security measures. Fires of incendiary and suspicious origin are among the leading causes of fires in lumberyards. However, security measures should not prevent fire department access to the site. See Chapter 18 for fire department access requirements.

31.3.2.1.5 Miscellaneous occupancy hazards such as vehicle storage and repair shops, cutting and welding operations, flammable liquid storage, liquefied petroleum gas storage, and similar operations shall be safeguarded in accordance with recognized good practice and this *Code*.

Fire prevention and fire protection requirements in this *Code* and other NFPA codes and standards must be followed for hazardous operations and installations within lumber storage yards to reduce the risk of exposure fires and ignition sources.

The following chapters provide additional guidance and requirements:

1. Chapter 30 for motor fuel dispensing
2. Chapter 41 for hot work operations
3. Chapter 66 for handling and use of flammable and combustible liquids
4. Chapter 69 for handling and use of liquefied petroleum gas (LP-Gas) and liquefied natural gas (LNG)

31.3.2.1.6 Vehicles and other power devices shall be of an approved type and shall be safely maintained and operated.

31.3.2.1.6.1* Vehicle fueling operations shall be conducted in specified safe locations, isolated from storage areas and principal operating buildings.

Δ **A.31.3.2.1.6.1** See NFPA 505.

31.3.2.1.6.2 Diesel- or gasoline-fueled vehicles that operate on hogged material or chip piles, in log storage areas, or in lumber storage areas shall be equipped with fixed fire-extinguishing systems of a type approved for off-road vehicles.

31.3.2.1.7 All electrical equipment and installations shall conform to the provisions of Section 11.1.

31.3.2.1.8 Salamanders, braziers, open fires, and similar dangerous heating arrangements shall be prohibited.

31.3.2.1.9 Heating devices shall be limited to approved-type equipment installed in an approved manner.

31.3.2.1.10 Suitable safeguards shall be provided to minimize the hazard of sparks caused by equipment such as refuse burners, boiler stacks, vehicle exhausts, and locomotives.

In addition to sparks from locomotives, the combustion process of locomotives traveling through a storage area is also a concern. Diesel locomotives should be equipped with spark arresters or other devices to prevent the escape of glowing carbon particles from the exhaust. Steam locomotives, where still used, should have a means to prevent hot ashes (coal-fired) or burning oil (oil-fired) from dropping out of the locomotive.

31.3.2.1.10.1* Burning of shavings, sawdust, and refuse materials shall be conducted only in an approved, enclosed refuse burner equipped with an approved spark arrester and located at a safe distance from the nearest point of any yard. *(See Section 10.10.)*

Δ **A.31.3.2.1.10.1** See NFPA 82 for small rubbish burners.

Section 10.10 provides additional guidance on, and requirements for, open burning.

31.3.2.1.10.2 The design and location of large burners presents special problems, and the AHJ shall be consulted.

31.3.2.1.11 Stacks from solid fuel-burning furnaces and boilers shall be equipped with spark-arresting equipment to prevent hot sparks from reaching the ground, and consideration shall be given to spark hazard in determining the height of such stacks.

31.3.2.1.12 Cutting, welding, or other use of open flames or spark-producing equipment shall not be permitted in the storage area unless by an approved permit system.

Chapter 41 provides additional guidance on, and requirements for, hot work operations.

31.3.2.2 Exposure Protection. Exposure to the yard shall be protected in accordance with the requirements of 31.3.2.2.1 through 31.3.2.2.2.2.

31.3.2.2.1* Yard areas shall be separated from plant operations and other structures so that fire exposure into the yard is minimized.

This *Code* requires adequate separation between buildings and yard storage so that the risk of a building fire starting a fire in outdoor forest products storage is minimized. The clearance between the outdoor storage and the building must be increased for unsprinklered buildings, because a fire in such a facility is expected to result in a greater exposure hazard.

Δ **A.31.3.2.2.1** Saw mills, planing mills, treating plants, adzing mills, and similar buildings without blank walls should be separated from yard storage by a clear space in accordance with the recommendations of NFPA 80A.

Unsprinklered manufacturing buildings and other large structures with combustible contents represent a severe exposure to yard storage, unless the exterior walls have the necessary fire resistance to act as a fire separation and are essentially absent of unprotected openings.

Providing an adequate clear space between piles, exposures, and other combustible material is no different from that for houses threatened by wildland fires. A clear space must be maintained that will not burn and spread fire to the forest products storage from the wildland area or from the forest products storage to the wildland area. See 10.13.10 for additional provisions for exterior vegetation.

31.3.2.2.1.1 Minimum separation shall be by means of a clear space permanently available for fire-fighting operations.

31.3.2.2.1.2 The width of the clear space shall be based on the severity of exposure, which varies with the area, height, occupancy, construction, and protection of the exposing structure and the type of stacking and height of adjacent stacks.

31.3.2.2.2* Forest, brush, and grass fire exposure shall be minimized by providing adequate clear space that is carefully kept free of combustible vegetation.

A.31.3.2.2.2 Weeds, grass, and similar vegetation should be prevented throughout the entire yard, and any vegetation growth should be sprayed as often as needed with an herbicide or ground sterilizer, or should be grubbed out. Dead weeds should be removed after destruction. Weed burners should not be used.

31.3.2.2.2.1 Clear space of a width at least equivalent to the fire department access road shall be provided for grass exposures, and clear space of a width not less than 100 ft (30 m) shall be provided for light brush exposures.

31.3.2.2.2.2 In forested areas, a wider clear space than in 31.3.2.2.2.1 shall be provided.

31.3.2.3* Fire Detection and Extinguishment. A reliable means for prompt transmission of fire alarms to public fire departments and plant emergency organizations shall be provided.

A.31.3.2.3 Where practical, some form of fixed system of alarm notification or communication equipment should be provided within the storage yard (e.g., telephones, radios).

Portable fire extinguishers suitable for the fire hazard involved should be provided at convenient, conspicuously accessible locations in the yard. Approved portable fire-extinguishing equipment should be located so that the travel distance to the nearest unit is not more than 75 ft (23 m). See Section 13.6. Approved fire extinguishers suitable for the fire hazard involved should be provided on all power vehicles and units, including haulage or private locomotives in the yard.

The property owner is required to provide a means for early detection of a fire and a reliable means to notify both on-site and public emergency response organizations. The requirement of 31.3.2.3 is performancebased and must be discussed with the AHJ. The term *detection* in 31.3.2.3 does not necessarily imply a requirement for electronic fire or smoke detection equipment, although such equipment could provide the required protection.

31.3.3 Outside Storage of Lumber and Wood Panel Products at Retail and Wholesale Storage Yards.

31.3.3.1 Application.

31.3.3.1.1 The requirements of 31.3.3 shall apply to the following areas:

(1) Retail lumberyards handling forest products and other building materials
(2) Wholesale lumber storage yards, including distribution, holding, and transshipment areas

31.3.3.1.2* The requirements of 31.3.4 shall apply to other than large outside wholesale and retail distribution yards.

A.31.3.3.1.2 The type of operations at properties where the provisions of 31.3.4 apply vary widely. Retail lumber and building material operations are often characterized by large area buildings with minor outside storage areas. On the other hand, wholesale and distribution yards can involve large outside storage areas that present fire protection problems similar to mill yards.

31.3.3.2 General.

31.3.3.2.1* The fire hazard potential inherent in lumber storage operations with large quantities of combustible materials shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:

(1) Selection, design, and arrangement of storage yard areas and materials-handling equipment based upon proven fire prevention and protection principles
(2) Means for early fire detection, transmission of alarm, and fire extinguishment
(3) Fire department access roads to separate large stacks and provide access for effective fire-fighting operations
(4) Separation of yard storage from yard buildings and other exposing properties
(5) Effective fire prevention maintenance program, including regular yard inspections by trained personnel

A.31.3.3.2.1 Fire loss experience in lumberyards indicates that the following are the principal factors that allow lumberyard fires to reach serious proportions:

(1) Large, undivided stacks
(2) Congested storage conditions
(3) Delayed fire detection
(4) Inadequate fire protection
(5) Ineffective fire-fighting tactics

31.3.3.2.2* Water supplies shall be provided in accordance with this *Code*.

Δ **A.31.3.3.2.2** It is recognized that retail and wholesale lumber storage yards are normally located within municipal system boundaries, where the system should be capable of supplying not less than four 2½ in. (65 mm) hose streams simultaneously [1000 gpm (4000 L/min)]. Where large-scale fire-fighting operations can be expected, larger water supplies are needed. Where protection from municipal water supplies and hydrant systems is not provided or is not considered adequate by the AHJ, a yard fire hydrant system should be provided and installed in accordance with NFPA 24.

See Sections 18.3, 18.4, and 18.5 for additional requirements for water supplies, fire flow, and fire hydrant locations and distribution.

31.3.3.3 Open Yard Storage.

31.3.3.3.1* Lumber stacks shall be on stable ground, and paved or surfaced with materials such as cinders, fine gravel, or stone.

A.31.3.3.3.1 Where the danger of underground fire is present, refuse-filled or sawdust-filled land should not be used.

31.3.3.3.2 The method of stacking shall be stable and in an orderly and regular manner.

31.3.3.3.3* The height of stacks shall not exceed 20 ft (6 m) with consideration for stability.

A.31.3.3.3.3 Air-dried stickered stacks are subject to rapid-fire spread through the air spaces and should therefore be kept as low as practicable.

31.3.3.3.4 Where stacks are supported clear of the ground, 6 in. (150 mm) of clearance shall be provided for cleaning operations under the stacks.

Exhibit 31.1 shows outdoor storage at a retail lumberyard. Several design considerations must be met to help minimize the impact of a fire on adjacent lumber stacks and/or fire fighter operations. Lumber stacks must be on stable ground and must be stacked in an orderly and regular manner. Should a fire occur, unstable stacks can easily collapse, causing obstructions to access roads and spreading the fire to adjacent areas. Unstable lumber stacks can also mean dangerous conditions for fire fighter operations. In addition, the height of storage stacks cannot exceed 20 ft (6 m). Storage stacks taller than 20 ft (6 m) can significantly impede handheld hose stream operations by fire suppression personnel.

Exhibit 31.1

Outdoor storage at a retail lumberyard. (Thinkstock)

31.3.3.3.5 Fire department access roads shall be spaced so that a grid system of not more than 50 ft × 150 ft (15 m × 46 m) is produced.

Storage stacks wider than 50 ft × 150 ft (15 m × 46 m) can significantly impede handheld hose stream operations by fire suppression personnel.

31.3.3.3.6 Fire department access roads shall comply with Section 18.2.

31.3.3.3.7 Stacking limits shall be designated to indicate yard area and alleyway limits in accordance with 31.3.3.3.7.1 or 31.3.3.3.7.2.

31.3.3.3.7.1 The stacking limits shall be designated with boundary posts having signs that indicate stacking limits unless otherwise permitted by 31.3.3.3.7.2.

31.3.3.3.7.2 Where yards have paved areas, painted boundary limits shall be permitted to be used to designate stacking limits.

31.3.3.4 Exposure Protection.

31.3.3.4.1 Exposure to the Yard.

Automatic sprinkler protection in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, should be considered for all buildings that might constitute an exposure to outside lumber storage.

31.3.3.4.1.1 Open yard stacking shall be located with not less than 15 ft (4.6 m) clear space to buildings.

31.3.3.4.1.2 Boundary posts with signs designating stacking limits shall be provided to designate the clear space to unsprinklered buildings in which hazardous manufacturing or other operations take place.

31.3.3.4.2* Exposure from the Yard.

A.31.3.3.4.2 Because of the large quantities of material generally involved in lumberyard fires, some form of exposure protection for adjoining properties is recommended. Clear spaces or walls capable of providing fire barriers between yard storage and the exposed properties should be used. The responsibility for the protection of properties adjoining a lumberyard is often a joint responsibility to be worked out between the lumberyard and adjoining property owners. The AHJ should be consulted.

31.3.3.4.2.1 Open yard stacking shall be located with not less than 15 ft (4.6 m) clear space to adjacent property lines.

31.3.3.4.2.2 Alternative forms of exposure protection shall be permitted where approved by the AHJ.

31.3.4 Outside Storage of Lumber and Wood Panel Products at Other Than Retail and Wholesale Storage Yards.

31.3.4.1* Application. The requirements of 31.3.4 shall apply to large yard storage areas containing lumber, wood panels, and other similar wood products not intended for retail or wholesale distribution at the site.

A.31.3.4.1 Each individual property has its own special conditions of yard use, material-handling methods, and topography. For this reason, only basic fire protection principles are discussed herein and are intended to be applied with due consideration of all local factors involved. The AHJ should be consulted.

31.3.4.2* General. The fire hazard potential inherent in forest product storage operations with large quantities of combustible materials shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:

(1) Selection, design, and arrangement of storage yard areas and materials-handling equipment based on sound fire prevention and protection principles
(2) Means for early fire detection, transmission of alarm, and fire extinguishment
(3) Fire department access roads to separate large stacks and provide access for effective fire-fighting operations
(4) Separation of yard storage from mill or other plant operations and other exposing properties
(5) Effective fire prevention maintenance program, including regular yard inspections by trained personnel

A.31.3.4.2 Fire loss experience in lumber storage yards indicates that the following are the principal factors that allow lumberyard fires to reach serious proportions:

(1) Large, undivided stacks
(2) Congested storage conditions
(3) Delayed fire detection
(4) Inadequate fire protection
(5) Ineffective fire-fighting tactics

31.3.4.3* Open Yard Storage.

A.31.3.4.3 Refuse-filled or sawdust-filled land, swampy ground, or areas where the hazard of underground fire is present should not be used as a storage site.

31.3.4.3.1* Water supplies shall be provided in accordance with this *Code*.

A.31.3.4.3.1 For basic fire protection, the hydrant system should be capable of supplying not less than four 2½ in. (65 mm) hose streams simultaneously [1000 gpm (4000 L/min)] while maintaining a positive residual pressure in the fire protection hydrant system of not less than 20 psi (1.38 bar).

Where large-scale fire-fighting operations can be expected, larger water supplies with adequate mains are needed.

For early extinguishment with basic fire protection, hydrants should be spaced with sufficient 2½ in. (65 mm) hose attached to allow rapid hose laying to all parts of the stacking areas. For this reason, the hydrants should be spaced at about 250 ft (76 m) intervals so that any part of the yard can be reached with 250 ft (60 m) of hose. Hydrants preferably should be located at fire department access road intersections. A hydrant hose house with not less than 250 ft (60 m) of fire hose and auxiliary equipment should be provided at each hydrant. *(See NFPA 24.)*

31.3.4.3.2 Access to the plant and yard from public highways shall be provided by all-weather roadways capable of supporting fire department apparatus.

Unlike typical retail and wholesale yards, forest product processing facilities might not be accessible by public roadways. In many instances, they are accessed by dirt roads of considerable length.

31.3.4.3.3 The storage site shall be reasonably level, on solid ground, and paved or surfaced with materials such as cinders, fine gravel, or stone.

31.3.4.3.4 Stack height shall be limited to 20 ft (6 m).

31.3.5 Outside Storage of Ties, Poles, Piles, Posts, and Other Similar Forest Products at Pressure-Treating Plant Yards.

31.3.5.1 Application.

31.3.5.1.1* The requirements of 31.3.5 shall apply to yard storage areas containing treated and untreated ties, poles, piles, posts, and other similar forest products in yards connected with pressure-treating plants.

A.31.3.5.1.1 Each individual property has its own special conditions of yard use, stock-handling methods, and topography. For this reason, only basic fire protection principles are discussed herein, and are intended to be applied with due consideration of all local factors involved. Ties, as used herein, include ties, poles, piles, posts, and other similar forest products. Treated ties are ties that are pressure impregnated with preservatives.

31.3.5.1.2 The requirements of 31.3.5 shall not apply to pressure-treating buildings, processes, or storage of treating materials.

31.3.5.2* General. The fire hazard potential inherent in tie storage operations with large quantities of combustible materials shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:

(1) Selection, design, and arrangement of storage yard areas and materials-handling equipment based upon sound fire prevention and protection principles
(2) Means for early fire detection, transmission of alarm, and fire extinguishment
(3) Fire department access roads to separate large stacks and provide access for effective fire-fighting operations
(4) Separation of yard storage from mill buildings and other exposing properties
(5) Effective fire prevention maintenance program, including regular yard inspections by trained personnel

A.31.3.5.2 Fire loss experience in tie storage yards indicates that the following are the principal factors that allow fires to reach serious proportions:

(1) Large, undivided stacks
(2) Congested storage conditions
(3) Delayed fire detection
(4) Inadequate fire protection
(5) Ineffective fire-fighting tactics

31.3.5.3* Tie Yard Protection.

A.31.3.5.3 Refuse-filled or sawdust-filled land, swampy ground, or areas where the hazard of underground fire is present should not be used as storage site.

31.3.5.3.1* Unobstructed alleyways of sufficient width for hand or cart fire hose laying operations shall be provided between piles.

A.31.3.5.3.1 With relatively open stacking (that is, stacking that allows for penetration of fire-extinguishing streams), sufficient alleyway width can usually be accomplished by providing a not-less-than 4 ft (1.2 m) alleyway width between alternate rows of tie stacks. *[See Figure A.31.3.5.3.1(a).]* Flat crib-style stacking without space between the stacks that forms solid packed rows should require a not-less-than 4 ft (1.2 m) alleyway width between each row. *[See Figure A.31.3.5.3.1(b).]*

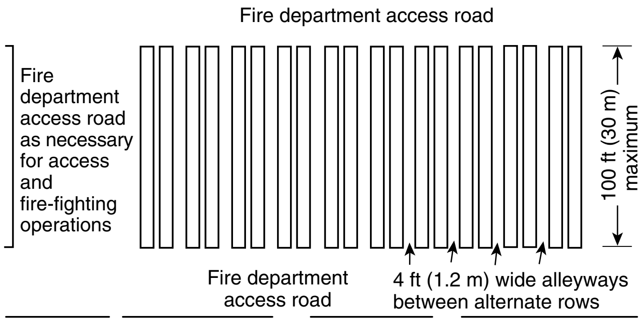

FIGURE A.31.3.5.3.1(a) Relatively Open Stacking Methods.

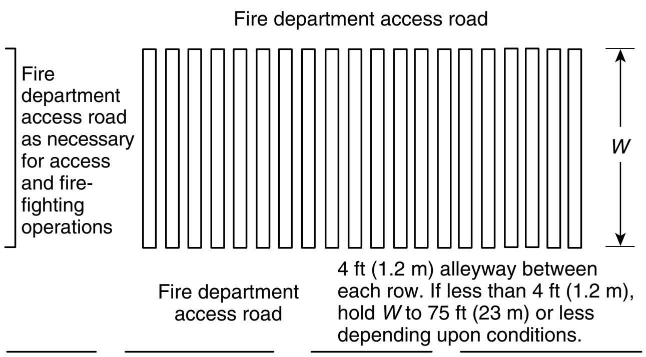

FIGURE A.31.3.5.3.1(b) Crib-Style Stacking into Solid Rows.

31.3.5.3.1.1 Alleyways shall not be less than 2 ft (0.6 m) in width.

31.3.5.3.1.2 Where a minimum alleyway width of 4 ft (1.2 m) is provided, the length of the rows shall be not more than 100 ft (30 m).

31.3.5.3.1.3 Where an alleyway width less than 4 ft (1.2 m) is provided, the length of the rows shall be not more than 75 ft (23 m).

31.3.5.3.2* Water supplies shall be provided in accordance with this *Code*.

A.31.3.5.3.2 For basic fire protection, the hydrant system should be capable of supplying not less than four 2½ in. (65 mm) hose streams simultaneously [not less than 1000 gpm (4000 L/min)] while maintaining a positive residual pressure in the fire protection hydrant system of not less than 20 psi (1.38 bar).

Where large-scale fire-fighting operations can be expected, larger water supplies with adequate mains are needed.

For early extinguishment with basic fire protection, hydrants should be spaced with sufficient 2½ in. (65 mm) hose attached to allow rapid hose laying to all parts of the stacking areas. For this reason, hydrants should be spaced at about 250 ft (76 m) intervals so that any part of the yard can be reached with 200 ft (60 m) of hose. Hydrants preferably should be located at fire department access road intersections. A hydrant hose house with not less than 200 ft (60 m) of fire hose and auxiliary equipment should be provided at each hydrant. *(See NFPA 24.)*

31.3.5.3.3 Access to the plant and yard from public highways shall be provided by all-weather roadways capable of supporting fire department apparatus.

31.3.5.3.4 The storage site shall be reasonably level, on solid ground, and paved or surfaced with materials such as cinders, fine gravel, or stone.

31.3.5.3.5* Stack heights shall be limited to 20 ft (6 m).

A.31.3.5.3.5 Heights in excess of 20 ft (6 m) seriously restrict effective extinguishing operations.

31.3.6 Outside Storage of Wood Chips and Hogged Material.

31.3.6.1* Application. The requirements of 31.3.6 shall apply to yard storage areas containing wood chips and hogged material.

A.31.3.6.1 Each individual property has its own special conditions of yard use, stock-handling methods, and topography. It is recognized that climate conditions, wood species, and the age of piles are all factors affecting fire safety. For these reasons, only basic fire protection principles are discussed herein, and are intended to be applied with due consideration of all local factors involved. Except for the surface layer, the moisture content of a pile of wood chips or hogged material is quite high, so surface fires do not generally penetrate more than a few inches into the pile. Fire tests indicate that, for areas of average humidity conditions, the flame propagation over the surface is relatively slow. These conditions allow ready extinguishment, provided that there is early detection and good access. It is expected that, in areas where long periods of low humidity prevail, faster surface flame spread can be anticipated, increasing the importance of early detection and good access.

Hogged material, shown in Exhibit 31.2, is defined in 3.3.155 as mill waste consisting mainly of hogged bark but possibly including a mixture of bark, chips, dust, or other by-products from trees; it also includes material designated as hogged fuel. Exhibit 31.3 shows outside storage of wood chips.

31.3.6.2 General.

31.3.6.2.1* The fire hazard potential inherent in storage piles shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:

(1) Selection, design, and arrangement of storage yard areas and materials-handling equipment based upon sound fire prevention and protection principles
(2) Establishment of control over the various factors that lead to spontaneous heating, including provisions for monitoring the internal condition of the pile
(3) Means for early fire detection and extinguishment
(4) Fire department access roads around the piles and access roads to the top of the piles for effective fire-fighting operations
(5) Facilities for calling the public fire department and facilities needed by the fire department for fire extinguishment
(6) Effective fire prevention maintenance program, including regular yard inspections by trained personnel

A.31.3.6.2.1 Fire experience and fire tests indicate that two completely different types of fires can occur in storage piles — surface

Exhibit 31.2

Hogged material. (Courtesy of Advanced Biomass Consulting, Inc.)

Exhibit 31.3

Outside storage of wood chips. (Thinkstock) fires and internal fires. Fire prevention activities and fire protection facilities should, therefore, include preparations for coping with both situations.

Internal heating is a hazard inherent to long-term bulk storage of chips and hogged material that progresses to spontaneous combustion under certain pile conditions. Internal fires are difficult to detect and extinguish. Unless provisions are made for measuring internal temperatures, such fires can burn for long periods before emission of smoke at the surface indicates an internal fire.

Extinguishment then becomes a lengthy and expensive loss-control and operating problem requiring equipment and manpower to move large portions of the pile, either by digging out the burning portions or removing the unburned portions of the pile. Experience has shown that these conditions create very large losses, and special attention should be given to the prevention of spontaneous combustion and to pre-fire planning where evaluating how best to handle an imminent or actual fire in a particular pile.

Spontaneous combustion can also occur in smaller wood chip piles typically found at retail and commercial landscaping supply yards.

31.3.6.2.2* The following items shall be addressed when establishing operating procedures:

A.31.3.6.2.2 Prevention of internal fires requires an understanding of the factors that cause exothermic oxidation so that steps can be taken to minimize this hazard and to provide means of monitoring temperature conditions inside the pile. Refuse and old chips should not be permitted in the chip pile base. The storage site should be thoroughly cleaned before starting a new pile.

The quality of chip supplies should be controlled in terms of percentage of fines. The concentration of fines should not be allowed during pile buildup.

Pneumatic systems produce an air classification of stored materials that should be recognized, and appropriate steps should be taken to minimize concentration of fines.

It is preferable to spread new stored materials in a relatively even layer over the pile.

Vehicles used on all piles should be of a type that minimizes compaction.

Veneer chip piles should be limited to 50 ft (15 m) in height.

(1) The storage site shall be reasonably level, solid ground, or shall be paved with blacktop, concrete, or other hard-surface material.
(2) Sites shall be cleaned before transferring wood products to the site.
(3) Operating plans for the buildup and reclaiming of the pile shall be based on a turnover time of not more than 1 year under ideal conditions.
(4)* Piles containing other than screened chips made from cleaned and barked logs shall be minimized.

A.31.3.6.2.2(4) For example, whole-tree chip piles containing bark, leaves, and other extraneous or hogged material can be subject to greater degrees of spontaneous heating and thermal degradation and should be reclaimed more frequently.

Where deep-seated fires in large piles occur, the fire department could spray water on the pile for long periods of time with little result, unless a means is available on site to dig through the pile and spread the burning material. The problems associated with extinguishing such fires are similar to those in large trash or scrap tire piles, some of which have been known to burn for years.

(5)* The pile size shall be limited.

A.31.3.6.2.2(5) Fundamentally, several small piles are better than one large pile.

(6) Pile heights shall be kept low, particularly piles that inherently carry a larger percentage of fines and are subject to greater compaction.
(7) Thermocouples shall be installed during pile buildup, or other means for measuring temperatures within the pile shall be provided with regular (normally weekly) reports to management.
(8)* The pile shall be wetted regularly to help keep fines from drying out and help maintain the moisture content of the surface layer of the pile.

A.31.3.6.2.2(8) Minimizing the diffusion of water from wet, stored material into dry fires is important to reduce exothermic heating caused by adsorption effects. Maintaining surface moisture content is also important so as to reduce the hazard of surface fires during periods of hot, dry weather.

31.3.6.3* Pile Protection.

A.31.3.6.3 A high standard of housekeeping should be maintained around all potential heat sources.

Care should be exercised to prevent tramp metal from entering the piles, or sections of blower pipes from being buried in the piles.

31.3.6.3.1* Piles shall be constructed with an access roadway to the top of the pile in order to reach any part of the pile.

A.31.3.6.3.1 For very large piles, two or more access roadways should be provided on opposite sides of the pile.

31.3.6.3.2* Piles shall not exceed 60 ft (18 m) in height, 300 ft (90 m) in width, and 500 ft (150 m) in length.

A.31.3.6.3.2 Narrow, low piles facilitate fire extinguishment.

31.3.6.3.2.1 Where pile height and width are such that all portions of the pile cannot be reached by direct hose streams from the ground, arrangements shall be made to provide fire-fighting service in these areas, and small fire stream supplies shall be available on the top of the pile for handling small surface fires and for wetting the pile in dry weather.

31.3.6.3.2.2 When more than one pile exists, they shall be subdivided by fire department access roads having not less than 30 ft (9 m) of clear space at the base of the piles.

31.3.6.3.2.3 Low barrier walls around piles shall be provided to clearly define pile perimeters, prevent creeping, and facilitate cleanup of fire department access roads.

Barrier walls around piles prevent materials from encroaching on the fire department access road or from expanding too close to other piles.

31.3.6.3.3 Where suitable, a small, motorized vehicle amply equipped with portable extinguishing equipment or a water tank and pump shall be provided.

31.3.6.3.3.1 Lightweight ladders that can be placed against the side of the pile shall be placed at convenient locations throughout the yard for use by the plant emergency organization.

31.3.6.3.3.2 Training of the plant emergency organization also shall include procedures and precautions to be observed by yard crews employing power equipment in fighting internal fires.

31.3.6.3.4* Portable fire extinguishers for Class A fires shall be provided in accordance with Section 13.6 on all vehicles operating on the pile in addition to the normal Class B units for the vehicle.

A.31.3.6.3.4 Due to the size and configuration of piles, providing portable fire extinguishers within 75 ft (23 m) of travel distance to any point is not practical.

31.3.6.3.5* Water supplies shall be provided in accordance with this *Code*.

A.31.3.6.3.5 Fire hydrants connected to yard mains should be provided so that any part of the pile(s) can be reached by hose equipment provided in each hydrant hose house. Each hydrant hose house should be equipped with a complement of 2½ in. (65 mm) and 1½ in. (38 mm) hose, a 2½ in. (65 mm) and 1½ in. (38 mm) gated wye, and 1½ in. (38 mm) combination nozzles.

Hydrants should be spaced at about 250 ft (76 m) intervals so that any part of the yard can be reached with 200 ft (60 m) of hose.

Where pile configurations are such that all parts of the pile cannot be reached by the hose, a fire hose cart(s) equipped with an ample supply of hose and nozzles should be strategically placed in the storage area.

The amount of water needed to control a pile fire varies substantially depending on the size of the pile. Weather conditions, operating methods, geographic location, type of material stored, and the degree to which wetting can be employed affect the potential for a large area surface fire. Experience indicates that exposure to long periods of hot, dry weather with no regular surface wetting creates conditions under which fast-spreading surface fires, which require many hose streams for control depending on the size of the pile, can occur.

Likewise, the frequency of pile turnover and operating methods affect the potential for serious internal fires. Piles built using methods that allow a concentration of fines and piles stored for long periods of time with no turnover are subject to internal heating that, if undetected, can create intense internal fires.

A flow of not less than 500 gpm (2000 L/min) should be provided at any fire hydrant in the pile area. Additional flows should be provided as needed where conditions are likely to produce serious surface fires or large internal fires. Fire mains should be engineered to deliver the recommended gallonage plus allowance for operational uses and special extinguishing equipment at a residual pressure of 60 psi to 100 psi (4.1 bar to 6.9 bar) at the hydrants.

See Sections 18.3, 18.4, and 18.5 for additional requirements on water supplies, fire flow, and fire hydrant locations and distribution.

31.3.6.3.6 All motor and switchgear enclosures shall be provided with approved, portable fire extinguishers suitable for the hazard involved in accordance with Section 13.6.

31.3.6.3.7* Power-operated, shovel-type or scoop-type vehicles, dozers, or similar equipment shall be available for use in moving stored material for fire fighting.

A.31.3.6.3.7 With the use of the equipment specified in 31.3.6.3.7, surface types of pile fires can usually be removed from the affected areas and extinguished.

Where deep-seated fires occur within the pile or under the pile in tunnels or other enclosures, this equipment is invaluable in breaking down the entire pile and spreading it out in a safe yard area, which allows fire fighters using hand hose lines or deluge units to extinguish both the pile and ground-spread stored material.

31.3.6.3.8 Temporary conveyors and motors on the surface or adjacent to the piles shall not be permitted.

31.3.6.3.9 Physical protection shall be provided to prevent heat sources such as steam lines, air lines, electrical motors, and mechanical drive equipment from becoming buried or heavily coated with combustible material.

31.3.6.3.10 Tramp metal collectors or detectors shall be required on all conveyor and blower systems.

31.3.6.4 Exposure Protection.

31.3.6.4.1* Incinerators or open refuse burning shall not be permitted in any area where sparks could reach the storage piles.

A.31.3.6.4.1 Experience indicates that radiated heat from exposing fires in storage piles does not ordinarily pose a serious ignition threat to other piles, provided that recommended clear spaces are maintained. Flying brands from exposing fires, especially during high winds, do present a hazardous ignition source. Upwind forest or brush fires can also present a problem in relation to flying sparks and brands.

31.3.6.4.2* A clear space of not less than 15 ft (4.6 m) shall be maintained between piles and exposing structures, yard equipment, or stock, depending on the degree of exposure hazard.

A.31.3.6.4.2 Buildings or other structures near storage piles can pose a serious exposure hazard to the pile.

31.3.6.4.3* Pile-to-pile clearance of not less than 30 ft (9 m) at the base of the pile shall be provided.

A.31.3.6.4.3 Greater clearance is desirable when piles are high and side slopes are greater than 60 degrees.

31.3.6.5 Emergency Action Plan. The facility shall have an emergency action plan for monitoring, controlling, and extinguishing spot fires.

31.3.7* Storage and Processing of Wood Chips, Hogged Material, Fines, Compost, and Raw Products at Yard Waste Recycling Facilities.

A.31.3.7 This type of chip has a much higher aliphatic hydrocarbon (sugar) content and spontaneously ignites readily. Lumber chips are debarked and thus lose the cambium layer associated with stored sugars. It is these sugars that start the bacterial decomposition that proceeds to spontaneous ignition.

31.3.7.1 The storage and processing of wood chips, hogged material, fines, compost, and raw products produced from yard waste recycling facilities shall comply with 31.3.6 and 31.3.7.

31.3.7.2 When not protected by a fixed fire-extinguishing system in accordance with Chapter 13, piles shall not exceed 25 ft (7.6 m) in height, 150 ft (45 m) in width, and 250 ft (76.2 m) in length.

31.3.7.3 Static Pile Protection.

31.3.7.3.1 Static piles shall be monitored by an approved means to measure temperatures within the piles.

31.3.7.3.2 Internal pile temperatures shall be recorded weekly.

31.3.7.3.3 Records shall be kept on file at the facility and made available for inspection.

31.3.7.3.4 The facility shall have an operational plan indicating procedures and schedules for the inspection, monitoring, and restricting of excessive internal temperatures in static piles.

31.3.7.4 Fire Protection.

31.3.7.4.1 Conveyor tunnels and combustible enclosures that pass under a pile shall be protected with automatic sprinklers complying with Section 13.3.

31.3.7.4.2 Combustible or enclosed conveyor systems shall be protected with automatic sprinklers complying with Section 13.3.

Yard waste (also referred to as green waste) is vegetative material and organic brush resulting from landscaping and maintenance of yards, lawns, or gardens. It includes grass clippings, leaves, tree stumps and large branches, garden remnants, and clippings from pruned bushes. It can also include Christmas trees. The constant seasonal care and maintenance of landscaping or cleanup from a weather event such as a windstorm, blizzard, or hurricane can generate massive amounts of yard waste. The waste is transported by consumers or hired professionals to a recycling facility. Yard waste can be composted at the private residence or at a recycling facility, or it can be processed into mulch. The provisions of 31.3.6 and 31.3.7 work together to ensure safe storage and fire protection practices at such facilities.

31.3.8 Outside Storage of Logs.

31.3.8.1 Application.

31.3.8.1.1* The requirements of 31.3.8 shall apply to log yard storage areas containing saw, plywood veneer, or pulpwood logs stored in ranked piles commonly referred to as cold decks.

A.31.3.8.1.1 Each individual property has its own special conditions for yard use, stock-handling methods, and topography. For this reason, only basic fire protection principles are discussed herein, and are intended to be applied with due consideration of all local factors involved.

31.3.8.1.2 The requirements of 31.3.8 shall not apply to cordwood.

31.3.8.2* General. The fire hazard potential inherent in log storage operations with large quantities of combustible materials shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:

(1) Selection, design, and arrangement of storage yard areas and materials-handling equipment based on sound fire prevention and protection principles
(2) Means for early fire detection, transmission of alarm, and fire extinguishment
(3) Fire department access roads to separate large piles and provide access for effective fire-fighting operations
(4) Separation of yard storage from mill operations and other exposing properties
(5) Effective fire prevention maintenance program, including regular yard inspections by trained personnel

A.31.3.8.2 Fire loss experience in outside storage of logs indicates that the following are the principal factors that allow log pile fires to reach serious proportions:

(1) Large, undivided piles
(2) Congested storage conditions
(3) Delayed fire detection
(4) Inadequate fire protection
(5) Ineffective fire-fighting tactics

31.3.8.3* Log Yard Protection.

A.31.3.8.3 Refuse-filled or sawdust-filled land, swampy ground, or areas where the hazard of underground fire is present should not be used as a storage site.

31.3.8.3.1 The storage site shall be reasonably level, on solid ground, and paved or surfaced with materials such as cinders, fine gravel, or stone.

31.3.8.3.2 Access to the plant and yard from public highways shall be provided by all-weather roadways capable of supporting fire department apparatus.

31.3.8.3.3* All sides of each cold deck shall be accessible by means of fire department access roads.

A.31.3.8.3.3 Where practical, greater widths should be provided to minimize the effects of radiated heat, particularly in high-piled yards.

31.3.8.3.3.1 A fire department access road width of 1½ times the pile height but not less than 20 ft (6 m) shall be provided, with fire department access roads between alternate rows of two pile groups providing a clear space of at least 100 ft (30 m).

31.3.8.3.3.2* Each cold deck shall not exceed 500 ft (150 m) in length, 300 ft (90 m) in width, and 20 ft (6 m) in height.

A.31.3.8.3.3.2 Heights in excess of 20 ft (6 m) seriously restrict effective extinguishing operations, since successful extinguishment of log pile fires requires penetration of the pile from the side by hose streams.

31.3.8.3.3.3* Fire department access roads for access across each end, with a clear space of not less than 100 ft (30 m) to adjacent pile rows or other exposed property, shall be provided.

A.31.3.8.3.3.3 See Figure A.31.3.8.3.3.3.

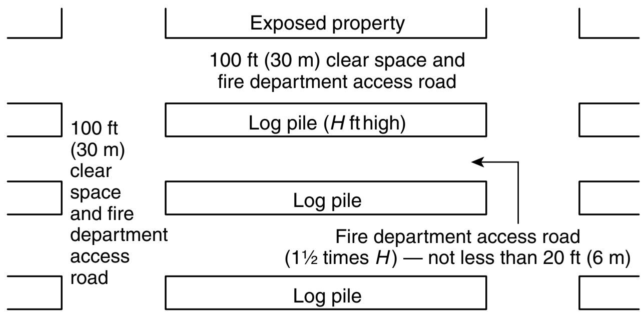

FIGURE A.31.3.8.3.3.3 *Layout of Log Storage Yard.*

31.3.8.3.3.4* The size of cold decks shall be permitted to be increased where additional fire flow and fixed fire protection equipment is provided and the approval of the AHJ is obtained.

A.31.3.8.3.3.4 For basic fire protection, the hydrant system should be capable of supplying not less than four 2½ in. (65 mm) hose streams simultaneously [not less than 1000 gpm (4000 L/min)] while maintaining a positive residual pressure in the fire protection hydrant system of not less than 20 psi (1.38 bar).

Where large-scale fire-fighting operations can be expected, larger water supplies with adequate mains are needed.

For early extinguishment with basic fire protection, hydrants should be spaced with sufficient 2½ in. (65 mm) hose attached to allow rapid hose laying to all parts of the piling areas. For this reason, hydrants should be spaced at about 250 ft (76 m) intervals so that any part of the yard can be reached with 200 ft (60 m) of hose. Hydrants should be located at fire department access road intersections. A hydrant hose house with not less than 200 ft (60 m) of fire hose and auxiliary equipment should be provided at each hydrant. *(See NFPA 24.)*

31.3.8.3.4 Water supplies shall be provided in accordance with this *Code*.

31.3.8.3.5 Dynamite shall never be used as a means to reclaim frozen log piles.

31.3.8.3.6* During dry weather, piles shall be wet down.

A.31.3.8.3.6 The installation of a portable piping system equipped with irrigation or lawn-type sprinklers on the top of each log pile is recommended.

31.3.9 Wood Processing and Woodworking Facilities. Dust control shall be in accordance with NFPA 664 for combustible dust-producing operations that occupy areas of more than 5000 ft^2 (464 m^2), or to areas where dust-producing equipment requires an aggregate dust collection flow rate of more than 1500 ft^3/min (2549 m^3/hr).

N **31.3.10 Outside Storage of Biomass Feedstock.**

Subsection 31.3.10 is new to the 2018 edition of the *Code*. According to the U.S. Office of Energy Efficiency and Renewable Energy, a *biomass* is defined as "any renewable, biological material that can be used directly as a fuel or converted to another form of fuel or energy product." Biomass is the plant and animal material used as a source of fuel. Biomass feedstocks are the raw materials used to derive fuels like ethanol, butanol, biodiesel, and other hydrocarbon fuels. Examples include corn starch, sugarcane juice, purpose-grown grass crops, and woody plants. Biomass fuel is a renewable energy source and its relevance is sure to increase as society becomes more reliant on renewable energy.

The new provisions of this subsection provide for the safe storage of biomass feedstock at biomass-to-ethanol manufacturing facilities. While some similar hazards and safety concerns exist, the requirements of Chapter 31 in previous editions for the storage of agricultural products were not sufficient for these types of operations. The requirements for securing the site in an approved manner and for the provision of lightning protection recognize the two main causes of fires in this type of storage: arson and lightning strikes.

N **31.3.10.1** The fire hazard potential inherent in biomass feedstock storage operations with large quantities of combustible materials shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:

(1) Selection, design, and arrangement of storage yard areas and materials-handling equipment based upon proven fire prevention and protection principles
(2) Means for early fire detection, transmission of alarm, and fire extinguishment
(3) Establishment of control over the various factors that lead to spontaneous heating, including provisions for monitoring the internal condition of the pile
(4) Fire department access roads to separate large stacks and provide access for effective fire-fighting operations
(5) Separation of yard storage from yard buildings and other exposing properties
(6) Effective fire prevention maintenance program, including regular yard inspections by trained personnel

N **31.3.10.2** Bale stacks shall not exceed 25 ft (7.6 m) in height, 150 ft (45 m) in width, and 250 ft (76.2 m) in length.

N **31.3.10.3** The storage site shall be reasonably level, on solid ground.

N **31.3.10.4** Access to the plant and yard from public highways shall be provided by all-weather roadways capable of supporting fire department apparatus.

N **31.3.10.5** All sides of each storage site shall be accessible by means of fire department access roads.

N **31.3.10.6** Where more than one pile exists, they shall be subdivided by fire department access roads having not less than 30 ft (9 m) of clear space at the base of the piles.

N **31.3.10.7** Power-operated, shovel-type or scoop-type vehicles, dozers, bale movers, or similar equipment shall be available for use in moving stored material for fire fighting.

N **31.3.10.8** Training of the plant emergency organization also shall include procedures and precautions to be observed by yard crews employing power equipment in fighting internal fires.

N **31.3.10.9** Portable fire extinguishers for Class A fires shall be provided in accordance with Section 13.6 on all vehicles operating in the storage yard in addition to the normal Class B units for the vehicle.

N **31.3.10.10** Lightning protection shall be provided for the outside storage yard in accordance with NFPA 780.

N **31.3.10.11** Outside storage yards shall be secured against unauthorized access in an approved manner.

N **31.3.10.12** Water supplies shall be provided in accordance with this *Code*.

Motion Picture and Television Production Studio Soundstages and Approved Production Facilities

32

This chapter provides additional requirements to address the unique hazards of motion picture and television production studio soundstages and production facilities. These facilities still require an occupancy classification (see Chapter 6). Typically, these types of facilities fall into the industrial occupancy category. However, careful consideration needs to be given to the individual facility to determine the occupancy classification. The presence of an audience and the size of that audience will affect the classification. For example, if more than 50 people are present, the facility should be considered an assembly occupancy. Chapter 32 contains provisions for production locations, as well as requirements for motion picture and television production studio soundstages and production facilities.

Certain practices are unique to the motion picture and television industries that require the application of NFPA 140, *Standard on Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations*. These practices include the ability to make the areas sound and light free, filming from various locations, building temporary sets and constructing temporary buildings within buildings, creating special effects, and filming in front of live audiences. These practices create unique challenges for fire and life safety, due to means of egress sometimes being moved or obstructed from view, sprinklers being obstructed, installed fire protection systems being placed out of service, and special effects being executed indoors.

Filming on location creates additional fire and life safety issues. Chapter 5 of NFPA 140 is extracted in this chapter (see Section 32.5) to provide guidance to the authority having jurisdiction (AHJ) for working with film and production companies on locations away from studios.

Chapter 32 applies to the following:

1. New buildings, or portions thereof, used as soundstages or approved production facilities in motion picture and television industry productions
2. Existing buildings, or portions thereof, used as soundstages or approved production facilities in motion picture and television industry productions to the extent specifically required by other portions of this document
3. Additions to buildings used as soundstages or approved production facilities in motion picture and television industry productions
4. Alterations, modernizations, or renovations of existing buildings used as soundstages or approved production facilities in motion picture and television industry productions
5. Existing buildings, or portions thereof, upon change of occupancy for use as soundstages or approved production facilities in motion picture and television industry productions
6. Production locations used in motion picture and television industry productions

Section 32.6, on operating features, applies to new and existing soundstages, approved production facilities, and production locations.

Existing soundstages, approved production facilities, and production locations that are in conformance with the requirements of the AHJ at the time of the adoption of this *Code* are permitted to remain in use under the following conditions:

1. The occupancy classification and use remain the same.
2. No serious hazards to life safety exist that would constitute an imminent hazard.

Chapter 32 does not apply to facilities used exclusively for radio broadcasts, theaters and auditoriums, live broadcasts of news or sporting events, or post-production facilities.

32.1 General

The design, construction, operation, and maintenance of soundstages and approved production facilities used in motion picture and television industry productions shall comply with NFPA 140 and Chapter 32.

32.2 Permits

Permits, where required, shall comply with Section 1.12.

32.3 Housekeeping

Soundstages and approved production facilities shall maintain housekeeping in accordance with Chapters 10 and 19 where applicable.

Housekeeping is an important issue due to construction, temporary installations, and the amount of wiring, cables, and combustible materials present. Housekeeping is especially critical during the use of special effects.

32.4 Soundstages and Approved Production Facilities

32.4.1 General. Section 32.4 shall apply to new and existing motion picture and television soundstages and approved production facilities. [**140:**4.1]

32.4.2 Permits. Where required by the AHJ, a permit shall be obtained for any of the activities that follow:

(1) Use of pyrotechnic special effects
(2) Use of open flames
(3) Welding
(4) Use of flammable or combustible liquids or gases
(5) Use of aircraft
(6) Presence of motor vehicles within a building
(7) Productions with live audiences
(8)* Change of use or change of occupancy classification

[**140:**4.2]

A.32.4.2(8) An example of a *change of use* would be a soundstage with audience facilities for 50 persons being used for a preview party for 500 persons. An example of a *change of occupancy classification* would be a soundstage without audience facilities being used for a preview party for 500 persons. [**140:**A.4.2(8)]

Depending on the production being filmed, some permits are issued on an annual basis. Other permits, such as those for open flames, live audiences, and pyrotechnics, are issued for each event by the AHJ and sometimes require standby fire personnel to be present during some or all of the production. The specifications for standby fire personnel are at the discretion of the AHJ. See 1.7.17 for additional guidance on standby fire personnel.

32.4.3 Pyrotechnic Special Effects and Open Flames.

32.4.3.1* The use of pyrotechnic special effects and open flames shall be subject to the approval of the AHJ. [**140:**4.3.1]

A.32.4.3.1 Particular attention needs to be given to combustible materials used in close proximity to pyrotechnic and open-flame special effects. On-site verification of the fire retardant properties of set components, furnishings, props, and other combustible materials is essential to ensure the safety of pyrotechnic and open-flame special effects. The provisions of 32.4.5 address the need to render drapes, greens, foamed plastics, and other combustible materials fire retardant. [**140:**A.4.3.1]

A comprehensive safety meeting should be conducted to define the intended scope of a special effect and establish appropriate safe areas. The safe areas need to be sized in consideration of the variable predictability of the materials used in the special effect. The safety meeting should include the participation of all persons who will be present during the special effect. The meeting discussion should also include consideration of the following:

(1) Conducting a test in an approved location of all devices and materials intended to be used in the special effect
(2) Excluding nonessential persons from the area of the effect until special effects personnel and a representative of the AHJ declare the area to be safe
(3) Evaluating the potential impact of the special effect on the uninvolved public
(4) Establishing an emergency plan that includes initial actions to take if the special effect exceeds its intended size, intensity, or duration
(5) Maintaining safe escape routes from the special effects area
(6) Developing methods of communication to be used during the special effect
(7) Identifying the individuals authorized to require that emergency actions be taken
(8) Specifying the licensing requirements for the individuals initiating the special effect
(9) Specifying the clothing to be worn by all special effects and safety personnel
(10) Evaluating the assignments and required abilities of all special effects and safety personnel
(11) Assigning the appropriate number of safety personnel to implement the plan
(12) Determining adequate and appropriate fire protection tailored to the materials used
(13) Establishing primary and backup methods of requesting additional fire suppression resources
(14) Identifying a definitive point when the special effect is complete

[**140:**A.4.3.1]

Δ **32.4.3.2** When an audience is present, NFPA 1126 shall be used to regulate any pyrotechnic use. [**140:**4.3.2]

Section 65.3 provides requirements for the use of pyrotechnics before a proximate audience, including requirements for permits.

Δ **32.4.3.3** When an audience is present, NFPA 160 shall be used to regulate any flame effects use. [**140:**4.3.3]

Section 65.4 provides requirements for use of flame effects before an audience, including requirements for permits.

32.4.4 Standby Fire Personnel.

32.4.4.1 Where required by the AHJ, standby fire personnel shall be provided for soundstages and approved production facilities where pyrotechnic special effects are used. [**140:**4.4.1]

Subsection 1.7.17 provides additional requirements for standby fire personnel.

32.4.4.2 Other Hazards. Where required by the AHJ, standby fire personnel shall be provided for hazardous operations, other than pyrotechnic special effects. [**140:**4.4.2]

32.4.5 Decorative Materials.

Δ **32.4.5.1** Foamed plastic materials used for decorative purposes, scenery, sets, or props shall have a heat release rate not exceeding 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or where tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source. [**140:**4.5.1]

32.4.5.2 Combustible drapes, drops, and any other similar combustible hangings or vertically placed materials shall comply with one of the following options:

(1) The materials meet the requirements of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*.
(2) The materials exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source.
(3) The materials are present in such limited quantity that a hazard of fire development or spread is minimal.
(4)* The materials are considered by the AHJ to exhibit acceptable fire performance.

A.32.4.5.2(4) It is important that combustible drapes, drops, and similar materials exhibit adequate fire performance. The AHJ might be able to make a judgment of adequate fire performance without requiring testing of the materials. [**140:**A.4.5.2(4)]

(5)* Approved interim measures are provided for the period during which the combustible materials are present.

[**140:**4.5.2]

A.32.4.5.2(5) Examples of interim measures that could be approved by the AHJ include, but are not limited to, the following:

(1) Providing a fire watch
(2) Removing the combustible materials at the end of the day's filming
(3) Keeping lighting and other heat-producing sources away from the combustible materials
(4) Providing baffles around heat-producing sources

[**140:**A.4.5.2(5)]

32.4.5.3 Cut greens shall be treated with an approved or listed fire retardant, and the process shall be repeated as often as necessary to maintain its effectiveness. [**140:**4.5.3]

Cut greens are vegetation separated from the live portion of the plant. Particular attention needs to be given to combustible materials used in close proximity to pyrotechnic and open flame special effects. On-site verification of the fire-retardant properties of set components, furnishings, props, and other combustible materials is essential to ensure the safety of pyrotechnic and open flame special effects. The provisions of 32.4.5 address the need to render drapes, drops, cut greens, foamed plastics, and other combustible materials fire retardant. The five options specified in 32.4.5.2 offer prescriptive and performance-based measures for determining whether drapes and other loosely hanging materials are flame retardant.

32.4.6 Smoking.

32.4.6.1 Smoking shall be prohibited on soundstages and in approved production facilities unless otherwise provided in 32.4.6.2 or 32.4.6.3. [**140:**4.6.1]

Section 10.9 provides additional requirements for regulating smoking.

32.4.6.2 Smoking shall be permitted when it is a necessary part of a performance, and only when the smoker is a member of the cast. [**140:**4.6.2]

32.4.6.3 Except where prohibited by the AHJ, smoking shall be permitted where all of the following conditions are met:

(1) The smoking area is outdoors.
(2) Hazardous materials are not present.
(3) Approved ash trays or receivers are provided.

[**140:**4.6.3]

32.4.7 Structural Loads.

32.4.7.1 Approved production facilities and soundstages shall be designed, constructed, or altered to sustain all structural load combinations in accordance with the local building code. [**140:**4.7.1]

32.4.7.2 Where the anticipated loads exceed those specified in the local building code for the purpose of suspending sets, ceilings, backings, and other heavy production set pieces, the building shall be designed and constructed for the additional loads. [**140:**4.7.2]

32.4.8 Electrical Requirements.

32.4.8.1 Electrical equipment shall be in accordance with Section 11.1. [**140:**4.8.1]

32.4.8.2* Soundstages and approved production facilities shall be provided with a minimum of 35 W/ft2 (377 W/m2) dedicated for production lighting and power. [**140:**4.8.2]

A.32.4.8.2 This requirement does not prohibit the use of mobile generators for auxiliary power. [**140:**A.4.8.2]

Δ **32.4.8.3** The electrical distribution equipment used shall comply with UL 1640, *Standard for Portable Power-Distribution Equipment*, and the provisions of Article 530 of NFPA 70. [**140:**4.8.3]

Δ **32.4.8.4** The wiring method to electrical distribution equipment shall comply with the provisions of Article 530 of NFPA 70. [**140:**4.8.4]

32.4.8.5 The location of portable, mobile, or stationary power-generating equipment shall be subject to the approval of the AHJ. [**140:**4.8.5]

See 10.14.10 and 11.7.2 for additional requirements for locating generators.

32.4.8.6 Exterior penetrations shall be located near the predesignated location for portable and mobile power-generating equipment. [**140:**4.8.6]

32.4.8.7 Auxiliary power cables supplied from mobile generators or adjacent buildings shall not be routed through fire-rated windows and doors. [**140:**4.8.7]

Δ **32.4.8.8** Portable feeder cables shall be permitted to temporarily penetrate fire-rated walls, floors, or ceilings, provided that all of the following apply:

(1) The opening is of noncombustible material.
(2) When in use, the penetration is sealed with a temporary seal of a listed firestop material.
(3) When not in use, the opening shall be capped with a material of equivalent fire rating.

[**140:**4.8.8]

32.4.8.9 Where the penetration utilizes a conduit, metal-threaded caps shall be attached to the pipe by means of chain or cable and shall effectively cap the conduit when not in use. [**140:**4.8.9]

Δ **32.4.8.10** The lighting equipment used shall comply with UL 1573, *Standard for Stage and Studio Luminaires and Connector Strips*, and the provisions of Article 530 of NFPA 70. [**140:***4.8.10*]

32.4.9 Fire Department Access. Fire department access shall be maintained as required by the AHJ. [**140:**4.9]

Section 18.2 provides detailed requirements for fire department access.

32.4.10 Means of Egress.

Δ **32.4.10.1** Means of egress shall be in accordance with NFPA *101* unless otherwise modified by 32.4.10.2 through 32.4.10.6. [**140:**4.10.1]

32.4.10.2 The maximum travel distance to an exit within the soundstage shall be 150 ft (45 m). [**140:**4.10.2]

32.4.10.3 Soundstages and approved production facilities shall have an aisle along the perimeter of the soundstage or facility as approved by the AHJ unless otherwise provided in 32.4.10.3.2. [**140:**4.10.3]

32.4.10.3.1 A clear unobstructed aisle height of 7 ft (2.1 m) shall be maintained. [**140:**4.10.3.1]

32.4.10.3.2 A soundstage or approved production facility with a gross area not exceeding 1500 ft² (139 m²) shall be exempt from the perimeter aisle requirement of 32.4.10.3 provided there is a minimum of two means of egress. [**140:**4.10.3.2]

Δ **32.4.10.4** Emergency lighting shall be provided for the means of egress in accordance with NFPA *101*. [**140:**4.10.4]

32.4.10.5 Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if it is panic hardware or fire exit hardware. [**140:**4.10.5]

32.4.10.6 Means of egress shall be kept clear of obstructions and tripping hazards. [**140:**4.10.6]

Section 32.4.10 refers back to NFPA *101*®, *Life Safety Code*®, for means of egress and emergency lighting requirements. The means of egress and emergency lighting requirements of the appropriate occupancy in NFPA *101* apply unless modified by 32.4.10.2 through 32.4.10.6. Emergency egress perimeter aisles required by 32.4.10.3 must be identified and kept clear. Where conduit or wires pass through such areas, they must be elevated above the 7 ft (2.1 m) height as required by 32.4.10.3.1 or provided with a clearly identified ramp over the installations. See Exhibit 32.1 for an example of cables properly protected in an aisle.

Δ **32.4.10.7** When an audience is present, an announcement shall be made notifying the audience of the following:

(1) The location of exits to be used in case of fire or other emergency
(2) The means that will be used to notify the audience of fire or other emergency

[**140:**4.10.7]

Exhibit 32.1

Example of properly protected cables in an aisle.

The requirement of 32.4.10.7 is consistent with the requirements of NFPA *101*, which also require emergency instructions to be provided to audience members prior to the commencement of theatrical performances. See 12.7.7.3 and 13.7.7.3 of NFPA *101*.

32.4.11 Fire Protection.

32.4.11.1 Extinguishment Requirements.

32.4.11.1.1 Existing soundstages and existing approved production facilities equipped with automatic sprinkler systems shall maintain those systems in accordance with 13.3.3. [**140:**4.11.1.1]

32.4.11.1.2 A new soundstage or new approved production facility shall be equipped with an approved, supervised automatic sprinkler system. [**140:**4.11.1.2]

32.4.11.1.3 The automatic sprinkler system required by 32.4.11.1.2 shall be installed in accordance with Section 13.3, unless otherwise provided in 32.4.11.1.3.1 or 32.4.11.1.3.2. [**140:**4.11.1.3]

32.4.11.1.3.1* The requirements of NFPA 13 prohibiting obstructions to sprinkler discharge shall not be applicable if approved mitigation is employed. [**140:**4.11.1.3.1]

A.32.4.11.1.3.1 Paragraphs 32.4.11.1.3.1 and 32.4.11.1.3.2 recognize motion picture and television industry practices that require sets to change constantly and that sets are "temporary" construction not subject to building codes or standards. Solid ceilings that obstruct the stage sprinklers are "flown" (moved) in or out to permit special shooting angles or lighting requirements, often on a scene-by-scene basis. With temporary walls and ceilings, it would be impractical to install a sprinkler system in a constantly changing structure. Therefore, one or more of the following mitigation techniques should be used to compensate for the areas shielded from sprinkler spray by solid or hard ceilings or platforms:

(1) Approved and listed heat detectors or smoke detectors can be installed beneath such solid or hard ceilings in excess of 600 ft^2 (55.7 m^2) in area and platforms in excess of 600 ft^2 (55.7 m^2) in area and 3 ft (0.9 m) in height. Detectors should be connected to an approved and listed central, proprietary, or remote station service or to a local alarm that will provide an audible signal (i.e., a bell or horn) at a constantly attended location. The detector system, including the alarm panel, is defined as a portable system because it is intended to be reinstalled when platforms or sets are changed. The detectors that are secured to standard outlet boxes and the listed fire alarm panels can be temporarily supported by sets, platforms, or pedestals. Spacing of detectors should be per manufacturers' requirements.
(2) The ceiling can be positioned to allow for the operation of the building's automatic fire sprinkler system after videotaping, filming, or broadcasting of programs has been completed for the day.
(3) A fire watch should be provided when the set is not in use.
(4) No combustible materials should be stored under any platforms. Consideration should be given to secure such covered areas with screen wire or other materials that will permit visual inspection and emergency access.
(5) Approved/listed fire retardants can be applied beneath combustible platforms.
(6) Approved/listed fire retardants can be applied to scenery, props, framework and deck of combustible platforms, and the hard-ceilings of combustible sets.

[**140:**A.4.11.1.3.1]

Motion picture and television productions need the ability to film from a multitude of angles. This need for flexibility requires the construction of platforms to elevate the actors and stages, as well as the use of movable walls and ceilings, which are constantly repositioned during filming.

In the example provided in A.32.4.11.1.3.1, smoke detectors are positioned according to the main wood platform manufacturer's specifications. When the ceiling is removed or "flown" away, as shown in Exhibit 32.2, the smoke detector wiring remains operational. Automatic sprinklers for theatrical purposes are also shown in Exhibit 32.3. The AHJ should inspect such installations

Exhibit 32.2

Smoke detector above a grid ceiling.

Exhibit 32.3

Automatic sprinklers on a production set.

Exhibit 32.4

Platform protected from storage being placed underneath.

to determine whether the sprinklers are operational or nonfunctioning set components. Exhibit 32.4 shows a platform side with a screen wall to prevent the placement of storage beneath it.

32.4.11.1.3.2* The requirements of NFPA 13 prohibiting obstructions to sprinkler discharge shall not be applicable if the building sprinkler system meets the design criteria for Extra Hazard, Group 2. [**140:**4.11.1.3.2]

A.32.4.11.1.3.2 See A.32.4.11.1.3.1. [**140:**A.4.11.1.3.2]

32.4.11.1.4 The automatic sprinkler system required by 32.4.11.1.2 shall be maintained in accordance with 13.3.3. [**140:**4.11.1.4]

32.4.11.1.5 Portable fire extinguishers shall be installed and maintained in accordance with Section 13.6. [**140:**4.11.1.5]

Δ **32.4.11.2 Fire Alarm System.** Fire alarm system notification appliances within soundstages and approved production facilities shall be permitted to be deactivated with the approval of the AHJ during videotaping, filming, or broadcasting of programs provided the following conditions exist:

(1) In the event of alarm system activation, notification appliances shall activate at a location that is constantly attended during the videotaping, filming, or broadcasting of programs.
(2) The attendants of the location identified in 32.4.11.2(1) shall be provided with a means of communicating with the fire command center for the building, where one is provided, and with the occupants of the soundstage to initiate emergency action.
(3) Deactivation of notification appliances shall cause activation of a visual signal at an approved location, which shall remain illuminated while notification appliances on the soundstage are deactivated.
(4) The visual signal shall be identified by a sign that shall read, "When Illuminated, Soundstage Fire Alarm System Notification Appliances Are Deactivated."

[**140:**4.11.2]

32.4.12 Air Conditioning, Heating, and Ventilating. Air-conditioning, heating, and ventilating ductwork and related equipment shall be in good working order and in compliance with the requirements of the AHJ. [**140:**4.12]

32.5 Production Locations

32.5.1 General. Section 32.5 shall apply to production locations. [**140:**5.1]

Δ **32.5.2 Permits.** A permit shall be obtained, unless waived by the AHJ, for any of the following activities:

(1)* Use of the site as a production location

A.32.5.2(1) The AHJ might waive the production location permit provided the AHJ is notified that the site is to be used as a production location. [**140:**A.5.2(1)]

(2) Use of pyrotechnic special effects
(3) Use of open flames
(4) Welding
(5) Use of flammable or combustible liquids or gases
(6) Use of aircraft
(7) Presence of motor vehicles within a building

[**140:**5.2]

Depending on the production being filmed, some permits are issued on an annual basis. Other permits, such as for open flames, live audiences, and pyrotechnics, are issued by the AHJ for each event and sometimes require the presence of standby fire personnel during some or all of the production. See 1.7.17 for additional guidance on standby fire personnel.

32.5.3 Pyrotechnic Special Effects and Open Flames.

32.5.3.1 The use of pyrotechnic special effects and open flames shall be subject to the approval of the AHJ. [**140:**5.3.1]

32.5.3.2 When an audience is present, NFPA 1126 shall be used to regulate any pyrotechnic use. [**140:**5.3.2]

32.5.3.3 When an audience is present, NFPA 160 shall be used to regulate any flame effects use. [**140:**5.3.3]

NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*, and NFPA 160, *Standard for the Use of Flame Effects Before an Audience*, apply only when an audience is present; however, in all situations, the safe use of pyrotechnic special effects and open flames must be determined by the AHJ in accordance with 32.5.3.1. See Section 65.3 for additional requirements for pyrotechnics before a proximate audience. See Section 65.4 for additional requirements for flame effects before an audience.

32.5.4 Standby Fire Personnel.

32.5.4.1 Pyrotechnics. Standby fire personnel shall be required for production locations where pyrotechnic special effects are used, unless otherwise waived by the AHJ. [**140:**5.4.1]

Subsection 1.7.17 provides additional requirements for standby fire personnel.

32.5.4.2 Other Hazards. Where required by the AHJ, standby fire personnel shall be provided for hazardous operations, other than pyrotechnic special effects. [**140:**5.4.2]

32.5.5 Foamed Plastic Materials. Foamed plastic materials used for decorative purposes, scenery, sets, or props shall have a heat release rate not exceeding 100 kW when tested in accordance with UL 1975, *Fire Tests for Foamed Plastics Used for Decorative Purposes*, or where tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source. [**140:**5.5]

32.5.6 Smoking.

32.5.6.1 Smoking shall be prohibited in production location buildings unless otherwise provided in 32.5.6.2 or 32.5.6.3. [**140:**5.6.1]

See Section 10.9 for additional guidance on smoking prohibitions.

32.5.6.2 Smoking shall be permitted when it is a necessary part of a performance, and only when the smoker is a member of the cast. [**140:**5.6.2]

Δ **32.5.6.3** Except where prohibited by the AHJ, smoking shall be permitted where all of the following conditions are met:

(1) The smoking area is outdoors.
(2) Hazardous materials are not present.
(3) Approved ash trays or receivers are provided.

[**140:**5.6.3]

32.5.7 Structural Loads.

32.5.7.1 Sets, scenery, and other equipment shall not impact the structural integrity of existing buildings. [**140:**5.7.1]

32.5.7.2 Additional loads applied onto the building shall require the approval of the AHJ. [**140:**5.7.2]

32.5.8 Electrical Requirements.

32.5.8.1 Electrical power connections made to the site electrical service shall be made by an approved electrician under permit from the AHJ. [**140:**5.8.1]

32.5.8.2 Portable cables shall be positioned to allow for emergency egress as approved by the AHJ. [**140:**5.8.2]

32.5.8.3* Auxiliary power cables supplied from mobile generators or adjacent buildings shall be permitted to be routed through fire-rated windows and doors with the approval of the AHJ. [**140:**5.8.3]

A.32.5.8.3 The AHJ might approve the routing of power cables through fire-rated windows or doors if standby fire personnel or other approved safeguards are provided during such periods. [**140:**A.5.8.3]

Δ **32.5.8.4** Where power from both mobile generators and site electrical services are used to energize equipment in the same proximate location at production locations, grounds for the two systems shall be bonded in accordance with *NFPA 70*. [**140:**5.8.4]

32.5.9* Fire Department Access. Fire department access shall be maintained as required by the AHJ. [**140:**5.9]

A.32.5.9 The AHJ, when granting a permit to a production company to film on location should consider the placement of the support equipment. Typically, the production support vehicles are numerous, and unregulated placement of these vehicles could impede emergency access or egress. Additionally, the types of support vehicles need to be arranged so that a hazardous operation (e.g., fueling or special effects) is distant from sources of ignition and crew gathering areas (e.g., catering locations). The location permit should include a plot plan so the AHJ can adequately assess potential problems. [**140:**A.5.9]

32.5.10* Means of Egress. The production location shall be provided with means of egress appropriate for the intended use as approved by the AHJ. [**140:**5.10]

A.32.5.10 Where a production company films *on location*, such activity might interfere with, or prevent, the normal use of the facility or area. As such, the facility being occupied as a production location is often used for a purpose different from that of its normal use. Where the production company filming causes the facility or area to curtail normal operations, the facility should not be required to meet the life safety provisions applicable to the normal occupancy. Rather, life safety features should be maintained consistent with provisions required for the temporary use. For example, consider a single story assembly occupancy building with occupant load of 600 persons that has three exits for compliance with the provision of NFPA *101*, that requires a minimum of three exits where the occupant load of a floor exceeds 500 persons. The assembly occupancy building is used as a production location for a total of 200 persons. The production crew presents, for approval of the AHJ, a plan to block off one of the three exits while maintaining compliance with the requirements for egress width, travel distance, common path of travel, and dead-end corridors. The AHJ approves the proposed means of egress as appropriate for the intended use as required by 32.5.10. [**140:**A.5.10]

32.5.11 Fire Protection.

32.5.11.1* Building areas used as production locations shall be designed, constructed, and maintained to protect the occupants not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place. [**140:**5.11.1]

A.32.5.11.1 The phrase "intimate with the initial fire development" refers to the person(s) at the ignition source or first materials burning, not to all persons within the same room or area. [**140:**A.5.11.1]

The occupant protection requirement of 32.5.11.1 is the same as that required for all occupancies by NFPA *101*. The activities associated with filming at a production location without an audience are characteristic of the occupancy classification of industrial occupancy. Industrial occupancies are not required by NFPA *101* to be sprinklered. The objective of protecting occupants not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place is accomplished for industrial occupancies by prescriptive provisions not dependent on sprinkler protection. [**140:**A.5.11.1]

Where production location filming occurs in a building area not provided with the life safety systems required for industrial occupancies (e.g., in a tower with a single means of egress provided by an unenclosed stair), sprinklers, a fire alarm system, or other mitigation techniques acceptable to the AHJ will need to be employed for compliance with 32.5.11.1. Where sprinklers are provided, see 32.5.11.2 and 32.5.11.6. [**140:**A.5.11.1]

32.5.11.2 Where an automatic sprinkler system is provided for compliance with 32.5.11.1, the automatic sprinkler system shall be installed in accordance with Section 13.3, unless otherwise provided in 32.5.11.4 or 32.5.11.5. [**140:**5.11.2]

32.5.11.3 In any production location building protected by an existing automatic sprinkler system, where solid- or hard-ceiling sets or platforms are introduced to create an obstruction to sprinkler discharge, the provisions of 32.5.11.4 or 32.5.11.5 shall be met. [**140:**5.11.3]

32.5.11.4* The requirements of NFPA 13 prohibiting obstructions to sprinkler discharge shall not be applicable if approved mitigation is employed. [**140:**5.11.4]

A.32.5.11.4 See A.32.4.11.1.3.1. [**140:**A.5.11.4]

Where a production company installs a platform or solid-ceiling set in a building at a production location that is protected by an automatic sprinkler system, one or more of the mitigation techniques outlined in A.32.4.11.1.3.1 should be used to compensate for the areas shielded from sprinkler spray.

32.5.11.5* The requirements of NFPA 13 prohibiting obstructions to sprinkler discharge shall not be applicable if the building sprinkler system meets the design criteria for Extra Hazard, Group 2. [**140:**5.11.5]

A.32.5.11.5 See A.32.4.11.1.3.1. [**140:**A.5.11.5]

32.5.11.6 Automatic sprinkler systems, where provided, shall be maintained in accordance with 13.3.3. [**140:**5.11.6]

32.5.11.7 Portable fire extinguishers shall be provided as required by the AHJ. [**140:**5.11.7]

32.5.11.8 Fire Hydrants and Fire Appliances. Hydrants, standpipes, and fire department connections (FDCs) shall not be obstructed, blocked, or rendered inoperable unless approved by the AHJ. [**140:**5.11.8]

32.6 Operating Features

32.6.1 Waste or Refuse. Waste or refuse shall not be allowed to accumulate in any area or in any manner that creates a fire hazard. [**140:**6.1]

Chapter 19 provides additional requirements for waste removal.

32.6.2 Flammable or Combustible Liquids.

32.6.2.1 The use, mixing, dispensing, and storage of flammable or combustible liquids shall be in accordance with this *Code* and the following codes, as applicable, unless otherwise permitted by 32.6.2.2:

(1) NFPA 30, *Flammable and Combustible Liquids Code (See Chapter 66.)*

(2) NFPA 58, *Liquefied Petroleum Gas Code (See Chapter 69.)* [**140:**6.2.1]

Chapter 66 regulates the storage, use, and handling of flammable and combustible liquids. Chapter 69 regulates the storage, use, and handling of liquefied petroleum gas (LP-Gas).

32.6.2.2 Approved flammable or combustible liquids and liquefied petroleum gases used for special effects shall be permitted. [**140:**6.2.2]

Δ **32.6.3 Welding.** Welding shall be in accordance with NFPA 51 and NFPA 51B. *(See Chapter 41.)* [**140:**6.3]

Chapter 41 provides additional requirements for welding, cutting, and other hot work.

32.6.4* Audience Life Safety. When an audience is present during productions, provisions for life safety and means of egress shall be subject to the approval of the AHJ. [**140:**6.4]

A.32.6.4 Special attention should be focused on any possible obstructions to the means of egress. The means of egress and the marking of it might be confusing to the audience due to the numerous bright lights, scenery, video and film cameras, and other equipment in and around the soundstage. [**140:**A.6.4]

Where 50 or more audience members are present, the production facility takes on the life safety risks of an assembly occupancy. As such, the requirements of Chapters 12 and 13 of NFPA *101*, applicable to new and existing assembly occupancies, respectively, must be followed to ensure audience safety. Audience members might not be familiar with the facility's means of egress arrangement or the potential hazards associated with the production. For such assembly uses, the presence of at least one trained crowd manager is of paramount importance. See 20.1.5.6 and NFPA *101* for additional details on the requirements for crowd managers.

32.6.5 Emergency Services Notification. The production company shall provide a procedure acceptable to the AHJ for notifying the public emergency services of emergency incidents. [**140:**6.5]

33

Outside Storage of Tires

Chapter 33 addresses new and existing outside storage piles of tires and altered tire material, as well as emergency response planning, fire control measures, site access, and signs and security for these areas.

33.1* General

Δ **A.33.1** Fire service professionals who have managed major scrap tire piles believe that the best approach is to allow the tire pile to burn while protecting exposures like buildings, heavy equipment, and surrounding tire piles. Once the tire pile is in a smoldering stage, heavy equipment can be used to pull the pile apart and the tire material can be extinguished incrementally. For additional information, see *Rings of Fire: Tire Fire Prevention and Suppression*.

33.1.1 Facilities storing more than 500 tires outside shall be in accordance with Chapter 33.

The outdoor storage of tire piles of not more than 500 tires can be typically found behind retail tire stores. Standard fire-fighting operational guidelines using water and/or foam for tire piles of fewer than 500 tires will effectively extinguish fires in such small piles in most cases.

Chapter 33 covers outdoor tire pile storage of more than 500 tires and the potential for large-scale environmental disasters, such as the 1999 Westley tire fire in California, shown in Exhibit 33.1. A lightning strike ignited the pile, which contained an estimated 7 million scrap tires. The fire burned for 30 days and significantly impacted the environment due to the runoff of pyrolitic oil and contaminated fire-fighting water. The cost of the fire to the U.S. Environmental Protection Agency was $3.5 million.

Exhibit 33.1

Large tire fire.

33.1.2 Permits. Permits, where required, shall comply with Section 1.12.

Per Table 1.12.8(a), permits are required to use an open area or portion thereof to store tires in excess of 500 tires.

33.1.3 Fire department access roads to separate tire piles and for effective fire-fighting operations shall be in accordance with Table 33.1.3.

Table 33.1.3 was developed from research conducted by the University of California, Berkeley, and sponsored by the California State Fire Marshal's Office. Whole, bundled, and shredded tires were burned to study the radiant heat flux from the various tire pile configurations. The data collected were then computer modeled to develop the specified separation distances.

Exhibit 33.2 shows 100 whole tires being tested for radiant heat by UC Berkeley.

The requirement for fire department access roads provides two functions: (1) to provide access to the tire piles by fire apparatus and (2) to provide a fuel break between tire piles to prevent fire spread. See 18.2.3 for more information on fire department access roads.

33.1.4 Separation of yard storage from buildings, vehicles, flammable materials, and other exposures shall be in accordance with Table 33.1.3.

33.1.5 Trees, plants, and vegetation within the separation areas shall be managed in accordance with Section 10.13.

Off-site vegetation fires have been known to start tire pile fires. Proper maintenance of vegetation at the facility perimeter, as well as between tire piles, helps to mitigate this risk.

***TABLE 33.1.3** Representative Minimum Exposure Separation Distances in Feet (Meters) for Tire Storage*

Exposed Face Dimension		Pile Height													
ft	m	8 ft	2.4 m	10 ft	3 m	12 ft	3.7 m	14 ft	4.3 m	16 ft	4.9 m	18 ft	5.5 m	20 ft	6.1 m
25	7.6	56	17	62	19	67	20	73	22	77	23	82	25	85	26
50	15.2	75	23	84	26	93	28	100	30	107	33	113	34	118	36
100	30	100	30	116	35	128	39	137	42	146	44	155	47	164	50

Exhibit 33.2

Tires being tested for radiant heat.

33.1.6 Ignition Sources.

All ignition sources should be prohibited within the tire storage facility. Where ignition sources must be present for operational purposes, such as vehicles or equipment, additional safeguards should be required to prevent ignition of the tire storage piles. Safeguards, such as spark arresters on vehicle and equipment exhaust systems, along with fire extinguishers mounted on vehicles, are appropriate fire control measures. See Section 13.6 and NFPA 10, *Standard for Portable Fire Extinguishers*, for additional details on portable fire extinguishers. Also see Section 10.17 and NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations*, for additional details on powered industrial trucks.

33.1.6.1 Smoking shall be prohibited within the tire storage area.

33.1.6.2 Sources of ignition such as cutting and welding, heating devices, and open fires shall be prohibited within the tire storage area.

33.1.6.3 Safeguards shall be provided to minimize the hazard of sparks from equipment such as refuse burners, boiler stacks, and vehicle exhaust when such hazards are located near the tire storage area.

33.1.7 Piles of tires or altered tire material shall not be located beneath power lines or structures.

The requirement of 33.1.7, which prohibits the storage of tires under power lines, serves two purposes. First, it eliminates downed electrical power lines as a source of ignition in tire piles. Second, it prevents the radiant heat from large tire pile fires from burning through power lines, disrupting service.

The roadside storage of whole tires beneath power lines and in a storm drain, as shown in Exhibit 33.3, is not considered *Code* compliant.

33.1.8 Piles of tires or altered tire material shall be at least 50 ft (15 m) from the perimeter fence.

33.1.9 Provisions for surface water drainage and measures to provide protection of pyrolitic oil runoff shall be directed around and away from the outdoor tire storage site to an approved location.

An average passenger car tire has been estimated to contain up to 2 gal (7.6 L) of pyrolitic oil. Much of the pyrolitic oil is burned off when the stored tire pile is allowed to freely burn. Once the tire pile begins to smolder, or if the combustion process is hampered by suppression efforts, the tires melt and release pyrolitic

Exhibit 33.3

Tire storage configuration that is not code compliant.

Exhibit 33.4

Westley, California, tire fire.

Exhibit 33.5

Tire pile and fire in abandoned quarry.

oil. The Westley, California, tire pile fire, for example, generated at least 250,000 gal (946,000 L) of pyrolitic oil. The Westley tire pile was located in a box canyon, as shown in Exhibit 33.4. The cogeneration plant that burned tires for electricity is seen in the background; the containment dam full of pyrolitic oil is shown in the foreground.

33.1.10 Tires shall be removed from rims immediately upon arrival at the storage site.

Tires stored on rims can reinflate to the point of bursting in the extreme temperatures generated by tire fires. Rims involved in a tire fire will contribute heavy metals, such as chromium and cadmium, to the smoke and ash. Rims can also be made from combustible metals, such as magnesium and titanium, which provide additional hazards and challenges to fire-fighter safety and fire extinguishment. Tires are required to be removed from their rims prior to being placed in storage to mitigate such hazards.

33.1.11 Tires shall not be stored on wetlands, flood plains, ravines, canyons, or steeply graded surfaces.

Site location of tire storage is an important consideration. Tires should not be stored where runoff control is impractical, such as on steeply graded surfaces, ravines, and canyons. Similarly, the potential pyrolitic oil runoff precludes the storage of tires in areas that are proximate to surface and groundwater sources, such as wetlands and flood plains. Tires and tire piles stored on inclines have the potential to become unstable under fire conditions, causing tires to roll down the incline and spread fire to other piles or buildings.

The tire pile shown in Exhibit 33.5 was sited in an abandoned sand and gravel quarry in Tracy, California. A grass fire ignited the tires at the facility in 1998, and the resulting fire was allowed to burn for more than 2 years to prevent the pyrolitic oil from entering the underground water supply, which was located only 80 ft (24 m) from the bottom of the quarry.

33.2 Individual Piles

The tire storage arrangements specified in Section 33.2 provide a measure of safety for employees and for fire fighters working at a tire pile fire. Limitations on pile size impact the size of the fuel package, which leads to smaller fires and facilitates rapid extinguishment.

33.2.1 New Outside Tire Storage Sites and Piles.

33.2.1.1 New individual outside tire storage piles containing more than 500 tires shall be limited in volume to 125,000 ft^3 (3540 m^3).

33.2.1.2 The dimensions of new tire storage piles shall not exceed 10 ft (3 m) in height, 50 ft (15 m) in width, and 250 ft (75 m) in length.

33.2.1.3 Individual piles shall be separated in accordance with Table 33.1.3.

33.2.2 Existing Individual Piles.

The *Code* recognizes that many tire storage facilities are existing facilities. Such existing facilities that do not meet the requirements for existing tire piles must bring their tire piles into compliance. All existing tire piles must be brought into compliance with the new outside tire storage site and pile requirements of 33.2.1 within 5 years of the adoption of this *Code*. If a previous edition of NFPA 1, *Fire Code,* was adopted in the jurisdiction, the *Code's* intent is to require compliance within 5 years of the adoption of that previous edition where the previous edition contains such requirement. The 5-year compliance requirement first appeared in the 2006 edition of NFPA 1. The *Code's* intent is to not permit an additional 5-year grace period each time a new edition of the *Code* is adopted by the jurisdiction.

33.2.2.1 Existing outside tire storage piles shall be in accordance with the provisions of 33.2.1 within 5 years of the adoption of this *Code*.

33.2.2.2 Existing individual outside tire storage piles containing more than 500 tires shall be limited in volume to 250,000 ft^3 (7080 m^3).

33.2.2.3 Existing pile dimensions shall not exceed 20 ft (6 m) in height, 50 ft (15 m) in width, and 250 ft (75 m) in length.

33.2.2.4 Individual piles shall be separated in accordance with Table 33.1.3.

33.3 Emergency Response Plan

Fire departments that have large tire piles in their jurisdictions should be actively involved in the development of emergency response plans. Effective preplanning for potential tire fire emergencies will save time and energy if resources and contact information are identified in advance.

33.3.1 The operator of the outside tire storage facility shall develop an emergency response plan and submit it for approval by the AHJ.

33.3.2 The AHJ shall retain a copy of the approved emergency response plan.

33.3.3 The operator of the outside tire storage facility shall keep a copy of the approved emergency response plan at the facility.

33.3.4 The AHJ shall be immediately notified of and approve any proposed changes to the emergency response plan.

33.4 Fire Control Measures

Measures to aid in the control of fire shall be in accordance with Section 33.4.

The requirements of Section 33.4 are intended to provide the employees of a tire storage facility the tools to mitigate a tire fire in its incipient stage. This section gives the authority having jurisdiction (AHJ) the flexibility to require the additional equipment and/or supplies it deems necessary to manage a fire in a particular facility. The quicker manual fire-fighting operations commence, the easier extinguishment will be. Personnel should be familiar with, and trained on, the emergency plan, locations and operation of fire-fighting equipment, and operating procedures for the machinery used to separate piles. Personnel should know how to notify the fire department and should be aware of the need to notify the fire department as soon as possible.

33.4.1 Manual Fire-Fighting Equipment.

33.4.1.1 At a minimum, the following items shall be maintained on site and in working order:

(1) One 2-A:10-B:C fire extinguisher
(2) One 2.5 gal (10 L) water extinguisher
(3) One 10 ft (3 m) long pike pole
(4) One rigid rake
(5) One round point shovel
(6) One square point shovel

33.4.1.2 One dry chemical fire extinguisher with a minimum rating of 4-A:40-B:C shall be carried on each piece of fuel-powered equipment used to handle scrap tires.

33.4.1.3 On-site personnel shall be trained in the use and function of this equipment to mitigate tire pile ignition.

33.4.2 An approved water supply capable of supplying the required fire flow to protect exposures and perform fire suppression and overhaul operations shall be provided.

Large volumes of water are essential for quick extinguishment of tire fires. See Sections 18.3 and 18.4 for additional information on providing an adequate water supply.

33.4.3* The AHJ shall be permitted to require additional tools and equipment for fire control and the protection of life and property.

A.33.4.3 This can include but is not limited to the availability of earth-moving equipment or other approved means of controlling a fire.

33.5 Site Access

33.5.1 Access to the site and each tire storage yard and pile shall be in accordance with Section 18.2 and this section.

Section 18.2 addresses fire department access roads and access boxes. Fire department access is important to ensure that fire-fighting apparatus and equipment can reach the site in a timely manner in the event of an emergency.

33.5.2 Accesses shall be maintained clear of combustible waste or vegetation and shall remain accessible to the fire department at all times.

Access gates should be kept clear of vegetation, combustible waste, and other materials that can prevent their use. Many times, due to the size of tire storage facilities, multiple access points are provided.

33.6 Signs and Security

Access by unauthorized persons and security of the site shall be in accordance with Section 33.6.

Steps should be taken to prohibit unauthorized individuals from entering tire storage sites. Complete fencing of the site can help to prevent unauthorized access.

33.6.1 Signs bearing the name of the operator, the operating hours, emergency telephone numbers, and site rules shall be posted at site entrances.

33.6.2 The facility shall have noncombustible fencing at least 10 ft (3 m) high with intruder controls on top, in accordance with local laws, around the entire perimeter of the property.

33.6.3 Access.

33.6.3.1 Access to the facility shall be in accordance with Section 18.2.

33.6.3.2 An attendant shall be on site at all times when the site is open.

33.7 Outdoor Storage of Altered Tire Material

Outdoor storage of altered tire material in the form of chunks, chips, or crumbs shall be protected in accordance with 33.7.1 through 33.7.5.

Tires are often chipped into smaller pieces to aid in future processing and removal. These pieces present a unique fire problem compared to intact tires, due to their compact size and tighter packing. During the chipping process, certain portions of the tires that are not normally exposed to the air are exposed (e.g., steel belts). If these materials are exposed to moisture, they will oxidize and could spontaneously combust.

33.7.1 A 10 ft (3 m) fence shall be maintained around the altered tire material storage area.

33.7.2 Altered tire material piles shall be kept 50 ft (15 m) from perimeter fencing.

33.7.3 Potential ignition sources such as welding, smoking, or other open flame uses shall not be allowed within 20 ft (6 m) of the altered tire pile.

33.7.4 Individual altered tire material piles shall not be located on site in excess of 90 days.

33.7.5* Individual altered tire material piles shall be kept sheltered from precipitation.

A.33.7.5 Altered tire material piles have been known to spontaneously combust after a heavy precipitation. Investigators have considered anaerobic action and potential heat from oxidation of steel belts as the source of exothermic reaction.

General Storage

34

Chapter 34 addresses fire protection for general storage facilities. The term *storage occupancy* is defined in 3.3.192.31 as "an occupancy used primarily for the storage or sheltering of goods, merchandise, products, or vehicles." These occupancies contain a wide variety of stored material, including materials from commodity Class I through Class IV (as defined by NFPA 13, *Standard for the Installation of Sprinkler Systems*), plastics, rubber tires, rolled paper, and other special commodities. The requirements of Chapter 34 originally came from NFPA 230, *Standard for the Fire Protection of Storage*, which was withdrawn in 2005.

34.1 General

34.1.1 Application. This chapter shall apply to the indoor and outdoor storage of materials representing the broad range of combustibles, including plastics, rubber tires, and roll paper.

34.1.1.1 Storage configurations shall include palletized storage, solid-piled storage, and storage in bin boxes, on shelves, or on racks.

34.1.1.2 Chapter 34 shall not apply to the following:

(1) Storage of commodities that, with their packaging and storage aids, would be classified as noncombustible
(2) Unpackaged bulk materials such as grain, coal, or similar commodities but excluding wood chips and sawdust, which are addressed in Chapter 31
(3) Inside or outside storage of commodities covered by this *Code*, except where specifically mentioned herein (e.g., pyroxylin plastics)

See Chapter 33 for requirements for outdoor tire storage.

(4) Storage of high-hazard materials covered by this *Code*, except where specifically mentioned herein

See Chapters 60 through 75 for additional storage requirements for hazardous materials.

(5) Storage on plastic shelves on racks
(6)* Miscellaneous tire storage

A.34.1.1.2(6) The limitations on the type and size of storage are intended to identify those situations where tire storage is present in limited quantity and incidental to the main use of the building. Occupancies such as aircraft hangars, automobile dealers, repair garages, retail storage facilities, automotive and truck assembly plants, and mobile home assembly plants are types of facilities where miscellaneous tire storage could be present. The fire protection sprinkler design densities specified by NFPA 13 are adequate to provide protection for the storage heights indicated. Storage beyond these heights or areas presents hazards that are addressed by this *Code* and are outside the scope of NFPA 13.

(7) Combustible fiber storage, which is covered in Chapter 45

The *Code* defines the term *miscellaneous tire storage* as the storage of rubber tires that is incidental to the main use of the building and does not exceed 2000 ft² (186 m²). On-tread storage piles, regardless of storage method, must not exceed 25 ft (7.6 m) in the direction of the wheel holes. Acceptable miscellaneous tire storage arrangements include the following:

1. On-floor, on-side storage up to 12 ft (3.7 m) high
2. On-floor, on-tread storage up to 5 ft (1.5 m) high
3. Double-row or multirow fixed or portable rack storage, on-side or on-tread, up to 5 ft (1.5 m) high
4. Single-row fixed or portable rack storage, on-side or on-tread, up to 12 ft (3.7 m) high
5. Laced tires in racks up to 5 ft (1.5 m) high

The miscellaneous storage of car or truck tires in facilities such as automobile service centers presents significant fire safety concerns. Burning tires tend to create very hot and smoky fires that are difficult to control and extinguish. Because of tire geometry, inherent flue spaces permit unobstructed air supply during a fire. Additionally, fires burning on the interior surface of tires are often obstructed from sprinkler system discharge.

See Exhibit 34.1 through Exhibit 34.4 for examples of different types of tire storage.

34.1.2 Permits. Permits, where required, shall comply with Section 1.12.

34.2 Classification of Commodities

34.2.1 Commodity classification and the corresponding protection requirements shall be determined based on the makeup of individual storage units (i.e., unit load, pallet load). [**13:**5.6.1.1.1]

N **34.2.1.1** The type and amount of materials used as part of the product and its primary packaging as well as the storage pallet shall be considered in the classification of the commodity. [**13:**5.6.1.1.1.1]

34.2.2 When specific test data of commodity classification by a nationally recognized testing agency are available, the data shall be permitted to be used in determining classification of commodities. [**13:**5.6.1.1.2]

One of the main reasons that specific test data are required when determining the commodity classification of a new or unknown commodity is that the current ability of an engineering analysis is incapable of defining sprinkler suppression characteristics.

34.2.3 Mixed Commodities.

In many cases, fire testing for storage of mixed commodities has shown that the fire takes on the characteristics of the higher commodity. For that reason, the requirements of 34.2.3 were developed to provide guidance on choosing the appropriate commodity classification to govern sprinkler system design. Exhibit 34.5 shows a mixed commodity arrangement typical of any big-box home improvement store.

34.2.3.1 Protection requirements shall not be based on the overall commodity mix in a fire area. [**13:**5.6.1.2.1]

34.2.3.2 Unless the requirements of 34.2.3.3 or 34.2.3.4 are met, mixed commodity storage shall be protected by the requirements for the highest classified commodity and storage arrangement. [**13:**5.6.1.2.2]

34.2.3.3 The protection requirements for the lower commodity class shall be permitted to be utilized where all of the following are met:

(1) Up to 10 pallet loads of a higher hazard commodity, as described in 34.2.5 and 34.2.6, shall be permitted to be present in an area not exceeding 40,000 ft^2 (3720 m^2).

Exhibit 34.5

Mixed commodity arrangement in a retail warehouse.

(2) The higher hazard commodity shall be randomly dispersed with no adjacent loads in any direction (including diagonally).
(3) Where the ceiling protection is based on Class I or Class II commodities, the allowable number of pallet loads for Class IV or Group A plastics shall be reduced to five.

[**13:**5.6.1.2.3]

34.2.3.4 Mixed Commodity Segregation. The protection requirements for the lower commodity class shall be permitted to be utilized in the area of lower commodity class, where the higher hazard material is confined to a designated area and the area is protected to the higher hazard in accordance with the requirements of this *Code*. [**13:**5.6.1.2.4]

The fire area anticipated during sprinkler design is often mistakenly assumed to be the same as the sprinkler operating area. In fact, the fire area for successfully controlled storage fires seldom exceeds 200 ft^2 (18.6 m^2) during testing and often is less than 100 ft^2 (9.3 m^2). Regardless of the overall mix of commodities in a storage area, the possibility that 100 ft^2 to 200 ft^2 (9.3 m^2 to 18.6 m^2) of the highest hazard commodity will accumulate always exists.

34.2.4 Pallet Types.

34.2.4.1 General. When loads are palletized, the use of wood or metal pallets, or listed pallets equivalent to wood, shall be assumed in the classification of commodities. [**13:**5.6.2.1]

In addition to wood and metal, as described in 34.2.4.1, pallets are constructed of various reinforced and nonreinforced plastics. The effect on the commodity classification of the plastic-type pallets exhibiting different fire characteristics requires consideration. The requirements in 34.2.4.2 through 34.2.4.7 reflect the results of available test data regarding this issue. Properly identifying plastic pallets as reinforced or unreinforced can have a significant impact on the hydraulic requirements for sprinkler systems. The use of reinforced plastic pallets requires an increase of two commodity classes, which can have a large impact on the amount of water required to meet the intent of the systems. In some cases, this increase in commodity classification can result in the need for major changes to a facility's proposed fire protection, such as modifications to the sprinkler system itself and/or possible upgrades to the water supply (potential need for a fire pump); therefore, proper classification can have a significant financial effect on a project.

34.2.4.2* Unreinforced Plastic Pallets. For Class I through Class IV commodities, when unreinforced polypropylene or unreinforced high-density polyethylene plastic pallets are used, the classification of the commodity unit shall be increased one class. [**13.**5.6.2.2]

A.34.2.4.2 For example, Class III will become Class IV, and Class IV will become a cartoned unexpanded Group A plastic commodity. [**13:**A.5.6.2.2]

34.2.4.2.1 Unreinforced polypropylene or unreinforced high-density polyethylene plastic pallets shall be marked with a permanent symbol to indicate that the pallet is unreinforced. [**13:**5.6.2.2.1]

34.2.4.3* For Class I through Class IV commodities, when reinforced polypropylene or reinforced high-density polyethylene plastic pallets are used, the classification of the commodity unit shall be increased two classes except for Class IV commodity, which shall be increased to a cartoned unexpanded Group A Plastic commodity. [**13:**5.6.2.3]

A.34.2.4.3 For example, Class II will become Class IV, and Class III and Class IV will become a cartoned unexpanded Group A plastic commodity. [**13:**A.5.6.2.3]

34.2.4.3.1 Pallets shall be assumed to be reinforced if no permanent marking or manufacturer's certification of non-reinforcement is provided. [**13:**5.6.2.3.1]

34.2.4.4 No increase in the commodity classification shall be required for Group A plastic commodities stored on plastic pallets. [**13:**5.6.2.4]

34.2.4.5 For ceiling-only sprinkler protection, the requirements of 34.2.4.2 and 34.2.4.3 shall not apply where plastic pallets are used and where the sprinkler system uses spray sprinklers with a minimum K-factor of K-16.8 (240). [**13:**5.6.2.5]

The requirements associated with the impact of the use of plastic pallets on commodity class have been expanded based on available test results. Several types of plastic pallets, including reinforced and nonreinforced polypropylene and high-density polyethylene pallets, have been tested using large-scale calorimeter fire testing.

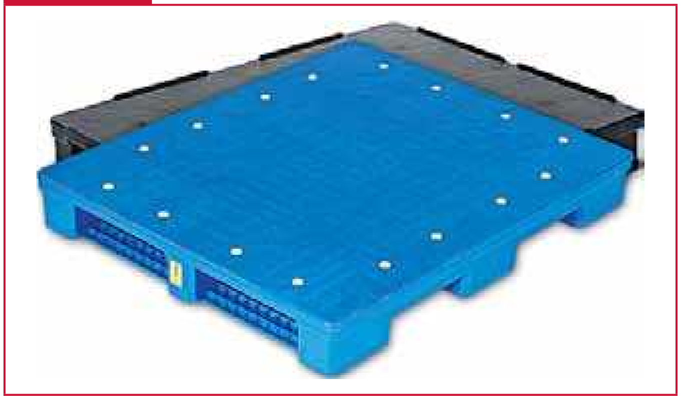
For many pallets, there is no external way to determine if the pallet is reinforced or nonreinforced, so 34.2.4.3 requires that the pallet be assumed to be reinforced. Therefore, a two commodity increase would be required, unless the pallet has a permanent marking or manufacturer's certification of nonreinforcement.

Exhibit 34.6 illustrates a nonreinforced plastic pallet. See also Exhibit 34.7 and Exhibit 34.8 for examples of other plastic pallets.

Exhibit 34.6

Nonreinforced plastic pallet. (Courtesy of ORBIS Corporation)

Exhibit 34.7



Reinforced 40 in. × 48 in. solid deck plastic pallet. (Courtesy of ORBIS Corporation)

Exhibit 34.8

Repairable nonreinforced 40 in. × 40 in. plastic pallet. (Courtesy of ORBIS Corporation)

34.2.4.6 The requirements of 34.2.4.2 through 34.2.4.7 shall not apply to nonwood pallets that have demonstrated a fire hazard that is equal to or less than wood pallets and are listed as such. [**13:**5.6.2.6]

Available full-scale test data for K-16.8 orifice sprinkler devices demonstrated no need for an increase in commodity classification for plastic pallets, as stated in 34.2.4.6.

34.2.4.7 For Class I through Class IV commodities stored on plastic pallets, when other than wood, metal, or polypropylene or high-density polyethylene plastic pallets are used, the classification of the commodity unit shall be determined by specific testing conducted by a national testing laboratory or shall be increased two classes. [**13:**5.6.2.7]

The requirements for adjustments in the commodity classification due to the use of different types of plastic pallets are based on UL 2335, *Standard for Fire Tests of Storage Pallets,* and ANSI/FM 4996, *American National Standard for Classification of Idle Plastic Pallets as Equivalent to Wood Pallets,* large-scale calorimeter tests. Listed plastic pallets are available that exhibit fire performance similar to that of wood pallets in these tests and can be treated as equivalent to wood pallets for commodity classification (see Exhibit 34.9). Actual fire test data from recognized testing laboratories such as FM Global and UL should be reviewed and taken into account to determine if any unique design requirements are needed to protect a specific plastic pallet.

Exhibit 34.9

Classified fire-retardant plastic pallet (40 in. × 48 in.) equivalent to a wood pallet. (Courtesy of ORBIS Corporation)

34.2.5* Commodity Classes.

A.34.2.5 See Table A.34.2.5 [**13:**A.5.6.3].

For the 2016 edition of NFPA 13, Table A.34.2.5 was reformatted. The commodities previously listed in Table A.34.2.5 were reviewed and are now alphabetized under a grouping indicated as the "Product Heading." The previous heading of "Commodity" was changed to "Product," and those items are also alphabetized. Further, products indicated as Group A are listed as either "Expanded" or "Nonexpanded" when the physical state of the plastic is inconsequential. If a product is listed simply as "Group A Plastic" and is not indicated as either "Expanded" or "Nonexpanded," then the physical state of the plastic determines whether to treat it as either expanded or nonexpanded.

Paragraph 34.2.4.7 refers to nonwood pallets that have demonstrated a fire hazard that is equal to or less than that of wood pallets. Plastic pallets present a unique challenge for sprinkler protection. Recent studies and product development, along with significant fire testing, have shown that some plastic pallets have been tested and have demonstrated a fire hazard that is equivalent to or less than the fire hazard presented by wood pallets. Plastic pallets meeting these requirements are specifically listed as such.

The NFPA 13 technical committee conducted a thorough review of all the commodities previously listed in Table A.34.2.5 as well as commodities listed in other codes and standards, such as those from FM Global and XL Gaps and the *International Building Code* (*IBC*). That review resulted in a few changes to the products now listed in Table A.34.2.5, including the introduction of new products such as the following:

1. Appliances with no appreciable exterior plastic but appreciable interior plastic
2. Plastic PET (polyethylene terephthalate) bottles greater than 5 gal (20 L) filled with noncombustible liquids
3. Mineral spirit impregnated charcoal
4. Gypsum board
5. Snack foods

N ***TABLE A.34.2.5*** *Alphabetical Listing of Commodity Classes*

Product Heading	Product	NFPA 13
Batteries	Dry cells (excludes lithium, lithium-ion, and other similar exotic metals or combustible electrolyte); without blister packing (if blister packed refer to commodity classification definitions)	Class I
	Vehicle; any size (e.g., automobile or truck); empty plastic casing	Group A Nonexpanded
	Vehicle; large (e.g., truck or larger); dry or wet (excludes lithium-ion and other cells containing combustible electrolyte) cells	Group A Nonexpanded
	Vehicle; small (e.g., automobile); wet (excludes lithium-ion and other cells containing combustible electrolyte) cells	Class I
Empty Containers	Noncombustible	Class I
	PET, bottles or jars	Class IV
	Rigid plastic (not including PET), up to 32 oz. (1 L)	Group A Nonexpanded
	Rigid plastic (not including PET), greater than 32 oz. (1 L)	Group A Expanded
	Wood; solid sided (e.g., crates, boxes)	Class II
Film Rolls, Including Photographic	Film (polypropylene, polyesther, polyethylene); rolled on any reel type	Group A Nonexpanded
	Film; 35 mm metal film cartridges in polyethylene cans; cartoned	Class III
	Film; motion picture or bulk rolls in polycarbonate, polyethylene or in metal cans; polyethylene bagged; cartoned	Class II
	Film; rolls in polycarbonate plastic cassettes; cartoned	Class IV
	Photographic paper; sheets; bagged in polyethylene; cartoned	Class III
Flammable/Combustible Liquids	Aerosol; Level 1	Class III
	Lighters; butane; blister-packed; cartoned	Group A Nonexpanded
	Liquids; up to 20 percent alcohol (e.g. alcoholic beverages, flavoring extracts); greater than 5 gallon (20 L) plastic containers with wall thickness greater than ¼ in. (6 mm)	Group A Nonexpanded
	Liquids; up to 20 percent alcohol (e.g., alcoholic beverages, flavoring extracts); metal, glass or ceramic containers	Class I
	Liquids; up to 20 percent alcohol (e.g., alcoholic beverages, flavoring extracts); plastic containers greater than 5 gallons (20 L) and wall thickness up to ¼ in. (6 mm)	Class II
	Liquids; up to 20 percent alcohol (e.g., alcoholic beverages, flavoring extracts); up to 5 gallons (20 L) plastic bottles or jars	Class I
	Liquids; up to 20 percent alcohol (e.g., alcoholic beverages, flavoring extracts); wood containers	Class II
Food Products — Frozen	Frozen foods; nonwaxed or nonplastic packaging	Class I
	Frozen foods; plastic trays	Class III
	Frozen foods; waxed or plastic-coated paper packaging	Class II

(continues)

N *TABLE A.34.2.5 Continued*

Product Heading	Product	NFPA 13
Food Products — Non-Frozen	Butter (stick or whipped spread) or margarine (up to 50 percent oil)	Class III
	Dry foods (such as baked goods, candy, cereals, cheese, chocolate, cocoa, coffee, grains, granular sugar, nuts, etc.); bagged or cartoned	Class III
	Foods (e.g., coffee, fish products, fruit, meat products, nuts, poultry, etc.); metal cans	Class I
	Fruits and vegetables (noncombustible semi-liquids); crushed; plastic containers up to 5 gallons (20 L)	Class I
	Fruits and vegetables; fresh; wood spacers, nonplastic trays or containers	Class I
	Margarine; over 50 and up to 80 percent oil	Group A Nonexpanded
	Meat; fresh; no plastic packaging; uncartoned	Class I
	Meat; fresh; no plastic packaging; cartoned	Class II
	Meat; fresh; plastic trays	Class III
	Milk; any container; stored in solid plastic crates	Group A Nonexpanded
	Milk; paper containers, or plastic bottles or jars up to 5 gallons (20 L) plastic bottles or jars	Class I
	Salt; bagged	Class I
	Salt; cartoned	Class II
	Snack foods (e.g., potato chips); plasticized aluminum bags; cartoned	Group A Nonexpanded
	Syrup; wooden container	Class II
Furniture and Bedding	Furniture and bedding; with foam cushioning	Group A Expanded
	Furniture; metal (e.g., file cabinets or desks with plastic trim); cartoned	Class I
	Furniture; wood (e.g., doors, windows, cabinets, etc.); no plastic coverings or foam cushioning	Class III
	Furniture; wood; plastic coverings nonexpanded plastic trim	Class IV
	Box spring; standard (minimal plastic materials)	Class III
	Box spring; wrapped in plastic cover	Class IV
	Mattress; foam (in finished form)	Group A Expanded
Housing Materials/Appliances	Appliances; major (e.g., stoves, refrigerators); no appreciable plastic interior or exterior trim; cartoned	Class II
	Appliances; major (e.g., stoves, refrigerators); no appreciable plastic interior or exterior trim; uncartoned	Class I
	Appliances; no appreciable plastic exterior trim (interior of unit can have appreciable plastic)	Class III
	Carpet tiles; cartoned	Group A Nonexpanded
	Fiberglass insulation; paper-backed rolls; bagged or unbagged	Class IV
	Floor coverings; vinyl, stacked tiles	Class IV
	Floor coverings; vinyl; rolled	Group A Nonexpanded
	Gypsum board	Class I
	Housing materials (such as sinks, countertops, etc.); noncombustible, cartoned or crated	Class II
	Paint; oil-based; friction-top metal containers; cartoned	Class IV
	Paint; water-based (latex); friction-top metal containers; cartoned	Class I
	Roofing shingles; asphalt-coated fiberglass	Class III
	Roofing shingles; asphalt-impregnated felt	Class IV

N ***TABLE A.34.2.5*** *Continued*

Product Heading	Product	NFPA 13
Miscellaneous	Ammunition; small arms and shotgun; cartoned	Class IV
	Charcoal; mineral spirit impregnated; bagged	Group A Expanded
	Charcoal; standard (non-mineral spirit impregnated); bagged	Class III
	Leather hides; baled	Class II
	Leather; finished products (e.g., shoes, jackets, gloves, bags, luggage, belts)	Class III
	Motors; electric	Class I
	Shock absorbers; metal dust cover	Class II
	Shock absorbers; plastic dust cover	Class III
	Skis; composite materials (plastic, fiberglass, foam, etc.)	Class IV
	Tobacco products; cartoned	Class III
	Toys; stuffed; foam or synthetic	Group A Expanded
	Transformer; dry or empty (i.e., void of oil)-filled	Class I
Noncombustible Liquids	Liquids or semi-liquids; PET containers greater than 5 gallon (20 L) having a nominal wall thickness greater than 0.25 in (6 mm)	Class IV
	Liquids or semi-liquids; PET containers up to 5 gallon (20 L) or greater than 5 gallon (20 L) having a nominal wall thickness up to 0.25 in (6 mm)	Class I
	Liquids or semi-liquids (e.g., crushed fruits and vegetables); plastic containers up to 5 gallon (18.9 L) capacity	Class I
	Liquids or semi-liquids; plastic (except PET) containers greater than 5 gallon (20 L) capacity having a nominal wall thickness greater than 0.25 in. (6 mm)	Group A Nonexpanded
	Liquids or semi-liquids; plastic (except PET) containers greater than 5 gallon (20 L) capacity having a nominal wall thickness up to 0.25 in. (6 mm)	Class II
	Liquids; cardboard drink boxes, plastic-coated, wax-coated, and/or aluminum-lined; uncartoned or on corrugated carton trays with plastic sheeting.	Class I
	Liquids; cardboard drink boxes, plastic-coated, wax-coated, and/or aluminum-lined; stored in plastic containers	Group A Nonexpanded
	Liquids; glass bottles or jars; cartoned	Class I
	Liquids; pharmaceuticals (nonflammable); glass bottles or jars; cartoned	Class II
	Liquids; plastic bottles or jars; stored in open or solid plastic crates	Group A Nonexpanded
Paper Products	Book signatures (paper part of book without hard cover)	Class II
	Cartons (i.e., cardboard flats); corrugated; partially assembled	Class IV
	Cartons (i.e., cardboard flats); corrugated; unassembled in neat piles	Class III
	Cartons; wax-coated, single-walled corrugated	Group A Nonexpanded
	Cellulosic paper products; nonwax-coated (e.g., books, cardboard games, cartoned tissue products, magazines, newspapers, paper cups, paper plates, paper towels, plastic-coated paper food containers, stationery)	Class III
	Cellulosic paper products; wax-coated (e.g., paper plates, cups); loosely packed; cartoned	Group A Nonexpanded
	Cellulosic paper products; wax-coated (e.g., paper plates, cups.); nested; cartoned	Class IV
	Matches; paper-type; cartoned	Class IV
	Matches; wooden; cartoned	Group A Nonexpanded
	Rolled; lightweight; in storage racks	Class IV
	Rolled; medium or heavyweight; in storage racks or on-side	Class III
	Tissue products; plastic-wrapped; cartoned	Class III
	Tissue products; plastic-wrapped; uncartoned	Group A Nonexpanded

(continues)

N ***TABLE A.34.2.5*** *Continued*

Product Heading	Product	NFPA 13
Plastic/Rubber	ABS (Acrylonitrile-butadiene-styrene copolymer)	Group A Nonexpanded
	Acetal (polyformaldehyde)	Group A Nonexpanded
	Acrylic (polymethyl methacrylate)	Group A Nonexpanded
	Automobile bumpers and dashboards	Group A Expanded
	Butyl rubber	Group A Nonexpanded
	Cellulose Acetate	Class IV
	Cellulose Acetate Butyrate	Group A Nonexpanded
	Chloroprene rubber	Class IV
	Containers; nonexpanded plastic gridded or solid; collapsed or nested with no air spaces	Group A Nonexpanded
	ECTFE (ethylene-chlorotrifluoro-ethylene copolymer)	Class IV
	EPDM (ethylene-propylene rubber)	Group A Nonexpanded
	ETFE (ethylene-tetrafluoroethylene copolymer)	Class IV
	Ethyl Cellulose	Group A Nonexpanded
	FEP (fluorinated ethylene-propylene copolymer)	Class IV
	FRP (fiberglass-reinforced polyester)	Group A Nonexpanded
	Melamine (melamine formaldehyde)	Class III
	Nitrile Rubber (acrylonitrile-butadiene rubber)	Group A Nonexpanded
	Nylon (nylon 6, nylon 6/6)	Group A Nonexpanded
	PCTFE (polychlorotrifluoroethylene)	Class III
	PET (Polyethylene Terephthalate — thermoplastic polyester)	Group A Nonexpanded
	Phenolic	Class III
	Plastics; stored in fully closed and solid (no openings), metal containers	Class I
	Polybutadiene	Group A Nonexpanded
	Polycarbonate	Group A Nonexpanded
	Polyester elastomer	Group A Nonexpanded
	Polyethylene	Group A Nonexpanded
	Polypropylene	Group A Nonexpanded
	Polystyrene; foam products (plates, cups, etc.)	Group A Expanded
	Polystyrene; rigid products	Group A Nonexpanded
	Polyurethane	Group A Expanded
	PTFE (polytetrafluoroethylene)	Class III
	PVC (polyvinyl chloride) products, up to 20% plasticizer	Class III
	PVC (polyvinyl chloride) products, greater than 20% plasticizer	Group A Nonexpanded
	PVC resins; bagged	Class III
	PVDC (polyvinylidene chloride)	Class III
	PVDF (polyvinylidene fluoride)	Class III
	PVF (polyvinyl fluoride)	Group A Nonexpanded
	Rubber; natural in blocks; cartoned	Group A Nonexpanded
	Rubber; natural; expanded	Group A Expanded
	Rubber; natural; nonexpanded	Group A Nonexpanded
	Rubber; synthetic (santoprene)	Group A Nonexpanded
	SAN (styrene acrylonitrile)	Group A Nonexpanded
	SBR (styrene-butadiene rubber)	Group A Nonexpanded
	Silicone rubber	Class IV
	Urea (urea formaldehyde)	Class III

N *TABLE A.34.2.5 Continued*

Product Heading	Product	NFPA 13
Plastic Containers	Bottles or jars (except PET) greater than 1 gallon (4 L) containing noncombustible solids	Group A Nonexpanded
	Bottles or jars (except PET) up to 1 gallon (4 L) containing noncombustible solids	Group A, cartoned (treat as cartoned even if uncartoned) Nonexpanded
Powders/Pills	Pharmaceutical pills; glass bottles or jars; cartoned	Class II
	Pharmaceuticals pills; plastic bottles or jars; cartoned	Class IV
	Polyvinyl Alcohol (PVA) resins; bagged	Class IV
	Powders; combustible (ordinary such as sugar or flour); free-flowing; bagged	Class II
	Powders; noncombustible free-flowing powdered or granular materials (cement, calcium chloride, clay, iron oxide, sodium chloride, sodium silicate, etc.)	Class I
	Powders; noncombustible; glass bottles or jars; cartoned	Class I
	Powders; noncombustible; PET bottles or jars	Class II
	Powders; noncombustible; plastic (other than PET) bottles or jars; uncartoned	Group A Nonexpanded
	Powders; noncombustible; plastic bottles or jars greater than 1 gallon (4 L) capacity	Group A Nonexpanded
	Powders; noncombustible; plastic bottles or jars up to 1 gallon (4 L) capacity; cartoned	Class IV
Textile Materials/Products	Cloth; natural fibers; baled	Class III
	Cloth; synthetic cloth	Class IV
	Clothing; natural fibers (e.g., wool, cotton) and viscose	Class III
	Cotton; cartoned	Class III
	Diapers; cotton or linen	Class III
	Diapers; plastic or nonwoven fabric; cartoned	Class IV
	Diapers; plastic or nonwoven fabric; plastic-wrapped; uncartoned	Group A Nonexpanded
	Fabric; rayon and nylon	Class IV
	Fabric; synthetic (except rayon and nylon); greater than 50/50 blend	Group A Nonexpanded
	Fabric; synthetic (except rayon and nylon); up to 50/50 blend	Class III
	Fabric; vinyl-coated (e.g. tablecloth); cartoned	Group A Nonexpanded
	Fibers; rayon and nylon; baled	Class IV
	Fibers; synthetic (except rayon and nylon); baled	Group A Nonexpanded
	Thread or yarn; rayon and nylon; wood or paper spools	Class IV
	Thread or yarn; rayon or nylon; plastic spools	Group A Nonexpanded
	Thread or yarn; synthetic (except rayon and nylon); greater than 50/50 blend; paper or wood spools	Class IV
	Thread or yarn; synthetic (except rayon and nylon); greater than 50/50 blend; plastic spools	Group A Nonexpanded
	Thread or yarn; synthetic (except rayon and nylon); up to 50/50 blend; plastic spools	Group A Nonexpanded
	Thread or yarn; synthetic (except rayon and nylon); up to 50/50 blend; wood or paper spools	Class III
Wax Products	Candles	Group A Expanded
	Paraffin or petroleum wax; blocks	Group A Expanded

N ***TABLE A.34.2.5*** *Continued*

Product Heading	Product	NFPA 13
Wire/Cable/Spools	Spools; plastic; empty	Group A Nonexpanded
	Spools; wood; empty	Class III
	Wire or cable; PVC insulated; metal or wood spools	Class II
	Wire or cable; PVC insulated; plastic spools	Class IV
	Wire; bare; metal spools, uncartoned	Class I
	Wire; bare; metal spools; cartoned	Class II
	Wire; bare; plastic spools; cartoned	Class IV
	Wire; bare; plastic spools; uncartoned	Group A Nonexpanded
	Wire; bare; wood or cardboard spools	Class II
Wood Products	Wood patterns	Class IV
	Wood products (e.g., fiberboard, lumber, particle board, plywood, pressboard with smooth ends and edges); bundled solid blocks	Class II
	Wood products (e.g., fiberboard, lumber, particle board, plywood, pressboard with smooth ends and edges); unbundled or non-solid blocks	Class III
	Wood products (e.g., toothpicks, clothespins and hangers)	Class III

34.2.5.1 Class I. A Class I commodity shall be defined as a noncombustible product that meets one of the following criteria:

(1) Placed directly on wood pallets
(2) Placed in single-layer corrugated cartons, with or without single-thickness cardboard dividers, with or without pallets
(3) Shrink-wrapped or paper-wrapped as a unit load with or without pallets

[**13:**5.6.3.1]

See Table A.34.2.5 for examples of Class I commodities.

34.2.5.2 Class II. A Class II commodity shall be defined as a noncombustible product that is in slatted wooden crates, solid wood boxes, multiple-layered corrugated cartons, or equivalent combustible packaging material with or without pallets. [**13:**5.6.3.2]

See Table A.34.2.5 for examples of Class II commodities.

34.2.5.3 Class III.

34.2.5.3.1 A Class III commodity shall be defined as a product fashioned from wood, paper, natural fibers, or Group C plastics with or without cartons, boxes, or crates and with or without pallets. [**13:**5.6.3.3.1]

For the 2016 edition of NFPA 13, 34.2.5.3 was revised to clarify the guidelines for Class III commodities. The requirement in 34.2.5.3.2 was modified to clarify that (1) the percentages of plastic were equal to or less than 5, (2) the indicated values for weight applied to unexpanded Group A plastic, and (3) the indicated values for volume applied to expanded Group A plastic.

34.2.5.3.2 A Class III commodity shall be permitted to contain a limited amount (5 percent or less by weight of unexpanded plastic or 5 percent or less by volume of expanded plastic) of Group A or Group B plastics. [**13:**5.6.3.3.2]

N **34.2.5.3.3** Commodities containing a mix of both Group A expanded and unexpanded plastics shall comply with Figure 5.6.3.4.2. [**13:**5.6.3.3.3]

34.2.5.4 Class IV.

Where a designer is considering classifying a commodity mixed with plastics, the designer needs to consider the location of the plastic commodity within a carton. A cartoned commodity that is 15 percent plastic by weight, where all of the nonplastic content is surrounded by plastic, behaves as a plastic commodity in a fire. Likewise, a heavy metal item encased in expanded plastic packaging that occupies 25 percent of the carton behaves as an expanded plastic commodity in a fire.

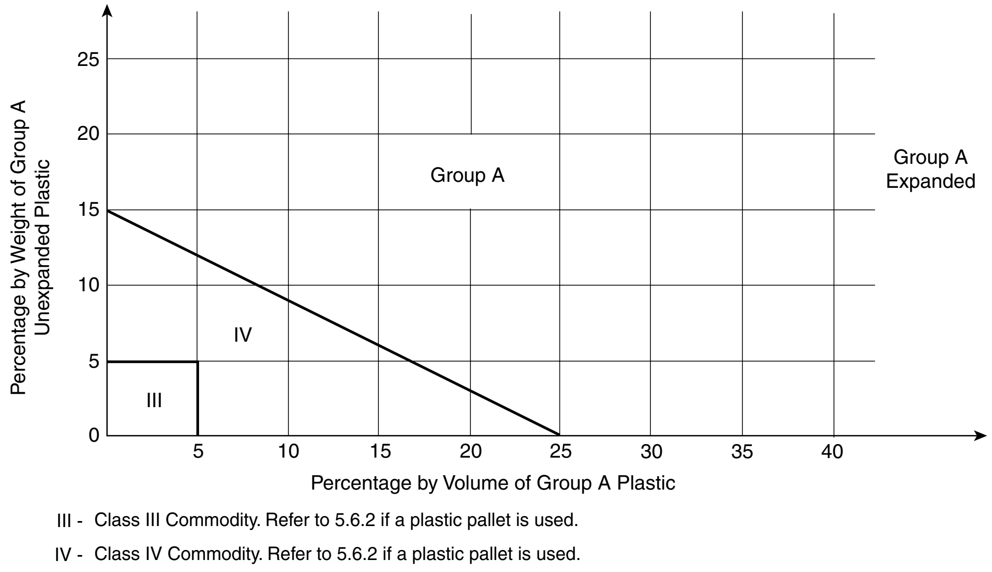
34.2.5.4.1 A Class IV commodity shall be defined as a product, with or without pallets, that meets one of the following criteria:

(1) Constructed partially or totally of Group B plastics
(2) Consists of free-flowing Group A plastic materials
(3) Contains within itself or its packaging an appreciable amount (greater than 5 to 15 percent by weight of Group A unexpanded plastic or greater than 5 percent to 25 percent by volume of expanded Group A plastic) of Group A plastics

[**13:**5.6.3.4.1]

34.2.5.4.2 Commodities containing a mix of both Group A expanded and unexpanded plastics shall comply with Figure 34.2.5.4.2. [**13:**5.6.3.4.2]

N **34.2.5.4.3** The remaining materials shall be permitted to be metal, wood, paper, natural or synthetic fibers, or Group B or Group C plastics. [**13:**5.6.3.4.3]



N ***FIGURE 34.2.5.4.2*** *Commodities Containing a Mixture of Expanded and Unexpanded Group A Plastics*

34.2.6 Classification of Plastics, Elastomers, and Rubber. Plastics, elastomers, and rubber shall be classified as Group A, Group B, or Group C. [**13:**5.6.4]

Δ **34.2.6.1 Group A.** The following materials shall be classified as Group A:

(1) ABS (acrylonitrile-butadiene-styrene copolymer)
(2) Acetal (polyformaldehyde)
(3) Acrylic (polymethyl methacrylate)
(4) Butyl rubber
(5) Cellulosics (cellulose acetate, cellulose acetate butyrate, ethyl cellulose)
(6) EPDM (ethylene-propylene rubber)
(7) FRP (fiberglass-reinforced polyester)
(8) Natural rubber
(9) Nitrile-rubber (acrylonitrile-butadiene-rubber)
(10) Nylon (nylon 6, nylon 6/6)
(11) PET (thermoplastic polyester)
(12) Polybutadiene
(13) Polycarbonate
(14) Polyester elastomer
(15) Polyethylene
(16) Polypropylene
(17) Polystyrene
(18) Polyurethane
(19) PVC (polyvinyl chloride — highly plasticized, with plasticizer content greater than 20 percent) (rarely found)
(20) PVF (polyvinyl fluoride)
(21) SAN (styrene acrylonitrile)
(22) SBR (styrene-butadiene rubber)

[**13:**5.6.4.1]

For the 2016 edition of NFPA 13, some of the listings for Group A, Group B, and Group C plastics were modified so that they were consistent with their indicated heat of combustion. This change resulted in cellulosics, natural rubber (not expanded), and nylon being moved from Group B to Group A, along with PVF being moved from Group C to Group A. Although some of the listings have been changed, it is important to understand that these listings are generally for plastics in their chemical state and have not taken into consideration the effect on their commodity classification for their physical state as a product. See Table A.34.2.5 for general guidance on the commodity classification of a Group A plastic product in its finished form.

If a tenant is storing one of the plastics in the Group A list, and the plastic has been modified with fire retardants, the AHJ might be presented with a question to accept a lesser hazard commodity classification than Group A plastics. Without laboratory testing that demonstrates that the modified Group A plastic can be classified as a lesser hazard classification, plastics appearing on the Group A list need to be considered as Group A plastics.

N **34.2.6.1.1** Group A plastics shall be further subdivided as either expanded or unexpanded. [**13:**5.6.4.1.1]

N **34.2.6.1.1.1** If a cartoned commodity is more than 40 percent (by volume) expanded plastic, it shall be protected as a cartoned expanded plastic. [**13:**5.6.4.1.1.1]

N **34.2.6.1.1.2** Exposed commodities containing greater than 25 percent by volume expanded plastic shall be protected as an exposed expanded plastic. [**13:**5.6.4.1.1.2]

Based on the definition in 3.9.1.12 of NFPA 13, expanded plastics are those with air pockets embedded within the plastic, such as foam coolers, exercise mats, foam presentation boards, shipping peanuts, and foam insulation boards found at home improvement stores. If the plastic does not fit that description, it would be considered a nonexpanded (or unexpanded) plastic, such as plastic totes or plastic water bottles.

34.2.6.2 Group B. The following materials shall be classified as Group B:

(1) Chloroprene rubber
(2) Fluoroplastics (ECTFE — ethylene-chlorotrifluoro-ethylene copolymer; ETFE — ethylene tetrafluoroethylene copolymer; FEP — fluorinated ethylene-propylene copolymer)
(3) Silicone rubber [**13:**5.6.4.2]

34.2.6.3 Group C. The following materials shall be classified as Group C:

(1) Fluoroplastics (PCTFE — polychlorotrifluoroethylene; PTFE — polytetrafluoroethylene)
(2) Melamine (melamine formaldehyde)
(3) Phenolic
(4) PVC (polyvinyl chloride — flexible — PVCs with plasticizer content up to 20 percent)
(5) PVDC (polyvinylidene chloride)
(6) PVDF (polyvinylidene fluoride)
(7) Urea (urea formaldehyde) [**13:**5.6.4.3]

•
Where the specific plastic commodity cannot be determined, the most conservative approach is to use the highest plastic hazard, Group A plastics. Designing the system to a lesser hazard might lead to insufficient water getting to the fire, allowing the fire to spread and overwhelm the system.

34.2.7* Classification of Rolled Paper Storage. For the purposes of this *Code*, the classifications of paper described in 34.2.7.1 through 34.2.7.4 shall apply and shall be used to determine the sprinkler system design criteria. [**13:**5.6.5]

Δ **A.34.2.7** *Paper Classification.* These classifications were derived from a series of large-scale and laboratory-type small-scale fire tests. It is recognized that not all paper in a class burns with exactly the same characteristics. [**13:**A.5.6.5]

Paper can be soft or hard, thick or thin, or heavy or light and can also be coated with various materials. The broad range of papers can be classified according to various properties. One important property is basis weight, which is defined as the weight of a sheet of paper of a specified area. Two broad categories of paper are recognized by industry — paper and paperboard. Paperboard normally has a basis weight of 20 lb (9.1 kg) or greater measured on a 1000 ft^2 (93 m^2) sheet. Stock with a basis weight less than 20 lb/1000 ft^2 (0.1 kg/m^2) is normally categorized as paper. The basis weight of paper is usually measured on a 3000 ft^2 (278.7 m^2) sheet. The basis weight of paper can also be measured on the total area of a ream of paper, which is normally the case for the following types of printing and writing papers:

(1) *Bond paper* — 500 sheets, 17 in. × 22 in. (425 mm × 550 mm) = 1300 ft^2 (121 m^2) per ream
(2) *Book paper* — 500 sheets, 25 in. × 38 in. (635 mm × 950 mm) = 3300 ft^2 (310 m^2) per ream
(3) *Index paper* — 500 sheets, 25½ in. × 30½ in. (640 mm × 765 mm) = 2700 ft^2 (250.8 m^2) per ream
(4) *Bristol paper* — 500 sheets, 22½ in. × 35 in. (565 mm × 890 mm) = 2734 ft^2 (254 m^2) per ream
(5) *Tag paper* — 500 sheets, 24 in. × 36 in. (600 mm × 900 mm) = 3000 ft^2 (280 m^2) per ream

[**13:**A.5.6.5]

For the purposes of this *Code*, all basis weights are expressed in lb/1000 ft^2 (kg/93 m^2) of paper. To determine the basis weight per 1000 ft^2 (93 m^2) for papers measured on a sheet of different area, the following formula should be applied:

$$\frac{\text{Basis weight}}{1000\ \text{ft}^2} = \text{basis weight} \times 1000\ \text{measured area}$$

Example: To determine the basis weight per 1000 ft^2 (93 m^2) of 16 lb (7.3 kg) bond paper:

$$\left(\frac{16\ \text{lb}}{1300\ \text{ft}^2}\right)1000 = \frac{12.3\ \text{lb}}{1000\ \text{ft}^2}$$

Large- and small-scale fire tests indicate that the burning rate of paper varies with the basis weight. Heavyweight paper burns more slowly than lightweight paper. Full-scale roll paper fire tests were conducted with the following types of paper:

(1) *Linerboard* — 42 lb/1000 ft^2 (0.2 kg/m^2) nominal basis weight
(2) *Newsprint* — 10 lb/1000 ft^2 (0.05 kg/m^2) nominal basis weight
(3) *Tissue* — 5 lb/1000 ft^2 (0.2 kg/m^2) nominal basis weight

[**13:**A.5.6.5]

The rate of firespread over the surface of the tissue rolls was extremely rapid in the full-scale fire tests. The rate of fire spread over the surface of the linerboard rolls was slower. Based on the overall results of these full-scale tests, along with additional data from small-scale testing of various paper grades, the broad range of papers has been classified into three major categories as follows:

(1) *Heavyweight* — Basis weight of 20 lb/1000 ft^2 (0.098 kg/m^2) or greater
(2) *Mediumweight* — Basis weight of 10 lb to 20 lb/1000 ft^2 (0.05 kg to 0.098 kg/m^2)
(3) *Lightweight* — Basis weight of less than 10 lb/1000 ft^2 (0.05 kg/m^2) and tissues regardless of basis weight

[**13:**A.5.6.5]

The following SI units were used for conversion of U.S. customary units:

(1) 1 lb = 0.454 kg
(2) 1 in. = 25.4 mm
(3) 1 ft = 0.3048 m; 1 ft^2 = 0.0929 m^2

[**13:**A.5.6.5]

The various types of papers normally found in each of the four major categories are provided in Table A.34.2.7. [**13:**A.5.6.5]

TABLE A.34.2.7 Paper Classification

Heavyweight	Mediumweight	Lightweight	Tissue
Linerboards	Bond and reproduction	Carbonizing tissue	Toilet tissue
Medium	Vellum	Cigarette	Towel tissue
Kraft roll wrappers	Offset	Fruit wrap	
Milk carton board	Tablet	Onion skin	
Folding carton board	Computer		
Bristol board	Envelope		
Tag	Book		
Vellum bristol board	Label		
Index	Magazine		
Cupstock	Butcher		
Pulp board	Bag		
	Newsprint (unwrapped)		

[**13:** Table A.5.6.5]

The material in A.34.2.7 applies to the classification of large rolls of paper stored on-end or on-side in piles greater than 10 ft (3.0 m) high. This type of paper storage is typically found in the finished goods storage warehouses at paper mills, in the raw stock storage warehouses of manufacturing plants that convert paper into finished products, or in other warehouses of similar occupancy. Fire experience and full-scale fire testing of this type of paper storage demonstrate unique burning characteristics that vary with the type of paper and the method of wrapping. The classifications for this type of paper storage are based on a series of full-scale and small-scale fire tests as described in A.34.2.7.

34.2.7.1 Heavyweight Class. Heavyweight class shall be defined so as to include paperboard and paper stock having a basis weight [weight per 1000 ft^2 (92.9 m^2)] of 20 lb (9.1 kg). [**13:**5.6.5.1]

34.2.7.2 Mediumweight Class. Mediumweight class shall be defined so as to include all the broad range of papers having a basis weight [weight per 1000 ft^2 (92.9 m^2)] of 10 lb to 20 lb (4.5 kg to 9.1 kg). [**13:**5.6.5.2]

34.2.7.3 Lightweight Class. Lightweight class shall be defined so as to include all papers having a basis weight [weight per 1000 ft^2 (92.9 m^2)] of less than 10 lb (4.5 kg). [**13:**5.6.5.3]

34.2.7.4 Tissue.

34.2.7.4.1 Tissue shall be defined so as to include the broad range of papers of characteristic gauzy texture, which, in some cases, are fairly transparent. [**13:**5.6.5.4.1]

34.2.7.4.2 For the purposes of this *Code*, tissue shall be defined as the soft, absorbent type, regardless of basis weight — specifically, crepe wadding and the sanitary class including facial tissue, paper napkins, bathroom tissue, and toweling. [**13:**5.6.5.4.2]

34.3 Building Construction

Δ **34.3.1* Construction Type.** Buildings used for storage of materials that are stored and protected in accordance with this chapter shall be permitted to be of any of the types described in NFPA 220.

A.34.3.1 With protection installed in accordance with this *Code*, fire protection of overhead steel and steel columns might not be necessary. Consideration should be given to subdividing large area warehouses in order to reduce the amount of merchandise that could be affected by a single fire.

Walls or partitions are recommended to be provided to separate the storage area from mercantile, manufacturing, or other occupancies to prevent the possibility of transmission of fire or smoke between the two occupancies. Door openings should be equipped with automatic-closing fire doors appropriate for the fire resistance rating of the wall or partition.

While storage occupancies can be located in buildings of any type of construction, combustible construction adds to the fire load and can create combustible concealed spaces that contribute to fire spread. Lightweight steel and wood truss construction, now commonly used in newer buildings, can or might be susceptible to early structural collapse. The height and area limitations provided in *NFPA 5000®, Building Construction and Safety Code®*, restrict the type of construction permitted.

Additional protection of steel columns and overhead steel might be required to ensure that the structural integrity of the building is maintained during sprinkler system operation. This added protection could be provided by way of fireproofing or sprinkler protection. NFPA 13 provides requirements for protection of steel in rack storage arrangements.

In some buildings with rack systems, the structural framework of the racks themselves supports the building's exterior walls and roof. Buildings up to 100 ft (9.3 m) high used for rack storage are not uncommon. Fire involving upper portions of high rack storage can present severe risks to fire fighters. Access to the upper portions for complete extinguishment and overhaul is very limited, and the use of ground ladders inside buildings can be extremely difficult and dangerous.

34.3.2 Fire-Fighting Access. Access shall be provided to all portions of the premises for fire-fighting purposes.

Perimeter access doors should be placed not only with occupant means of egress in mind but also with consideration for fire suppression efforts. Additional doors might be required beyond those provided for egress purposes. Door placement should take into account specific hazards located in the building. Advancing hose lines through the interior of a burning warehouse is time consuming and dangerous. Standpipe hose connections are required in storage occupancies, and initial placement should be made at each exterior perimeter door, with additional hose stations installed as required, so that all portions of the storage area can be reached. Placement of hose stations at exterior perimeter doors allows quick access for fire department personnel and, hence, faster water application to the fire. See 18.2.3.2 for additional information on fire department building access requirements.

34.3.3* Emergency Smoke and Heat Venting.

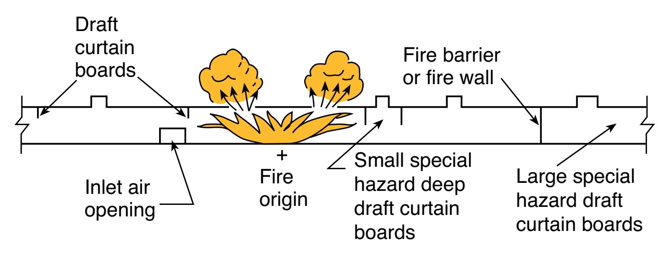
The following list provides a general description of the significant phenomena that occur during a fire when a fire-venting strategy is implemented:

1. Due to buoyancy, hot gases rise vertically from the combustion zone and flow horizontally below the roof until blocked by a vertical barrier (a wall or draft curtain), thus forming a layer of hot gases below the roof.
2. The volume and temperature of gases to be vented are a function of the fire's rate of heat release and the amount of air entrained into the buoyant plume produced.
3. As the depth of the layer of hot gases increases, the layer temperature continues to rise and the vents open.
4. The operation of vents within a curtained area enables some of the upper layer of hot gases to escape and thus slows the thickening rate of the layer of hot gases. With sufficient venting area, the thickening rate of the layer can be arrested and even reversed. The rate of discharge through a vent of a given area is primarily determined by the depth of the layer of hot gases and the layer temperature. Adequate quantities of replacement inlet air from air inlets located below the hot upper layer are needed if the products of combustion-laden upper gases are to be exhausted according to design. See Exhibit 34.10 for an illustration of the behavior of fire under a vented and curtained roof, and see Exhibit 34.11 for an example of a roof with vents.

Objectives of the vent system should be defined and considered. Objectives can include the following:

1. Provide for fire fighter safety and facilitate post-fire smoke removal by the fire department. The two key issues include activation type (remote or manual removal at roof level by fire fighters) and vent ratio (gross vent area to roof area). Remote activation is a preferred method; however, manual activation at roof level does considerably reduce the time a fire fighter must spend on the roof (versus cutting a hole in the roof) and might be considered acceptable.
2. Allow extended egress travel distances.
3. Reduce smoke damage to the contents. Design features such as ganging all vents within a sprinkler zone and automatically activating all the vents within one zone following sprinkler activation might achieve objectives 2 and 3; however, additional research is needed to validate this concept.

Exhibit 34.10



Behavior of combustion products under vented and curtained roof.

Exhibit 34.11

View of roof vents on building.

Chapter 11 of NFPA 204, *Standard for Smoke and Heat Venting*, provides a design methodology for smoke and heat venting in sprinklered buildings. Designers are strongly cautioned that use of venting with automatic sprinklers is an area of ongoing research to determine its benefit and effect in conjunction with automatic suppression.

The Fire Protection Research Foundation organized large-scale tests to study the interaction of sprinklers, roof vents, and draft curtains [McGrattan et al., 1998] involving heptane spray fires and arrays of cartoned plastic commodity of a standard configuration. The test space was ventilated by a smoke abatement system. As a result of the research, the following guidelines are provided for the design of venting systems in those areas of a building protected with an automatic sprinkler system designed and installed in accordance with NFPA 13 for the specific occupancy hazard:

1. Draft curtains and open vents of venting systems should not adversely affect sprinklers that are capable of discharging water onto the fire, either in time of operation or in the water discharge pattern.
2. Vents that are open prior to sprinkler operations in a region surrounding the ignition point, within a radius of one and one-half sprinkler spacings, can interfere with the opening of sprinklers capable of delivering water to the fire. The vent system design should consider the following:
   a. This interference is likely to be a factor if the total vent area is divided among many closely spaced vents, as in the investigation by Hinkley et al. (1992) and commented on by Gustafsson (1992).
   b. If the vent spacing is several times as large as the sprinkler spacing, model fire tests simulating a 4.0 ft × 4.0 ft (1.2 m × 1.2 m) vent in a 25 ft (7.6 m) high building [Heskestad, 1995] showed that sprinkler operations were significantly delayed whenever ignition occurred anywhere under the area of an open vent. Otherwise, the delay was minimal. This delay can be important for systems with early suppression fast-response (ESFR) sprinklers.
   c. Use of high-temperature, heat-responsive actuation mechanisms, compared to the sprinklers, can mitigate the problem of open vents. For example, for 165°F (74°C) rated ESFR sprinklers, a minimum 356°F (180°C) activation temperature should be provided for vents. Another approach would be to provide gang operation of the vents at the moment a conservative number of sprinklers are operating.
   d. The vent system design should consider the effects of the venting system on the ceiling jet.
3. The location of draft curtains should be determined considering the following:
   a. Draft curtains can delay or prevent operation and can interfere with the discharge of sprinklers capable of delivering water to the fire. In practice, sprinklers capable of delivering water to the fire can be considered to be those that are within one and one-half sprinkler spacings of the ignition point.
   b. Draft curtains should be located in aisles and should be horizontally separated from combustible contents.
   c. The layout of the sprinkler protection and the width of the aisle below the draft curtain should be sufficient to prevent the fire from jumping the aisle space. Accordingly, if a draft curtain is positioned midway between two sprinklers, the nearest possible ignition point should be at least three quarters of one sprinkler spacing away from the draft curtain. In other words, no storage of combustible material can be within three quarters of one sprinkler spacing of a draft curtain. Aisles free of combustible storage, centered under draft curtains, should be at least one and one-half sprinkler spacings wide [e.g., a minimum of 15 ft (4.57 m) aisle for 10 ft (3.05 m) sprinkler spacing in the direction perpendicular to the draft curtain]. For situations where such an aisle width is not practical, the aisle space can be reduced to a minimum of 8 ft (2.44 m), if a line of sprinklers is provided on each side of the draft curtain, 4 in. to 12 in. (101.6 mm to 304.8 mm) horizontally from the face of the draft curtain. For existing sprinkler installations, the sprinklers near the draft curtain might need to be staggered horizontally with respect to an adjacent line of sprinklers in order to maintain the minimum separation required by NFPA 13 and to prevent sprinkler skipping.
   d. Where aisles of sufficient width cannot be maintained, full-height partitions can be used in lieu of draft curtains.
4. The design fire's rate of heat release rate–time history should account for the operation of the sprinkler system.
5. Determination of the smoke layer temperature should take into account the operation of the control mode sprinkler system. (See Section F.3 in NFPA 204.)
6. The vent flow, smoke movement, and position of the smoke layer boundary should take into account the down-drag effect produced by operation of the sprinkler system.
7. The effect of control mode sprinkler cooling may limit the number of vents opening if control of the vent is only by fusible link or if drop-out panels are used. If the fusible link or drop-out panel operating temperature is equal to or higher than the control mode sprinkler fusible element operating temperature, vents outside the outer ring of operating control mode sprinklers are unlikely to open. This could significantly limit the effectiveness of the smoke vent system. Use of ganged vents operated from detectors or a sprinkler flow switch is a way to avoid this situation.

Δ **A.34.3.3** Since most of the fire tests were conducted without heat and smoke venting and draft curtains, protection specified in NFPA 13 was developed without their use.

For guidance on smoke and heat venting, see NFPA 204.

Smoke removal is important to manual fire fighting and overhaul. Vents through eave-line windows, doors, monitors, or gravity or mechanical exhaust systems facilitate smoke removal after control of the fire is achieved.

Results of tests organized by the Fire Protection Research Foundation and the Retail Committee on Group A Plastics to study the interaction of sprinklers, vents, and draft curtains indicate that the impact of automatic vents on sprinkler performance is neutral when automatic sprinkler discharge is adequate for the hazard and that draft curtains are potentially negative. Test results show that the placement of sprinklers and the thermal sensitivity of sprinklers and vents should be considered. Care should be exercised in the placement of draft curtains. Where required to be installed, draft curtains should be aligned where possible with aisles or other clear spaces in storage areas. Draft curtains where positioned over storage could adversely affect sprinkler operations. The number of operating sprinklers increased and led to a fire that consumed more commodity compared to other tests with fires ignited away from the draft curtains.

34.3.3.1 Protection outlined in this chapter shall apply to buildings with or without smoke and heat vents.

34.3.3.2 Protection outlined in this chapter shall apply to buildings with or without draft curtains.

Draft curtains are recommended only to separate ESFR sprinklers from control mode sprinklers.

34.3.3.3 Where local codes require smoke and heat vents in buildings protected by early suppression fast response (ESFR) sprinklers, the vents shall be manually operated or have an operating mechanism with a standard response fusible element rated not less than 360°F (182°C).

The requirement for the 360°F (182°C) rated fusible element ensures that the ESFR sprinklers will operate before the vents. If everything works correctly, the vents should never open at all.

Some codes and fire departments require manual vents to be installed on roofs to assist the fire department in ventilating a building in the event of a fire. Where manual vents are provided, consideration should be given to a means to operate the vents from a location other than the roof so that fire fighters do not have to go up on the roof to activate the vents.

34.4 Storage Arrangement

Storage configuration and arrangement has a major impact on how a fire will behave in a storage situation. Therefore, a commodity's storage arrangement must be considered in the preparation of the fire protection plan. Important factors to consider for storage arrangements that affect fire behavior and the difficulty of controlling a fire are as follows:

1. Storage height
2. Storage depth
3. Aisle width
4. Commodity classification
5. Flue space
6. Commodity encapsulation

Storage height affects the ability of the sprinkler water to reach the base of a fire if the fire starts at lower levels. In rack storage, higher racking arrangements may require the installation of in-rack sprinklers. Deep storage arrangements allow for fire to spread from pile to pile and require more water for fire control and pre-wetting. The narrower the aisle, the more likely the fire can jump the aisle and spread to storage arrays on the other side of the aisle. Commodity classification is discussed in Section 34.2.

Storage configurations create horizontal and vertical air spaces. Air passes through flue spaces, increasing air entrainment to the fire. Flue spaces are a key component for the proper operation of the sprinkler system, and they should not be obstructed where present. Property owners/operators and fire prevention personnel must ensure that flue spaces, where provided, are not obstructed. To ensure that flue spaces do not become obstructed, a permanent means to prevent blockage should be installed. Obstructed flue spaces can prevent heat and combustion products from reaching sprinklers and can also prevent water from reaching the fire. Encapsulation is defined as a method of packaging using a plastic sheet that completely encloses all sides and the top of the pallet load. Encapsulation prevents pre-wetting of the combustible commodity. When the fire burns through the plastic, it has access to fresh, dry fuel.

The most common types of storage arrangements used are as follows:

1. Bulk storage
2. Solid pile storage
3. Palletized pile storage
4. Rack storage (See Section 34.7.)

Solid pile storage arrangements are loads of storage that do not have voids within the load and that burn only on the exterior of the load. Water is generally able to reach most surfaces available to burn. Solid pile storage is piled on the floor of the area and not on racks or shelves.

Piles are further categorized into stable and unstable piles. Stable piles are those arrays where collapse, spillage of contents, or leaning of stacks across flue spaces is not likely to occur soon after initial fire development. Pile stability performance can be a difficult factor to judge prior to a pile being subjected to an actual fire. Storage on pallets, compartmented storage, and plastic components that are held in place by materials that do not deform readily under fire conditions are examples of stable storage. Unstable piles are those arrays where collapse, spillage of contents, or leaning of stacks across flue spaces occurs soon after initial fire development. Examples of unstable piles are leaning stacks, crushed bottom cartons, and reliance on combustible bands for stability. Additionally, an increase in pile height tends to increase instability.

Palletized storage is the storage of commodities on pallets or other storage aids that form horizontal spaces between tiers of storage. Palletized storage can be found in solid pile storage or in rack storage.

34.4.1* Piling Procedures and Precautions.

A.34.4.1 Commodities that are particularly susceptible to water damage should be stored on skids, dunnage, pallets, or elevated platforms in order to maintain at least 4 in. (100 mm) clearance from the floor.

34.4.1.1 Any commodities that are hazardous in combination with each other shall be stored so they cannot come into contact with each other.

34.4.1.2 Safe floor loads shall not be exceeded.

34.4.1.3 Where storing water-absorbent commodities, normal floor loads shall be reduced to take into account the added weight of water that can be absorbed during fire-fighting operations.

34.4.2 Commodity Clearance.

An 18 in. (457 mm) minimum clearance between a sprinkler deflector and the top of storage is the base requirement and provides for discharge pattern development and standardization between sprinklers. If another standard specifies a greater clearance, that standard should be followed.

Additionally, a minimum clearance to storage of 36 in. (0.9 m) is required for special sprinklers and where rubber tires are stored. Special sprinklers are intended for the protection of specific hazards or construction features. Subsection 8.4.8 of NFPA 13 provides more information on special sprinklers. A minimum clearance to storage of less than 18 in. (457 mm) between the top of storage and ceiling sprinkler deflectors is permitted where proven by successful large-scale fire tests for the particular hazard.

The clearance between the storage and the roof/ceiling is also an important factor for control mode density/area. High clearance affects sprinkler performance in two ways. First, as the clearance increases, the size of the fire before sprinklers operate also increases. Second, as the clearance increases, the fire plume that the sprinkler discharge must penetrate to reach the burning materials also increases. These two factors together significantly reduce the effectiveness of sprinklers.

Implicit in storage protection requirements is that the protection for a given storage height in a building of a given height can fluctuate widely over both the short and the long term. Clearances greater than 20 ft (6 m) are beyond the scope of testing used to develop the protection requirements for control mode density/area sprinklers. Therefore, protection adequate for a storage height that results in a clearance of less than 20 ft (6 m) will be adequate for lesser storage heights, despite the fact that clearance exceeds 20 ft (6 m).

34.4.2.1 The clearance between top of storage and sprinkler deflectors shall conform to NFPA 13.

34.4.2.2* If the commodity is stored above the lower chord of roof trusses, not less than 1 ft (0.3 m) of clear space shall be maintained to allow wetting of the truss, unless the truss is protected with 1-hour fireproofing.

A.34.4.2.2 Protection for exposed steel structural roof members could be needed and should be provided as indicated by the AHJ.

Subsection 14.3.6 in NFPA 13 eliminates special protection for building steel under certain storage configurations.

Δ **34.4.2.3** Storage clearance from ducts shall be maintained in accordance with NFPA 91.

34.4.2.4 The clearance between stored materials and unit heaters, radiant space heaters, duct furnaces, and flues shall not be less than 3 ft (0.9 m) in all directions or shall be in accordance with the clearances shown on the approval agency label.

34.4.2.5* Clearance shall be maintained to lights or light fixtures to prevent ignition.

A.34.4.2.5 Incandescent light fixtures should have shades or guards to prevent the ignition of commodity from hot bulbs where possibility of contact with storage exists.

34.4.2.6 Clearance shall be maintained around the path of fire door travel to ensure the door's proper operation and inspection.

34.4.2.7 Operation and inspection clearance shall be maintained around fire-extinguishing and fire protection equipment.

34.4.3 Aisles.

34.4.3.1 For the storage of commodities that expand with the absorption of water, such as roll paper, wall aisles not less than 24 in. (0.6 m) wide shall be provided.

34.4.3.2 Aisles shall be maintained to retard the transfer of fire from one pile to another and to allow convenient access for fire fighting, salvage, and removal of storage.

Aisles should separate storage so that piles are not more than 50 ft (15.2 m) wide, or 25 ft (7.6 m) wide if they abut a wall. This separation allows effective reach by hose streams. Main aisles and cross-aisles should be located opposite window or door openings in exterior walls. Such aisle location is of particular importance in buildings where few exterior openings exist. Aisle width should be at least 8 ft (2.4 m). Aisle spacing and frequency should be given consideration to judge the adequacy of existing sprinkler protection and manual fire suppression efforts (including the efforts of the local fire department).

34.4.4 Flammable and Combustible Liquids. Storage of flammable or combustible liquids shall be in accordance with Chapter 60.

34.5 General Fire Protection

34.5.1* Sprinkler Systems. Sprinkler systems installed in buildings used for storage shall be in accordance with Section 13.3.

A.34.5.1 Wet systems are recommended for storage occupancies. Dry systems are permitted only where it is impractical to provide heat. Preaction systems should be considered for storage occupancies that are unheated, particularly where in-rack sprinklers are installed or for those occupancies that are highly susceptible to water damage.

Where dry pipe sprinkler systems are used, the delay in water discharge from the earliest operating sprinkler will allow heat to spread and open a larger number of sprinklers beyond the immediate fire than would be the case with a wet pipe system. A review of fire loss data by FM Global showed that about 30 percent more sprinklers operate with a dry pipe system than with a wet pipe system.

34.5.2 High-Expansion Foam.

Δ **34.5.2.1** High-expansion foam systems installed in addition to automatic sprinklers shall be installed in accordance with NFPA 11 except where modified by other requirements in this chapter.

While automatic high-expansion foam extinguishing systems can be an independent means of fire suppression, a reluctance persists in the industry for using them as the sole means of automatic fire control. They are expensive, are complicated (relative to sprinkler systems), require more maintenance and testing, do not protect the roof structure until foam reaches that level, involve the entire contents of a protected area regardless of the fire's size, and present the problem of foam residue removal after discharge.

Such extinguishing systems have found acceptance as a partner to automatic sprinklers for certain high-challenge storage occupancies, such as those storing rubber tires, roll paper, exposed plastics, and pallets. The sprinklers are needed to help maintain the structural integrity of the building columns and roof structure by keeping them relatively cool while foam covers the fire. Note that sprinkler discharge breaks down the foam, a fact that needs to be taken into account when the system is being designed. Very few tests have been conducted using high-expansion foam in conjunction with sprinkler protection.

34.5.2.2 High-expansion foam used to protect idle pallets shall have a fill time of not more than 4 minutes.

34.5.2.3 High-expansion foam systems shall be automatic in operation.

34.5.2.4 Detectors for high-expansion foam systems shall be listed and shall be installed at the ceiling at not more than one-half the listed spacing in accordance with *NFPA 72*.

34.5.2.5 Detection systems, concentrate pumps, generators, and other system components essential to the operation of the system shall have an approved standby power source.

34.5.3 Manual Protection.

34.5.3.1 Portable Fire Extinguishers.

34.5.3.1.1 Portable fire extinguishers shall be provided in accordance with Section 13.6, unless 34.5.3.1.2 applies.

Section 13.6 and NFPA 10, *Standard for Portable Fire Extinguishers*, specify minimum requirements for proper placement, use, and maintenance of portable fire extinguishers. To ensure the usability of fire extinguishers, storage facility managers should ensure that the following criteria are met:

1. Extinguishers are visible, accessible, and not blocked by storage or equipment.
2. Extinguishers are near normal paths of travel.
3. Extinguishers are protected from accidental or malicious damage.
4. Extinguishers are properly charged with extinguishing agent.
5. Extinguisher lock pins and tamper seals are not damaged.
6. Extinguisher discharge nozzles are free from obstructions.
7. Extinguisher inspection tags indicate that proper inspections and maintenance have been performed.

Employees expected to use fire extinguishers are required to meet certain training and safety standards established by the U.S. Department of Labor Occupational Safety & Health Administration (OSHA).

34.5.3.1.2 Where 1½ in. (38 mm) hose lines are available to reach all portions of areas with Class A fire loads, up to one-half of the portable fire extinguishers required by Section 13.6 shall be permitted to be omitted.

Hose stations are required to be installed and located throughout the building so that the fire department does not have to stretch its own fire hose from outside the building to the fire. These hose stations are similar to standpipe systems in high-rise buildings, with the only difference being that they are installed horizontally instead of vertically in the building. Only fire department personnel or employees that have received special training should use the hose lines.

Charged hose lines are difficult to control and maneuver, especially when fed by a fire pump. Additionally, employees should only be expected to use hose lines on relatively small fires. As with fire extinguishers, employees expected to fight fires with hose lines are required to meet certain training and safety standards established by OSHA.

34.5.3.2 Hydrants. At locations without public hydrants, or where hydrants are not within 250 ft (75 m), private hydrants shall be installed in accordance with Section 13.5.

Buildings of moderate area close to city hydrants present no special problem. However, where the small dimension of a building exceeds about 250 ft (75 m), hose lays from public hydrants to the far side of the building can be a serious problem. Private hydrants around the perimeter of a warehouse with access doors near them then become important.

34.5.4 Fire Organization.

34.5.4.1 Arrangements shall be made to allow rapid entry into the premises by the municipal fire department, police department, or other authorized personnel in case of fire or other emergency.

Section 18.2 provides requirements for access boxes.

34.5.4.2* Due to the unique nature of storage fires and the hazards associated with fighting such fires, facility emergency personnel shall be trained to have knowledge of the following:

(1) Pile and building collapse potential during fire-fighting and mop-up operations due to sprinkler water absorption, use of hose streams, and the undermining of piles by fire that is likely to cause material or piles to fall (especially roll tissue paper), resulting in injury
(2) Operation of sprinkler systems and water supply equipment

(3) Location of the controlling sprinkler valves so that the correct sprinkler system can be turned on or off as necessary
(4) Correct operation of emergency smoke and heat vent systems where they have been provided
(5) Use of material-handling equipment while sprinklers are operating to effect final extinguishment
(6) Procedure for summoning outside aid immediately in an emergency
(7) Maintenance of the security features of the premises
(8) Operation of foam systems, evacuation procedures, and safety precautions during all foam operations

A.34.5.4.2 See Annex B of NFPA 13E.

34.5.4.3 A fire watch shall be maintained when the sprinkler system is not in service.

34.5.5 Alarm Service.

Warehouse facilities typically experience rapidly growing fires and include large open areas and relatively few employees, so alarm systems are needed to provide prompt fire department and employee responses.

34.5.5.1 Automatic sprinkler systems and foam systems, where provided, shall have approved central station, auxiliary, remote station, or proprietary waterflow alarm service unless otherwise permitted by 34.5.5.1.1 or 34.5.5.1.2.

34.5.5.1.1 Local waterflow alarm service shall be permitted when recorded guard service also is provided.

34.5.5.1.2 Local waterflow alarm service shall be permitted where the storage facilities are occupied on a 24-hour basis.

34.5.5.2 Alarm service shall comply with *NFPA 72*.

Δ **34.5.6 Security Service.** Security service, where provided, shall comply with NFPA 601.

While a warehouse facility is in operation, most areas of the building will probably be occupied, and the occupants will provide a measure of fire surveillance. During operation, an employee's discovery of a fire at an early stage might lead to the fire's prompt extinguishment before it grows out of control. However, because many arson fires originate while a facility is not in operation, premises security is important, not only from the standpoint of theft and security of contents but also from a fire protection standpoint. A security service is an effective tool used to guard against arson-type fires.

See NFPA 730, *Guide for Premises Security*, and NFPA 731, *Standard for the Installation of Electronic Premises Security Systems*, for additional guidance.

34.6 Building Equipment, Maintenance, and Operations

34.6.1 Industrial Trucks.

Δ **34.6.1.1** Power-operated industrial trucks and their use shall comply with NFPA 505.

34.6.1.2 Industrial trucks using liquefied petroleum gas (LP-Gas) or liquid fuel shall be refueled outside of the storage building at a location designated for the purpose.

The importance of fueling industrial trucks outside the warehouse is magnified by the economic impracticality of installing sprinkler protection that will handle a liquid spill fire in typical rack storage. If industrial trucks were fueled inside, a fuel spill and potential fire could spread to the storage, causing unnecessary losses. Fueling of all vehicles and equipment is best suited for outdoors, away from any buildings or other hazards.

34.6.2 Building Service Equipment. Electrical equipment shall be installed in accordance with the provisions of Section 11.1.

34.6.3 Cutting and Welding Operations.

34.6.3.1 Where welding or cutting operations are necessary, the requirements of Chapter 41 shall apply.

Repair or replacement of steel racks or overhead structures sometimes necessitates cutting and welding operations. Hot sparks from such operations are a fire hazard. Proper hot work procedures and the requirements of Chapter 41 should be followed. In Kaukauna, Wisconsin, in a roll-paper warehouse fire, sparks from an arc welding unit used on the second floor fell onto cardboard boxes on the first floor below, which caught fire. There was no fire watch on the first floor, and when the fire was discovered 15 minutes later, employees could not put it out. They called the fire department, but the actions were too late to save the two-story building of ordinary construction. The facility and its contents were a $1.6 million loss.

34.6.3.2* Welding, soldering, brazing, and cutting shall be permitted to be performed on building components or contents that cannot be removed, provided that no storage is located below and within 25 ft (7.6 m) of the working area and flameproof tarpaulins enclose the area.

A.34.6.3.2 The use of welding, cutting, soldering, or brazing torches in the storage areas introduces a severe fire hazard and, when possible, should be relocated to a designated area. The use of mechanical fastenings and mechanical saws or cutting wheels is recommended.

34.6.3.3 During any of the operations identified in 34.6.3.2, all of the following shall apply:

(1) The sprinkler system shall be in service.
(2) Extinguishers suitable for Class A fires with a minimum rating of 2-A shall be located in the working area.
(3) Where inside hose lines are available, charged and attended inside hose lines shall be located in the working area.
(4) A fire watch shall be maintained during the operations specified in 34.6.3.2 and for not less than 30 minutes following completion of open-flame operation.

34.6.4 Waste Disposal.

34.6.4.1 Approved containers for rubbish and other trash materials shall be provided.

34.6.4.2 Rubbish, trash, and other waste material shall be disposed of at regular intervals.

The importance of good housekeeping cannot be overstated. Packing or unpacking goods usually results in quantities of loose combustibles, such as foamed polystyrene beads, cocoons of foamed plastic, shredded paper, excelsior, and straw. Other combustibles, such as baled fibers and detached labels or tags, can act as kindling to ignite stored materials. Containers should be emptied after each shift or more often as needed due to operations.

See Chapter 19 for additional guidance on rubbish and trash handling and containers.

34.6.5 Smoking.

Smoking should always be controlled. Control of smoking requires management's sincere effort to enforce observance of permissible and prohibited smoking areas for employees and visitors. Smoking should be confined to specific areas separated from storage that are kept clean and are provided with proper disposal containers. Loading docks can be a particular area of concern, because truck drivers who smoke do not always properly extinguish cigarettes before starting to unload. See Section 10.9 for additional requirements on smoking.

34.6.5.1 Smoking shall be prohibited except in locations designated as smoking areas.

34.6.5.2 Signs that read "No Smoking" shall be posted in prohibited areas.

34.6.6* Maintenance and Inspection.

A.34.6.6 Periodic inspections of all fire protection equipment should be made in conjunction with regular inspections of the premises. Unsatisfactory conditions should be reported immediately and necessary corrective measures taken promptly.

34.6.6.1 Fire walls, fire doors, and floors shall be maintained in functional condition at all times.

34.6.6.2* All water-based fire protection systems and the water supplies shall be inspected, tested, and maintained in accordance with NFPA 25.

Δ **A.34.6.6.2** All fire-fighting and safety personnel should realize the great danger in shutting off sprinklers once opened by heat from fire. Shutting off sprinklers to locate fire could cause a disaster. Ventilation, use of smoke masks, smoke removal equipment, and removal of material are more safe. *(See NFPA 1620.)*

Sprinkler water should be shut off only after the fire is extinguished or completely under the control of hose streams. Even then, rekindling is a possibility. To be ready for prompt valve reopening if fire rekindles, a person stationed at the valve, a fire watch, and dependable communications between them are needed until automatic sprinkler protection is restored.

Prefire emergency planning is important and should be done by management and fire protection personnel, and the action to be taken discussed and correlated with the local fire department personnel. The critical time during any fire is in the incipient stage, and the action taken by fire protection personnel upon notification of fire can allow the fire to be contained in its early stages.

Pre-emergency planning should incorporate the following:

(1) Availability of hand fire-fighting equipment for the height and type of commodity involved
(2) Availability of fire-fighting equipment and personnel trained for the type of storage arrangement involved
(3) Assurance that all automatic fire protection equipment, such as sprinkler systems, water supplies, fire pumps, and hand hose, is in service at all times

Sprinkler protection installed as required in this *Code* is expected to protect the building occupancy without supplemental fire department activity. Fires that occur in rack storage occupancies protected in accordance with this *Code* are likely to be controlled. Fire department activity can, however, minimize the extent of loss. The first fire department pumper arriving at a rack storage–type fire should connect immediately to the sprinkler system's fire department connection and start pumping operations.

In the test series for storage up to 25 ft (7.6 m), the average time from ignition to smoke obscuration in the test building was about 13 minutes. The first sprinkler operating time in these same fires averaged about 3 minutes. Considering response time for the waterflow device to transmit a waterflow signal, approximately 9 minutes remains between the time of receipt of a waterflow alarm signal at fire department headquarters and the time of smoke obscuration within the building as an overall average.

In the test series for storage over 25 ft (7.6 m), the visibility time was extended. If the fire department facility emergency personnel arrive at the building in time to have sufficient visibility to locate the fire, suppression activities with small hose lines should be started. (Self-contained breathing apparatus is recommended.) If, on the other hand, the fire is not readily visible, hose should be laid to exterior doors or exterior openings in the building and charged lines provided to these points, ready for ultimate mop-up operations. Manual fire-fighting operations in such a warehouse should not be considered a substitute for sprinkler protection.

Important: The sprinkler system should be kept in operation during manual fire-fighting and mop-up operations.

During the testing program, the installed automatic extinguishing system was capable of controlling the fire and reducing all temperatures to ambient within 30 minutes of ignition. Ventilation operations and mop-up were not started until this point. The use of smoke removal equipment is important.

Smoke removal capability should be provided. Examples of smoke removal equipment include the following:

(1) Mechanical air-handling systems
(2) Powered exhaust fans
(3) Roof-mounted gravity vents
(4) Perimeter gravity vents

Whichever system is selected, it should be designed for manual actuation by the fire department, thus allowing personnel to coordinate the smoke removal (ventilation) with mop-up operations.

See also NFPA 600 and Annex B of NFPA 13E and NFPA 1031.

34.6.7 Refrigeration Systems. Refrigeration systems, if used, shall be in accordance with ASHRAE 15, *Safety Code for Mechanical Refrigeration*.

34.6.8 Lighting. Where metal halide lighting is installed, it shall be selected, installed, and maintained such that catastrophic failure of the bulb shall not ignite materials below.

34.7 Protection of Rack Storage

34.7.1 Application. Section 34.7 shall apply to the indoor storage of normal combustibles (Class I through Class IV) and plastics that are stored on racks.

34.7.2 Building Construction.

34.7.2.1 Fire protection of roof steel shall not be required when sprinkler systems are installed in accordance with Section 13.3.

In tests that were conducted with roof (steel) sprinkler densities that were in accordance with the design curves specified by NFPA 13, no critical temperatures were recorded in bar joists 12½ ft (3.8 m) from the ignition source. Therefore, where sprinkler systems designed in accordance with NFPA 13 are used, fireproofing of roof steel should not be necessary.

34.7.2.2 Fire protection of steel building columns and vertical rack members that support the building shall not be required when ceiling sprinklers and in-rack sprinklers are installed in accordance with Section 13.3.

34.7.2.3 For sprinklered buildings with rack storage of over 15 ft (4.6 m) in height and only ceiling sprinklers installed, steel building columns within the rack structure and vertical rack members that support the building shall have a fire resistance rating not less than 1 hour, unless the installation meets the requirements of 16.1.4 of NFPA 13.

Protection of steel columns is necessary, primarily to ensure that the structural integrity of the building is maintained during sprinkler system operation.

34.7.3 Storage Arrangement.

34.7.3.1* Rack Structure. Rack configurations shall be approved.

A.34.7.3.1 Rack storage as referred to in this *Code* contains commodities in a rack structure, usually steel. Many variations of dimensions are found. Racks can be single-row, double-row, or multiple-row, with or without solid shelves. The standard commodity used in most of the tests was 42 in. (1.07 m) on a side. The types of racks covered in this *Code* are as follows:

(1) Double-row racks, in which pallets rest on two beams parallel to the aisle. Any number of pallets can be supported by one pair of beams. *[See Figure A.34.7.3.1(a) through Figure A.34.7.3.1(d).]*
(2) Automatic storage-type rack, in which the pallet is supported by two rails running perpendicular to the aisle. *[See Figure A.34.7.3.1(e).]*

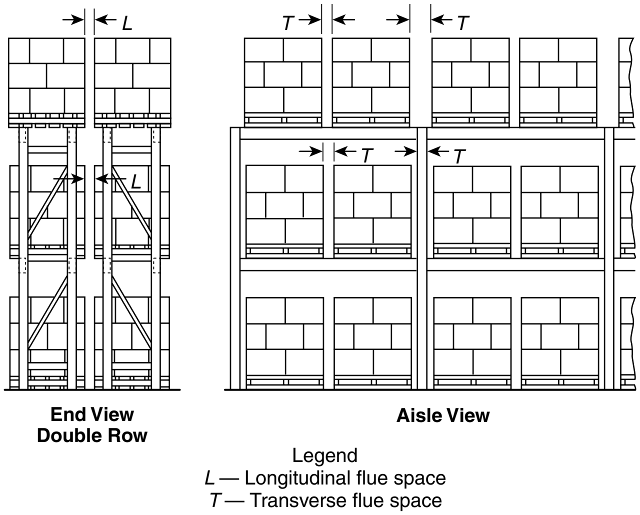


FIGURE A.34.7.3.1(a) *Conventional Pallet Rack.*

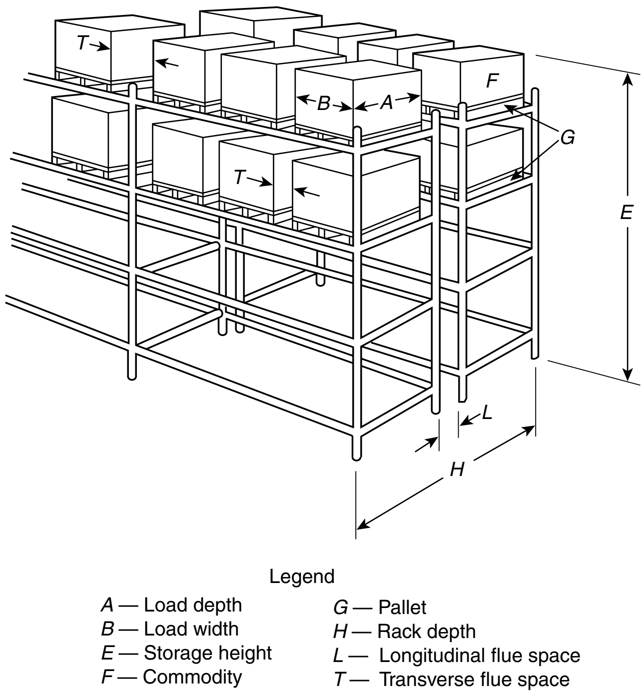

FIGURE A.34.7.3.1(b) *Double-Row Racks Without Solid or Slatted Shelves.*

(3) Multiple-row racks more than two pallets deep, measured aisle to aisle, which include drive-in racks, drive-through racks, flow-through racks, and portable racks arranged in the same manner, and conventional or automatic racks with aisles less than 42 in. (1.07 m) wide. *[See Figure A.34.7.3.1(f) through Figure A.34.7.3.1(j).]*
(4) Movable racks, which are racks on fixed rails or guides. They can be moved back and forth only in a horizontal two-dimensional plane. A moving aisle is created as abutting racks

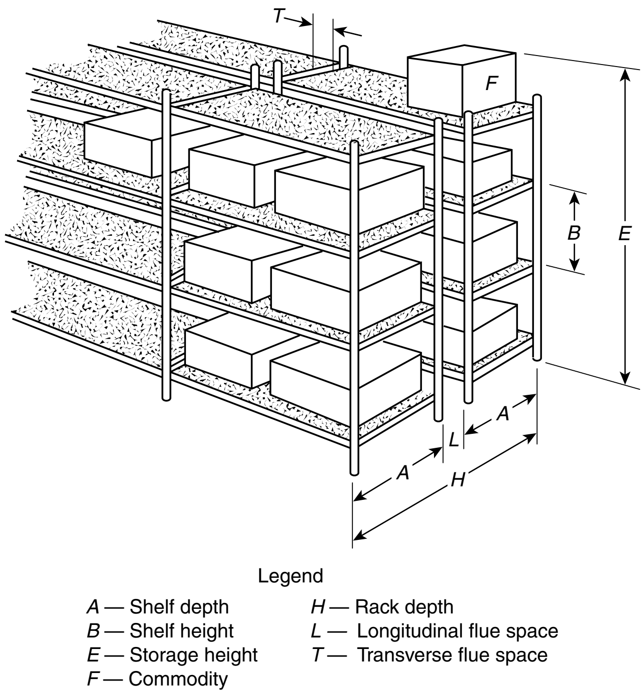

FIGURE A.34.7.3.1(c) *Double-Row Racks with Solid Shelves.*

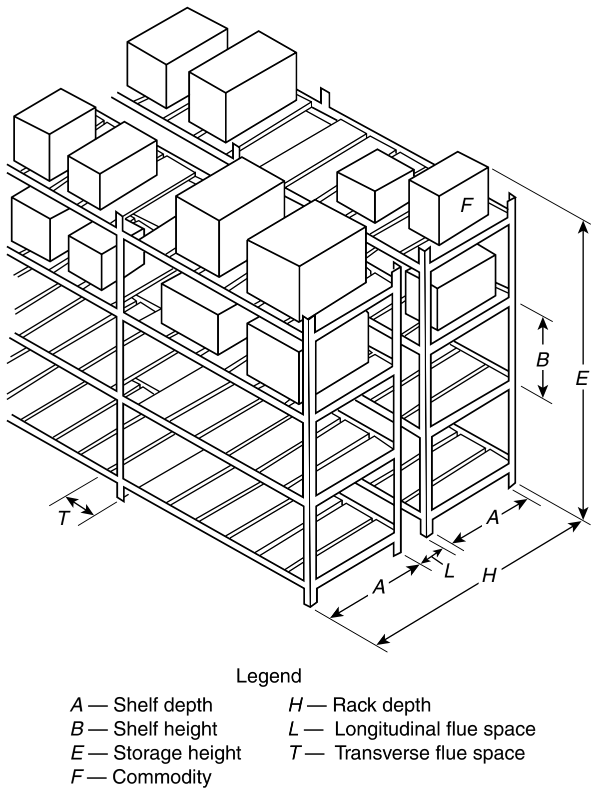

FIGURE A.34.7.3.1(d) *Double-Row Racks with Slatted Shelves.*

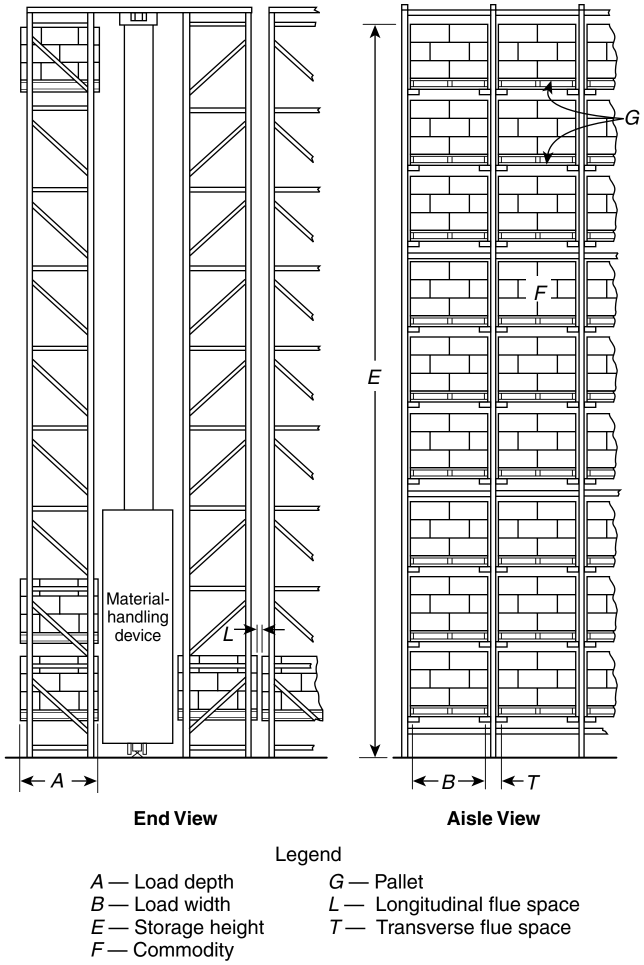

FIGURE A.34.7.3.1(e) *Automatic Storage-Type Rack.*

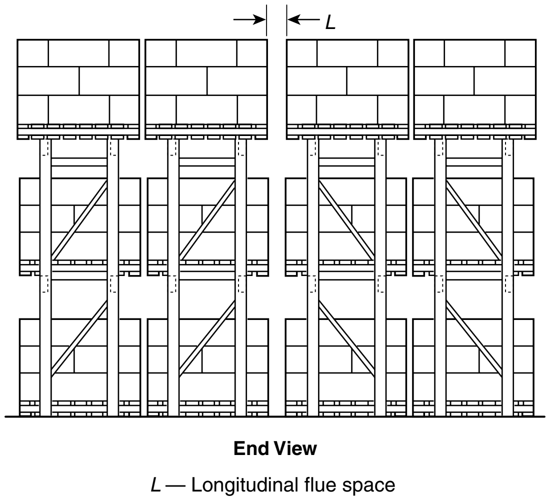

FIGURE A.34.7.3.1(f) *Multiple-Row Rack to be Served by a Reach Truck.*

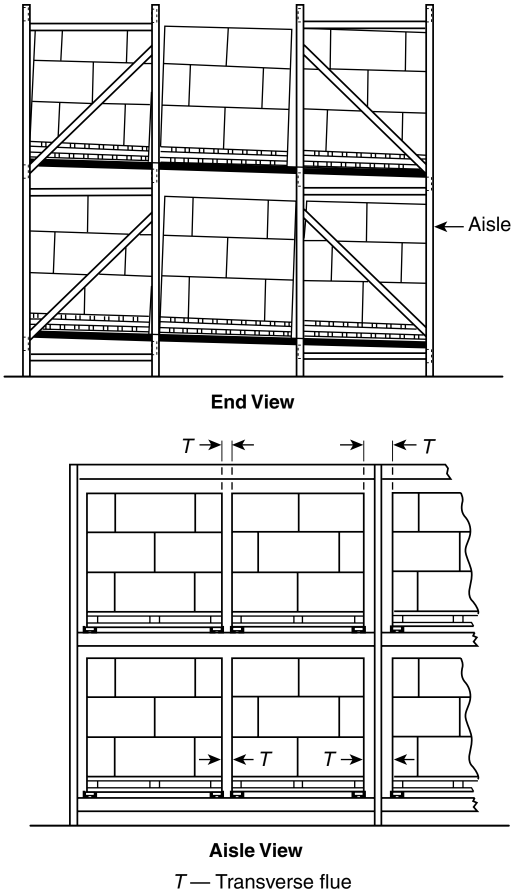

FIGURE A.34.7.3.1(g) Flow-Through Pallet Rack.

are either loaded or unloaded, then moved across the aisle to abut other racks. *[See Figure A.34.7.3.1(k).]*

(5) Solid shelving, which are conventional pallet racks with plywood shelves on the shelf beams *[see Figure A.34.7.3.1(c) and Figure A.34.7.3.1(d)]*. These are used in special cases.

(6) Cantilever rack, in which the load is supported on arms that extend horizontally from columns. The load can rest on the arms or on the shelves supported by the arms. *[See Figure A.34.7.3.1(l).]*

Load depth in conventional or automatic racks should be considered a nominal 4 ft (1.22 m). *[See Figure A.34.7.3.1(b).]*

34.7.3.2* Rack Loading. Racks shall not be loaded beyond their design capacity.

A.34.7.3.2 Fixed rack structures should be designed to facilitate removal or repair of damaged sections without resorting to flame cutting or welding in the storage area. Where sprinklers are to be installed in racks, rack design should anticipate the additional clearances necessary to facilitate installation of sprinklers. The rack structure should be anchored to prevent damage to sprinkler lines and supply piping in racks.

Rack structures should be designed for seismic conditions in areas where seismic resistance of building structure is required.

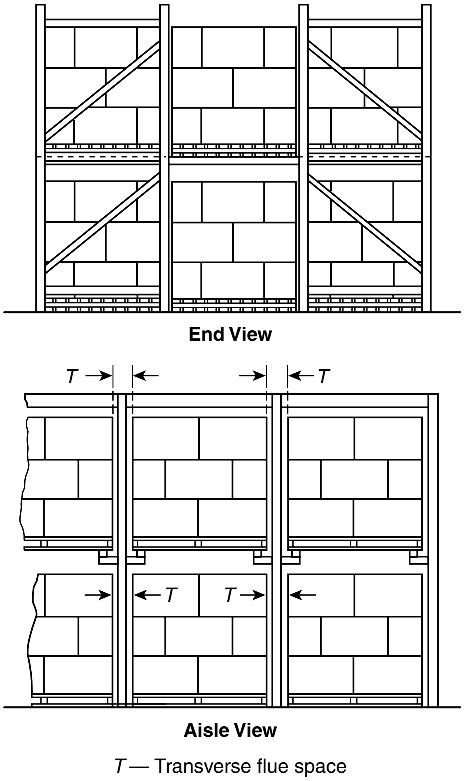

FIGURE A.34.7.3.1(h) Drive-In Rack — Two or More Pallets Deep (Fork Truck Drives into the Rack to Deposit and Withdraw Loads in the Depth of the Rack).

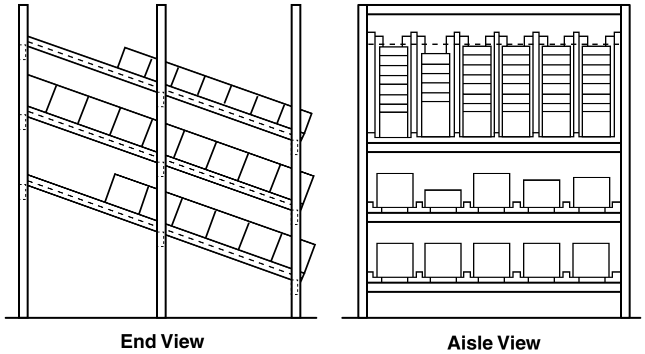

FIGURE A.34.7.3.1(i) Flow-Through Rack.

34.7.3.3* Aisle Widths.

A.34.7.3.3 Storage in aisles can render protection ineffective and should be discouraged.

Aisles must be kept free of product. If product is allowed to be stored in the aisle, a fire could spread easily from one rack to another and overtax the sprinkler system.

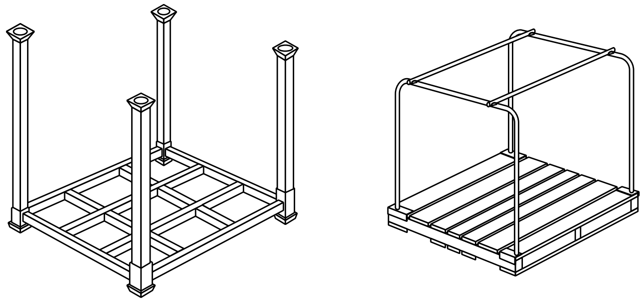

FIGURE A.34.7.3.1(j) Portable Racks.

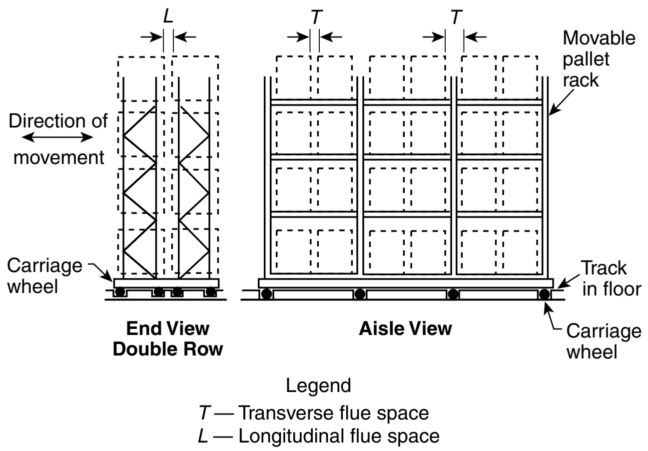

FIGURE A.34.7.3.1(k) Movable Rack.

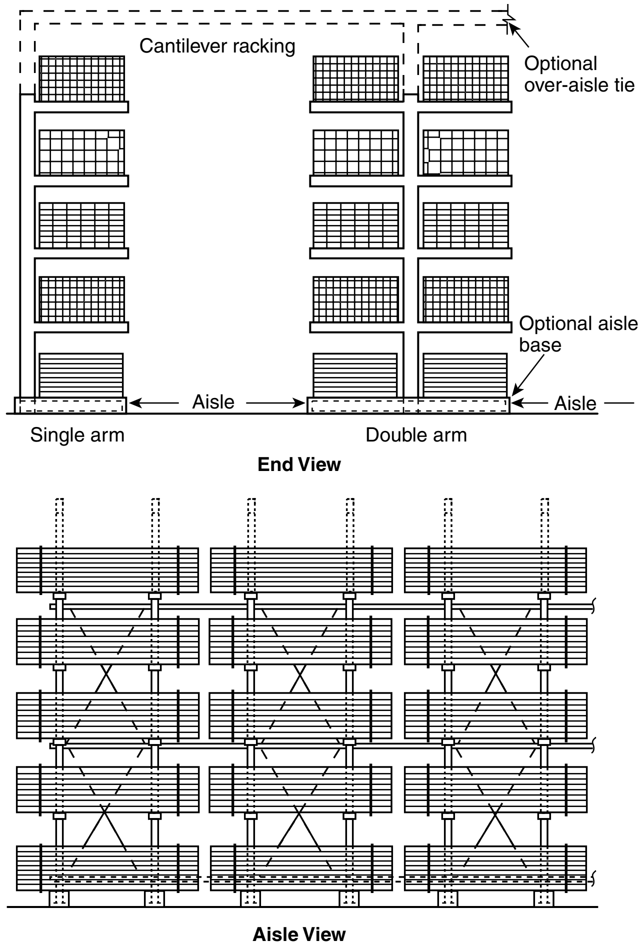

FIGURE A.34.7.3.1(l) Cantilever Rack.

34.7.3.3.1 Aisle widths and depth of racks shall be determined by material-handling methods.

34.7.3.3.2 The width of aisles shall be considered in the design of the protection system.

Aisle spaces between stored materials permit water from the ceiling sprinklers to reach the fire and restrict its spread from one rack to another. Wider aisles give greater benefits to the effectiveness of the fire protection system. In addition, aisles provide access for fire-fighting and salvage operations. Aisle widths are also a key factor in determining whether the rack arrangement is single, double, or multiple rows.

34.7.3.3.3* Aisle widths shall be maintained by either fixed rack structures or control in placement of portable racks.

A.34.7.3.3.3 See Chapter 12 of NFPA 13.

For rack storage up to 25 ft (7.6 m) high, aisle widths significantly impact sprinkler system requirements. NFPA 13 provides sprinkler criteria for single- and double-row racks with 4 ft (1.2 m) and 8 ft (2.4 m) aisles. Racks incorporating 4 ft (1.2 m) aisles require greater sprinkler protection than those using 8 ft (2.4 m) aisles. Aisles wider than 8 ft (2.4 m) provide no more benefit than do 8 ft (2.4 m) wide aisles, and, therefore, no reduction in sprinkler criteria is required. If aisles are less than 3½ ft (1 m) in width, then the rack arrangement is considered multiple row. Multiple-row racks demand a more powerful sprinkler system than double-row racks. The narrow aisles increase the likelihood of a fire spreading from rack to rack by jumping the aisle.

34.7.3.3.4 Any decrease in aisle width shall require a review of the adequacy of the protection system.

34.7.3.4 General Fire Protection.

34.7.3.4.1 High-Expansion Foam.

34.7.3.4.1.1* Where high-expansion foam systems are installed, they shall be automatic in operation and shall be in accordance with NFPA 11, except when modified by 34.7.3.4.

A.34.7.3.4.1.1 Detection systems, concentrate pumps, generators, and other system components essential to the operation of the system should have an approved standby power source.

34.7.3.4.1.2 When high-expansion foam systems are used in combination with ceiling sprinklers, in-rack sprinklers shall not be required.

While automatic high-expansion foam extinguishing systems can be an independent means of fire suppression, a reluctance persists in the industry for using them as the sole means of automatic fire control. They are expensive, are complicated (relative to sprinkler systems), require more maintenance and testing, do not protect the roof structure until foam reaches that level, involve the entire contents of a protected area regardless of the fire's size, and present the problem of foam residue removal after discharge.

Such extinguishing systems have found acceptance as a partner to automatic sprinklers for certain high-challenge storage occupancies, such as those storing rubber tires, roll paper, exposed plastics, and pallets. The sprinklers are needed to help maintain the structural integrity of the building columns and roof structure by keeping them relatively cool while foam covers the fire. Note that sprinkler discharge breaks down the foam, a fact that needs to be taken into account when the system is being designed. Very few tests have been conducted using high-expansion foam in conjunction with sprinkler protection.

34.7.3.4.1.3 Detectors shall be listed and shall be installed in one of the following configurations:

(1) At one-half listed linear spacing [e.g., 15 ft × 15 ft (4.6 m × 4.6 m) rather than 30 ft × 30 ft (9.1 m × 9.1 m)] when the following conditions exist:
  (a) Detectors are installed at the ceiling only.
  (b) The clearance from the top of storage does not exceed 10 ft (3 m).
  (c) The height of storage does not exceed 25 ft (7.6 m).
(2) At the ceiling at listed spacing and on racks at alternate levels
(3) Where listed for rack storage installation and installed in accordance with ceiling detector listing to provide response within 1 minute after ignition using an ignition source equivalent to that used in a rack storage testing program

Quick detection of a fire in a warehouse protected by high-expansion foam is essential. The foam requires a period of time to cover the burning stock. The faster the foam is discharged onto the fire, the less damage that will occur. Reducing the detector spacing at the ceiling by one-half of what is typically required helps ensure faster response of the foam system.

34.7.3.4.2 High-Expansion Foam Submergence.

34.7.3.4.2.1 The following requirements shall apply to storage of Class I, Class II, Class III, and Class IV commodities, as classified in Section 34.2, up to and including 25 ft (7.6 m) in height:

(1)* When high-expansion foam systems are used without sprinklers, the submergence time shall be not more than 5 minutes for Class I, Class II, or Class III commodities.
(2) When high-expansion foam systems are used without sprinklers, the submergence time shall be not more than 4 minutes for Class IV commodities.
(3) When high-expansion foam systems are used in combination with ceiling sprinklers, the submergence time shall be not more than 7 minutes for Class I, Class II, or Class III commodities.
(4) When high-expansion foam systems are used in combination with ceiling sprinklers, the submergence time shall be not more than 5 minutes for Class IV commodities.

A.34.7.3.4.2.1(1) Where high-expansion foam is contemplated as the protection media, consideration should be given to possible damage to the commodity from soaking and corrosion. Consideration also should be given to the problems associated with removal of foam after discharge.

34.7.3.4.2.2 The following requirements shall apply to storage of Class I, Class II, Class III, and Class IV commodities stored over 25 ft (7.6 m) high up to and including 35 ft (10.7 m) in height:

(1) Ceiling sprinklers shall be used in combination with the high-expansion foam system.
(2) The submergence time for the high-expansion foam shall be not more than 5 minutes for Class I, Class II, or Class III commodities.
(3) The submergence time for the high-expansion foam shall be not more than 4 minutes for Class IV commodities.

34.8 Protection of Rubber Tires

Rubber tires are defined as pneumatic tires for passenger automobiles, aircraft, light and heavy trucks, trailers, farm equipment, construction equipment (i.e., off-the-road), and buses. This commodity presents its own unique hazards, not only for the different storage arrangements but also for the by-products of burned tires, which include oil. Additionally, because of their structure, tires possess inherent air spaces that provide a sufficient amount of air for combustion. Fires burning on the interior surface of a tire are usually shielded from sprinkler discharge.

34.8.1* Application.

A.34.8.1 Illustrations of some, but not necessarily all, tire storage arrangements are shown in Figure A.34.8.1(a) through Figure A.34.8.1(g).

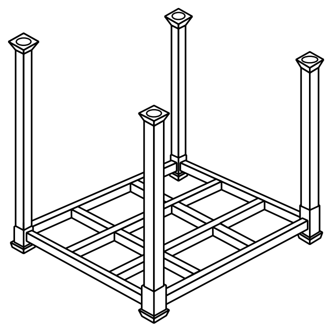

FIGURE A.34.8.1(a) *Typical Open Portable Rack Unit.*

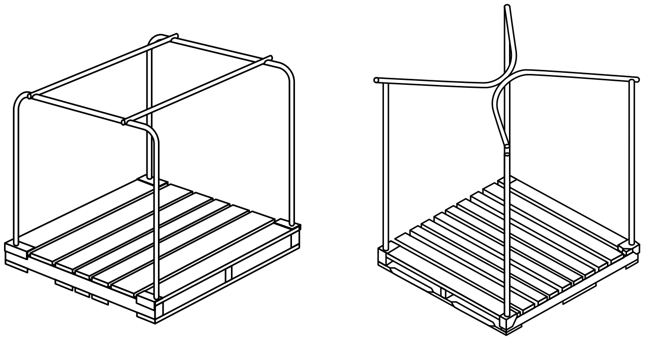

FIGURE A.34.8.1(b) *Typical Palletized Portable Rack Units.*

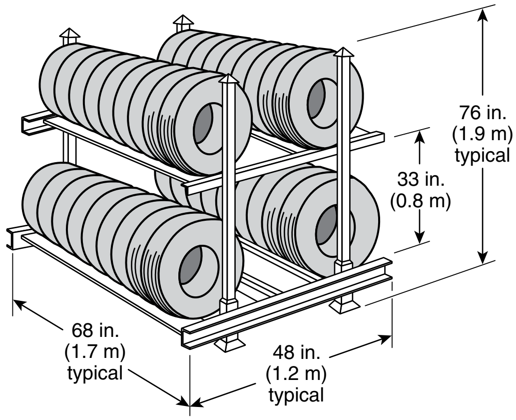

FIGURE A.34.8.1(c) *Open Portable Tire Rack.*

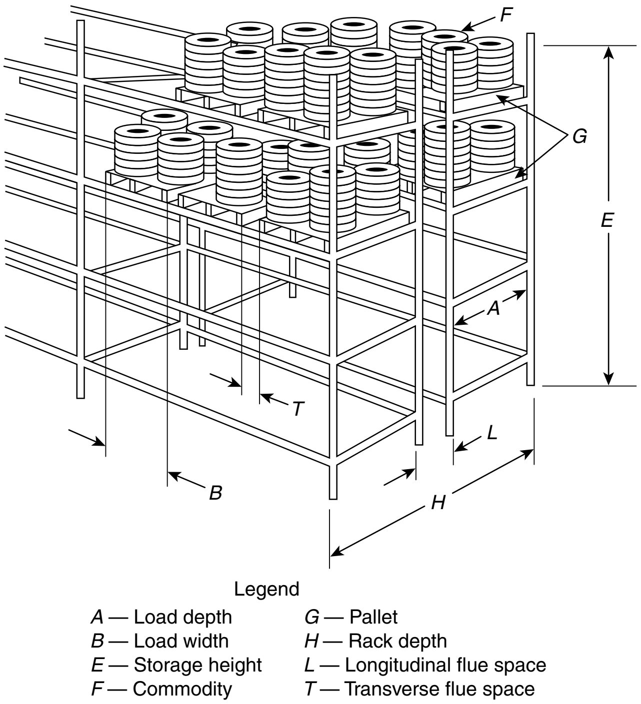

FIGURE A.34.8.1(d) *Double-Row Fixed Rack Tire Storage.*

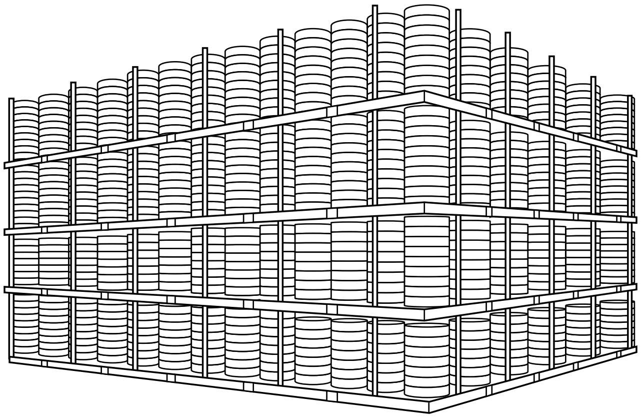

FIGURE A.34.8.1(e) *Palletized Portable Rack On-Side Tire Storage Arrangement (Banded or Unbanded).*

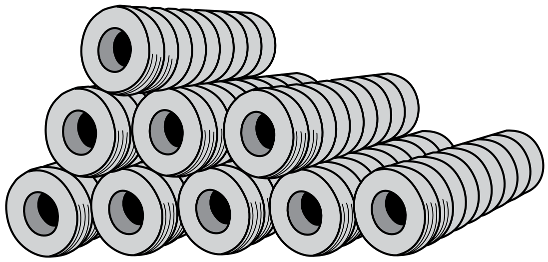

FIGURE A.34.8.1(f) *On-Tread, On-Floor Tire Storage Arrangement (Normally Banded).*

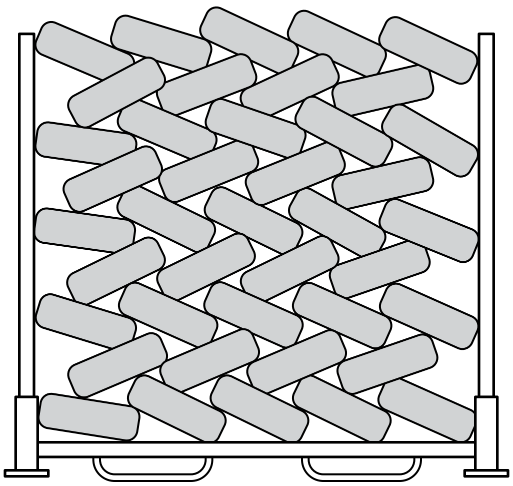

FIGURE A.34.8.1(g) *Typical Laced Tire Storage.*

34.8.1.1 Section 34.8 shall apply to new facilities with indoor storage of usable tires and to existing facilities being converted to the indoor storage of usable tires.

34.8.1.2 Existing buildings storing rubber tires shall be exempted from complying with Section 34.8.

34.8.1.3 This section shall not apply to scrap tire storage.

Scrap tire storage (whether whole or in fragments) is not the same as miscellaneous tire storage. The term *miscellaneous tire storage* is defined in 3.3.258.7. Any indoor storage of scrap tires, however, should be removed from the building daily and disposed of in a safe manner outside the building. The level of fire safety is greatly improved when good housekeeping is practiced. See Chapter 33 for outside storage of tires.

34.8.2 Building Arrangement.

34.8.2.1 Steel Columns. Steel columns shall be protected as follows unless protected in accordance with 16.1.4 of NFPA 13:

(1) For storage exceeding 15 ft to 20 ft (4.6 m to 6 m) in height, columns shall have 1-hour fireproofing.
(2) For storage exceeding 20 ft (6 m) in height, columns shall have 2-hour fireproofing for the entire length of the column, including connections with other structural members.

34.8.2.2 Fire Walls.

34.8.2.2.1 Four-hour fire walls shall be provided between the tire warehouse and tire manufacturing areas.

Δ **34.8.2.2.2** Fire walls shall be designed in accordance with NFPA 221.

34.8.2.3* Travel Distance to Exits. Travel distance to exits shall be in accordance with NFPA *101*.

A.34.8.2.3 NFPA *101* accurately reflects the travel distance requirements as follows:

(1) Tire storage is classified as ordinary hazard.
(2) Tire fires begin burning slowly. In combination with an acceptable automatic sprinkler system, this slower burning allows time for egress.
(3) Tire storage warehouses have a low occupant load.
(4) Large aisle widths [8 ft (2.4 m) minimum] required in 34.8.3.1.4 of this *Code* facilitate egress.

34.8.3 Storage Arrangement.

34.8.3.1 Piling Procedures.

34.8.3.1.1* Piles that are not adjacent to or located along a wall shall be not more than 50 ft (15 m) in width.

A.34.8.3.1.1 Limiting the pile length is not intended. *(See Figure A.34.8.3.1.1.)*

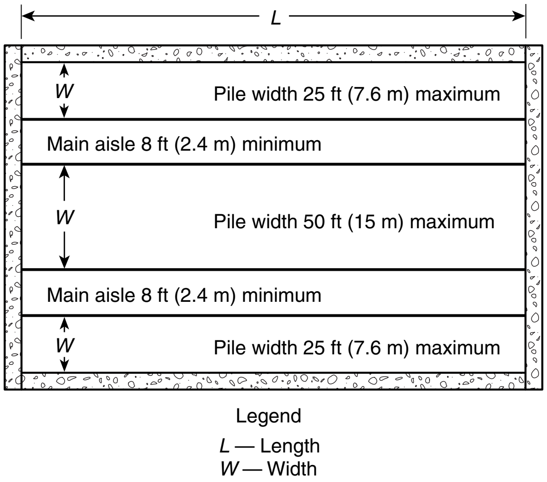

***FIGURE A.34.8.3.1.1** Typical Tire Piling Arrangement.*

34.8.3.1.2 Tires stored adjacent to or along one wall shall not extend more than 25 ft (7.6 m) from the wall.

34.8.3.1.3 Where tires are stored on-tread, the dimension of the pile in the direction of the wheel hole shall be not more than 50 ft (15 m).

34.8.3.1.4 The width of the main aisles between piles shall be not less than 8 ft (2.4 m).

Aisles should separate storage so that piles are not more than 50 ft (15 m) wide. This distance allows effective reach by hose streams. Main aisles and cross-aisles should be located opposite window or door openings in exterior walls. Such location is of particular importance in buildings where few exterior openings exist. Aisle width should be at least 8 ft (2.4 m). Aisle spacing and frequency should be given consideration in an evaluation of the adequacy of existing sprinkler protection and manual fire suppression efforts, including the response capability of the local fire department.

34.8.3.2 Clearances.

34.8.3.2.1 Storage clearance from roof structures shall be not less than 18 in. (470 mm) in all directions.

34.8.3.2.2 A clearance of not less than 24 in. (610 mm) shall be maintained around the path of fire door travel unless a barricade is provided.

34.8.3.2.3 Where protection in accordance with this chapter is provided, stored tires shall be segregated from other combustible storage by aisles not less than 8 ft (2.4 m) wide.

34.9 Protection of Roll Paper

34.9.1 Application. Section 34.9 shall apply to new facilities with indoor storage of roll paper, and to existing facilities being converted to the indoor storage of roll paper, except for the following types of roll paper:

(1) Waxed paper
(2) Synthetic paper
(3) Palletized roll paper storage other than that stored on a single floor pallet or raised floor platform

34.9.2* Building Construction. The protection outlined in Section 34.9 shall apply to buildings with or without fireproofing or other modes of steel protection, unless modified by the requirements of 34.4.2.2.

A.34.9.2 With protection installed in accordance with this *Code*, fire protection of overhead steel and steel columns is not necessary. However, some lightweight beams and joists can distort and necessitate replacement, particularly following fires involving plastic-wrapped rolls stored 20 ft (6.1 m) and higher.

The maximum challenge to sprinkler protection is presented by uninsulated structural steel. Fire spread and development are unusually severe and rapid and can quickly raise exposed building steel to temperatures at which it fails structurally. Steel failure can rupture sprinkler piping and deprive roll paper of fire protection at a time of maximum need.

34.9.3 Storage Arrangement. The floor load design shall take into account the added weight of water that could be absorbed by the commodity during fire-fighting operations.

The most common rolled paper storage arrangement is where the center core is stored vertically, such as the storage arrangement shown in Exhibit 34.12. The fire challenge created by this style of storage is fire spreading up the side of a paper column, which quickly burns through the outer ply; the rolled paper then unwinds and peels away from the rolls. Peeled-away material greatly and quickly increases the burning surfaces. Rolls continually shed outer layers wet by sprinkler discharge, thereby exposing dry paper and fresh fuel for the fire. Peeled material also spreads fire by contact with adjacent paper columns. Methods used to reduce this hazard include tightly banding the rolled paper with metal banding or enclosing the paper rolls with fire retardant–treated, tight paper wrappers. Because rolled paper tends to absorb water from a discharging sprinkler and swell in size, it should be stored with sufficient clearance from walls.

Storing rolls of paper on-side avoids dangerous peeling; they can be nested between the rolls of a lower tier. A fire in this location, which is well shielded from fire-fighting efforts, can involve a large portion of the storage and become quite intense in the vertical flues created between roll ends.

Exhibit 34.12

Rolled paper storage. (Thinkstock)

34.10 Storage of Idle Pallets

34.10.1* General. Idle pallets shall be stored outside or in a separate building designated for pallet storage, unless permitted by 34.10.2.

A.34.10.1 Idle pallet storage introduces a severe fire condition. Stacking idle pallets in piles is the best arrangement of combustibles to promote rapid spread of fire, heat release, and complete combustion. After pallets are used for a short time in warehouses, they dry out and edges become frayed and splintered. In this condition they are subject to easy ignition from a small ignition source. Again, high piling increases considerably both the challenge to sprinklers and the probability of involving a large number of pallets when fire occurs. Therefore storing idle pallets outdoors where possible is preferable. A fire in idle plastic or wooden pallets is one of the greatest challenges to sprinklers. The undersides of the pallets create a dry area on which a fire can grow and expand to other dry or partially wet areas. This process of jumping to other dry, closely located, parallel, combustible surfaces continues until the fire bursts through the top of the stack. Once this happens, very little water is able to reach the base of the fire. The only practical method of stopping a fire in a large concentration of pallets with ceiling sprinklers is by means of prewetting. In high stacks, prewetting cannot be done without abnormally high water supplies. The storage of idle pallets should not be permitted in an unsprinklered warehouse containing other storage.

34.10.2 Indoor Storage. Idle pallets shall be permitted to be stored in a building used for other storage or other purpose if the building is sprinklered in accordance with Section 13.3.

See 34.2.4 for requirements related to the use of plastic pallets.

34.10.3* Outdoor Storage.

A.34.10.3 The practice that some materials are stored on pallets in an open yard is recognized. Since stacks of idle pallets present a severe fire problem, attention needs to be paid to the storage arrangements of the pallets. Manual outside open sprinklers generally are not a reliable means of protection unless property is attended to at all times by plant emergency personnel. Open sprinklers with a deluge valve are preferred.

• *N* **34.10.3.1** The storage of wood and wood composite pallets or listed pallets equivalent to wood at pallet manufacturing and pallet recycling facility sites shall comply with 34.10.4.

N **34.10.3.2** Idle pallets stored outside shall be stored in accordance with Table 34.10.3.2(a) and Table 34.10.3.2(b).

34.10.3.3 Idle pallet stacks shall not exceed 15 ft (4.6 m) in height nor shall cover an area of greater than 400 ft^2 (37 m^2). Pallet stacks shall be arranged to form stable piles. A distance of not less than 8 ft (2.4 m) shall separate stacks. Piles shall be no closer than 8 ft (2.4 m) to any property line.

N **34.10.4 Outside Storage at Pallet Manufacturing and Pallet Recycling Facilities.**

N **34.10.4.1*** The outside storage of wood and wood composite pallets or listed pallets equivalent to wood on the same site as a pallet manufacturing or pallet recycling facility shall comply with 34.10.4.

N **A.34.10.4.1** Pallets staged outdoors at pallet manufacturing and recycling facilities should not be defined as idle (i.e., not active or not in use) considering that these facilities stage work-in-process pallets in an active management environment according to the following:

(1) Pallets are the primary business activity at these manufacturing and recycling facilities.
(2) Pallet inventories are organized in a specific manner based on size and quality.
(3) Pallet inventories are rotated on a routine basis.
(4) Personnel are a frequent presence in the staging area during hours of operation.

Combustible pallets listed and labeled to ANSI/FM 4996, *Classification of Pallets and Other Material Handling Products as Equivalent to Wood Pallets,* or to UL 2335, *Standard for Fire Tests of Storage Pallets*, should be treated as wood pallets.

Subsection 34.10.4, which is new for the 2018 edition of the *Code*, addresses the outside storage of wood and wood composite pallets and those listed pallets equivalent to wood, specifically at pallet manufacturing and pallet recycling facilities. It is not the intent of this subsection that it apply to pallets that are not wood or not a listed equivalent.

UL 2335 and ANSI/FM 4996 are large-scale calorimeter tests. Listed plastic pallets are available that exhibit fire performance

***TABLE 34.10.3.2(a)** Required Clearance Between Outside Idle Pallet Storage and Other Yard Storage*

Pile Size	Minimum Distance ft	Minimum Distance m
Under 50 pallets	20	6
50–200 pallets	30	9
Over 200 pallets	50	15

***TABLE 34.10.3.2(b)** Required Clearance Between Outside Idle Pallet Storage and Building*

	Minimum Distance of Wall from Storage					
	Under 50 Pallets		50 to 200 Pallets		Over 200 Pallets	
Wall Construction	ft	m	ft	m	ft	m
Masonry with no openings	0	0	0	0	15	4.6
Masonry with wired glass in openings, outside sprinklers, and 1-hour doors	0	0	10	3	20	6
Masonry with wired or plain glass, outside sprinklers, and ¾-hour doors	10	3	20	6	30	9
Wood or metal with outside sprinklers	10	3	20	6	30	9
Wood, metal, or other	20	6	30	9	50	15

similar to that of wood pallets in these tests and can be treated as equivalent to wood pallets for commodity classification (see Exhibit 34.9).

Outdoor pallet storage areas for manufacturing and recyclers of pallets are treated differently from the storage of idle pallets currently in the *Code* because pallets at those facilities are not idle, nor are they managed in a manner like idle pallets. Pallet manufacturers and recyclers have intimate knowledge of their pallet inventory, because it is considered an asset. The storage areas are fluid environments in which pallets are being moved and replaced on a daily basis.

The outdoor storage area of pallet manufacturing and recycling facilities is an active management environment. Personnel are a constant presence within the storage area so that fire hazards can be identified and reported, and immediate corrective action can occur. Storage yards are organized by pallet type and into recycle streams for high operational efficiency and are kept sufficiently free of waste and debris, and perimeters are well maintained. The intent of the new requirement in 34.10.4 is to reduce the likelihood of fire at pallet manufacturing and recycling facilities through best practices. In the event that a fire does occur, measures are described that will mitigate the spread of fire to adjoining structures and properties through the establishment of pallet pile spacing between buildings and property lines.

N **34.10.4.2** Each site shall maintain a current site plan. The site plan shall be submitted to the authority having jurisdiction for review and approval and shall include all of the following:

(1) Lot lines
(2) Utilities
(3) Size, location, and type of construction of the buildings on the property
(4) Presence of fire protection systems
(5) Water supply sources for fire-fighting purposes
(6) Locations of hazardous material storage areas
(7) Location of pallet storage
(8) Equipment protected with a dust collection system
(9) Fire department access routes
(10) Designated smoking areas
(11) Locations of fire alarm control panels

N **34.10.4.3** The owner or designated representative shall submit a fire prevention plan for review and approval by the authority having jurisdiction that includes all of the following:

(1) Frequency of walk-through inspections to verify compliance with the approved fire prevention plan
(2) Hot work permit process in accordance with Chapter 41
(3) Preventive maintenance program for equipment associated with the pallet activities
(4) Inspection, testing, and maintenance of fire protection systems in accordance with Chapter 13
(5) Frequency of walk-through inspections to verify pallet stack height, area, and setbacks are in compliance with 34.10.4

N **34.10.4.4** The owner or designated representative shall prepare and train employees in an approved emergency action plan in accordance with Section 10.8.

N **34.10.4.5** The owner or designated representative shall prepare a security management plan based on a security risk assessment and shall make the plan and assessment available to the AHJ upon request.

N **34.10.4.6** Unless permitted by 34.10.4.11, stacks of pallets shall not be stored within 0.75 times the stack height or 8 ft (2.4 m), whichever is greater, of any property line.

N **34.10.4.7** Unless permitted by 34.10.4.11, stacks of pallets shall not be stored within 0.75 times the stack height of any important building on site.

N **34.10.4.8** Pallet stacks shall not exceed 20 ft (6 m) in height.

Example 1

A facility has pallet stacks that are the maximum 20 ft (6 m) in height.

Paragraph 34.10.4.6 would limit the stacks from being located within 16 ft (4.9 m) of any property line:

$$20 \text{ ft } (6 \text{ m}) \times 0.75 = 16 \text{ ft } (4.9 \text{ m})$$

Paragraph 34.10.4.7 would limit the stacks from being located within 16 ft (4.9 m) from any important building on site:

$$20 \text{ ft } (6 \text{ m}) \times 0.75 = 16 \text{ ft } (4.9 \text{ m})$$

Example 2

A facility has pallet stacks that are 9 ft (2.7 m) in height.

Per 34.10.4.6, the stacks cannot be stored within 8 ft (2.4 m) of any property line.

9 ft (2.7 m) × 0.75 = 6.75 ft (2.06 m), but 34.10.4.6 permits 0.75 times the stack height or 8 ft (2.4 m), whichever is greater.

Per 34.10.4.7, the stacks cannot be stored within 8 ft (2.4 m) of any important building on site.

9 ft (2.7 m) × 0.75 = 6.75 ft (2.06 m), but 34.10.4.6 permits 0.75 times the stack height or 8 ft (2.4 m), whichever is greater.

The term *important building* is defined in 3.3.29.7 as "a building that is considered not expendable in any exposure fire."

N **34.10.4.9*** The size of pallet arrays shall comply with one of the following:

(1) Where the access to the pallet array is less than 20 ft (6 m) in width but at least 8 ft (2.4 m) in width, the nearest edge of any individual pallet stack shall be no more than 30 ft (9 m) from the access.
(2) Where the access to the pallet array is by a fire department access route complying with Section 18.2, the nearest edge of any individual pallet stack shall be no more than 50 ft (15 m) from the access.
(3) The individual pallet stack depth from access within pallet arrays at existing facilities that exceed 34.10.4.9(1) or 34.10.4.9(2) shall be as approved by the AHJ.

N **A.34.10.4.9** The access to the individual pallet stacks within a pallet array is based upon water stream reach. The 30 ft (9 m) depth in 34.10.4.9(1) using an 8 ft (2.4 m) wide aisle is based upon hand hose line stream reach. The 50 ft (15 m) depth in 34.10.4.9(2) is based upon master stream reach whether from a deck gun mounted upon an engine or from an aerial device.

The arrangement can be in any configuration as long the measurement to the individual pallet stack within the pallet array meets 34.10.4.9(1) or 34.10.4.9(2). The configuration can be with 8 ft or 50 ft (2.4 m or 15 m) aisle on one side, an 8 ft or 50 ft (2.4 m or 15 m) aisles on both sides, or a combination of aisle widths.

Paragraph 34.10.4.9 controls the depth of a pallet array based upon effective fire stream discharge. Where the discharge may be from hand lines or surface master stream devices, the depth of the individual pallet stack within the pallet array is restricted by requiring that no pallet be more than 30 ft (9 m) from the access provided to the pallet arrays. Where the discharge may be by engine-mounted or aerial master stream devices, the depth of the pallet array is restricted such that no pallet is more than 50 ft (15 m) from the fire department access route complying with Section 18.2 [20 ft (6 m) in width].

Exhibit 34.13 shows an aerial view of wood pallet storage governed by 34.10.4. The stacks are arranged to provide adequate fire department access in accordance with 34.10.4.9. The stacks would be limited to a height of not more than 20 ft (6 m) in accordance with 34.10.4.8.

Exhibit 34.13

Wood pallet storage arrays. (© 2016 Google)

N **34.10.4.10*** Fire flow requirements for the site shall be determined by the AHJ.

N **A.34.10.4.10** The required fire flow should be based on available water supplies, fire department response capabilities, and exposure hazards.

N **34.10.4.11** Portable fire extinguishers shall be selected, installed, and maintained in accordance with Section 13.6.

N **34.10.4.12** The AHJ shall be permitted to allow pallet stacks closer to a property line or structure on site where additional fire protection is provided, including, but not limited to, the following:

(1) The storage yard areas and materials-handling equipment selection, design, and arrangement are based upon an approved risk assessment.
(2) Automatic fire detection transmits an alarm signal to a supervising station in accordance with *NFPA 72*.
(3) Fire department access roads are provided around all storage areas.

Animal Housing Facilities

35

N 35.1 General

General. Animal housing facilities shall comply with NFPA 150 and this chapter.

N 35.2 Permits

Permits, where required, shall comply with Section 1.12.

Chapter 35 is new to the 2018 edition of the *Code* and mandates compliance with NFPA 150, *Standard on Fire and Life Safety in Animal Housing Facilities*. The edition of NFPA 150 referenced by this *Code* is the 2016 edition. NFPA 150 provides the minimum requirements for the design, construction, fire protection, and classification of animal housing facilities. Animal housing facilities are to be designed, constructed, and maintained in accordance with the adopted building, fire, and life safety codes in addition to the provisions of NFPA 150. In addition, NFPA 150 also addresses the protection of the animal handlers (life safety) who work within animal housing facilities.

Reference Cited in Commentary

NFPA 150, *Standard on Fire and Life Safety in Animal Housing Facilities,* 2016 edition.

Telecommunication Facilities and Information Technology Equipment

36

Chapter 36 provides mandatory references to NFPA 75, *Standard for the Fire Protection of Information Technology Equipment*, and NFPA 76, *Standard for the Fire Protection of Telecommunications Facilities,* recognizing the unique hazards posed by, and risks to, such facilities from fire. Neither NFPA 75 nor NFPA 76 is intended to be applied retroactively to existing facilities (i.e., facilities constructed prior to the adoption date of this *Code* by the jurisdiction) unless specifically indicated by the applicable reference standard.

36.1 General

Δ **36.1.1** Telecommunication facilities shall comply with NFPA 76.

NFPA 76 is not intended to be applied to telecommunications rooms used to provide private telecommunications services. The facilities intended to be regulated by NFPA 76 are referred to by NFPA *101*®, *Life Safety Code*®, and *NFPA 5000*®, *Building Construction and Safety Code*®, as telephone exchanges.

Δ **36.1.2** Information technology equipment and information technology equipment areas shall comply with NFPA 75.

NFPA 75 defines the term *ITE [information technology equipment] system* as "any electronic digital or analog computer, along with all peripheral, support, memory, programming, or other directly associated equipment, records, storage, and activities." The application of NFPA 75 is based on the risk considerations outlined in Chapter 4 of that standard. The mere presence of information technology equipment should not constitute the need to invoke the requirements of NFPA 75.

Fixed Guideway Transit and Passenger Rail Systems

37

Chapter 37 provides a mandatory reference to NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems*. NFPA 130 addresses life safety from fire and fire protection requirements for underground, surface, and elevated fixed guideway transit and passenger rail systems, including, but not limited to, stations, trainways, emergency ventilation systems, vehicles, emergency procedures, communications, and control systems. A subway station, such as the one pictured in Exhibit 37.1, would be regulated by NFPA 130.

Exhibit 37.1

Subway station. (Thinkstock)

Δ 37.1 General

Fixed guideway transit and passenger rail system facilities shall comply with NFPA 130.

NFPA 130 applies to new fixed guideway transit and passenger rail systems and to extensions of existing systems. The portion of the standard dealing with emergency procedures applies to new and existing systems.

NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems*, 2017 edition.

Marijuana Growing, Processing, or Extraction Facilities

38

Chapter 38 is new to the 2018 edition of the *Code*. It was developed in response to a request from jurisdictions that are seeing an increase in facilities processing marijuana, either growing, harvesting, or extracting tetrahydrocannabinol (THC) oils from the plant to use in other marijuana based products. Over the past few years, the number of states that recognize the legal use of marijuana, on either a medicinal or a recreational level, has increased. As a result, more facilities, either newly constructed or moving into existing buildings, are being used for marijuana production. Prior to Chapter 38, no NFPA code or standard addressed the hazards specific to marijuana production facilities. This new chapter addresses the hazards unique to these types of facilities and processes while also recognizing other necessary fire protection measures addressed elsewhere in the *Code*. It is not intended to create a new occupancy; rather, it highlights those requirements necessary for fire inspectors to help ensure the safety of building occupants, property protection, and fire fighter safety where the growing or processing or marijuana occurs.

The September/October 2016 issue of NFPA Journal featured a lead article on the commercial marijuana industry and the fire and life safety lessons learned by industry experts in the field. The article and other features provide expert insight into an unlikely industry and their need for standardization. This article should be referenced for additional information along with the commentary contained in this Chapter.

N 38.1* Application

N **A.38.1** Processing of other agricultural products not addressed by this chapter should comply with other applicable sections of this *Code*.

N **38.1.1*** Chapter 38 shall apply to the growing and processing of marijuana within new and existing buildings.

N **A.38.1.1** For the purposes of this *Code*, the term *marijuana* includes all forms of cannabis, including hemp.

N **38.1.2** The use, storage, transfilling, and handling of hazardous materials shall comply with this chapter, and other applicable provisions of this *Code*.

Hazardous materials are used throughout the production of marijuana, mainly during the extraction of THC. Chapter 38 does not regulate the storage, use, and handling of these hazardous materials but references the other chapters of the *Code* that contain requirements for these materials. Requirements for hazardous materials include limitations on the maximum allowable quantities (MAQs), protection of areas using excessive quantities of hazardous materials, separation of areas using hazardous material, and safe practices for those materials in use. See Chapters 60 through 75 for additional details as necessary.

N **38.1.3** Chapter 38 shall not apply to the retail sale of marijuana where growing and processing does not occur.

N **38.1.4** Where a material, its use, or associated process poses multiple hazards, all hazards shall be addressed in accordance with applicable requirements of this *Code*.

N **38.1.5*** The occupancy of buildings or portions of buildings where the growing or processing of marijuana occurs shall be in accordance with Chapter 6 and the applicable building code.

N **A.38.1.5** Occupancy classification should take into consideration the hazards associated with the process occurring in the facility and the quantities of high-hazard contents.

Marijuana growing, processing, and extraction facilities are not a separate occupancy classification. The occupancy classification of the facility should be based on the occupancy definitions found in Chapter 6 of this Code and the applicable building code. Depending on the facility, likely occupancy classifications for marijuana growing, processing, and extraction facilities are industrial or storage occupancies. A facility that does not grow, process, or use marijuana in an extraction process but does sell marijuana and associated products should not utilize the provisions of this chapter, which do not apply to the retail sale of marijuana. An occupancy used for the display and sale of merchandise is defined as a mercantile occupancy. See Chapter 6 for additional details on occupancy classification.

N 38.2 Permits

Permits, where required, shall comply with Section 1.12.

N 38.3 Fire Protection Systems

Fire protection systems shall be provided in accordance with Chapter 13.

N 38.4* Means of Egress

Means of egress shall be in accordance with Chapter 14.

N **A.38.4** Due to security of growing and processing operations, access control, electromagnetic locks, and other locking arrangements are used. Chapter 14 addresses the installation of specialized locking devices.

Marijuana growing facilities, in particular, can be crowded because much of the space is occupied by plants. Growing facilities can be very large and are set up with various rooms or partitioned areas of plants sorted by their stage in the grow cycle. It can be easy for the plants to overtake the designated egress facilities or for a grow setup to block or obstruct access to exits. One of the more common egress issues with grow facilities is obstruction of egress or lack of signage to identify the egress paths. Compliance with Chapter 14 of this *Code* ensures that egress is continuously maintained free of obstructions or impediments to full instant use in the case of fire or other emergency and also that appropriate signage is provided to guide both occupants and fire fighters to the required exits. Like other industrial-type facilities, egress capacity is generally not a concern since occupant load is relatively low and most of the space is occupied by plants or equipment. See Chapter 14 for additional requirements for means of egress.

N 38.5 Growing or Production of Marijuana

N **38.5.1 Ventilation for Light Fixtures.** Light fixture ductwork shall be installed in accordance with the manufacturer and NFPA 90A.

Exhibit 38.1 shows the sophisticated arrangement of light fixtures in a marijuana growing facility. Marijuana plants are grown in a controlled environment and rely heavily on special grow lights for the most efficient growth and for healthy plants. The grow lights, as well as other equipment such as heating, ventilating, and air-conditioning (HVAC) units for climate control can place a high demand on electrical systems. Light fixture ductwork must be installed in accordance with the manufacturer's instructions as well as the provisions of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*. For additional requirements for electrical fire safety, including wiring, fixtures and equipment, see Section 11.1 of this *Code*.

Exhibit 38.1

Complex arrangement of light fixtures in marijuana growing area.

N **38.5.2 Odor Control.** The use of ozone generators used for odor control shall comply with Chapter 54.

N **38.5.3 Interior Finish, Contents, and Furnishings.**

N **38.5.3.1** Interior finish, including the use of any plastic, mylar, or other thin film sheeting to enclose rooms or cover any walls or ceilings shall be in accordance with Sections 12.5 and 12.6.

N **38.5.3.2** Hanging of plastic from ceiling or from suspended overhead structures to create wall dividers shall not be permitted.

N **38.5.4 Fumigation.**

N **38.5.4.1* General.** Any marijuana growing facility that is fumigated shall comply with 38.5.4.

N **A.38.5.4.1** Fumigation for marijuana growing, processing, or extraction facility includes the production or use of sulfur dioxide.

The quality and integrity of the marijuana plants are critical to the success of the product. An infestation of insects or invasion from mold or fungi could result in millions of dollars lost. Fumigants often are used during the grow process to control invasive pests and plant diseases. Some fumigants may be flammable and some can be toxic or poisonous, which can be dangerous to both occupants and fire fighters. A common fumigation method is the use of sulfur burners to control mildew. Sulfur burners create sulfur dioxide, which can be harmful to respiratory systems.

Subsection 38.5.4 addresses issues with fumigation such as reduction or elimination of ignition sources, notification of the local authority having jurisdiction (AHJ) or fire department when fumigation occurs, warning signage, watch personnel, occupancy during the fumigation process, and clean up.

N **38.5.4.2* Sources of Ignition.** Sources of ignition shall be shut off during the fumigation activity and remain shut off until the required ventilation is completed.

N **A.38.5.4.2** Fires, open flames, and similar sources of ignition should be eliminated from the space under fumigation or insecticidal fogging. Electricity in any part of the building, structure, or space where operation of switches or electrical devices, equipment, or systems could serve as a source of ignition should be shut off. In addition, electronic devices, including portable equipment and cellular phones, should be shut off and telephone lines should be disconnected from telephones.

N **38.5.4.3 Notification.**

N **38.5.4.3.1** The AHJ and fire department shall be notified in writing not less than 48 hours before the building, structure, or space is to be closed in connection with the utilization of any toxic or flammable fumigant.

N **38.5.4.3.2** Notification, as required by 38.5.4.3.1, shall include the following:

(1) The location of the enclosed space to be fumigated or fogged
(2) The occupancy
(3) The fumigants or insecticides to be utilized
(4) The person or persons responsible for the operation
(5) The date and time at which the operation will begin

N **38.5.4.3.3** Written notice of any fumigation or insecticidal fogging operation shall be given to all affected occupants of the building, structure, or space in which such operations are to be conducted with sufficient advance notice to allow the occupants to evacuate the building, structure, or space.

N **38.5.4.3.4** Written notice, as required by 38.5.4.3.3, shall inform the occupants as to the purposes, anticipated duration, and hazards associated with the fumigation or insecticidal fogging operation.

N **38.5.4.4 Signage.**

N **38.5.4.4.1** Approved warning signs indicating the danger, type of chemical involved, and necessary precautions shall be posted on all doors and entrances to the premises, including interior rooms and areas.

N **38.5.4.4.2** Signage shall be located at the exterior main entry and at the entries to those areas being fumigated indicating the duration of the fumigation.

N **38.5.4.5 Watch Personnel.**

N **38.5.4.5.1** During the period fumigation is in progress a watchperson shall remain on duty at the entrance or entrances to the enclosed fumigated space until after the fumigation is completed and the building, structure, or space is properly ventilated and safe for occupancy.

N **38.5.4.5.2** Sufficient watchpersons shall be provided to prevent any person from entering the enclosed space under fumigation unobserved.

N **38.5.4.6 Occupancy During Fumigation.** Occupants of the building, structure, or space to be fumigated, except the personnel conducting the fumigation, shall be evacuated from such building, structure, or space prior to commencing fumigation operations.

N **38.5.4.7 Sealing of Building Structure, or Space.** Paper, and other similar materials, used to wrap or cover a building, structure, or space in excess of that required for the sealing of cracks, casements, and similar openings shall meet the flame propagation performance criteria of Test Method 1 or Test Method 2 of NFPA 701.

N **38.5.4.8 Maintenance of Openings.** All openings to the building, structure, or space to be fumigated or fogged shall be kept securely closed during such operation.

N **38.5.4.9 Venting and Cleanup.** At the end of the exposure period the following procedures shall be followed:

(1) Fumigators shall safely and properly ventilate the premises and contents.
(2) Fumigant containers, residues, debris, and other materials used for such fumigation shall be properly disposed.
(3) Obstructions shall be cleared from gas-fired appliance vents.

N **38.5.5 Pesticide Application.**

N **38.5.5.1** A warning sign shall be provided to indicate that pesticides have been applied.

Pesticides, like fumigants, are used to prevent an infestation from insects or other organisms that could cause damage to and risk loss of the marijuana crop.

N **38.5.5.2** A record of pesticide application shall be provided and shall include the following:

(1) The pesticide product or chemical used
(2) The date and time the pesticide was applied
(3) When the room or area is safe to reoccupy

N 38.6* Processing or Extraction

N **A.38.6** Flammable or combustible liquids, flammable gases, liquefied petroleum gases, or nonflammable gases used in extraction processing of oils and fats are hereinafter referred to as “solvents.”

The extraction process includes extracting the oils and fats by use of a solvent, desolventizing the raw material and producing the miscella, distilling the solvent from the miscella, and recovering the solvent.

Another phase in marijuana cultivation and production is extraction. During the extraction process, THC is separated from the plant and processed into an oil that can be used in products. Extraction of the THC-based oils from the plants utilizes specialty equipment and solvents. One of the biggest hazards during the extraction process is the use of flammable/combustible liquids, liquefied petroleum gases, and carbon dioxide (CO_2).

Section 38.6 addresses general requirements for extraction, including the construction and protection of the extraction room, staffing of extraction areas and equipment, equipment operator training, signage, and equipment.

N **38.6.1 General.**

N **38.6.1.1 Extraction Room.**

N **38.6.1.1.1** Extraction rooms in a marijuana extraction facility shall be constructed in accordance with the building code and this *Code*.

N **38.6.1.1.2*** For other than CO_2 and nonhazardous extraction process, the marijuana extraction equipment and process shall be located in a room of noncombustible construction dedicated to the extraction process and the room shall not be used for any other purpose.

N **A.38.6.1.1.2** The dedicated room should not be used for any other purpose, including storage. Materials that might interfere with the operation of exhaust systems should be prohibited, such as acoustical ceiling tiles.

The requirement to locate the extraction equipment and the process area in a room of noncombustible construction helps to isolate the hazards associated with the process and provide a separation between the extraction process and the remainder of the building should an emergency occur during extraction.

N **38.6.1.1.3** Marijuana extraction shall not be located in any building containing assembly, educational, day care, health care, ambulatory health care, residential board and care, residential, or detention and correctional facilities.

N **38.6.1.1.4* Means of Egress.** For extraction rooms using hazardous materials, each room shall be provided with at least one exit access door complying with the following:

(1) The door shall swing in the direction of egress travel.
(2) The door shall be provided with a self-closing or automatic closing device.
(3) The door shall be equipped with panic or fire exit hardware.

N **A.38.6.1.1.4** Examples of rooms using hazardous materials for extraction are those using flammable and combustible liquids and CO_2.

When an emergency occurs where hazardous materials are being used, there is little time for egress. The requirements in 38.6.1.1.4(1) through (3) ensure that personnel who are in the extraction room are not held up by attempting to operate an egress door. Doors that swing in the direction of egress travel and are equipped with panic or fire exit hardware require only the force of an occupant(s) to release the latch and open the door. The presence of self-closing or automatic closing devices ensures that the door will close on its own and protect the opening to the extraction room.

N **38.6.1.2 Staffing.**

N **38.6.1.2.1*** For other than approved, unattended processes, the extraction process shall be continuously staffed.

N **A.38.6.1.2.1** Nonhazardous processes might not warrant constant attendance by trained personnel.

The marijuana extraction process is a specialized process utilizing equipment designed specifically for that process. Because a majority of the THC extraction process involves the use of flammable and combustible liquids and gases, it is critical that the process be continuously staffed to monitor for any safety issues, leaks, system malfunctions, or incidents requiring immediate response or reporting.

N **38.6.1.2.2*** Staff monitoring the extraction process shall be trained in the following:

(1) The extraction process
(2)* The transfer of solvents, where applicable

N **A.38.6.1.2.2(2)** The transfer of solvent includes LPG liquid transfilling.

(3) All emergency procedures

N **A.38.6.1.2.2** Staff monitoring the extraction process do not need to meet the training requirements of 38.6.1.3.

N **38.6.1.2.3** All staff training records shall be maintained on-site and made available to the AHJ upon request.

N **38.6.1.3 Operator Training.**

N **38.6.1.3.1** In addition to the provisions of 38.6.1.2, the operator of the marijuana extraction equipment shall also receive training in safe operation of the equipment.

N **38.6.1.3.2*** Documentation of training required by 38.6.1.3.1 shall be maintained on-site and made available to the AHJ upon request.

N **A.38.6.1.3.2** Examples of these programs include, but are not limited to, the following:

(1) Training programs developed by extraction equipment manufacturers
(2) Compressed Gas Association CGA P-1, *Safe Handling of Compressed Gases in Containers*, for operators of CO_2 equipment
(3) Programs by governmental organizations

N **38.6.1.4 Signage.**

N **38.6.1.4.1** All applicable safety data sheets (SDS) shall be posted in the extraction room.

Exhibit 38.2 shows the material safety data sheets available posted in the extraction facility.

N **38.6.1.4.2** The NFPA 704 hazard rating diamond sign and no smoking signs shall be posted on the exterior of the extraction room door.

Exhibit 38.2

Safety data sheets posted in extraction area.

N **38.6.1.4.3** Applicable hazard warning signage shall be posted throughout the facility as applicable for emergency equipment.

N **38.6.1.5 Systems, Equipment, and Processes.**

N **38.6.1.5.1 General.**

N **38.6.1.5.1.1** Systems, equipment, and processes shall be in accordance with 38.6.1.5.1 through 38.6.1.5.6.3.

N **38.6.1.5.1.2** Systems, equipment, and processes shall include, but are not limited to, vessels, chambers, containers, cylinders, tanks, piping, tubing, valves, fittings, and pumps.

N **38.6.1.5.1.3** In addition to the requirements in 38.6.1.5, systems, equipment, and processes shall also comply with 60.5.1.6, other applicable provisions of this *Code*, the building code, and NFPA 90A.

N **38.6.1.5.1.4** Systems or equipment used for the extraction of marijuana/cannabis oils and products from plant material shall be performed using equipment that has been listed or approved.

N **38.6.1.5.2 Equipment.**

N **38.6.1.5.2.1** Where an explosion condition exists, heating equipment such as vacuum ovens, heating mantels, heat guns, or other equipment shall not be used to heat flammable or combustible liquids or oils containing liquefied petroleum gasses.

N **38.6.1.5.2.2** Refrigerators, freezers, and other cooling equipment used to store or cool flammable liquids shall be listed for the storage of flammable/combustible liquids or be listed for Class I, Division 1 locations, as described in Article 501 of *NFPA 70*.

N **38.6.1.5.2.3*** LPG tanks shall comply with 69.2.1.

N **A.38.6.1.5.2.3** The provisions for container (i.e., tank) construction are applicable to the working tank or the supply tank that is connected to the extraction equipment.

N **38.6.1.5.3 Approval for Systems and Equipment with No Listing.**

N **38.6.1.5.3.1** Where the system used for extraction of marijuana oils and products from plant material is not listed, the system shall have a designer of record.

N **38.6.1.5.3.2** The designer of record shall be a registered design professional.

N **38.6.1.5.4* Documentation for Equipment with No Listing.** For systems and equipment not listed for the specific use, a technical report in accordance with Section 1.15 documenting the design or peer review of the equipment shall be prepared and submitted to the AHJ for review and approval.

N **A.38.6.1.5.4** The technical report documenting the design or peer review should be submitted for review and approval to the AHJ prior to the equipment being located or installed at the facility.

Where a technical report is required to be submitted for review and approval by the AHJ, the following should occur:

(1) Prior to submittal of the technical report, the engineer should submit to the AHJ any educational background and professional experience specific to the review and approval of system, equipment, and processes with like hazards of those associated with the marijuana extraction system.
(2) Once the proof of qualifications are found acceptable by the AHJ, the engineer of record should produce the technical report and the report should be signed and sealed in accordance with respective state requirements.

All of, but not limited to, the following items should be included in the technical report:

(1) Manufacturer information.
(2) Engineer of record information.
(3) Date of review and report revision history
(4) Signature page, which should include the following:
    (a) Author of the report
    (b) Date of report
    (c) Seal, date, and signature of engineer of record performing the design or peer review
    (d) Date and signature of the engineer performing the engineering check of the report (which cannot be performed by the authoring engineer though it can be from the same firm as the authoring engineer)
(5) Model number of the item evaluated. If the equipment is provided with a serial number, the serial number should be included for verification at time of site inspection.
(6) Methodology of the design or peer review process used to determine minimum safety requirements. Methodology should consider the basis of design, and should include a code analysis and code path to demonstrate the reason as to why specific code or standards are applicable or not.
(7) Equipment description. A list of all components and subassemblies of the system or equipment, indicating the materials, solvent compatibility, maximum temperature, and pressure limits.

(8) A general flow schematic or general process flow diagram (PFD) of the process. All primary components of the process equipment should be identified and match the aforementioned list. Operating temperatures, pressures, and solvent state of matter should be identified in each primary step or component. A piping and instrumentation diagram (PID or PI&D) might be provided but is not required.
(9) Analysis of the vessel(s) if pressurized beyond standard atmospheric pressure. Analysis should include purchased and fabricated components.
(10) Structural analysis for the frame system supporting the equipment.
(11) Process safety analysis of the extraction equipment, from the introduction of raw product to the end of the extraction process.
(12) Comprehensive process hazard analysis considering failure modes and points of failure throughout the process. This portion of the review should include review of emergency procedure information provided by the manufacturer of the equipment or process and not that of the facility, building, or room.
(13) Review of the assembly instructions, and operational and maintenance manuals provided by the manufacturer.
(14) Findings and observations of the analysis.
(15) List of references used in the analysis.

If the technical report or manufacturer's literature indicate specific requirements for the location, room, space, or building where the extraction process is to occur, the engineer of record, as approved, should review the construction documents of such location, room, space, or building and provide a report of their findings and observations to the AHJ.

The findings and observations should include the following:

(1) Process safety analysis of the entire process from raw material to finished product.
(2) Comprehensive process hazard analysis considering failure modes and points throughout the process and a review of emergency procedures as related to the equipment or process and the facility.

One of the biggest challenges to fire inspectors with marijuana extraction facilities in their jurisdictions is understanding and evaluating the extraction equipment setup. Paragraph 38.6.1.5.1.4 requires that systems or equipment used for the extraction of marijuana/cannabis oils and products from plant material be performed using equipment that has been listed or approved. However, at this time, no standard for which to list this equipment that is used exclusively for the extraction of THC from marijuana plants exists. Marijuana extraction equipment on the market has not been extensively tested or listed by large-scale testing laboratories. Fire inspectors and AHJs are often faced with enforcing regulations for facilities that may have different types of equipment setups for the extraction process. Because the marijuana production industry is so new, there is a lack of expertise in understanding the equipment to determine if it is safe to use in day-to-day operations. As the industry evolves, it is almost certain that further regulation and standardization will follow. It is the intent of this Chapter 38 of this Code to reference those standards as they become available.

For now, the purpose of 38.6.1.5.3 and 38.6.1.5.4 is to offer detailed requirements to offset the lack of formal listing standards for equipment. Where the system used for extraction of marijuana oils and products from plant material is not listed, the system must have a designer of record who is a registered design professional. A registered design professional (RDP), is defined in the *Code* as an individual who is registered or licensed to practice his or her design profession as defined by the statutory requirements of the professional registration laws of the state or jurisdiction in which the project is to be constructed.

For systems and equipment not listed for the specific use, a technical report in accordance with Section 1.15 documenting the design or peer review of the equipment shall be prepared and submitted to the AHJ for review and approval. A minimum of the 15 items listed in A.38.6.1.5.4 should be included in the technical report to aid the AHJ in evaluating the equipment design. When developing the provisions for this new chapter, the Technical Committee took very seriously the level of detail offered by A.38.6.1.5.4. Because there is a lack of regulation for extraction equipment, this information is what AHJs will use to make their judgement as to the safety of the extraction equipment. This is an essential piece to enforcing marijuana production regulations and the safety of occupants, the property, and fire fighters.

N **38.6.1.5.5 Change of Extraction Medium.**

N **38.6.1.5.5.1** Where the medium of extraction or solvent is changed from the material indicated in the technical report or as required by the manufacturer, the technical report shall be revised at the cost of the facility owner and submitted for review and approval by the AHJ prior to the use of the equipment with the new medium or solvent.

N **38.6.1.5.5.2** If the original designer of record is not available, then the new designer of record shall comply with 38.6.1.5.3.1.

An example of a change in extraction medium or solvent would be from liquid butane to another flammable or combustible liquid or to CO_2. Because the hazards associated with the new solvent will change, the technical report must be revised to reflect the impact that the new solvent will have on the extraction process and any associated safety requirements

N **38.6.1.5.6 Equipment Field Verification.**

N **38.6.1.5.6.1** Prior to operation of the extraction equipment, the designer of record for the equipment shall inspect the site of the extraction process once equipment has been installed for compliance with the technical report and the building analysis.

N **38.6.1.5.6.2** The designer of record performing the field verification shall provide a report of findings and observations of the site inspection to the AHJ for review and approval prior to the approval of the extraction process.

N **38.6.1.5.6.3** The field inspection report authored by designer of record shall include the serial number of the equipment used in the process and shall confirm the equipment installed is the same model and type of equipment identified in the technical report.

N **38.6.2 Liquified Petroleum Gas (LPG) Extraction.**

The remainder of Chapter 38 addresses the requirements for each specific solvent/extraction medium used in the extraction process. Different solvents present different hazards. This chapter does not attempt to rewrite requirements for hazardous materials that are found elsewhere in the *Code*; rather, it makes references to those requirements and highlights additional provisions that are necessary for the marijuana extraction process.

Extraction facilities are required to comply with 38.6.1 for general provisions as well as the additional requirements set forth in 38.6.2, 38.6.3, or 38.6.4, depending on the solvent being used in the extraction process.

N **38.6.2.1 General.** Marijuana extraction facilities using liquefied petroleum gas solvents shall comply with 38.6.1 and 38.6.2.

Butane is one of the most common solvents used to extract THC oils from the marijuana plants. It is used in its liquid form. While butane is one of the most common solvents used in the extraction process, it is also the cause of many residential incidents in which inexperienced consumers have used butane improperly, leading to explosions and even fatalities. Other hydrocarbons such as propane and hexane are also used.

N **38.6.2.2 Exhaust.**

N **38.6.2.2.1** An approved exhaust system shall be provided for LPG extractions.

N **38.6.2.2.2** The exhaust systems shall be installed and maintained accordance with NFPA 91 or the mechanical code.

N **38.6.2.2.3** All LPG extraction operations, including processes for off-gassing spent plant material and oil retrieval, shall be conducted within a chemical fume hood or enclosure in compliance with NFPA 91 or the mechanical code.

N **38.6.2.3 Electrical.**

N **38.6.2.3.1** All conductive equipment and conductive objects within the exhaust room shall be bonded and grounded with a resistance of less than 1.0 × 106 ohms in accordance with *NFPA 70*.

N **38.6.2.3.2** The area within a hood or enclosure used for LPG extractions shall be classified as a Class I, Division 1 hazardous location in accordance with *NFPA 70*.

Class I locations are those in which flammable gases, flammable liquid–produced vapors, or combustible liquid–produced vapors are or may be present in the air in quantities sufficient to produce explosive or ignitible mixtures. The following definition of a Class I, Division 1 location is from *NFPA 70*®, *National Electrical Code*®, Article 500.5(B)(1):

Class I, Division 1. A Class I, Division 1 location is a location:

(1) In which ignitible concentrations of flammable gases, flammable liquid–produced vapors, or combustible liquid–produced vapors can exist under normal operating conditions, or

(2) In which ignitible concentrations of such flammable gases, flammable liquid–produced vapors, or combustible liquids above their flash points may exist frequently because of repair or maintenance operations or because of leakage, or

(3) In which breakdown or faulty operation of equipment or processes might release ignitible concentrations of flammable gases, flammable liquid–produced vapors, or combustible liquid–produced vapors and might also cause simultaneous failure of electrical equipment in such a way as to directly cause the electrical equipment to become a source of ignition

N **38.6.2.3.3** Areas adjacent to Class I, Division 1 locations shall be classified in accordance with *NFPA 70*.

N **38.6.2.3.4** All electrical components within the extraction room shall be interlocked with the hazardous exhaust system such that room lighting and other extraction room electrical equipment will only operate when the exhaust system is in operation.

N **38.6.2.3.5** An automatic emergency power system shall be provided for the following items, when installed:

(1) Extraction room lighting
(2) Extraction room ventilation system
(3) Solvent gas detection system

N **38.6.2.4 Extraction Room Gas Detection System.**

N **38.6.2.4.1** An approved continuous gas detection system shall be provided.

A continuous gas detection system provides continuous operation, and the interval between samplings of any point generally does not exceed 30 minutes.

N **38.6.2.4.2*** The gas detection system shall alert the extraction operator in an approved manner at a gas detection threshold no greater than 25 percent of the gas LEL/LFL.

N **A.38.6.2.4.2** The purpose of alerting the extraction operator is to provide notification that the operator is in a flammable environment because the LP gas used is not odorized. This could be in the form of a visual warning, local alarm, or other approved means. However, it is not intended for evacuation or to dispatch the fire department.

N **38.6.2.4.3** Gas detection systems shall be provided with constant noninterlocked power.

N **38.6.2.5 Protection.** An automatic suppression system shall be provided within hoods or enclosures, including ductwork, in accordance with the following:

(1) An automatic water sprinkler system that meets all applicable requirements of NFPA 13
(2) A carbon dioxide extinguishing system that meets all applicable requirements of NFPA 12

(3) A dry chemical extinguishing system that meets all applicable requirements of NFPA 17
(4) A gaseous agent extinguishing system that meets all applicable requirements of NFPA 2001

N **38.6.2.6 Storage.** LPG containers not in use shall not be stored within extraction rooms.

For additional information on the storage of LPG containers, see Section 69.5 of this *Code*.

N **38.6.2.7 Facility Piping Systems.** LPG liquid piping systems shall be in compliance with NFPA 58.

N **38.6.3 Flammable and Combustible Liquid Extraction.**

N **38.6.3.1 General.** Marijuana extraction facilities using flammable and combustible liquid solvents shall comply with 38.6.1 and 38.6.3.

An example of a flammable and combustible liquid used as a solvent for marijuana extraction is alcohol (ethanol).

N **38.6.3.2 Exhaust.**

N **38.6.3.2.1*** Extraction and post oil processing operations, including dispensing of flammable liquids between containers, shall be performed in one of the following locations:

(1) A chemical fume hood in accordance with Chapter 7 of NFPA 45
(2) An approved exhaust system installed in accordance with NFPA 91 or the mechanical code

N **A.38.6.3.2.1** The intent of this section is to require an exhaust system utilization to capture velocities across the work area. Standard laboratory capture velocity is between 80 and 100 ft/min (24 and 30 m/min).

Most flammable liquid extractions and post oil processing are bench-top process that can be conducted in a chemical fume hood. Larger operations might need larger hoods or special full-room exhaust systems in compliance with NFPA 91 or the mechanical code. The exception is intended for small unheated processes where plant material might be soaked in flammable liquid and directly transferred to a food product.

N **38.6.3.2.2** Unheated processes at atmospheric pressure using less than 16 oz (473 ml) of flammable liquids shall not be required to comply with 38.6.3.2.1.

N **38.6.3.2.3** Classified electrical systems shall be in accordance with *NFPA 70*.

N **38.6.3.2.4** All electrical components within the chemical fume hood or exhausted enclosure shall be interlocked such that the exhaust system shall be in operation for lighting and components to be used.

N **38.6.3.3 Storage and Handling.** The storage, use, and handling of flammable liquids shall be in compliance with this chapter and Chapter 66.

N **38.6.3.4** Heating of flammable or combustible liquids over an open flame shall be prohibited.

N **38.6.4 Carbon Dioxide Extraction.**

N **38.6.4.1 General.** Marijuana extraction facilities using carbon dioxide solvents shall comply with 38.6.1 and 38.6.4.

Using CO_2 in the extraction process eliminates the need for a chemical-based solvent. (Generally, the term *solvent* refers to a chemical solvent. For the purposes of the extraction processes discussed in this chapter, CO_2 is considered a solvent.)

N **38.6.4.2 Storage and Handling.** All CO_2 compressed gas cylinders shall be secured to a fixed object to prevent falling.

N **38.6.4.3 CO_2 Gas Detection.**

N **38.6.4.3.1** An approved, listed CO_2 detector shall be installed in the CO_2 extraction room.

N **38.6.4.3.2** Auto calibrating and self-zeroing devices or detectors shall be prohibited.

N **38.6.4.3.3** The detector shall be set to alarm at 5000 ppm of CO_2.

N **38.6.4.4* CO_2 Discharges.** The extraction equipment pressure relief devices and blow-off valves shall be piped to the exterior of the building.

N **A.38.6.4.4** Exhaust piping can be of the flexible type as long as the piping or hose is capable of handling the force of the exhaust. Relief devices include spring-loaded pressure relief valves or rupture disks.

N 38.7* Transfilling

Filling LPG extraction equipment supply containers shall be in compliance with 69.3.5, 69.4.2, and NFPA 58.

N **A.38.7** The intent of this section is for filling the working container (i.e., tank) connected to the extraction equipment.

Reserved

In the 2018 edition of NFPA 1, *Fire Code,* Chapter 39 is reserved for future use.

Dust Explosion and Fire Prevention

40

Chapter 40 applies to environments in which operations involve the potential for dust explosions due to hazardous dust concentrations and refers the code official to a group of NFPA standards that prescribe requirements for protecting life and property from fire and explosion.

The average inspector responsible for code enforcement is more likely than ever to have the opportunity to inspect many of the types of facilities governed by the standards referenced in this chapter. Ensuring proper compliance with the appropriate standard is imperative. Fires in facilities that are subject to dust explosions can develop rapidly. Significant dust explosions can occur when accumulated combustible dust becomes airborne fuel by becoming suspended in air. These factors increase the potential for serious injury or death to both plant employees and fire fighters.

Eight NFPA standards, which are listed in Section 40.1, address the prevention of dust explosions. An additional standard, NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*, addresses generic dust collection systems, including ductwork for dust conveying. NFPA 652, *Standard on the Fundamentals of Combustible Dust*, was issued in 2016 and, along with commodity-specific documents, addresses specific hazards, including agricultural dusts, coal, combustible metals, sulfur, chemicals and pharmaceuticals, and wood dusts. The scope and application of each referenced standard are described in the commentary that follows the complete list. This list is intended to assist the user of this handbook in determining the applicability of each standard to a particular type of facility.

NFPA 652 is the fundamental document for combustible dust. It establishes minimum requirements for managing combustible dust hazards. It directs the user to other NFPA standards for industry- and commodity-specific requirements, which are listed below:

- NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities*
- NFPA 484, *Standard for Combustible Metals*
- NFPA 654, *Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids*
- NFPA 655, *Standard for the Prevention of Sulfur Fires and Explosions*
- NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*

Chapter 1 of NFPA 652 contains provisions on how to deal with conflicts between NFPA 652 and the industry- and commodity-specific standards. If a requirement in NFPA 652 differs from the requirement in an industry- or commodity-specific standard, either can be used. If the industry- or commodity-specific standard prohibits a requirement in NFPA 652, the prohibition stands. If the industry- or commodity-specific standard neither prohibits nor provides a requirement, the requirement contained in NFPA 652 applies.

Δ 40.1 Application

Equipment, processes, and operations that involve the manufacture, processing, blending, repackaging, or handling of combustible particulate solids or combustible dusts regardless of concentration or particle size shall be installed and maintained in accordance with this chapter.

N **40.1.1** All facilities and operations that manufacture, process, blend, convey, repackage, generate, or handle combustible dusts or combustible particulate solids shall be in compliance with NFPA 652 and, as applicable, NFPA 61, NFPA 69, NFPA 85, NFPA 120, NFPA 484, NFPA 654, NFPA 655, and NFPA 664.

The commentary that follows summarizes the standards listed in Section 40.1.1.

NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities.* NFPA 61 applies to the following:

1. Facilities that receive, handle, process, dry, blend, use, mill, package, store, or ship dry agricultural bulk materials or their by-products or dusts that include grains, oilseeds, agricultural seeds, legumes, sugar, flour, spices, feeds, dry dairy/food powders, and other related materials
2. Facilities designed for manufacturing and handling starch, including drying, grinding, conveying, processing, packaging, and storage of dry or modified starch and dry products and dusts generated from these processes
3. Seed preparation and meal-handling systems of oilseed processing plants not covered by NFPA 36, *Standard for Solvent Extraction Plants*
4. Facilities covered by NFPA 61, including, but not limited to, the following:
   a. Bakeries
   b. Grain elevators
   c. Feed mills
   d. Flour mills
   e. Corn milling (dry and wet) plants
   f. Rice milling plants
   g. Dry milk processing
   h. Mix plants
   i. Soybean and other oilseed preparation operations
   j. Cereal processing
   k. Snack food processing
   l. Tortilla plants
   m. Chocolate processing
   n. Pet food processing
   o. Cake mix processing
   p. Sugar refining and processing
   q. Seed plants

NFPA 61 does not apply to oilseed extraction plants; such plants are covered by NFPA 36.

Unless otherwise noted within NFPA 61, its provisions are not intended to be applied to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the *Code*, except in those cases where the authority having jurisdiction (AHJ) determines that the existing situation involves a distinct hazard to life or adjacent property.

Significant changes were made to the 2017 edition of NFPA 61 to align its organization and contents with NFPA 652. The purpose of those changes was to make it easier for the user to compare requirements between NFPA 652 and NFPA 61. Dust hazard analyses (DHAs) are now required for agricultural facilities. NFPA 61 requires that a DHA be performed for existing bucket elevators, conveyors, grinding equipment, spray dryer systems, and dust collection systems within five years of the effective date of the standard (i.e., by June 2, 2021). A DHA must be performed for new processes as part of the project. The 2017 edition also adds a chapter on performance-based design as an alternative to the prescriptive requirements contained in the standard.

Additional requirements can be found in 29 CFR, Part 1910.272, "Grain Handling Facilities."

NFPA 69, *Standard on Explosion Prevention Systems.* NFPA 69 applies to the design, installation, operation, maintenance, and testing of systems for the prevention of explosions by means of the following methods:

1. Control of oxidant concentration
2. Control of combustible concentration
3. Predeflagration detection and control of ignition sources
4. Explosion suppression
5. Active isolation
6. Passive isolation
7. Deflagration pressure containment
8. Passive explosion suppression

In general, explosion prevention systems are used to protect processing operations, storage, and materials-handling equipment.

NFPA 69 provides minimum requirements for installing systems for the prevention of explosions in enclosures that contain flammable concentrations of flammable gases, vapors, mists, dusts, or hybrid mixtures. Basic information is provided for design engineers, operating personnel, and AHJs. The provisions of NFPA 69 are considered necessary for a reasonable level of protection from loss of life and property from fire and explosion. Where techniques to prevent explosion are applied to rooms, buildings, or other enclosures where personnel are present, consideration must be given to life safety.

NFPA 69 does not apply to the following:

1. Devices or systems designed to protect against detonations
2. Design, construction, and installation of deflagration vents that are addressed by NFPA 68, *Standard on Explosion Protection by Deflagration Venting*
3. Protection against overpressure due to phenomena other than internal deflagrations
4. Chemical reactions other than combustion processes
5. Unconfined deflagrations, such as open-air explosions or vapor cloud explosions
6. Rock dusting of coal mines, as covered by 30 CFR, Part 75
7. General use of inert gas for fire extinguishment
8. Preparation of tanks, piping, or other enclosures for hot work, such as cutting and welding, which is covered by NFPA 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work*, and NFPA 326, *Standard for the Safeguarding of Tanks and Containers for Entry, Cleaning, or Repair*
9. Ovens or furnaces handling flammable or combustible atmospheres, which are covered by NFPA 86, *Standard for Ovens and Furnaces*

10. Marine vapor control systems regulated by 33 CFR, Part 154
11. Marine vessel tanks regulated by 46 CFR, Parts 30, 32, 35, and 39

Unless otherwise noted within NFPA 69, the provisions of the document are not intended to be applied to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard, except in those cases where the AHJ determines that the existing situation involves a distinct hazard to life or adjacent property. NFPA 69 recognizes two classes of techniques for the prevention of explosions. One technique is based on preventing combustion (prevention); the other is based on preventing or limiting damage after combustion occurs (control). However, other methods for preventing combustion are available, including changing the process itself to eliminate combustible material used in, or generated by, the process.

NFPA 85, *Boiler and Combustion Systems Hazards Code.* Chapter 9 of NFPA 85 specifies the requirements for pulverized fuel systems. Pulverized fuel systems begin with the raw fuel bunker, which is located upstream of the pulverizer and is the point at which primary air enters the pulverizing system, and terminate at the point where pressure can be relieved by fuel being burned or collected in a device that is built in accordance with NFPA 85. The pulverized fuel system includes the primary air ducts upstream of the pulverizer and continues to a point where pressure can be relieved by application of a suitable vent or other means.

Chapter 9 of NFPA 85 covers only fuels having a volatile content of 8 percent on a moisture-free basis. Systems with an oxygen content greater than 21 percent are not covered by NFPA 85 and require special attention.

The purpose of Chapter 9 of NFPA 85 is to establish minimum standards for design, installation, operation, maintenance, and personnel safety in connection with pulverized fuel systems; to contribute to operating safety; to minimize the probability of pulverized fuel system explosions; and to minimize the effects of explosions that do occur. The provisions of Chapter 9 of NFPA 85 are considered necessary to provide a reasonable level of protection from loss of life and property from fire and explosion.

Chapter 9 of NFPA 85 applies to new installations and to major alterations or extensions of existing equipment for the preparation and burning of fuel in pulverized form that were contracted for subsequent to the effective date of NFPA 85. NFPA 85 is not retroactive. However, Chapter 9 of NFPA 85 does apply to any retrofit program that involves replacement of the entire pulverized fuel system described in 9.4.1.1 and 9.5.1.1 of NFPA 85. For less than total system replacement, the components must meet the requirements of Chapter 9 of NFPA 85 or the original code or standard of construction for the pulverized fuel system.

NFPA 120, *Standard for Fire Prevention and Control in Coal Mines.* NFPA 120 contains minimum requirements for reducing the potential for loss of life and property from fire and explosion in coal preparation plants. Only plants designed to prepare coal for shipment are included in NFPA 120. Other equipment and processes, such as coal pulverizers, that are used to condition coal for firing in boilers at power-generating plants or gasification plants or for utilization in certain special processes are not covered in NFPA 120.

NFPA 120 is not retroactive, but operators are urged to avail themselves of any information that prevents dust dispersions, eliminates sources of ignition, or otherwise reduces fire and explosion hazards by improving conditions in their plants.

Because of the wide range of chemical and structural characteristics of coals, comprehensively rating the spontaneous ignition characteristics of coals is not possible. In general, coals of lower volatility do not ignite readily. Coals of higher sulfur content and higher oxygen content ignite more readily. Experience with a given coal is generally the only way to understand how it should be handled and compacted and how long it can be stored before it begins to heat significantly. As new mines open for mining lower-rank coals in the western United States, the problems of spontaneous ignition and fires in stored coal can be expected to increase.

NFPA 484, *Standard for Combustible Metals.* NFPA 484 was created with the purpose of incorporating six separate combustible metal standards into a single comprehensive combustible metal fire safety document.

The purpose of NFPA 484 is to minimize the occurrence of, and resulting damage from, fire and explosion hazards in areas where combustible metals or metal dusts are produced, processed, finished, handled, stored, and used. Therefore, NFPA 484 provides safety requirements for all combustible metals, including processing, storage, handling, dust collection, housekeeping, and fire protection.

NFPA 484 applies to the production, processing, finishing, handling, storage, and use of all metals and alloys that are in a form capable of combustion or explosion. The standard also applies to operations where metals or metal alloys are subjected to processing or finishing operations that produce combustible powder or dust. Metals and metal alloy parts and those materials, including scrap, that exhibit combustion characteristics of aluminum, lithium, magnesium, niobium, tantalum, titanium, or zirconium are subject to the requirements for the metal whose combustion characteristics they most closely match.

NFPA 484 does not apply to the transportation of metals in any form on public highways and waterways, by air, or by rail. It also does not apply to the primary production of aluminum, magnesium, and lithium metal. NFPA 484 addresses the following topics:

1. Chapter 11 covers the handling, processing, and storage of lithium and other alkali metals; the hazards of lithium were previously addressed by NFPA 485, *Standard for the Storage, Handling, Processing, and Use of Lithium Metal.*
2. Chapter 12 covers facilities where aluminum dusts, pastes, and/or powders are produced or handled, which were previously addressed by NFPA 651, *Standard for the Machining*

and Finishing of Aluminum and the Production and Handling of Aluminum Powders.

3. Chapter 13 covers facilities where magnesium dusts, pastes, and/or powders are handled, which were previously addressed by NFPA 480, *Standard for the Storage, Handling, and Processing of Magnesium Solids and Powders*.
4. Chapter 14 covers the hazards of niobium production and powder handling and storage.
5. Chapter 15 covers the hazards of tantalum production and powder handling and storage.
6. Chapter 16 covers the processing, handling, machining, and fabrication of titanium, which were previously addressed by NFPA 481, *Standard for the Production, Processing, Handling, and Storage of Titanium*.
7. Chapter 17 covers the processing, handling, machining, and fabrication of zirconium, which were previously addressed by NFPA 482, *Standard for the Production, Processing, Handling, and Storage of Zirconium*.
8. Chapter 18 addresses combustible metals not covered by one of the metal-specific chapters.
9. Chapter 19 addresses recycling and waste management facilities

In the United States, regulations for the domestic shipment of dangerous goods, which include combustible metals and metal powders, are issued by the U.S. Department of Transportation, 49 CFR, Parts 100–199, which has specific responsibility for promulgating the regulations. The United Nations, the International Air Transport Association, the International Maritime Organization, and other international agencies regulate international shipments.

See Commentary Table 40.1 for information on specific combustible metals.

Exhibit 40.1 and Exhibit 40.2 show examples of typical configurations of liquid precipitation separators for both fixed and portable dust-producing equipment. Exhibit 40.3 illustrates five

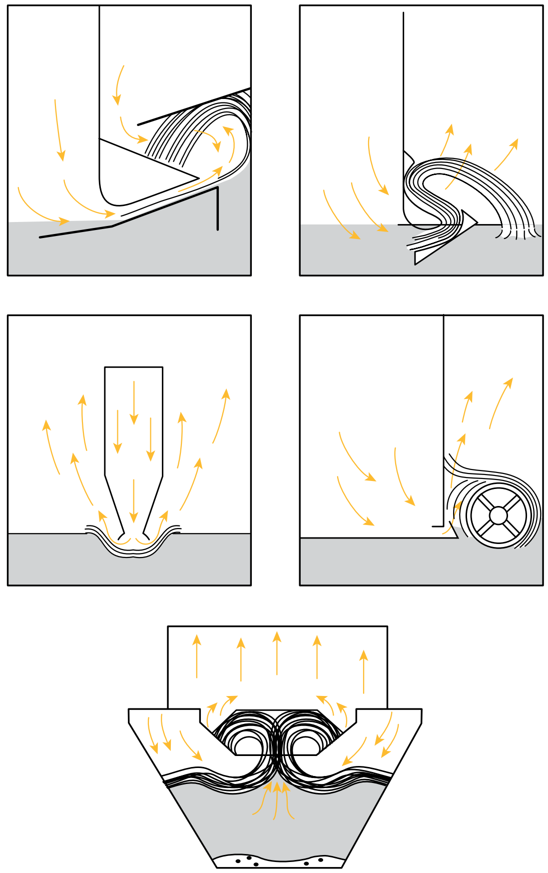
methods of precipitating dust for solving dust problems involving aluminum and tantalum dust.

NFPA 654, Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids. NFPA 654 contains a unified approach for protecting facilities handling most combustible particulate solids. NFPA 654 applies to all phases of the manufacturing, processing, blending, conveying, repackaging, and handling of combustible particulate solids or hybrid mixtures, regardless of concentration or particle size, where the materials present a fire or explosion hazard. NFPA 654 prescribes technical requirements for safety to life and property from fire and explosion and for minimizing the resulting damage from a fire or an

Exhibit 40.3



Five methods of precipitating dust in precipitators.

explosion. The standard is used to supplement the requirements established by NFPA 652.

The requirements for pneumatic conveying systems are found throughout NFPA 654. NFPA 91 does not apply to material transfer systems or dust control systems covered by NFPA 654. In addition, 1.4.3 of NFPA 654 states that NFPA 654 does not apply to materials covered by the following documents, unless specifically referenced by the applicable document:

1. NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*
2. NFPA 33, *Standard for Spray Application Using Flammable or Combustible Materials*
3. NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities*
4. NFPA 85, *Boiler and Combustion Systems Hazards Code*
5. NFPA 120, *Standard for Fire Prevention and Control in Coal Mines*
6. NFPA 400, *Hazardous Materials Code*
7. NFPA 484, *Standard for Combustible Metals*
8. NFPA 495, *Explosive Materials Code*
9. NFPA 655, *Standard for Prevention of Sulfur Fires and Explosions*

10. NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*

11. NFPA 1125, *Code for the Manufacture of Model Rocket and High-Power Rocket Motors*

NFPA 654 applies to facilities on which construction or in which installation was begun subsequent to the effective date of the standard.

See Exhibit 40.4 through Exhibit 40.10 for examples of dust collectors with fire prevention features installed and illustrated explanations of how the various features function.

NFPA 655, *Standard for Prevention of Sulfur Fires and Explosions.* NFPA 655 applies to the size reduction of sulfur and its handling in any form. NFPA 655 provides requirements to eliminate or reduce the hazards of explosion and fire inherent in the processing and handling of sulfur. The document does not apply to the mining of sulfur, recovery of sulfur from process streams, or transportation of sulfur. NFPA 655 is intended to be used in conjunction with the requirements of NFPA 654; if any conflicts exist between the two documents, the provisions of NFPA 655 apply. NFPA 655 applies to facilities on which construction was begun subsequent to the effective date of the standard.

Sulfur differs from most other combustible materials found in industry in that it has a relatively low melting point and ignition point. The normal handling temperature of liquid sulfur is 250°F to 309°F (121°C to 154°C), which is slightly above the melting point of 246°F (119°C). At the melting point, sulfur is a transparent, mobile liquid. As the temperature of the liquid is raised, it darkens, becoming deep orange in hue. Up to about 320°F (160°C), the viscosity drops with rising temperature. Above this point, the viscosity increases with rising temperature. At 370°F (188°C), the viscosity reaches a tremendously high maximum that practically prevents it from flowing, and the liquid is so intensely colored as to be nearly opaque. Above 370°F (188°C), it again acts in a more normal fashion, with its viscosity falling somewhat as the temperature continues to rise.

At the normal handling temperature of liquid sulfur [250°F to 309°F (121°C to 154°C)], the vapor concentration above the pure sulfur, free of hydrocarbons or hydrogen sulfide (H_2S), is too low to form a flammable mixture in air. While the flash point of liquid sulfur varies with purity, it is always higher than the normal handling temperature. For pure sulfur, the flash point can

Exhibit 40.4

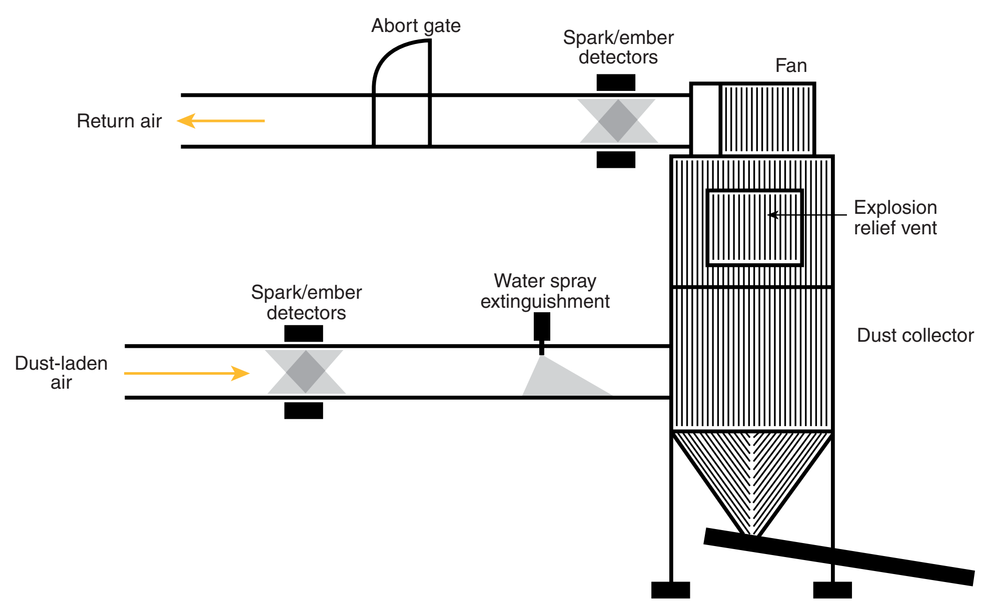
be as low as 370°F (188°C); for relatively impure crude sulfur, the flash point can be as low as 334°F (168°C).

The relatively low ignition temperature of sulfur and the possible presence of H_2S are the primary fire and explosion hazards of liquid sulfur. Impure sulfur (sometimes referred to as "dark sulfur") contains hydrocarbons, which react slowly with the liquid sulfur to form H_2S. Recovered sulfur, such as that produced from petroleum gas streams containing hydrogen sulfide, using the Claus process, often contains dissolved H_2S, which will be liberated slowly from a quiescent body of liquid sulfur. Agitation of such liquid sulfur causes rapid evolution of H_2S, which can create a flammable atmosphere within the storage tank. In the temperature range at which liquid sulfur is normally handled, the lower flammable limit for H_2S is about 3.4 percent compared to 4.3 percent at room temperature.

Exhibit 40.10



Basic spark detection and extinguishment system for a single air-material separator.

Case Study

On February 7, 2008, a series of sugar dust explosions at the Imperial Sugar Company manufacturing facility in Port Wentworth, Georgia, resulted in 14 worker fatalities. In addition to the 14 fatalities, 36 workers were treated for serious burns and injuries, some of which caused permanent, life altering conditions. The explosions and subsequent fires destroyed the sugar packing buildings, palletizer room, and silos and severely damaged the bulk train car loading area and parts of the sugar refining process areas. The Imperial Sugar manufacturing facility housed a refinery for converting raw cane sugar into granulated sugar. Through a system of conveyors and elevators, the raw sugar was transported from grain silos to sugar processing machines, and the final sugar products were stored in buildings surrounding the silos.

In its investigation report released in September 2009, the U.S. Chemical Safety Board (CSB) found that an initial dust explosion originated in the enclosed steel belt conveyor located below the sugar silos where high concentrations of sugar dust had accumulated inside the enclosure. The initial explosion stirred up sugar dust that had built up on the floors and other surfaces, causing a chain reaction of additional dust explosions through the buildings. Fires resulting from the explosions destroyed the packing buildings, silos, and palletizer building and severely damaged parts of the refinery and sugar loading area.

Many contributing factors to the explosions were identified, including the following:

- Equipment that was not designed or maintained to minimize the release of sugar and sugar dust into the work area
- Inadequate housekeeping practices, which resulted in accumulations of combustible sugar and sugar dust on the floors and other elevated surfaces throughout the packing buildings
- Accumulation of airborne combustible sugar dust above the maximum explosible concentration
- Inadequate evacuation plans

The investigation conducted by the CSB highlighted many safety concerns regarding buildings where dust explosions are a risk and resulted in a list of recommendations to ensure that buildings at risk for dust explosions reduce that risk and even prevent such explosions from occurring. Additional information on the Imperial Sugar Company explosion and fire, as well as the CSB investigation report, in its entirety, can be found online at http://www.csb.gov/investigations/detail.aspx?SID=6.

Exhibit CS40.1

(Courtesy of the U.S. Chemical Safety Board)

Pure sulfur will not generate a flammable atmosphere in the normal temperature range of the liquid. Transfer of liquid sulfur using air pressure should be avoided. If air pressure is applied to the vapor space of an enclosure containing molten sulfur with high concentrations of H_2S, there is a danger that the H_2S–air mixture will become flammable. Transfer by pressure should be restricted to using an inert gas. Use of pumps is the preferred transfer method.

Because impurities can cause generation of H_2S or pyrophoric iron sulfides, testing each incoming batch for carbon content and H_2S should be performed. These impurities should be kept to a minimum.

The finely divided sulfur produced during size reduction is the most hazardous from an explosion standpoint. Also, mixtures containing finely divided elemental sulfur can be just as hazardous if the sulfur is present in sufficient quantity. Some explosion and fire hazards also accompany the handling and processing of sulfur in bulk in coarse sizes due to the fine dust present.

NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities.* NFPA 664 addresses all the fire hazards associated with wood processing facilities (the occupancy), not just the dust (the commodity). The requirements contained in Chapters 4 though 9 do not apply to woodworking operations that occupy less than 5000 ft^2 (465 m^2) and where the dust producing equipment requires an aggregate dust collection flow rate less than 1500 ft^3/min (2549 m^3/hr). Note that the requirements of Chapters 10 and 11 (Human Element and Housekeeping) apply to all woodworking operations, regardless of size. It is used to supplement the requirements of NFPA 652.

NFPA 664 contains minimum requirements for fire and explosion prevention and protection of industrial, commercial, or institutional facilities that process wood or manufacture wood products using wood or other cellulosic fiber as a substitute for, or additive to, wood fiber; and that process wood, creating wood chips, particles, or dust. Woodworking and wood processing facilities include, but are not limited to, wood flour plants, industrial woodworking plants, furniture plants, plywood plants, composite board plants, lumber mills, and production-type woodworking shops and carpentry shops.

The purpose of NFPA 664 is to provide minimum requirements for the design, operation, and maintenance of woodworking and wood processing facilities for safety to life, property protection, and mission continuity from fire and explosion.

Commentary Table 40.2, which is extracted from NFPA 664, lists commonly used isolation devices; Commentary Table 40.3 outlines minimum testing and maintenance frequency for spark detection and extinguishing systems.

Unless otherwise noted in NFPA 664, the provisions of the standard are not intended to be applied to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the document, except in those cases where the AHJ determines that the existing situation involves a distinct hazard to life or adjacent property.

COMMENTARY TABLE 40.2 *Commonly Used Isolation Devices*

Isolation Device	Application	Limitations
Diversion Devices		
Abort gate	Fire and deflagration	Used on pneumatic conveying ducts. Most practical on positive pressure pneumatic systems (two abort gates needed for negative pressure systems).
Pant leg gate	Fire and deflagration	Used on gravity flow chutes at material transfer points.
Slide gate	Fire only	Used on the bottom of mechanical conveyors that slide material through the conveyor enclosure (e.g., screw and flight conveyors).
Reversing conveyor	Fire only	Used with mechanical conveyors (usually screw conveyors). Not effective with dusty material unless other blocking devices (e.g., rotary feeders) are also used.
Flame front diverter	Deflagration only	Used on pneumatic conveying ducts.
Blocking Devices		
Rotary feeders	Fire and deflagration	Must have metal-tipped vanes with narrow wall gap 0.007 in. (0.18 mm). Rubber-tipped vanes cannot be relied on. Must be stopped to remain effective.
Slide gate	Fire and deflagration	Used to block pneumatic ducts, chutes, and so forth. Usually actuated with high-pressure gas cylinder.
Flame front extinguishers	Deflagration only	Single-shot pressurized chemical extinguishers, typically used on ducts or enclosed conveyors.
Backblast dampers	Deflagration only	Used on pneumatic systems to prevent flow counter to normal flow.
Material chokes	Deflagration only	Normally used on mechanical screw conveyors or at material transfer points.

Note: NFPA 654 also discusses various types of explosion isolation devices.

Source: NFPA 664, 2017, Table A.8.2.4.3.

COMMENTARY TABLE 40.3 *Minimum Testing and Maintenance Frequency for Spark Detection and Extinguishing Systems*

Item	Operation	Weekly	Monthly	Semiannually	Comments
Control panel	Clean	X			Visual inspection of all warning/operational lights.
Emergency power	Test			X	See manufacturer's battery test procedure.
Detector and spray nozzle	Test	X[1]			See manufacturer's detector and spray nozzle test procedure. Remove and inspect strainers.
Detectors/test lights	Maintenance	X[2]			Inspect and clean.
Water lines	Flush		X		Flush for 2 minutes. Remove and inspect strainer.
Booster pump (if provided)	Test		X		See manufacturer's booster pump test procedure.
Freeze protection	Inspect		X		Check at plant winterization and monthly during freezing.
Rapid speed abort gates	Test			X	See manufacturer's test procedure.

[1]See manufacturer's test procedure. Where daily automatic detector response testing is provided by external means (test lights), monthly inspection is acceptable.

[2]The frequency of cleaning should be adjusted, based on the experience at each detector point. Detectors found to be dirty during scheduled cleaning should have their cleaning frequency increased, and those found to be clean can have their cleaning frequency decreased.

Source: NFPA 664, 2017, Table A.9.1.2.

40.2 Permits

Permits, where required, shall comply with Section 1.12.

•

A number of permits might be required, depending on the operations to be performed. The principal permit that applies to the hazards covered in Chapter 40, however, is a permit for dust-producing operations. [See Table 1.12.8(a).] The permit is required for the installation, modification, or operation of the following:

1. Dust-producing operations
2. Grain storage or elevators
3. Starch, flour, and feed mills
4. Malt houses
5. Lumberyards and woodworking plants
6. Wood flour manufacturing plants
7. Aluminum, coal, cocoa, magnesium, spice, and sugar facilities, or other facilities that pulverize materials subject to dust explosion
8. Central dust collection systems
9. Equipment that produces significant quantities of a dust that is subject to explosion

N 40.3 Retroactivity

This chapter shall apply to new and existing facilities and processes. [**652:**9.1]

N **40.3.1** Existing facilities shall perform a dust hazards analysis (DHA) in accordance with Chapter 7 of NFPA 652.

NFPA 652 requires that a DHA be performed for new processes as part of the project. For existing processes that are undergoing material modifications, the DHA must also be performed as part of the project. NFPA 652 defines a material modification as modifications or maintenance or repair activities that exceed 25 percent of the original cost.

For existing processes, the 2016 edition of NFPA 652 requires that a DHA be completed within 3 years of the effective date of that standard, which was September 7, 2015. That means that all DHAs must be completed by September 7, 2018.

The 2017 editions of the other industry- and commodity-specific standards (NFPA 61, NFPA 654, and NFPA 664) contain varying timelines for the completion of DHAs. NFPA 654 and NFPA 664 have contained the requirement to perform a hazard analysis since the mid 2000s. Those facilities and processes that were built to more recent editions of NFPA 654 and NFPA 664 should have conducted DHAs. Older facilities would have been grandfathered. Note that NFPA 61 did not require DHAs until the 2017 edition.

The 2017 editions of both NFPA 654 and NFPA 664 have DHA requirements for existing facilities that differ from those of NFPA 652. NFPA 654 has a 5-year deadline from the effective date of the standard, which will be June 2, 2021. NFPA 61 has the same deadline. Because NFPA 664 does not contain any requirements, the timeline defaults to NFPA 652, the deadline of which is September 7, 2018.

N 40.4* General

The procedures and training in this chapter shall be delivered in a language that the participants can understand. [**652:**9.2]

N **A.40.4** See ANSI/AIHA Z10, *Occupational Health and Safety Management Systems.* [**652:**A.9.2]

N 40.5 Operating Procedures and Practices

N **40.5.1*** The owner/operator shall establish written procedures for operating its facility and equipment to prevent or mitigate fires, deflagrations, and explosions from combustible particulate solids. [**652:**9.3.1]

N **A.40.5.1** The operating procedures should address both the normal operating conditions and the safe operating limits. Where possible, the basis for establishing the limits and the consequences of exceeding the limits should also be described. [**652:**A.9.3.1]

The operating procedures should address all aspects of the operation, including the following (as applicable):

(1) Normal startup
(2) Continuous operation
(3) Normal shutdown
(4) Emergency shutdown
(5) Restart after normal or emergency shutdown
(6) Anticipated process upset conditions
(7) System idling
[**652:**A.9.3.1]

For manual operations, the procedures and practices should describe techniques, procedural steps, and equipment that are intended to minimize or eliminate combustible dust hazards. [**652:**A.9.3.1]

Operating procedures and practices should be reviewed on a periodic basis, typically annually, to ensure they are current and accurate. [**652:**A.9.3.1]

N **40.5.2*** The owner/operator shall establish safe work practices to address hazards associated with maintenance and servicing operations. [**652:**9.3.2]

N **A.40.5.2** Safe work practices include, but are not limited to, hot work, confined space entry, and lockout/tagout, and the use of personal protective equipment. *(See NFPA 51B.)* Consideration for extending the duration of the fire watch could be warranted based on characteristics of the material, equipment configuration, and conditions. For example, the PRB Coal Users' Group practice for hot work suggests fire watches could be warranted for 2 to 12 hours following the completion of hot work due to the exothermic chemical reaction of subbituminous coals. In addition to the hazards of combustible dust, safe work practices should address the hazards of mitigation systems such as inerting and suppression. [**652:**A.9.3.2]

N **40.5.2.1** The safe work practices shall apply to employees and contractors. [**652:**9.3.2.1]

N 40.6 Inspection, Testing, and Maintenance

N **40.6.1*** Equipment affecting the prevention, control, and mitigation of combustible dust fires, deflagrations, and explosions shall be inspected and tested in accordance with the applicable NFPA standard and the manufacturers' recommendations. [**652:**9.4.1]

N **A.40.6.1** Process interlocks and protection systems should be inspected, calibrated, and tested in the manner in which they are intended to operate, with written records maintained for review. In this context, "test" implies a nondestructive means of verifying that the system will operate as intended. For active explosion protection systems, this can involve the disconnection of final elements (i.e., suppression discharge devices or fast-acting valve actuators) and the use of a simulated signal to verify the correct operation of the detection and control system. Testing can also include slow-stroke activation of fast acting valves to verify unrestricted travel. Some devices, such as explosion vent panels, suppression discharge devices, and some fast-acting valve actuators, cannot be functionally "tested" in a nondestructive manner, and so only periodic, preventive, and predictive inspection, maintenance, and replacement (if necessary) are applied. [**652:**A.9.4.1]

Inspection and maintenance requirements for explosion vents and other explosion protection systems are found in NFPA 68, and NFPA 69, respectively. [**652:**A.9.4.1]

N **40.6.2** The inspection, testing, and maintenance program shall include the following:

(1) Fire and explosion protection and prevention equipment in accordance with the applicable NFPA standards
(2) Dust control equipment
(3) Housekeeping
(4) Potential ignition sources
(5)* Electrical, process, and mechanical equipment, including process interlocks

N **A.40.6.2(5)** Process interlocks should be calibrated and tested in the manner in which they are intended to operate, with written test records maintained for review by management. Testing frequency should be determined in accordance with the *AIChE Guidelines for Safe Automation of Chemical Processes*. [**654:**A.12.1.2(5)] [**652:**A.9.4.2(5)]

(6) Process changes
(7) Lubrication of bearings
[**652:**9.4.2]

N **40.6.3** The owner/operator shall establish procedures and schedules for maintaining safe operating conditions for its facility and equipment in regard to the prevention, control, and mitigation of combustible dust fires and explosions. [**652:**9.4.3]

N **40.6.4*** Where equipment deficiencies that affect the prevention, control, and mitigation of dust fires, deflagrations, and explosions are identified or become known, the owner/operator shall establish and implement a corrective action plan with an explicit deadline. [**652:**9.4.4]

N **A.40.6.4** Corrective actions should be expedited on high-risk hazards (those that could result in a fatality or serious injury). Where in-kind repairs cannot be promptly implemented, consideration should be given to providing alternate means of protection. [**652:**A.9.4.4]

N **40.6.5*** Inspections and testing activities that affect the prevention, control, and mitigation of dust fires, deflagrations, and explosions shall be documented. [**652:**9.4.5]

N **A.40.6.5** See Section 9.10 for information regarding document retention. [**652:**A.9.4.5]

N **40.6.6** A thorough inspection of the operating area shall take place on an as-needed basis to help ensure that the equipment is in safe operating condition and that proper work practices are being followed. [**652:**9.4.6]

N 40.7 Training and Hazard Awareness

N **40.7.1*** Employees, contractors, temporary workers, and visitors shall be included in a training program according to the potential exposure to combustible dust hazards and the potential risks to which they might be exposed or could cause. [**652:**9.5.1]

N **A.40.7.1** Safety of a process depends on the employees who operate it and the knowledge and understanding they have of the process. It is important to maintain an effective and ongoing training program for all employees involved. Operator response and action to correct adverse conditions, as indicated by instrumentation or other means, are only as good as the frequency and thoroughness of training provided. [**652:**A.9.5.1]

N **40.7.2*** General safety training and hazard awareness training for combustible dusts and solids shall be provided to all affected employees. [**652:**9.5.2]

N **A.40.7.2** All plant personnel, including management; supervisors; and operating, housekeeping, and maintenance personnel should receive general awareness training for combustible dust hazards, commensurate with their job responsibilities, including training on locations where hazards can exist on site, appropriate measures to minimize hazards, and response to emergencies. [**652:**9.5.2]

N **40.7.2.1*** Job-specific training shall ensure that employees are knowledgeable about fire and explosion hazards of combustible dusts and particulate solids in their work environment. [**652:**9.5.2.1]

N **A.40.7.2.1** Safe work habits are developed and do not occur naturally. The training program should provide enough background information regarding the hazards of the materials and the process so that the employees can understand why it is important to follow the prescribed procedures. Training should address the following:

(1) The hazards of their working environment and procedures in case of emergencies, including fires, explosions, and hazardous materials releases
(2) Operating, inspection, testing, and maintenance procedures applicable to their assigned work
(3) Normal process procedures as well as emergency procedures and changes to procedures
(4) Emergency response plans, including safe and proper evacuation of their work area and the permissible methods for fighting incipient fires in their work area
(5) The necessity for proper functioning of related fire and explosion protection systems
(6) Safe handling, use, storage, and disposal of hazardous materials used in the employees' work areas
(7) The location and operation of fire protection equipment, manual pull stations and alarms, emergency phones, first-aid supplies, and safety equipment
(8) Equipment operation, safe startup and shutdown, and response to upset conditions

[**652:**9.5.2.1]

N **40.7.2.2** Employees shall be trained before taking responsibility for a task. [**652:**9.5.2.2]

N **40.7.2.3*** Where explosion protection systems are installed, training of affected personnel shall include the operations and potential hazards presented by such systems. [**652:**9.5.2.3]

N **A.40.7.2.3** The extent of this training should be based on the level of interaction the person is expected to have with the system. For example, operators need to be aware of the hazards presented by explosion suppression systems but might not need to know how to operate the suppression system (e.g., interfacing with the system control panel or locking out devices).

Maintenance personnel, on the other hand, might need to know how and when to lock out the devices and how to return the system to its operational state. [**652:**A.9.5.2.3]

N **40.7.3** Refresher training shall be provided as required by the AHJ and as required by other relevant industry- or commodity-specific NFPA standards. [**652:**9.5.3]

N **40.7.4** The training shall be documented. [**652:**9.5.4]

N 40.8 Contractors

N **40.8.1** Owner/operators shall ensure the requirements of Section 40.8 are met. [**652:**9.6.1]

N **40.8.2*** Only qualified contractors shall be employed for work involving the installation, repair, or modification of buildings (interior and exterior), machinery, and fire and explosion protection equipment that could adversely affect the prevention, control, or mitigation of fires and explosions. [**652:**9.6.2]

N **A.40.8.2** Qualified contractors should have proper credentials, which include applicable American Society of Mechanical Engineers (ASME) stamps, professional licenses, and so forth. [**652:**A.9.6.2]

N **40.8.3*** **Contractor Training.**

N **A.40.8.3** It is suggested that annual meetings be conducted with regular contractors to review the facility's safe work practices and policies. Some points to cover include to whom the contractors would report at the facility, who at the facility can authorize hot work or fire protection impairments, and smoking and nonsmoking areas. The owner/operator does not necessarily need to provide the training to the contractor. [**652:**A.9.6.3]

N **40.8.3.1** Contractors operating owner/operator equipment shall be trained and qualified to operate the equipment and perform the work. [**652:**9.6.3.1]

N **40.8.3.2** Contractor training shall be documented. [**652:**9.6.3.2]

N **40.8.3.3*** Contractors working on or near a given process shall be made aware of the potential hazards from and exposures to fires and explosions. [**652:**9.6.3.3]

N **A.40.8.3.3** In addition to the combustible dust fire and explosion hazards, contractors should also be made aware of other potential process and occupational hazards. There can be combustible materials other than combustible dusts in the equipment or immediate vicinity where contractors might be working. Combustion of dusts can generate toxic products, and some combustible dusts are acutely toxic. [**652:**A.9.6.3.3]

N **40.8.3.4** Contractors shall be trained and required to comply with the facility's safe work practices and policies in accordance with 40.5.2. [**652:**9.6.3.4]

N **40.8.3.5** Contractors shall be trained on the facility's emergency response and evacuation plan, including, but not limited to, emergency reporting procedures, safe egress points, and evacuation area. [**652:**9.6.3.5]

Prior to the addition of 40.8.3.5, NFPA 654 and this *Code* provided inadequate guidance on the qualifications of those people employed for work involving the installation, repair, or modification of buildings, and/or the commissioning, repair, or modification of explosion protection equipment. It is important to establish requirements applicable to contractors and subcontractors. Industry statistics demonstrate that contractors and subcontractors contribute to incidents involving dust fires and explosions and must be aware of practices and safeguards in place to prevent such incidents.

N 40.9 Emergency Planning and Response

N **40.9.1*** A written emergency response plan shall be developed for preparing for and responding to work-related emergencies including, but not limited to, fire and explosion. [**652:**9.7.1]

N **A.40.9.1** All plant personnel, including management, supervisors, and maintenance and operating personnel, should be trained to participate in plans for controlling plant emergencies.

The emergency plan should contain the following elements:

(1) A signal or alarm system
(2) Identification of means of egress
(3) Minimization of effects on operating personnel and the community
(4) Minimization of property and equipment losses
(5) Interdepartmental and interplant cooperation
(6) Cooperation of outside agencies
(7) The release of accurate information to the public

[**652:**A.9.7.1]

Emergency drills should be performed annually by plant personnel. Malfunctions of the process should be simulated and emergency actions undertaken. Disaster drills that simulate a major catastrophic situation should be undertaken periodically with the cooperation and participation of public fire, police, and other local community emergency units and nearby cooperating plants. [**652:**A.9.7.1]

Specialized training for public fire department(s) and industrial fire brigades can be warranted due to facility specific hazards where the methods to control and extinguish a fire can be outside of their normal arena of traditional fire fighting. [**652:**A.9.7.1]

N **40.9.2** The emergency response plan shall be reviewed and validated at least annually. [**652:**9.7.2]

N 40.10* Incident Investigation

N **A.40.10** To thoroughly assess the risks, analyze the incident, and take any corrective steps necessary, investigations should be conducted promptly based on the nature of the incident and in coordination with the AHJ (as applicable). [**652:**A.9.8]

The investigation should include root cause analysis and should include a review of existing control measures and underlying systemic factors. Appropriate corrective action should be taken to prevent recurrence and to assess and monitor the effectiveness of actions taken. [**652:**A.9.8]

Such investigations should be carried out by trained persons (internal or external) and include participation of workers. All investigations should conclude with a report on the action taken to prevent recurrence. [**652:**A.9.8]

Investigation reports should be reviewed with all affected personnel and their representatives (including contract employees where applicable) whose job tasks are relevant to the incident findings, and with the health and safety committee, to make any appropriate recommendations. Any recommendations from the safety and health committee should be communicated to the appropriate persons for corrective action, included in the management review, and considered for continual improvement activities. [**652:**A.9.8]

A system should be established to promptly address and resolve the incident report findings and recommendations. [**652:**A.9.8]

Corrective actions resulting from investigations should be implemented in all areas where there is a risk of similar incidents and subsequently checked to avoid repetition of injuries and incidents that gave rise to the investigation. [**652:**A.9.8]

Reports produced by external investigation agencies should be acted upon in the same manner as internal investigations. [**652:**A.9.8]

Incident investigation reports should be made available to affected employees and their representatives at no cost. [**652:**A.9.8]

N **40.10.1*** The owner/operator shall have a system to ensure that incidents that result in a fire, deflagration, or explosion are reported and investigated in a timely manner. [**652:**9.8.1]

N **A.40.10.1** Events where there are injuries, equipment damage, or significant business interruption are subject to investigation. [**652:**A.9.8.1]

In addition to investigation of fires and explosions, it is also a good practice to investigate near misses (events that could have resulted in fires or explosions under different circumstances) and all activations of active fire and explosion mitigation systems. It is important to educate facility personnel on the concept of what a near miss is and to clearly communicate their responsibility for reporting both incidents and near misses. [**652:**A.9.8.1]

Near-miss events often indicate an underlying problem that should be corrected. See NFPA 654 for additional information. Barriers to reporting should be removed, as described in ANSI/AIHA Z10, *Occupational Health and Safety Management Systems.* Investigations should include workers and their representatives, as appropriate. [**652:**A.9.8.1]

N **40.10.2** The investigation shall be documented and include findings and recommendations. [**652:**9.8.2]

N **40.10.3** A system shall be established to address and resolve the findings and recommendations. [**652:**9.8.3]

N **40.10.4*** The investigation findings and recommendations shall be reviewed with affected personnel. [**652:**9.8.4]

N **A.40.10.4** The term *affected personnel* is intended to include members of employee organizations such as safety committees and employee representatives of various types. [**652:**A.9.8.4]

N 40.11 Management of Change

N **40.11.1*** Written procedures shall be established and implemented to manage proposed changes to process materials, staffing, job tasks, technology, equipment, procedures, and facilities. [**652:**9.9.1]

N **A.40.11.1** It is essential to have thorough written documentation, as the slightest changes to procedures, processes, resources, staffing, and equipment, including equipment from suppliers, can have a dramatic impact on the overall hazard analysis. Change includes something as benign as process materials sourcing from a different manufacturer, the same raw material manufacturer using new methods to produce the product, or changes in formulation. These changes from a supplier's end can impact the characteristics of the processes and materials. Individuals involved should include those involved in the process such as maintenance, engineering, and purchasing personnel, and all others as deemed necessary. Staffing and job tasks are not intended for shift changes, but for overall staff and their representative tasks. For reference, see the documentation form in ANSI/AIHA Z10, *Occupational Health and Safety Management Systems.* [**652:**A.9.9.1]

The following changes in material or process should warrant a management of change review per Section 9.9, and new samples should be collected and analyzed:

(1) New process equipment is installed that presents new hazards.
(2) New operating conditions for existing equipment create a new hazard.
(3) A new material is used in the process.

[**652:**A.9.9.1]

N **40.11.2** The procedures shall ensure that the following are addressed prior to any change:

(1)* The basis for the proposed change

N **A.40.11.2(1)** The proposed change and why it is needed should be described. It should include sufficient technical information to facilitate review by the approvers, address adverse effects that could occur, and describe how such effects would be mitigated by the proposed change. [**652:**A.9.2.(1)]

(2)* Safety and health implications

N **A.40.11.2(2)** Some fire and explosion protection systems introduce additional hazards into the process environment. These hazards can include, but are not limited to, energy in suppression canisters, asphyxiation hazards from inert gases, and mechanical laceration/amputation hazards from explosion isolation systems. While these are not fire or explosion hazards, they should be addressed as part of the management of change review per this document so that appropriate controls can be applied. [**652:**A.9.9.2(2)]

(3) Whether the change is permanent or temporary, including the authorized duration of temporary changes
(4) Modifications to operating and maintenance procedures
(5) Employee training requirements
(6) Authorization requirements for the proposed change
(7) Results of characterization tests used to assess the hazard, if conducted

[**652:**9.9.2]

N **40.11.3*** Implementation of the management of change procedure shall not be required for replacements-in-kind. [**652:**9.9.3]

N **A.40.11.3** While implementation of the management of change procedure is not required for replacement in kind, it is critical that only qualified personnel are the ones who determine if the replacement is "in kind." These qualified personnel should be intimately familiar with the items listed in 9.9.2, as well as the broad scope of hazards associated with the particular process. [**652:**A.9.9.3]

Replacement "in kind" for raw materials. Care must be taken when substituting raw materials. There have been cases where a seemingly equivalent material substitution resulted in a large change in the process hazard. Not all safety properties of a material are characterized in, for example, an MSDS. Chemical composition might be identical, but quite different static ignition hazards due to bulk resistivity and charge relaxation rate can appreciably increase the hazard. Flowability differences can affect the hazard probability too. Differences in natural raw materials are generally less of a concern than manufactured materials in this regard.

N **40.11.4** Design and procedures documentation shall be updated to incorporate the change. [**652:**9.9.4]

N 40.12* Documentation Retention

N **A.40.12** The creation and retention of documentation is necessary in order to implement and periodically evaluate the effectiveness of the management systems presented in this standard. Documentation in any form (e.g., electronic) should remain legible and be readily identifiable and accessible. The documentation should be protected against damage, deterioration, or loss, and retained for the applicable period specified in this standard. [**652:**A.9.10]

N **40.12.1** The owner/operator shall establish a program and implement a process to manage the retention of documentation, including, but not limited to, the following:

(1) Training records
(2) Equipment inspection, testing, and maintenance records
(3)* Incident investigation reports

N **A.40.12.1(3)** Incident investigation reports should be maintained for review during cyclical hazards evaluation reviews at least until the changes are incorporated in the dust hazard analysis and for compliance with other regulatory requirements. [**652:**A.9.10.1(3)]

(4) Dust hazards analyses
(5)* Process and technology information

N **A.40.12.1(5)** Process and technology information includes process performance parameters, properties of the materials being handled, and documents such as design drawings, design codes and standards used as the basis for both the process and the equipment, equipment manufacturers' operating and maintenance manuals, standard operating procedures, and safety systems operation. [**652:**A.9.10.1(5)]

(6)* Management of change documents

N **A.40.12.1(6)** Management of change documents should be retained until the changes are incorporated into the next dust hazards analysis. [**652:**A.9.10.1(6)]

(7) Emergency response plan documents
(8)* Contractor records

[**652:**9.10.1]

N **A.40.12.1(8)** Contractor records typically include information such as the contract documentation with scope of work and necessary insurance coverage, the contractor's safety programs, records demonstrating the contractor's safety performance, qualifications and certifications necessary for the work to be done, periodic evaluations of the contractor's work performance, and records demonstrating that the employees of the contractor have been trained to safely perform the assigned work. [**652:**A.9.10.1(8)]

N 40.13 Management Systems Review

N **40.13.1** The owner/operator shall evaluate the effectiveness of the management systems presented in this standard by conducting a periodic review of each management system. [**652:**9.11.1]

N **40.13.2** The owner/operator shall be responsible for maintaining and evaluating the ongoing effectiveness of the management systems presented in this standard. [**652:**9.11.2]

N 40.14* Employee Participation

Owner/operators shall establish and implement a system to consult with and actively involve affected personnel and their representatives in the implementation of this standard. [**652:**9.2]

N **A.40.14** Effective employee participation is an essential element of the Occupational Health and Safety Management System (OHSMS) to achieve continuous improvement in risk reduction, as described in ANSI/AIHA Z10-2012, *Occupational Health and Safety Management Systems.* The OHSMS ensures that employees and their authorized representatives are involved, informed, and trained on all aspects of health associated with their work, including emergency arrangements. Employee participation includes items such as, but not limited to, the following:

(1) Involving employees and their authorized representatives, where they exist, in establishing, maintaining, and evaluating the OSHMS
(2) An occupational health and safety committee
(3) Access to safety and health information
(4) Risk assessment, implementation, and review of risk control measures
(5) Incident and near-miss investigations
(6) Inspections and audits
(7) Reporting unsafe conditions, tools, equipment, and practices
(8) Mentoring of new employees, apprentices, and for onsite orientation
(9) Identifying hazards with strong emphasis on high-risk jobs and the application of the hierarchy of controls
(10) In accordance with established and maintained procedures, appropriate arrangements to ensure that concerns, ideas, and input that employees and their representatives share are received, considered, and responded to
(11) Employees removing themselves from work situations that they have reasonable justification to believe present an imminent and serious danger to their safety or health

[**652:**A.9.12]

Employees who justifiably take those actions by notifying their supervisor should be protected from discrimination by removing those barriers as outlined in the OSHMS. [**652:**A.9.12]

Where this standard and annex refer to employees and their representatives (where representatives exist), the intention is that they should be consulted as the primary means to achieve appropriate participation in the development and implementation of all aspects of the OHSMS. In some instances, it might be appropriate to involve all employees and all representatives. [**652:**A.9.12]

Employee participation is a key component of an OHSMS. When employees and their representatives are engaged and their contributions are taken seriously, they tend to be more satisfied and committed to the OHSMS, and the system is more effective. Engaging employees and their representatives in dialogue with management and each other about safety and health can lead to improved relationships, better overall communication, improved compliance, and reduced rates of injury, illness, and death. The improved morale translates to greater safety and health results. [**652:**A.9.12]

Employees and their representatives need to be trained about how the OHSMS works and to evaluate it periodically to determine whether improvements need to be made. The information needs to be presented in a form and language that employees and their representatives easily understand.

(See also A.40.10.4.)

Welding, Cutting, and Other Hot Work

41

Chapter 41 covers provisions related to welding, cutting, and other hot work, including permitting requirements, parties responsible for the work, fire prevention precautions and practices, operators of hot work, and public exhibitions and demonstrations of the work. Chapter 41 references NFPA 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work, which* includes the following considerations:

- New definitions and requirements for designated and permitted areas
- Modified scope to clarify that the document is also concerned with preventing injuries and not just loss of life during hot work operations
- Revised purpose to clarify that the document provides requirements and not just guidance and that it applies to all those who are involved with hot work operations
- New requirement for welding blankets, pads, and curtains to be both listed and approved
- New requirement stating the maximum period for which a permit is valid is limited to a 24-hour period

These updates are incorporated in the 2018 edition of NFPA 1, *Fire Code*.

41.1 General

According to the NFPA report "Structure Fires Started by Hot Work," torches, soldering equipment, and burners were involved in an average of 4440 structure fires per year during 2010–2014. During those years, torches, soldering equipment, and burners were the equipment involved in ignition in 1860 home structure fires and 2590 non-home structure fires in the United States. Cutting or welding torches accounted for 68 percent of the non-home hot work fires, but only 44 percent of such incidents occurred in the home. Fourteen percent of the home fires were burner fires, reported as fires confined to a cooking vessel, which may have involved stovetop burners rather than the stand-alone burners anticipated by the burner designation under equipment involved in ignition. Most of the non-home cutting or welding torch fires could have been prevented with safer practices. For example, excluding fires reported as confined fires, 68 percent of the non-home structure hot work fires reported proximity of combustibles as a factor that contributed to ignition. Other specific factors contributing to ignition included improperly operated equipment, equipment unintentionally turned on or not turned off, unattended equipment, equipment used for a purpose never intended, mechanical failure or malfunction, and improper startup. The variety of factors leading to reported torch fires are mostly behavioral errors, which points to the substantial need for education and training, whether formal or on the job.

Many fires can originate because hot work is performed in areas not designed or permitted for such work. A single session of hot work can produce hundreds or thousands of potential ignition sources in the form of sparks and hot slag (globules of molten material), in addition to the dangers from the heat and flame of the torch itself. Any combustible or flammable material is susceptible to ignition during hot work. According to "Structure Fires Started by Hot Work," the materials most frequently ignited first in non-home cutting or welding torch fires are structural members and framing, insulation within the structural area, exterior wall coverings or finish, flammable and combustible liquids and gases, piping or filters, and exterior roof coverings. Sparks and slag can fly through the air horizontally as far as 35 ft (11 m) and, anecdotally, have been reported to travel in excess of 250 ft (76 m) vertically, while retaining heat and potentially igniting any combustible material they contact. Figure A.41.3.5.1(1)(b) shows work from an elevated location, considering spark travel as well as the potential need for multiple fire watches. Sparks and slag can fall through cracks, pipe holes, or other small openings in floors and partitions. Other forms of hot work, such as grinding or burning, can heat combustibles through conduction, convection, or radiation.

Fires can also start when hot work is done on containers that hold or have held combustibles and have not been cleaned and purged. Such containers are often fuel storage tanks, but they can also be individual gasoline and diesel fuel tanks on vehicles.

The heat of the metal that is being welded or cut can cause fires when the hot pieces are allowed to rest or fall on combustible materials such as wood shavings and wooden floors. Fires and explosions also result when heat is transmitted through metal (in the case of a container) to a flammable atmosphere or to combustibles within the container. This condition can occur not only when the container itself is being worked on, but when the metal is being removed from, or added to, the exterior of the container. An example of such a scenario is the removal of brackets or appendages from a tank or container by means of cutting.

Even though cutting and welding are statistically the most dangerous types of hot work, other types of hot work present the same dangers as cutting and welding and are controlled by the same precautions and regulatory requirements. Other types of hot work include heat treating, grinding, pipe thawing, use of powder-driven fasteners, hot riveting, and welding and allied processes (open flame soldering, brazing, thermal spraying, oxygen cutting, and arc cutting). Other similar applications — such as grinding, chipping, or abrasive blasting — that produce a spark, a flame, or heat should also be considered during an inspection.

Hot work operations are hazardous for a number of reasons. First, they can use flames burning at temperatures of 4000°F to 5000°F (2200°C to 2760°C) or electric arcs that are estimated by some to be hotter than the surface of the sun. They frequently take place in areas where combustible materials are present, in cramped or elevated areas, or in areas cluttered with tools and equipment that might hinder movement during an emergency. Molten metal and sparks are created that can cause burns and other injuries. Many types of hot work emit radiation that can harm improperly protected eyes.

41.1.1 Hot work shall comply with NFPA 51B and this chapter.

NFPA 51B provides basic requirements to prevent injury, loss of life, and loss of property from fire or explosion as a result of hot work. The scope of NFPA 51B was updated to emphasize the importance of addressing personal safety during hot work operations. Without proper precautions, hot work that results in a fire can be a source of injury such as burns. The scope was expanded to clarify that the document currently has provisions that prevent injuries and not just loss of life during hot work operations. According to the NFPA report "Structure Fires Started by Hot Work," such fires caused an average of 12 civilian deaths, 208 civilian injuries, and $287 million in direct property damage per year. In addition, five fire fighters were fatally injured from 2001–2015 in fires started unintentionally by torches. Compliance with the requirements in this chapter can reduce the number of injuries and fatalities.

41.1.2 Chapter 41 shall apply to the following hot work processes:

(1) Welding and allied processes
(2) Heat treating
(3) Grinding
(4) Thawing pipe
(5) Powder-driven fasteners
(6) Hot riveting
(7)* Torch-applied roofing in conjunction with the requirements of Section 16.6

A.41.1.2(7) There are more detailed, and in some cases more stringent, requirements for torch-applied roofing found in Section 16.6 and NFPA 241. [**51B:**A.1.3.1(7)]

(8) Similar applications producing or using a spark, flame, or heat [**51B:**1.3.1]

Hot work processes performed during construction, alteration, demolition, or repairs should be consistent with the requirements of Chapter 16 of this *Code*.

Δ **41.1.3** Chapter 41 shall not apply to the following:

(1) Candles
(2) Pyrotechnics or special effects
(3) Cooking operations
(4) Electric soldering irons
(5) Design and installation of gas cutting equipment and welding equipment covered in NFPA 51
(6) Additional requirements for hot work operations in confined spaces
(7) Lockout/tagout procedures during hot work

[**51B:**1.3.2]

Δ **41.1.4** Acetylene cylinder charging plants shall comply with NFPA 55.

Chapter 15 of NFPA 55, *Compressed Gases and Cryogenic Fluids Code*, provides safety requirements for the design, construction, and installation of acetylene cylinder charging plants to provide safeguards for the protection of the plant, its employees, and the public. The standard also applies to plants engaged in the generation and compression of acetylene and in the charging of acetylene cylinders, either as their sole operation or in conjunction with facilities for charging other compressed gas cylinders. These requirements were found in NFPA 51A, *Standard for Acetylene Cylinder Charging Plants*, prior to the standard being withdrawn and incorporated into NFPA 55 in 2013.

Chapter 15 of NFPA 55 does not apply to plants that only produce and compress acetylene for chemical operations or to plants that only produce and compress acetylene below a gauge pressure of 15 psi (103 kPa). (Refer to NFPA 51, *Standard for the Design and Installation of Oxygen–Fuel Gas Systems for Welding, Cutting, and Allied Processes*, for requirements covering acetylene-generating plants where the acetylene is used with oxygen for welding, cutting, heating, and heat-treating operations.)

An existing plant that is not in strict compliance with the provisions of this *Code* and NFPA 55 is permitted to continue operations where such use does not constitute a distinct hazard to life or adjoining property.

41.1.5 Permits.

41.1.5.1 Permits, where required, shall comply with Section 1.12.

41.1.5.2 Where an approved facility hot work permit program exists that meets the requirements of Chapter 41, the permit shall be permitted to be issued for an entire facility.

A permit is not always required. Figure A.41.3.4 shows a decision tree to assist in the decision process to determine whether a permit is needed. See Figure A.41.3.4.1 for a sample hot work permit.

The local jurisdiction may also require an additional permit process to the one described in this chapter. For example, in Boston, Massachusetts, before beginning any hot work, the hot work team must apply for and receive a permit from the Department of Fire Prevention. Because of a fire in March 2014 in which two fire fighters lost their lives after unpermitted hot work took place, the Boston City Council now requires that all hot work permit applicants receive a Hot Work Safety Certification prior to applying for the permit and conducting hot work. The permit authorizing individual (PAI) should be knowledgeable about any local or state ordinances before approving work.

41.2 Responsibility for Hot Work

41.2.1* Management. Management or a designated agent shall be responsible for the safe operations of hot work activity. [**51B:**4.1]

A.41.2.1 The Technical Committee on Hot Work Operations (NFPA 51B) recognizes that management might not always have expertise in hot work and, therefore, would need a knowledgeable designated agent or contractor to act on its behalf. Examples of those who might not have the expertise can include owners of small retail shops, a small apartment complex manager, or a grocery store owner who has no knowledge of hot work safe practices. [**51B:**A.4.1]

Management should ensure that the contractor has evidence of financial responsibility, which can take the form of an insurance certificate or other document attesting to coverage or responsibility. [**51B:**A.4.1]

41.2.1.1 Management shall establish permissible areas for hot work. [**51B:**4.1.1]

41.2.1.2 Management shall designate a permit authorizing individual (PAI). [**51B:**4.1.2]

41.2.1.3 All equipment shall be examined to ensure it is in a safe operating condition. [**51B:**4.1.3]

41.2.1.4 When found to be incapable of reliable safe operation, the equipment shall be repaired by qualified personnel prior to its next use or be withdrawn from service and tagged out of service. [**51B:**4.1.4]

41.2.1.5 Management shall ensure that only approved apparatus, such as torches, manifolds, regulators or pressure-reducing valves, and acetylene generators, are used. [**51B:**4.1.5]

41.2.1.6 Management shall ensure that all individuals involved in the hot work operations, including contractors, are familiar with the provisions of Chapter 41. [**51B:**4.1.6]

41.2.1.6.1 Individuals involved in hot work operations shall be trained in the safe operation of their equipment and in the safe use of the process. [**51B:**4.1.6.1]

41.2.1.6.2 Individuals involved in hot work operations shall have an awareness of the inherent risks involved and understand the emergency procedures in the event of a fire. [**51B:**4.1.6.2]

41.2.1.7 Management shall advise all contractors about site-specific flammable materials, hazardous processes or conditions, or other potential fire hazards. [**51B:**4.1.7]

41.2.2 Permit Authorizing Individual (PAI). In conjunction with management, the PAI shall be responsible for the safe operation of hot work activities. [**51B:**4.2]

The term *permit authorizing individual (PAI)* is used throughout this chapter. The PAI is defined in NFPA 51B as "the individual designated by management to authorize hot work."

The PAI is permitted to be, among others, the supervisor, foreperson, property owner or representative, or health and safety administrator. The PAI cannot be the hot work operator, except as permitted in Section 41.4 and Chapter 6 of NFPA 51B. The PAI is aware of the fire hazards involved and is familiar with the provisions of this *Code* and NFPA 51B.

41.2.2.1* The PAI shall consider the safety of the hot work operator and fire watch with respect to personal protective equipment (PPE) for other special hazards beyond hot work. (*See 41.3.1.*) [**51B:**4.2.1]

A.41.2.2.1 Other special hazards can include, but are not limited to, lead, noise, and radiation. Sometimes these special hazards require disposable outer garments that can catch fire. [**51B:**A.4.2.1]

41.2.2.2 The PAI shall determine site-specific flammable materials, hazardous processes, or other potential fire hazards that are present or likely to be present in the work location. [**51B:**4.2.2]

41.2.2.3 The PAI shall ensure the protection of combustibles from ignition by the following means:

(1)* Considering alternative methods to hot work
(2) Moving the work to a location that is free from combustibles
(3) If the work cannot be moved, moving the combustibles to a safe distance or having the combustibles properly shielded against ignition
(4) Scheduling hot work so that operations that could expose combustibles to ignition are not begun during hot work operations

[**51B:**4.2.3]

A.41.2.2.3(1) Alternatives to hot work can include the following:

(1) Mechanical removal and relocation of frozen piping to a heated area
(2) Manual hydraulic shears

(3) Mechanical bolting
(4) Screwed, flanged, or clamped pipe
(5) Reciprocating saw
(6) Mechanical pipe cutter
(7) Approved self-drilling or compressed air-actuated fasteners

[**51B:**A.4.2.3(1)]

Δ **41.2.2.4** If the criteria of 41.2.2.3(1) through 41.2.2.3(4) cannot be met, hot work shall not be performed. [**51B:**4.2.4]

41.2.2.5 The PAI shall determine that fire protection and extinguishing equipment are properly located at the site. [**51B:**4.2.5]

41.2.2.6 Where a fire watch is required *(see 41.3.5)*, the PAI shall be responsible for ensuring that a fire watch is at the site. [**51B:**4.2.6]

41.2.2.7* Where a fire watch is not required, the PAI shall make a final check ½ hour after the completion of hot work operations to detect and extinguish smoldering fires. [**51B:**4.2.7]

A.41.2.2.7 The inspection is usually made ½ hour after the completion of hot work to detect and extinguish possible smoldering fires. The inspector should be alert for circumstances that can require an extension of the final inspection interval. [**51B:**A.4.2.7]

Generally, if a fire develops from hot work, evidence of smoldering or fire occurs within 30 minutes. However, if the cutting was done in an area that contains a large quantity of finely divided or lightweight combustibles, even though the combustibles were shielded, a longer fire watch might be appropriate. Likewise, if sparks or slag could have entered a crack in a wall or floor, or if unusual conditions or hazards exist, a longer fire watch should be maintained.

Also, see the commentary following 41.3.4.2(2) for additional guidance on reference standards that address fire and explosion hazards of various combustible particulate solids.

Δ **41.2.3 Hot Work Operator.** The hot work operator shall handle equipment safely and use it as follows so as not to endanger lives and property:

(1) The operator shall have the PAI's approval before starting hot work operations.
(2) All equipment shall be examined to ensure it is in a safe operating condition, and, if found to be incapable of reliable safe operation, the equipment shall be repaired by qualified personnel prior to its next use or be withdrawn from service.
(3) The operator shall cease hot work operations if unsafe conditions develop and shall notify management, the area supervisor, or the PAI for reassessment of the situation.

[**51B:**4.3]

41.2.4 Fire Watch.

A fire watch is an individual(s) assigned to work with hot work operators for the purpose of watching for fire that could result from hot work. Fire watches normally watch for fires in areas that cannot be easily observed by the operator, such as the opposite sides of walls, levels below the work area, spaces behind the operator, or hidden areas. The fire watch should also keep a lookout to make sure that any clothing or personal protective equipment (PPE) worn by the operator does not ignite. Finally, they also observe an area after the hot work operations have stopped. It can be confusing to decide whether a fire watch is necessary; Figure A.41.3.5.1 is a decision tree that assists in determining whether one or more fire watches are needed.

41.2.4.1* The fire watch shall be trained to understand the inherent hazards of the work site and of the hot work. [**51B:**4.4.1]

A.41.2.4.1 The fire watch duties can be assigned to anyone who understands the hazard of the hot work being performed and the limitations placed on that hot work operation by the person issuing the hot work permit (PAI). The fire watch has the responsibility to make certain the hot work area is maintained in a fire-safe condition throughout performance of the hot work and has the authority to stop the hot work if unsafe conditions are observed. The fire watch must understand the basic hazards of any combustible construction involved with the hot work area, the fire exposure hazard hot work creates to occupancies adjacent to or below the hot work operation, the hazards associated with the occupancy, and the need to maintain proper isolation of all hot work operations from combustible or flammable materials. The fire watch should also be properly trained in use of manual, portable fire extinguishers and emergency notification procedures within the facility. The fire watch is not a replacement for proper planning to prevent conditions that allow a fire to develop, regardless of the fire-fighting equipment available and the capabilities of the individuals involved. [**51B:**A.4.4.1]

41.2.4.2 The fire watch shall ensure that safe conditions are maintained during hot work operations. [**51B:**4.4.2]

41.2.4.3 The fire watch shall have the authority to stop the hot work operations if unsafe conditions develop. [**51B:**4.4.3]

41.2.4.4* The fire watch shall have fire-extinguishing equipment readily available and shall be trained in its use. [**51B:**4.4.4]

A.41.2.4.4 The fire watch should have experience with test fires. [**51B:**A.4.4.4]

41.2.4.5 The fire watch shall be familiar with the facilities and procedures for sounding an alarm in the event of a fire. [**51B:**4.4.5]

41.2.4.6 The fire watch shall watch for fires in all exposed areas and try to extinguish them only when the fires are obviously within the capacity of the equipment available. If the fire watch determines that the fire is not within the capacity of the equipment, the fire watch shall sound the alarm immediately. [**51B:**4.4.6]

41.2.4.7* The fire watch shall be permitted to perform additional tasks, but those tasks shall not distract him or her from his or her fire watch responsibilities, except as outlined in Section 41.4. [**51B:**4.4.7]

A.41.2.4.7 These tasks might include moving partitions relating to the hot work, sweeping in the immediate area, and minimal assistance to the operator. [**51B:**A.4.4.7]

41.2.5* Contractors. Before starting any hot work, contractors and their clients shall discuss the planned project completely, including the type of hot work to be conducted and the hazards in the area. [**51B:**4.5]

A.41.2.5 The trend toward outsourcing facility maintenance and renovations can influence the risks associated with hot work. A contractor may have the technical expertise to perform hot work but is not likely to have a full understanding of fire prevention or of the specific combustible hazards within a client property. Additional safeguards to be considered include, but are not be limited to, how the hot work should be isolated to prevent fire hazards; who will be assigned as the fire watch for the hot work operations; the facility emergency notification procedures; available manual fire fighting tools (like portable fire extinguishers and small hose stations); identification of all areas where hot work is not allowed; connecting hot work equipment to existing utility systems (gas or electricity); and review of any requirements for completion of hot work by a certain time each day. [**51B:**A.4.5]

Hot work loss incidents involving contractors occur with regular frequency. For many of these incidents, facility management has not implemented a process for managing the fire hazards associated with the proposed contract work activity, views the contractor's personnel as the recognized subject matter expert, and is either ignorant of potential fire hazards with the planned contract activity or presumes the contractor is expert in all associated safety regulations and requirements and will address hazards accordingly. [**51B:**A.4.5]

41.2.6 Mutual Responsibility. Management, contractors, the PAI, the fire watch, and the operators shall recognize their mutual responsibility for safety in hot work operations. [**51B:**4.6]

41.3 Fire Prevention Precautions

NFPA 51B provides requirements for restricting hot work to designated areas or to permit-required areas. Provisions are also made for establishing a written permit system to ensure that the area is made safe by removing or protecting combustibles, making available fire-extinguishing equipment, and, under some conditions, requiring a fire watch. (See 41.2.4.)

Hot work fires can be prevented by separating combustibles from ignition sources, by shielding combustibles from the source of flame or heat, and by protecting combustibles anywhere that sparks and slag can travel.

NFPA 51B provides requirements for hot work operators, fire watches, supervisors (including outside contractors), and the management of property where hot work is performed. Chapter 16 of NFPA 1 provides requirements whenever construction, alterations, demolition, or repairs are conducted that might involve hot work processes.

All individuals involved in hot work should be aware of some relatively common circumstances in which fires, explosions, or severe injuries are likely. Some considerations include the following:

1. The proximity or the flammable nature of nearby combustible solids, liquids, or dusts
2. The presence or development of possibly explosive mixtures of flammable gases or vapors and air
3. The presence or nature of an oxygen-enriched atmosphere where the work is to be performed

Management, the PAI, the hot work operator, and the fire watch share responsibility for safe hot work procedures. The specific responsibilities of each individual for the safe use of hot work are described in Section 41.2 and Chapter 4 of NFPA 51B. An abbreviated form of these responsibilities follows.

Management has the following responsibilities:

1. Be responsible for the safe operations of hot work activity
2. Establish permissible areas for hot work
3. Designate a PAI
4. Ensure that only approved apparatus — such as torches, manifolds, regulators, pressure-reducing valves, and acetylene generators — are used
5. Ensure that all individuals involved in the hot work operations, including contractors, are familiar with the provisions of NFPA 51B and the safe operation of their equipment and process and that they understand emergency procedures to follow in the event of a fire
6. Advise all contractors about site-specific flammable materials and hazardous processes or other hazardous conditions

The PAI has the following responsibilities:

1. Be responsible for the safe operations of hot work activity
2. Consider the safety of the hot work operator and fire watch with respect to PPE for other special hazards beyond hot work
3. Identify site-specific flammable materials, hazardous processes, or other hazardous conditions present or likely to be present in the work location
4. Ensure the protection of combustibles from ignition by the following means and, if one or more of the following means cannot be met, not perform hot work:
   a. Ensure that work is moved to a location free of combustibles
   b. If the work cannot be moved, ensure that the combustibles are moved to a safe distance or are properly shielded
   c. Ensure that hot work is scheduled such that operations that could expose combustibles to ignition are not started during hot work operations

5. Determine that fire protection and extinguishing equipment are properly located at the site
6. Where a fire watch(es) is required, ensure that the fire watch is available at the site
7. Where a fire watch is not required, make a final check 30 minutes after the completion of hot work operations to detect and extinguish possible smoldering fires

The hot work operator has the following responsibilities:

1. Handle the equipment safely and use it so as not to endanger lives and property
2. Obtain the PAI's approval before starting hot work operations
3. Cease hot work operations if unsafe conditions develop or conditions change from those under which the permit was granted and notify the PAI for reassessment of the site

The fire watch has the following responsibilities:

1. Be aware of the inherent hazards of the work site and of the hot work
2. Ensure that safe conditions are maintained during hot work and stop hot work if conditions change and unsafe conditions develop
3. Have extinguishing equipment readily available and be trained in its use
4. Be familiar with the facility and the procedures for sounding an alarm in the event of a fire
5. Watch for fires in all exposed areas and extinguish only those fires within the capacity of the fire watch; if not within the capacity of the fire watch, sound the alarm immediately

Other non–fire safety requirements for many types of hot work are covered in ANSI Z49.1, *Safety in Welding, Cutting, and Allied Processes*. U.S. Department of Labor Occupational Safety and Health Administration (OSHA) regulations — in 29 CFR, Part 1910, Subpart Q, "Welding, Cutting and Brazing," and, for construction, 29 CFR, Part 1926, Subpart J, "Welding and Cutting" — are based on the requirements of NFPA 51, NFPA 51B, and ANSI Z49.1.

41.3.1* Personal Protective Clothing. Clothing shall be selected to minimize the potential for ignition, burning, trapping hot sparks, and electric shock. [**51B:**5.1]

A.41.3.1 At a work site, hazards other than hot work, such as radiation, lead, or noise, are often present. Any additional PPE donned for protection against these other hazards should also be appropriate for hot work. Heavier materials, such as woolen clothing or heavy cotton, are preferable to lighter materials because they

Case Study

On July 29, 2008, in Tomahawk, Wisconsin, three workers at the Packaging Corporation of America (PCA) fiberboard manufacturing facility were killed and one worker was injured while they were attempting to weld a temporary metal clamp to stabilize a damaged flange connection. The welding occurred on top of an 80-foot tall storage tank that at the time held recycled water and fiber waste.

The presence of or risk for development of possibly explosive mixtures of flammable gases or vapors and air can be a deadly combination when hot work is being performed; sparks from the hot work can potentially ignite the explosive gases and vapors, especially those that have gone undetected. At the PCA, facility workers were unaware of the potential risk of the development of flammable gas from the decomposition of the material in the tank. In this case, combustible gas monitoring was not present, nor was it typically performed prior to starting the work. A description of the incident states that, at the time of the accident, three workers were on a catwalk above the tank. One worker began welding the flange into place when sparks from the hot work ignited the flammable vapors in the tank. The explosion occurred in the tank, and the force of the explosion ripped the tank lid off. The flying tank lid and the explosion knocked two of the workers from the tank to the ground, 80 ft (24.4 m) below. A fourth worker, who was observing the work from a distance away from the tank, was injured.

The U.S. Chemical Safety and Hazard Investigation Board (CSB) performed an investigation into this accident and determined, after an analysis of the tank contents, that bacteria inside the tank had multiplied and likely produced hydrogen, which ignited and exploded during the welding operation. In its report, "Seven Key Lessons to Prevent Worker Deaths During Hot Work In and Around Tanks," the CSB documented that, at the time of the accident, personnel at PCA were unaware of the risks of flammable gas production from this tank. Hazard analyses and risk analyses should be conducted at sites where hot work is being performed to reduce the risk of an incident such as this occurring, as well as to ensure that gas monitoring is used where necessary. See the CSB website for additional information on this and other incidents occurring from hot work accidents.

Exhibit CS41.1

(Courtesy of the U.S. Chemical Safety Board)

are more difficult to ignite. Cotton clothing, if used for protection, should be chemically treated to reduce its combustibility. Clothing treated with flame-resistant materials can lose some of its protective characteristics after repeated washing or cleaning. Materials that can melt and cause severe burns should not be used as clothing when the wearer will be welding or cutting. [**51B:**A.5.1]

Sparks can lodge in rolled-up sleeves, pockets of clothing, or cuffs of overalls or trousers. Therefore, it is recommended that sleeves and collars be kept buttoned and pockets be eliminated from the front of clothing. Where pockets are present, they should be emptied of flammable or readily combustible materials. Trousers or overalls should not have cuffs and should not be turned up on the outside. Trousers should overlap shoe tops to prevent spatter from getting inside shoes. [**51B:**A.5.1]

Frayed clothing is particularly susceptible to ignition and burning and should not be worn when welding or cutting. [**51B:**A.5.1]

41.3.2 Permissible Areas.

The two permissible areas for hot work are designated areas (see 41.3.2.2.1) and permit-required areas. Hot work should preferably be done in specially designated areas that have been designed and constructed to minimize fire risk and are, therefore, theoretically inherently safe.

41.3.2.1 General. Hot work shall be permitted only in areas that are or have been made fire safe. [**51B:**5.2.1]

41.3.2.2 Designated or Permit-Required Areas. Hot work shall be performed in either designated areas or permit-required areas. [**51B:**5.2.2]

A *designated area* is defined in 3.3.14.9.1 as "a specific location designed and approved for hot work operations that is maintained fire safe such as a maintenance shop or a detached outside location that is of noncombustible or fire-resistive construction, essentially free of combustible and flammable contents, and suitably segregated from adjacent areas." A *permit-required area* is defined in 3.3.14.9.2 as "any location other than a designated area that is approved for hot work . . . [and] is made fire-safe by removing or protecting combustibles from ignition sources.

41.3.2.2.1 Designated Areas.

41.3.2.2.1.1 In order for a location to be a designated area, the area shall meet the requirements in 41.3.4.2. [**51B:**5.2.2.1.1]

41.3.2.2.1.2 Prior to the start of any hot work in a designated area, at a minimum, the hot work operator shall perform the following:

(1) The location is verified as fire resistant.
(2) The requirements of 41.3.4.2(3) are met.
(3) Fire extinguishers are in working condition and readily available.
(4) Ventilation is working properly.
(5) Equipment is in working order.

[**51B:**5.2.2.1.3]

41.3.2.2.1.3 Permanent areas designated for hot work shall be reviewed at least annually by the PAI. [**51B:**5.2.2.1.3]

There were limited requirements on designated areas in NFPA 51B prior to the 2014 edition. The industry identified the need for some general requirements regarding designated areas; thus, some additional requirements were developed for users and authorities having jurisdiction (AHJs) to better understand the use of designated areas for hot work and emphasize that these areas, just like permitted areas, need to be fire safe.

41.3.2.2.2 Signs shall be posted designating hot work areas as deemed necessary by the PAI. [**51B:**5.2.2.2]

Δ **41.3.3* Nonpermissible Areas.** Hot work shall not be permitted in the following areas:

(1) In areas not authorized by management

Management or its agents should always be aware of any hot work activity. Good management practices reduce the chance of inadvertent fires.

(2) In sprinklered buildings where sprinklers are impaired, unless the requirements of NFPA 25 are met

Hot work is permitted in many nonsprinklered buildings. However, a building in which the sprinklers are out of service is not the same situation as a nonsprinklered building. If the building was initially deemed to require sprinklers, they are required to be in working order during any hot work, because the hazards or value warrants sprinkler protection.

(3) In the presence of explosive atmospheres (i.e., where mixtures of flammable gases, vapors, liquids, or dusts with air exist)
(4) In the presence of uncleaned or improperly prepared equipment, drums, tanks, or other containers that have previously contained materials that could develop explosive atmospheres

All containers should be considered unsafe for hot work unless they have been rendered safe or have been declared safe by a qualified authority. Containers that are presumed to be empty could contain materials that are hidden in cracks and crevices and that can release hazardous fumes when heated. The by-products of corrosion can result in an explosive atmosphere (hydrogen) within a container. Consequently, even a water tank should be considered hazardous unless it has been declared safe for hot work.

(5) In areas with an accumulation of combustible dusts that could develop explosive atmospheres

[**51B:**5.3]

Finely divided bulk materials, such as bulk flour and its dust, that normally are considered safe in small bulk quantities can be explosive when suspended in air in sufficient concentrations if ignition sources are present, such as during hot work.

Δ **A.41.3.3** For additional information on cutting and welding of containers that have held flammable materials, see NFPA 326 and ANSI/AWS F-4.1, *Recommended Safe Practices for the Preparation for Welding and Cutting Containers and Piping*. [**51B:**A.5.3]

Additional consideration should be given when hot work is performed in areas near the storage of large quantities of exposed, readily ignitable materials such as bulk sulfur, baled paper, or cotton.

For additional information on welding and cutting in storage areas, refer to Chapter 34 and NFPA 655. [**51B:**A.5.3]

41.3.4* Hot Work Permit.

A.41.3.4 The decision tree in Figure A.41.3.4 can be used to determine if a hot work permit is necessary. [**51B:**A.5.4]

Table 1.12.8(a) requires a permit for hot work operations within the jurisdiction. Where hot work is performed on a regular, ongoing basis at a particular site (such as in an auto body shop or steel fabrication plant), a permit can be issued to cover the ongoing hot work procedure at the site, assuming no conditions change from the time the permit is issued.

Where the processes are performed repeatedly, additional written authorization for hot work is not always required. For example, managerial or supervisory control in the workplace can serve as an equivalent means of authorization (like a blanket permit) once a general permit is issued. However, for specific one-time operations, a written permit for each operation is required, with a time period for which the permit is valid. Paragraph 41.3.4.4 limits the hot work permit period to 24 hours (see the commentary following 41.3.4.4 for an explanation as to why). If the circumstances change (with either one-time or blanket-type permits), the existing permit would be void, and a new permit should be required.

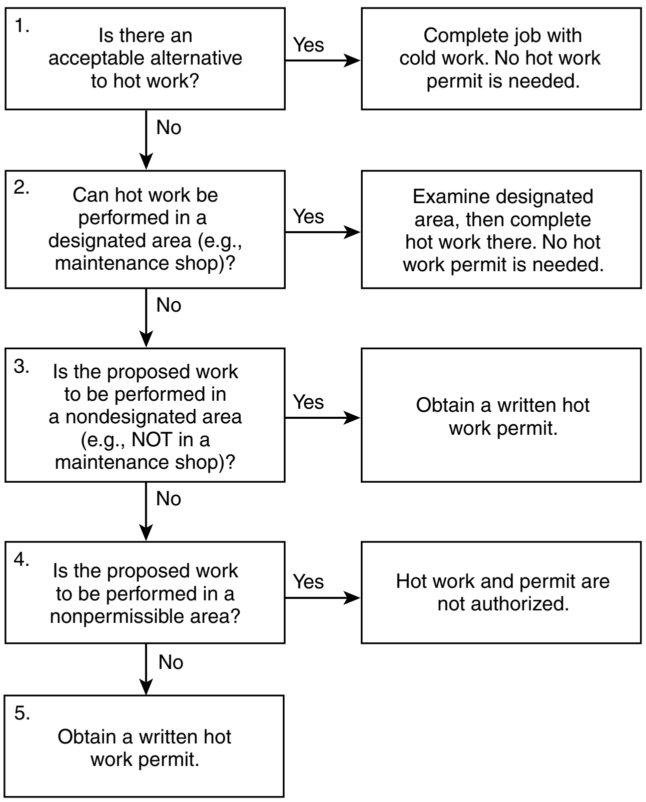

***FIGURE A.41.3.4** Hot Work Permit Decision Tree. [**51B:** Figure A.5.4]*

The operations described in 41.3.3 are typically conducted in areas that contain combustible materials. Therefore, special attention must be paid to protecting combustibles from accidental ignition. Providing members of the plumbing and painting trades and other trades likely to use torches with periodic reminders might be necessary to ensure that proper fire prevention measures are implemented on a regular basis. See the commentary and case study at the beginning of Section 41.3.

41.3.4.1* Before hot work operations begin in a nondesignated location, a written hot work permit by the PAI shall be required. [**51B:**5.4.1]

A.41.3.4.1 An example of a hot work permit is shown in Figure A.41.3.4.1. This permit can be modified to suit local conditions. [**51B:**A.5.4.1]

Paragraph 41.3.4.1 requires management to designate a PAI responsible for authorizing (permitting) hot work operations in areas not specifically designated for such processes. The PAI's responsibilities are outlined in the commentary at the beginning of Section 41.3 and following 41.2.2 and include familiarity with the provisions of NFPA 51B.

41.3.4.2 Before a hot work permit is issued, the following conditions shall be verified by the PAI:

(1) The hot work equipment to be used shall be in satisfactory operating condition and in good repair.

Hot work equipment can be the source of inadvertent ignition if it is in poor repair. For example, electrical current flowing through poor connections can melt the metal of the contacts, and poor insulation can permit arcing between conductors. Gas equipment can leak flammable gases or oxygen. A system of routine inspection and maintenance minimizes such hazards.

(2) Where combustible materials, such as paper clippings, wood shavings, or textile fibers, are on the floor, the floor shall be swept clean for a radius of 35 ft (11 m) and the following criteria also shall be met:
   (a) Combustible floors shall be kept wet, covered with damp sand, or protected by a listed welding blanket, welding pad, or equivalent.
   (b) Where floors have been wet down, personnel operating arc welding equipment or cutting equipment shall be protected from possible shock.

Many types of hot work can produce slag and spatter. Slag and spatter can be ejected from the work zone by the forces inherent in the processes, or they can fall to the floor and spread by rolling or by bouncing. NFPA 51B requires that flammable and combustible materials be cleared from within a minimum horizontal 35 ft (11 m) radius of the work area. However, vertical distances must also be considered. Anecdotally, sparks and slag have been reported to travel over 250 ft (76 m) vertically. Any place spark or slag can travel should be considered. Heat (radiation, conduction, or convection) produced from hot work must also be considered.

HOT WORK PERMIT

Seek an alternative/safer method if possible!

Before initiating hot work, ensure precautions are in place as required by NFPA 51B and ANSI Z49.1.
Make sure an appropriate fire extinguisher is readily available.

This Hot Work Permit is required for any operation involving open flame or producing heat and/or sparks. This work includes, but is not limited to, welding, brazing, cutting, grinding, soldering, thawing pipe, torch-applied roofing, or chemical welding.

Date	Hot work by ❑ employee ❑ contractor
Location/Building and floor ______________	Name (print) and signature of person doing hot work ______________
Work to be done ______________	I verify that the above location has been examined, the precautions marked on the checklist below have been taken, and permission is granted for this work.
Time started ________ Time completed ________ THIS PERMIT IS GOOD FOR ONE DAY ONLY	Name (print) and signature of permit-authorizing individual (PAI) ______________

❑ Available sprinklers, hose streams, and extinguishers are in service and operable.

❑ Hot work equipment is in good working condition in accordance with manufacturer's specifications.

❑ Special permission obtained to conduct hot work on metal vessels or piping lined with rubber or plastic.

Requirements within 35 ft (11 m) of hot work
❑ Flammable liquid, dust, lint, and oily deposits removed.
❑ Explosive atmosphere in area eliminated.
❑ Floors swept clean and trash removed.
❑ Combustible floors wet down or covered with damp sand or fire-resistive/noncombustible materials or equivalent.
❑ Personnel protected from electrical shock when floors are wet.
❑ Other combustible storage material removed or covered with listed or approved materials (welding pads, blankets, or curtains; fire-resistive tarpaulins), metal shields, or noncombustible materials.
❑ All wall and floor openings covered.
❑ Ducts and conveyors that might carry sparks to distant combustible material covered, protected, or shut down.

Requirements for hot work on walls, ceilings, or roofs
❑ Construction is noncombustible and without combustible coverings or insulation.
❑ Combustible material on other side of walls, ceilings, or roofs is moved away.

Requirements for hot work on enclosed equipment
❑ Enclosed equipment is cleaned of all combustibles.
❑ Containers are purged of flammable liquid/vapor.
❑ Pressurized vessels, piping, and equipment removed from service, isolated, and vented.

Requirements for hot work fire watch and fire monitoring
❑ Fire watch is provided during and for a minimum of 30 min. after hot work, including any break activity.
❑ Fire watch is provided with suitable extinguishers and, where practical, a charged small hose.
❑ Fire watch is trained in use of equipment and in sounding alarm.
❑ Fire watch can be required in adjoining areas, above and below.
❑ Yes ❑ No Per the PAI/fire watch, monitoring of hot work area has been extended beyond the 30 min.

 NFPA 51B

Δ ***FIGURE A.41.3.4.1*** *Sample of a Hot Work Permit. [**51B:**Figure A.5.4.1]*

See Chapter 40 for other NFPA documents that address the fire and explosion hazards of combustible particulate solids, including the following:

1. Agricultural dusts, covered by NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities*
2. Coal dust, addressed by NFPA 85, *Boiler and Combustion Systems Hazards Code*, and NFPA 120, *Standard for Fire Prevention and Control in Coal Mines*
3. Combustible metal dusts, covered by NFPA 484, *Standard for Combustible Metals*
4. Combustible particulate solids, addressed by NFPA 654, *Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids*
5. Sulfur dust, addressed by NFPA 655, *Standard for Prevention of Sulfur Fires and Explosions*
6. Wood shavings and sawdust, covered by NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*

(3)* All combustibles shall be relocated at least 35 ft (11 m) in all directions from the work site, and the following criteria also shall be met:
  (a) If relocation is impractical, combustibles shall be protected by a listed welding blanket, welding pad, or equivalent.
  (b) To prevent the entrance of sparks, the edges of covers at the floor shall be tight including at the point at which several covers overlap where a large pile is being protected.

A.41.3.4.2(3) When hot work is performed at an elevated level, it should be noted that the sparks or slag can fall at a trajectory and land further than 35 ft (11 m) horizontally from a point directly under the hot work operator. [**51B:**A.5.4.2(3)]

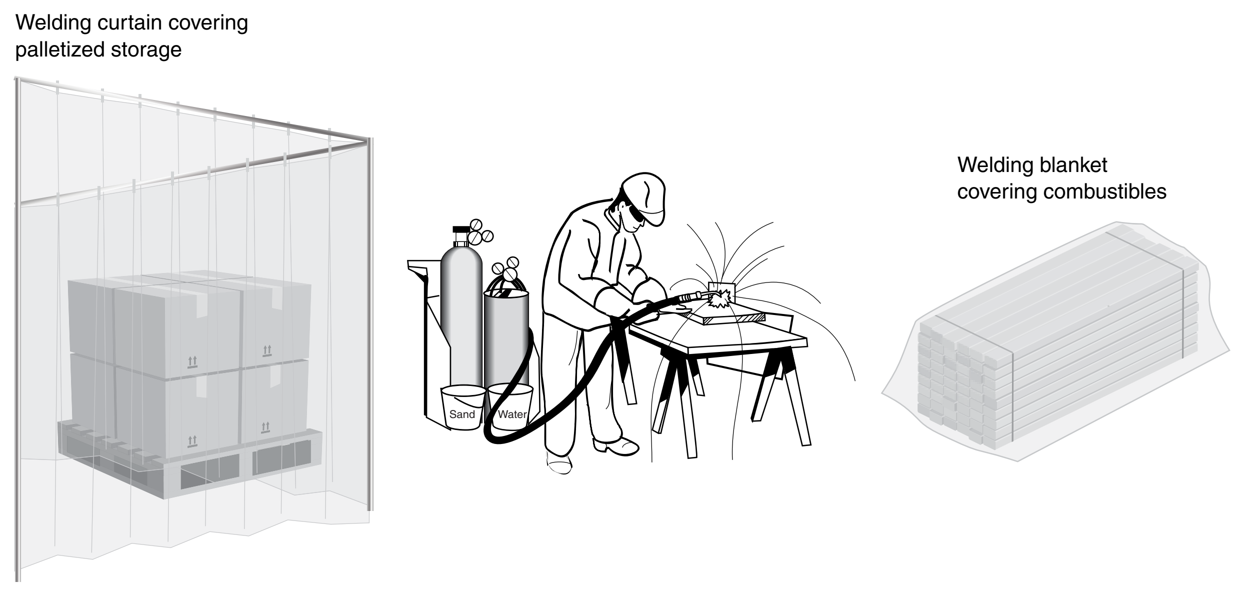
Moving combustibles away from hot work is not always possible. In such cases, protecting combustibles with listed welding blankets, pads, or curtains is important, as illustrated in Exhibit 41.1. Hot work cannot be performed safely on a metal wall, on a partition to which combustible material has been fastened on one side, or on a sandwich-type partition that contains combustible materials within the sandwiched portions.

Paint on metal walls or partitions can release toxic fumes when heated by conduction from hot work performed on the opposite side. This result is especially true for freshly painted surfaces. If the potential for release of toxic fumes exists, workers should not be allowed in the area while hot work is performed, and the operator and fire watch (if present) should use proper respiratory protection.

(4) Openings or cracks in walls, floors, or ducts within 35 ft (11 m) of the site shall be covered or sealed with listed fire-rated or noncombustible material to prevent the passage of sparks to adjacent areas.

Openings for the passage of piping and conduits can allow sparks, slag, flame, or heat to reach hidden or adjoining areas. Insulation or dust that covers the tops of pipes and conduits can act as a fuse or a wick that permits smoldering material, once ignited, to burn into hidden or adjacent areas. Many areas are often overlooked as potential passages for slag and spatter, such as elevator shafts, open doors, or windows. All such areas should be tightly covered to prevent the passage of sparks.

Exhibit 41.1



Safe hot work procedures.

(5) Ducts and conveyor systems that might carry sparks to distant combustibles shall be shielded, or shut down, or both.

(6) If hot work is done near walls, partitions, ceilings, or roofs of combustible construction, they shall be protected by a listed welding curtain, welding blanket, welding pad, or equivalent.

(7) If hot work is done on one side of a wall, partition, ceiling, or roof, one of the following criteria shall be met:
   (a) Precautions shall be taken to prevent ignition of combustibles on the other side by relocating the combustibles.
   (b) If it is impractical to relocate combustibles, a fire watch shall be provided on the side opposite from where the work is being performed.

If a fire watch is used on the side opposite from where work is performed, a system of communication should be established such that the fire watch can signal if the operator should stop the hot work. This action can be as simple as a bang on the wall or as complex as a two-way radio.

(8) Hot work shall not be attempted on a partition, wall, ceiling, or roof that has a combustible covering or insulation, or on walls or partitions of combustible sandwich-type panel construction.

Hot work cannot be performed safely on a metal wall, on a partition to which combustible material has been fastened on one side, or on a sandwich-type partition that contains combustible materials within the sandwiched portions, because heat can be radiated through the metal surface and expose the combustible materials to elevated temperatures that could cause a fire.

See the commentary following 41.3.4.2(2) for additional reference standards addressing fire and explosion hazards of various combustible particulate solids.

(9) Hot work that is performed on pipes or other metal that is in contact with combustible walls, partitions, ceilings, roofs, or other combustibles shall not be undertaken if the work is close enough to cause ignition by conduction.

(10) Fully charged and operable fire extinguishers that are appropriate for the type of possible fire shall be available immediately at the work area.

Fire-extinguishing equipment appropriate for any hazard in the area where hot work is to occur should be readily available in the work area before work begins. The fire watch should be trained in its use. An extinguisher located on a truck or outside the immediate work area is of limited value, because it might be inaccessible during an emergency. Even a simple garden hose connected and pressurized for immediate use or a bucket of water can be useful, depending on the potential size of a fire.

Distribution of portable fire extinguishers must be in accordance with this chapter and Section 13.6.

(11) If existing hose lines are located within the hot work area defined by the permit, they shall be connected and ready for service but shall not be required to be unrolled or charged.

(12) The following shall apply to hot work done in close proximity to a sprinkler head:
   (a) A wet rag shall be laid over the sprinkler head and then removed at the conclusion of the welding or cutting operation.
   (b) During hot work, special precautions shall be taken to avoid accidental operation of automatic fire detection or suppression systems (e.g., special extinguishing systems or sprinklers).

The accidental operation of sprinklers caused by the heat of hot work can be hazardous to persons using electrical equipment, because the water released by the sprinkler can create a serious shock hazard. If a sprinkler system is accidentally activated, hot work should stop until the system is fully restored.

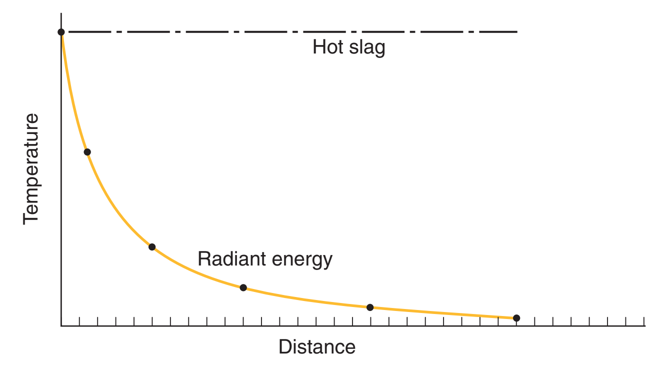
In addition, the activation of a sprinkler system, special hazard system, or fire detection system can send an alarm to the fire department, needlessly deploying responders and equipment and increasing the chance of an injury or a death if an accident occurs during the response. Accidental activation of a special hazard system also wastes extinguishing agent and can cause the fire protection system to be out of service. A careful inspection should be conducted when a system is activated to ensure that the activation was accidental and not the result of a fire that was started by the hot work. If any doubt persists, those on the site and the fire department should make a thorough inspection of the area.

(13) The operator and nearby personnel shall be suitably protected against dangers such as heat, sparks, and slag.

Although radiation energy decreases in proportion to the square of the distance from the source of the fire, as illustrated in Exhibit 41.2, the slag and spatter can continue to be hazardous after the radiation is no longer a threat. PPE is required for personnel working near welding and cutting processes.

(14)* In instances where the scope of work and the tools used to conduct hot work result in possible travel of slag, sparks, spatter, or similar mobile sources of ignition farther than 35 ft

Exhibit 41.2



Decrease in radiation energy relative to the square of the distance from the source.

(11 m), the PAI shall be permitted to extend the distances and areas addressed in 41.3.4.2(2) through 41.3.4.2(4).

A.41.3.4.2(14) Hot work operations that might fall into the category where the 35 Foot Rule could be enlarged include, but are not limited to, elevated hot work and windy areas. [**51B:**A.5.4.2(14)]

(15)* In instances where the scope of work and tools used to conduct hot work are known to be incapable of generating slag, sparks, spatter or similar mobile sources of ignition capable of leaving the immediate area of the applied hot work, the PAI shall be permitted to do the following:
   (a) Reduce the distances and areas addressed in 41.3.4.2(2) through 41.3.4.2(4) to distances and areas that he or she considers fire safe for the intended operation.
   (b) Describe those distances and areas on the hot work permit.

[**51B:**5.4.2]

A.41.3.4.2(15) Hot work operations that might fall into the category where the 35 Foot Rule could be reduced include, but are not limited to, torch soldering, gas tungsten arc welding, heat gun operations, and handheld pen-type soldering. [**51B:**A.5.4.2(15)]

41.3.4.3 The PAI shall determine the length of the period for which the hot work permit is valid. [**51B:**5.4.3]

41.3.4.4 The hot work permit shall not be valid for a period exceeding 24 hours. [**51B:**5.4.3.1]

For a period exceeding 24 hours, the chance for a change in personnel and/or conditions is significant. Due to the change in personnel and conditions, routine re-evaluation is essential to ensure a fire-safe environment during hot work operations.

41.3.4.5 The area shall be inspected by the PAI at least once per shift while the hot work permit is in effect to ensure that it is a fire-safe area. [**51B:**5.4.4]

41.3.5 Fire Watch.

Fire watches might have minimal additional duties in the immediate area; however, these other duties must not interfere with their fire watch responsibilities.

Δ **41.3.5.1*** A fire watch shall be required by the PAI when hot work is performed in a location where other than a minor fire might develop or where the following conditions exist:

(1)* Combustible materials in building construction or contents are closer than 35 ft (11 m) to the point of operation.
(2) Combustible materials are more than 35 ft (11 m) away from the point of operation but are easily ignited by sparks.
(3) Wall or floor openings within an 35 ft (11 m) radius expose combustible materials in adjacent areas, including concealed spaces in walls or floors.
(4) Combustible materials are adjacent to the opposite side of partitions, walls, ceilings, or roofs and are likely to be ignited.

[**51B:**5.5.1]

A.41.3.5.1 The decision tree in Figure A.41.3.5.1 can be used to determine if a fire watch is necessary. [**51B:**A.5.5.1]

Δ **A.41.3.5.1(1)** Figure A.41.3.5.1(1)(a) and Figure A.41.3.5.1(1)(b) demonstrate the hot work 35 Foot Rule. [**51B:**A.5.5.1(1)]

41.3.5.2 A fire watch shall be maintained for at least ½ hour after completion of hot work operations in order to detect and extinguish smoldering fires. The duration of the fire watch shall be extended if the PAI determines the fire hazards warrant the extension. [**51B:**5.5.2]

Generally, if a fire develops from hot work, evidence of smoldering or fire occurs within 30 minutes. However, if the cutting was done in an area that contains a large quantity of finely divided or lightweight combustibles, even though the combustibles were shielded, a longer fire watch might be appropriate and should be required by the PAI. Likewise, if sparks or slag could have entered a crack in a wall or floor, or if other conditions or hazards are unusual, a longer fire watch should be maintained.

See the commentary following 41.3.4.2(2) for additional guidance on reference standards addressing the fire and explosion hazards of various combustible particulate solids.

41.3.5.3* More than one fire watch shall be required if combustible materials that could be ignited by the hot work operation cannot be directly observed by the initial fire watch. [**51B:**5.5.3]

A.41.3.5.3 An additional fire watch(es) might be necessary in certain situations, such as where hot work is performed near open shafts, or at elevated heights or where sparks can travel through spaces such as openings. [**51B:**A.5.5.3]

41.3.6* Hot Tapping. Hot tapping or other cutting and welding on a flammable gas or liquid transmission or distribution utility pipeline shall be performed by a crew that is qualified to make hot taps. [**51B:**5.6]

A.41.3.6 For hot tapping on a gas pipeline, see ANSI/ASME B31.8, *Gas Transmission and Distribution Piping Systems*. [**51B:**A.5.6]

41.3.7 Cylinders. Cylinder use and storage shall be in accordance with Chapter 63. [**51B:**5.7]

41.4 Sole Proprietors and Individual Operators

41.4.1* Assignment of PAI and Fire Watch. In a site where hot work operations are not under the control of another authority, the individual hot work operator shall be permitted to serve as PAI and fire watch, provided that the operator is trained and follows the provisions of Chapter 41. [**51B:**6.1]

A.41.4.1 A common example of a situation where Section 41.4 would apply is work performed in a single-dwelling home by a plumber sweating a pipe. Another example is the repair of a wrought iron railing used for steps in a single-dwelling home. A third example is welding performed on construction or agricultural equipment on site. The NFPA 51B committee recognizes that it is not always practical to have more than one individual present,

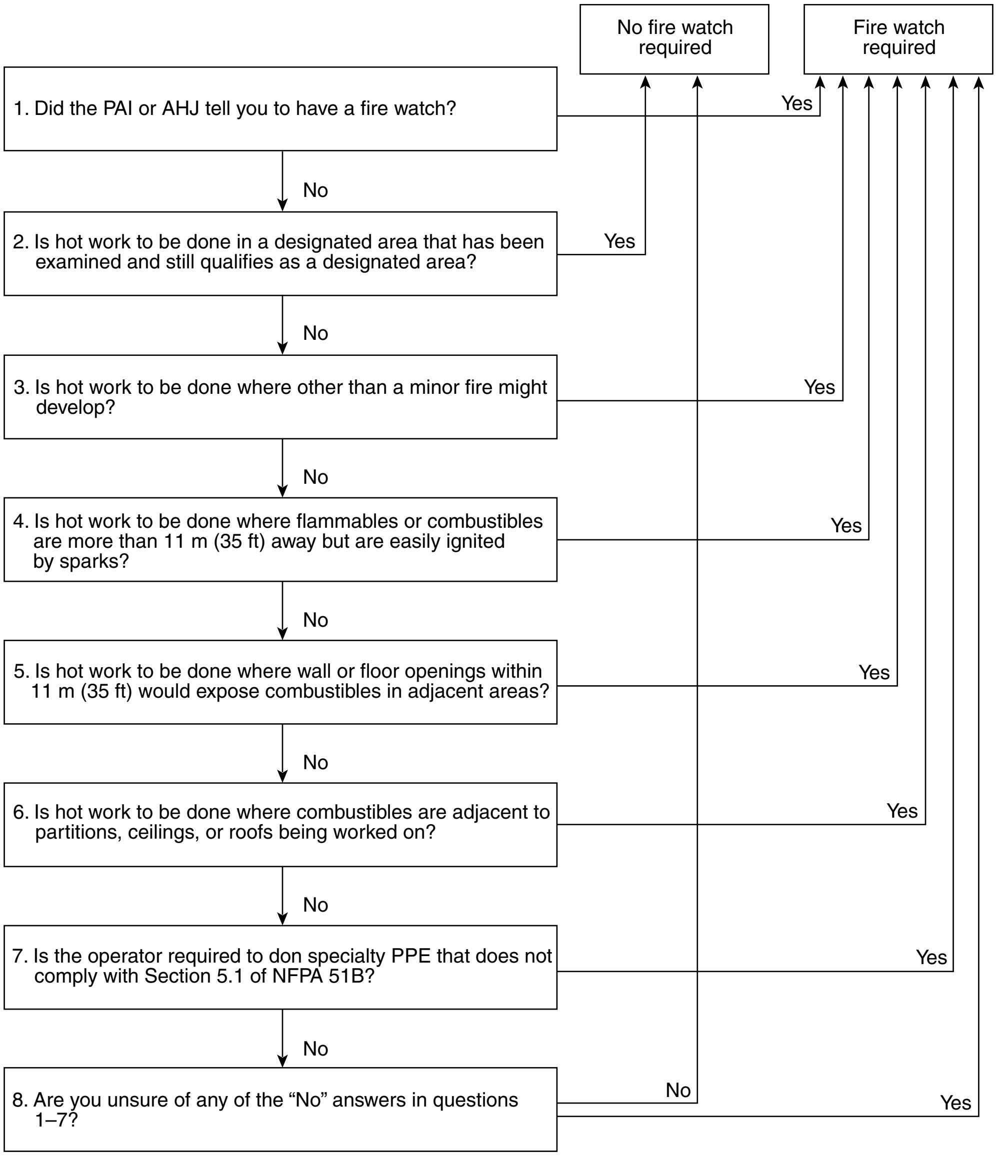


FIGURE A.41.3.5.1 *Fire Watch Decision Tree. [**51B:**Figure A.5.5.1]*

and completing a job with one person is a common practice. The NFPA 51B committee stresses that it is always better to have more than one individual present to ensure fire safety, but realizes that it is not always practical to do so. [**51B:**A.6.1]

41.4.2 Written Hot Work Permit. A checklist shall be permitted to serve as the written hot work permit. [**51B:**6.2]

41.5 Public Exhibitions and Demonstrations

41.5.1 Application. The provisions of Section 41.5 shall apply to oxy–fuel gas welding and cutting operations at public exhibitions, demonstrations, displays, and trade shows, referred to hereinafter as the “site,” in order to promote the safe use of compressed gases in public gatherings. [**51B:**7.1]

41.5.2 Supervision. Installation and operation of welding, cutting, and related equipment shall be done by, or under the supervision of, a competent operator, to ensure the personal protection of viewers and demonstrators as well as the protection from fire of materials in and around the site and the building itself. [**51B:**7.2]

41.5.3 Site.

41.5.3.1 Location. Sites involving the use and storage of compressed gases shall be located so as not to interfere with egress during an emergency. [**51B:**7.3.1]

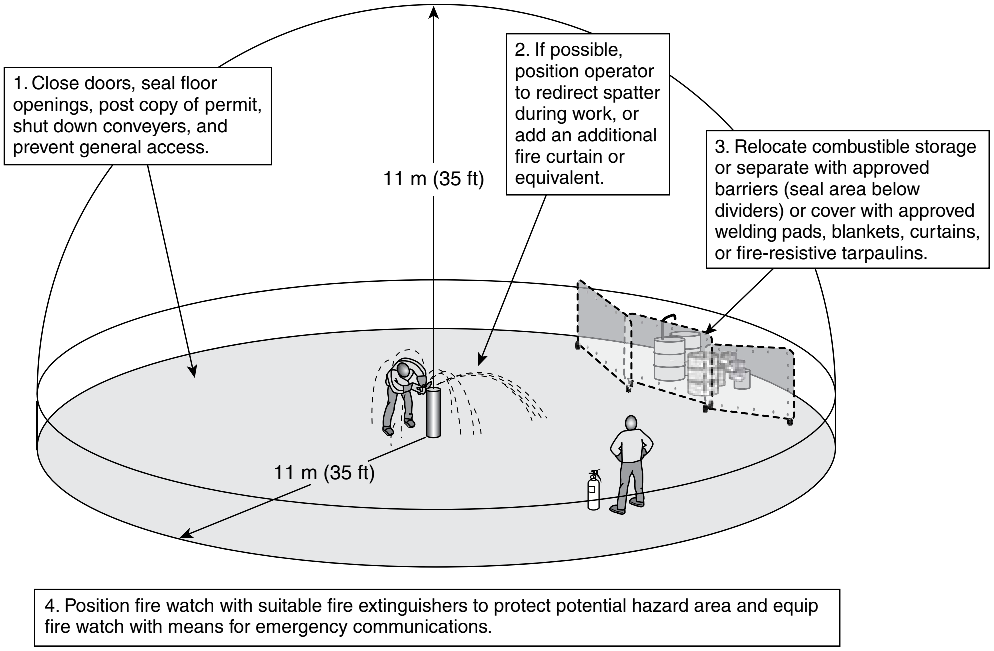

FIGURE A.41.3.5.1(1)(a) *The 35 Foot Rule Illustrated. [**51B:**Figure A.5.5.1(1)(a)]*

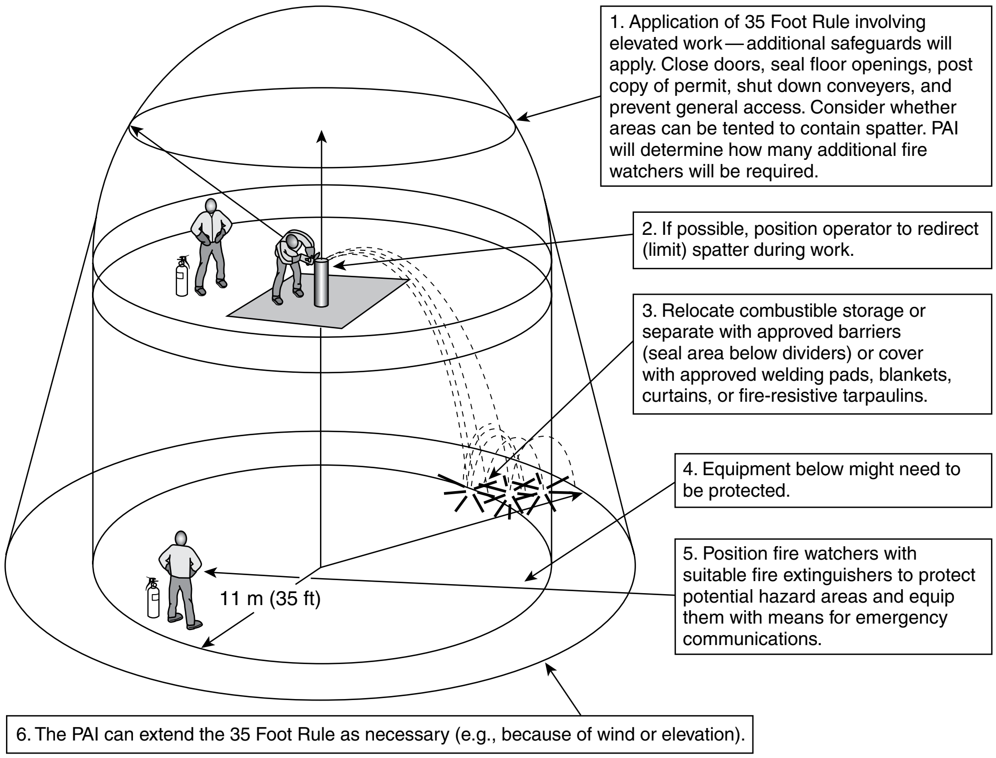

FIGURE A.41.3.5.1(1)(b) *Example of Where Multiple Fire Watches Are Needed. [**51B:**Figure A.5.5.1(1)(b)]*

41.5.3.2 Design. The site shall be constructed, equipped, and operated in such a manner that the demonstration minimizes the possibility of injury to viewers. [**51B:**7.3.2]

41.5.4 Fire Protection.

41.5.4.1 Fire Extinguishers. Each site shall be provided with a portable fire extinguisher of appropriate size and type in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*. [**51B:**7.4.1]

41.5.4.2 Shielding. The public, combustible materials, and compressed gas cylinders at the site shall be protected from flames, sparks, and molten metal. [**51B:**7.4.2]

41.5.4.3 Fire Department Notification. The fire department shall be notified in advance of the use of a site for public exhibitions, demonstrations, and trade shows. [**51B:**7.4.3]

41.5.5 Cylinders.

Compressed gas cylinders used in welding and cutting processes usually contain gases at pressures of approximately 2500 psi (17,237 kPa). However, these pressures can be significantly higher. Gases at these higher pressures are dangerous if not properly handled. The requirements in 41.5.5.1 through 41.5.5.7 are intended to ensure that gas cylinders are properly constructed and stored to prevent the development of a situation that might cause them to leak or ignite.

41.5.5.1 Gas Capacity Limitation.

41.5.5.1.1 Cylinders containing compressed gases for use at the site shall not be charged in excess of one-half their maximum permissible content. [**51B:**7.5.1.1]

41.5.5.1.2 Cylinders of nonliquefied gases and acetylene shall be charged to not more than one-half their maximum permissible charged gauge pressure [psi (kPa)]. [**51B:**7.5.1.2]

41.5.5.1.3 Cylinders of liquefied gases shall be charged to not more than one-half the maximum permissible capacity [lb (kg)]. [**51B:**7.5.1.3]

41.5.5.2 Storage.

41.5.5.2.1 Cylinders located at the site shall be connected for use. [**51B:**7.5.2.1]

41.5.5.2.2 A sufficient number of additional cylinders shall be permitted to be stored at the site to furnish approximately one day's consumption of each gas used. [**51B:**7.5.2.2]

41.5.5.2.3* Other cylinders shall be stored in an approved storage area, but not near a building exit. [**51B:**7.5.2.3]

A.41.5.5.2.3 The preferred location for cylinder storage is in an approved storage area outdoors. [**51B:**A.7.5.2.3]

41.5.5.3 Transporting Cylinders. Cylinders in excess of 40 lb (18 kg) total weight being transported to or from the site shall be carried on a hand truck or motorized truck. [**51B:**7.5.3]

41.5.5.4 Process Hose. Process hose shall be located and protected so that they will not be physically damaged. [**51B:**7.5.4]

41.5.5.5 Cylinder Valves. Cylinder valves shall be closed when equipment is unattended. [**51B:**7.5.5]

41.5.5.6 Valve Caps. If cylinders are designed to be equipped with valve protection caps, such caps shall be in place, except when the cylinders are in service or are connected and ready for service. [**51B:**7.5.6]

41.5.5.7 Cylinder Protection. Cylinders shall be secured so that they cannot be knocked over. [**51B:**7.5.7]

41.6 Arc Welding Equipment

41.6.1 Installation. Electrical equipment shall be of an approved type and shall be installed and used in accordance with Section 11.1 and manufacturers' requirements.

41.6.2 Damaged cables shall be removed from service until repaired or replaced.

Refueling

42

42.1 General

Chapter 42 shall apply to refueling of automotive vehicles, marine vessels, and aircraft.

Chapter 42 addresses refueling of all automotive vehicles, including passenger cars, trucks, and vans; marine vessels; and aircraft using traditional hydrocarbon and alternative fuels. This chapter and NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*, also apply to motor fuel dispensing facilities that are not engaged in the retail sale of motor fuels and are not patronized by the general public. These motor fuel dispensing facilities include refueling facilities at municipal garages, police and fire stations, industrial plants, motor freight terminals, and other private businesses, as well as private marinas.

NFPA 30A defines the term *motor fuel dispensing facility* as "that portion of a property where motor fuels are stored and dispensed from fixed equipment into the fuel tanks of motor vehicles or marine craft or into approved containers, including all equipment used in connection therewith."

42.2 Automotive Fuel Servicing

42.2.1 Applicability.

42.2.1.1 Fueling processes at automotive service stations, service stations located inside buildings, and fleet vehicle service stations shall comply with NFPA 30A and Sections 42.2 through 42.8.

42.2.1.2 If approved by the AHJ, mobile fleet fueling at commercial, industrial, and governmental sites shall be conducted in accordance with 42.7.6.

42.2.1.3* Sections 42.2 through 42.8 shall not apply to those motor fuel dispensing facilities where only liquefied petroleum gas (LP-Gas), liquefied natural gas (LNG), or compressed natural gas (CNG) is dispensed as motor fuel. [**30A:**1.1.3]

A.42.2.1.3 See NFPA 52 and NFPA 58 for requirements for facilities where only these fuels are dispensed. [**30A:**A.1.1.3]

Facilities that dispense only hydrogen, liquefied natural gas (LNG), or compressed natural gas (CNG) are covered directly by NFPA 2, *Hydrogen Technologies Code*, or NFPA 52, *Vehicular Natural Gas Fuel Systems Code*. Facilities that dispense only LP-Gas are covered directly by NFPA 58, *Liquefied Petroleum Gas Code*. However, the NFPA Standards Council has given the Technical Committee on Automotive and Marine Service Stations responsibility for developing appropriate requirements for refueling vehicles with gaseous fuels where those fuels are dispensed along with traditional liquid fuels (i.e., gasoline and diesel fuel). Facilities that dispense both gaseous and liquid fuels are, therefore, covered by NFPA 30A. Most of the requirements for the use of gaseous fuels at mixed fuel facilities are addressed by reference to the primary document for the fuel, such as NFPA 2 for hydrogen or NFPA 52 for LNG and CNG. Facilities that dispense both gaseous and liquid fuels are, therefore, covered by NFPA 30A.

42.2.2 General Requirements.

42.2.2.1 Permits. Permits, where required, shall comply with Section 1.12.

Table 1.12.8(a) requires a permit for the operation of repair garages and service stations. Table 1.12.8(a) also requires facilities to obtain a permit to do the following:

1. Store, handle, or use Class I, Class II, or Class IIIA flammable or combustible liquids inside buildings
2. Provide automotive fuel servicing
3. Provide marine craft fuel servicing
4. Provide aircraft fuel servicing or operate aircraft refueling vehicles
5. Store, use, handle, or dispense LP-Gas inside buildings
6. Remove Class I or Class II liquids from an underground storage tank used for fueling motor vehicles by any means other than the approved, stationary on-site pumps normally used for dispensing purposes
7. Install, alter, remove, abandon, place temporarily out of service, or otherwise dispose of a flammable or combustible liquid tank
8. Display, compete, or demonstrate liquid- or gas-fueled vehicles or equipment in assembly buildings

42.2.2.2 Plans and Specifications. Plans and specifications shall be submitted for review and approval prior to the installation or construction of a motor vehicle fuel dispensing station.

42.2.2.2.1 A site plan shall be submitted that illustrates the location of flammable and combustible liquids, LP-Gas or CNG storage vessels, and their spatial relation to each other, property lines, and building openings.

42.2.2.2.2 Aboveground and underground storage vessels shall be shown on plans.

42.2.2.2.3 For each type of fuel dispensing facility, plans and specifications shall also include, but not be limited to, the following:

(1) Type and design of underground and aboveground liquid storage tanks
(2) Quantity and types of liquids to be stored
(3) Location and design of the fuel dispensers and dispenser nozzles
(4) Distances from dispensers to tanks, property lines, and buildings
(5) Vehicle access
(6) Fire appliances
(7) Vehicle impact protection
(8) Method of storage and dispensing
(9) Overfill prevention
(10) Spill containment
(11) Vents
(12) Vapor recovery
(13) Other equipment and accessories
(14) Seismic design in accordance with the building code
(15) Secondary containment
(16) Design and specifications for related piping, valves, and fittings
(17) Location and classification of electrical equipment, including emergency fuel shutdown devices
(18) Specifications for fuel storage and venting components
(19) Other information as required by the AHJ

42.3 Storage of Liquids

42.3.1 Scope. Section 42.3 shall apply to the storage of liquid fuels and to the storage of related materials, such as lubricating oils and greases, cleaning solvents, and windshield washer solvents. [**30A:**4.1]

42.3.2 General Requirements.

Δ **42.3.2.1** Liquids shall be stored in the following:

(1) Approved closed containers that do not exceed 60 gal (227 L) capacity and are located outside buildings
(2) Tanks or approved closed containers located inside motor fuel dispensing facilities or repair garages

The quantity of liquid allowed to be stored indoors is covered in 42.3.3.9. Indoor storage still requires approved closed containers or storage tanks. Closed storage prevents evaporation of volatile materials and release of vapors that can accumulate in locations where there might be a source of ignition. Closed storage is also of particular concern where workers could be exposed to toxic materials.

(3) Aboveground tanks, underground tanks, and containers in accordance with the requirements of 42.3.3
(4) Tanks supplying marine service stations in accordance with 42.9.2.

[**30A:**4.2.1]

42.3.2.2 A motor fuel dispensing facility located at a bulk plant shall be separated from areas in which bulk plant operations are conducted by a fence or other approved barrier. Dispensing devices at the motor fuel dispensing facility shall not be supplied by aboveground tanks located in the bulk plant. Storage tanks at motor fuel dispensing facilities shall not be connected by piping to aboveground tanks located in the bulk plant. [**30A:**4.2.2]

The first sentence of 42.3.2.2 requires physical separation of the dispensing facility from the bulk plant (terminal). The separation is intended to prevent patrons from inadvertently driving into the bulk plant area and interfering with its operations. This safety measure takes into account that portions of the piping system at a bulk plant, particularly at loading racks, are exposed and subject to impact. The restriction forbidding connection of bulk storage tanks to service station tanks or dispensers is deemed necessary in order to reduce the likelihood of overfilling the service station tanks or unrestricted siphon flow due to a break in a pipeline leading to a dispenser. The intent is that bulk storage tanks must not be used to supply service station dispensers, either directly or indirectly, via underground tanks. See Exhibit 42.1.

Exhibit 42.1

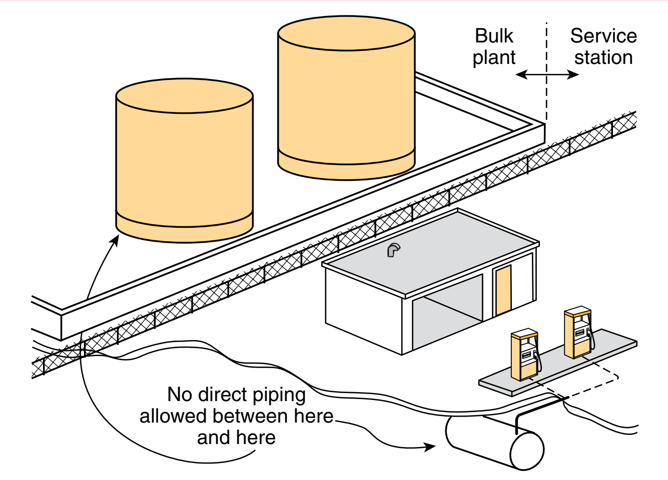

Diagram illustrating the separation requirements of the dispensing facility from the bulk plant.

42.3.2.3 Class I liquids shall not be stored or handled in a building that has a basement or pit into which ignitible vapors can travel, unless the basement or pit is provided with ventilation that will prevent the accumulation of vapors. The ventilation system shall be capable of providing at least 1 ft^3/min of exhaust per ft^2 of floor area (0.3 $m^3/min/m^2$), but not less than 150 ft^3/min (4 m^3/min). [**30A:**4.2.3]

For the purposes of 42.3.2.3, ventilation is considered adequate if the concentration of vapors in the exhaust air stream is maintained at not more than 25 percent of the lower flammable limit (LFL). Such a mixture is "too lean" to be ignited. The minimum ventilation rate required here, 1 cfm/min/ft^2 (0.3 m^3/min/m^2) of floor area, is sufficient to provide six air changes per hour, assuming a 10 ft (3 m) ceiling height.

Ventilation is vital to the prevention of flammable liquid fires and explosions; it collects vapors, dilutes them to a safe concentration, and then removes them to a safe location, usually outdoors. Ventilation can be accomplished by natural or forced air movement.

42.3.2.4 Where tanks are at an elevation that produces a gravity head on the dispensing device, the tank outlet shall be equipped with a device, such as a normally closed solenoid valve, positioned adjacent to and downstream from the valve specified in 22.13.1 of NFPA 30 that is installed and adjusted so that liquid cannot flow by gravity from the tank if the piping or hose fails when the dispenser is not in use. [**30A:**4.2.4]

The solenoid valve required by 42.3.2.4 is needed because even a small leak will eventually result in the loss of all, or a substantial portion of, the liquid in the tank by siphon flow. The valve required by 66.22.13.1, is typically manually operated, but it could be automatically operated. In the latter case, however, the valve is typically not a normally closed type, so it would not be considered a means of complying with 66.22.13.1. Exhibit 42.2 illustrates a situation that would be addressed by 42.3.2.4.

42.3.3 Storage of Liquids.

42.3.3.1 Underground Tanks. Underground storage tanks shall meet all applicable requirements of Chapters 21 and 23 of NFPA 30. [**30A:**4.3.1]

Compared with aboveground tanks, underground tanks offer absolute protection from accidental impact. However, if underground tanks leak, they can present greater remediation problems, particularly if the leak goes undetected for a long period of time. Also, the fuel released from the leak can have greater impact on groundwater and, therefore, presents difficult recovery problems. The fuel can also find its way to subterranean spaces or basements.

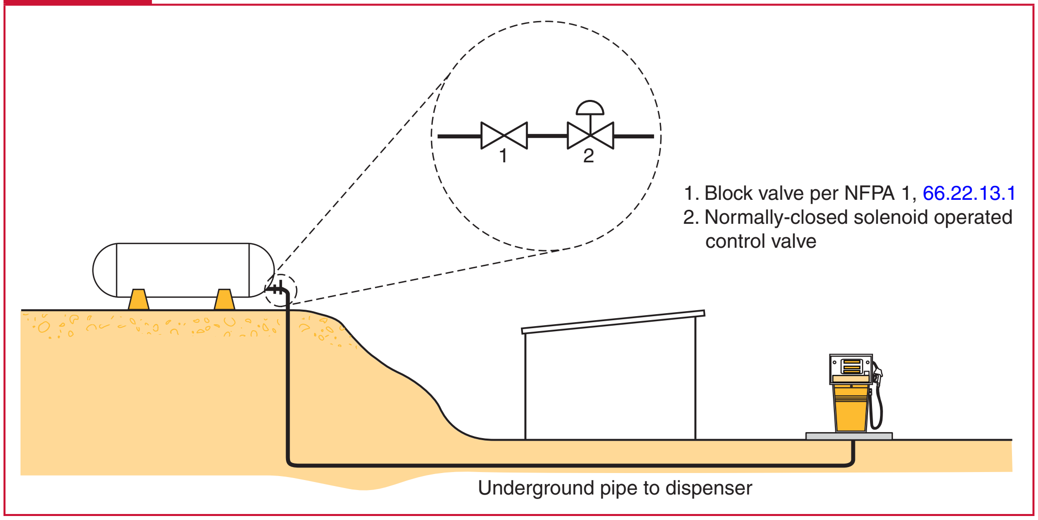
Exhibit 42.3 shows an underground tank being installed; in this case, the tank is being lowered into its excavation. Exhibit 42.4 shows a typical underground fuel storage system at a motor fuel dispensing facility and the components connected to it.

Any liquid storage system where 10 percent or more of the storage capacity is below grade is regulated as an underground tank by the U.S. Environmental Protection Agency (EPA). Thus, a relatively small fuel tank with a long run of underground piping could be considered an underground storage system, at least by the EPA. In this case, "system" includes all liquid-handling components, including the piping. The following publications are recommended as sources of information: STI R892, *Recommended Practice for Corrosion Protection of Underground Piping Networks Associated with Liquid Storage and Dispensing Systems*, from the Steel Tank Institute; and API RP1632, *Cathodic Protection of Underground Petroleum Storage Tanks and Piping Systems, from* the American Petroleum Institute.

42.3.3.2* Aboveground Storage Tanks. Except as modified by the provisions of this subsection, aboveground storage tanks shall meet all applicable requirements of Chapters 21 and 22 of NFPA 30. [**30A:**4.3.2]

It is important to understand that the installations allowed by 42.3.3.2 are not considered to be equivalent to an underground installation, although a vaulted tank probably comes closest in terms of fire protection and environmental protection. For example, aboveground tanks are subject to significant changes in ambient temperature, almost on a daily basis, that result in the evolution of vapors. Although underground tanks also respond to temperature changes of the surrounding ground, these changes are not nearly as great and occur more gradually

Exhibit 42.2



Fuel storage tank that can impose a gravity head on the dispensers.

Exhibit 42.3

Installation of an underground tank. (Courtesy of Fairfield Ledger)

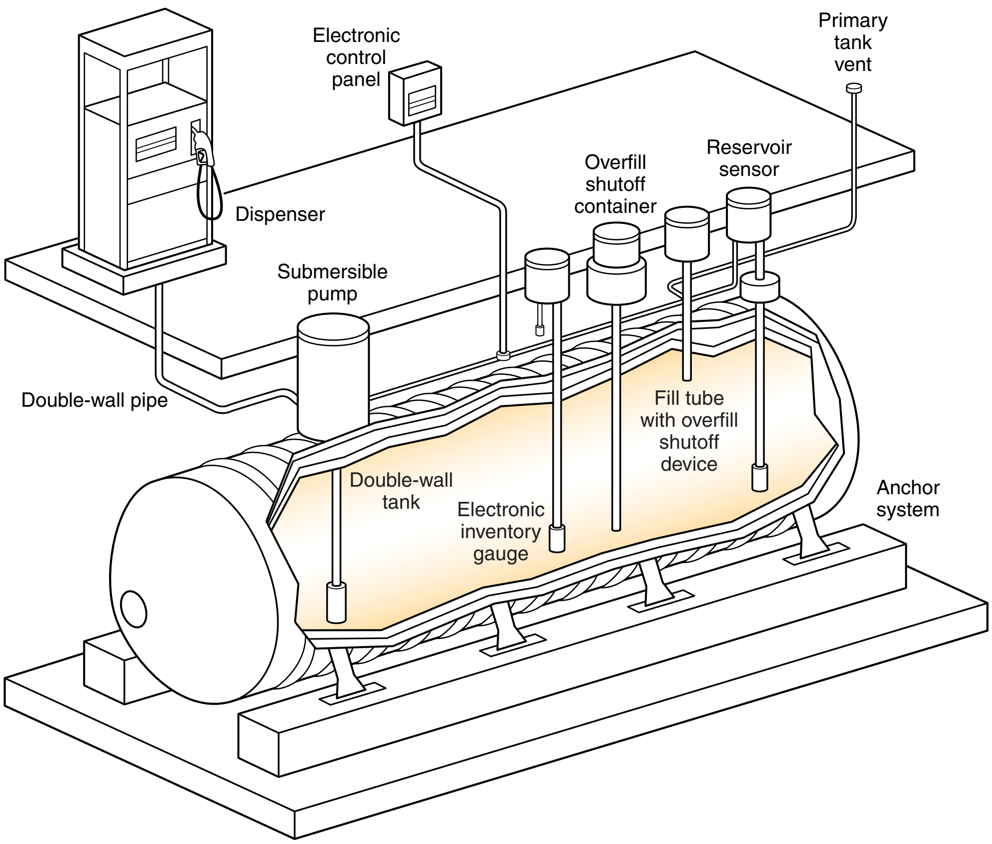
over time. However, the requirements that follow do provide a reasonable degree of fire safety that is commensurate with the hazards of aboveground storage tank installations.

Δ **A.42.3.3.2** PEI RP200, *Recommended Practices for Installation of Aboveground Storage Systems for Motor Vehicle Fueling*, provides information on proper installation, inspection, and maintenance of aboveground storage systems for motor vehicle fueling, including associated devices and components. The U.S. Environmental Protection Agency's regulation for Spill Prevention Control and Countermeasure (SPCC) Plans found in 40 CFR 112, provides additional requirements. [**30A:**A.4.3.2]

Paragraph 42.3.3.2 requires that aboveground storage tanks meet the provisions of NFPA 30, *Flammable and Combustible Liquids Code*, for tank design and construction. These provisions include the following:

1. Basic design and construction of the tank itself
2. Shell-to-shell spacing for multiple tank installations
3. Spill control
4. Basic requirements for vent piping
5. Sizing and installation of emergency vents
6. Supports and anchoring

Exhibit 42.4



Typical underground tank system for motor fuel dispensing.

7. Overfill prevention
8. Testing and maintenance

PEI RP200, *Recommended Practices for Installation of Aboveground Storage Systems for Motor Vehicle Fueling*, from the Petroleum Equipment Institute and referenced in A.42.3.3.2, provides detailed information on the proper installation of aboveground tank systems and is directed at the installation contractor. It is a valuable source of information for regulatory officials charged with approving such installations.

42.3.3.2.1 The use of aboveground storage tanks at motor fuel dispensing facilities, fleet vehicle motor fuel dispensing facilities, and marine motor fuel dispensing facilities shall be permitted when installed in accordance with the requirements of this subsection and with all applicable requirements of Chapters 21, 22, and 27 of NFPA 30 and, for tanks other than tanks in vaults, when the specific installation has been approved by the AHJ. [**30A:**4.3.2.1]

42.3.3.2.2 Tanks designed and built for underground use shall not be installed for aboveground use. [**30A:**4.3.2.2]

The provision of 42.3.3.2.2 prohibits the installation of an underground tank above ground, because the design of an underground tank assumes even support of the tank shell by the surrounding backfill.

42.3.3.2.3 Tanks storing liquid motor fuels at an individual site shall be limited to a maximum individual capacity of 12,000 gal (45,400 L) and aggregate capacity of 48,000 gal (181,700 L) unless such tanks are installed in vaults complying with 42.3.3.3, in which case the maximum individual capacity shall be permitted to be 15,000 gal (57,000 L). [**30A:**4.3.2.3]

The maximum capacities in 42.3.3.2.3 were deliberately chosen on the basis of typical underground systems in use, with due regard for fire safety. The maximum individual capacity accommodates the largest delivery of a single product grade that might be expected. The maximum aggregate capacity allows the facility owner or operator the flexibility needed to offer a full range of fuel products. These tank storage capacities are typical of automotive service stations, which usually have two or three 12,000 gal (45,400 L) tanks for different grades of gasoline and smaller tanks for kerosene or diesel fuel.

If tanks are installed in vaults, the maximum individual capacity is allowed to be increased by 25 percent, recognizing the superior safety provided by a vaulted installation.

In the 2012 edition, this paragraph was revised by replacing “Class I and Class II liquids” with “liquid motor fuels” to allow the use of alternative liquid fuels that are Class III liquids.

42.3.3.2.4 Tanks shall be located in accordance with Table 42.3.3.2.4. [**30A:**4.3.2.4]

A 50 ft (15 m) minimum separation between a single-wall bare steel aboveground tank and the dispensers is believed to be adequate to protect the tanks from a fire originating at

Δ ***TABLE 42.3.3.2.4*** *Minimum Separation Requirements for Aboveground Tanks*

		Minimum Distance (ft)				
Tank Type	**Individual Tank Capacity (gal)**[a]	**From the Nearest Important Building on the Same Property**	**From Nearest Fuel Dispensing Device**[b]	**From Lot Line That Is or Can Be Built Upon**[c]	**From the Nearest Side of Any Public Way**	**Between Tanks**
Tanks in vaults[d]	0–15,000	0	0	0	0	Separate compartments required for each tank
Protected aboveground tanks	Less than or equal to 6,000	5	0	15	5	3
	6,001–12,000	15	0	25	15	3
Fire-resistant tanks	0–12,000	25	25	50	25	3
Other tanks meeting the requirements of NFPA 30	0–12,000	50	50	100	50	3

For SI units, 1 ft = 0.30 m; 1 gal = 3.8 L.

[a]See 42.3.3.2.3 and 42.3.3.2.5.

[b]See 42.3.3.2.6.

[c]Including the opposite side of a public way.

[d]The separation distances given for vaults are measured from the outer perimeter of the vault.

[**30A:** Table 4.3.2.4]

the dispensers. This same 50 ft (15 m) distance was used for separation to the near side of a public road and to the nearest important building on the property. These separation distances are far greater than would be required by NFPA 30 for tanks of equal capacity. Similarly, the 100 ft (30 m) minimum separation specified between the tank and the property lines is more than three times what NFPA 30 would require, again under the most adverse conditions.

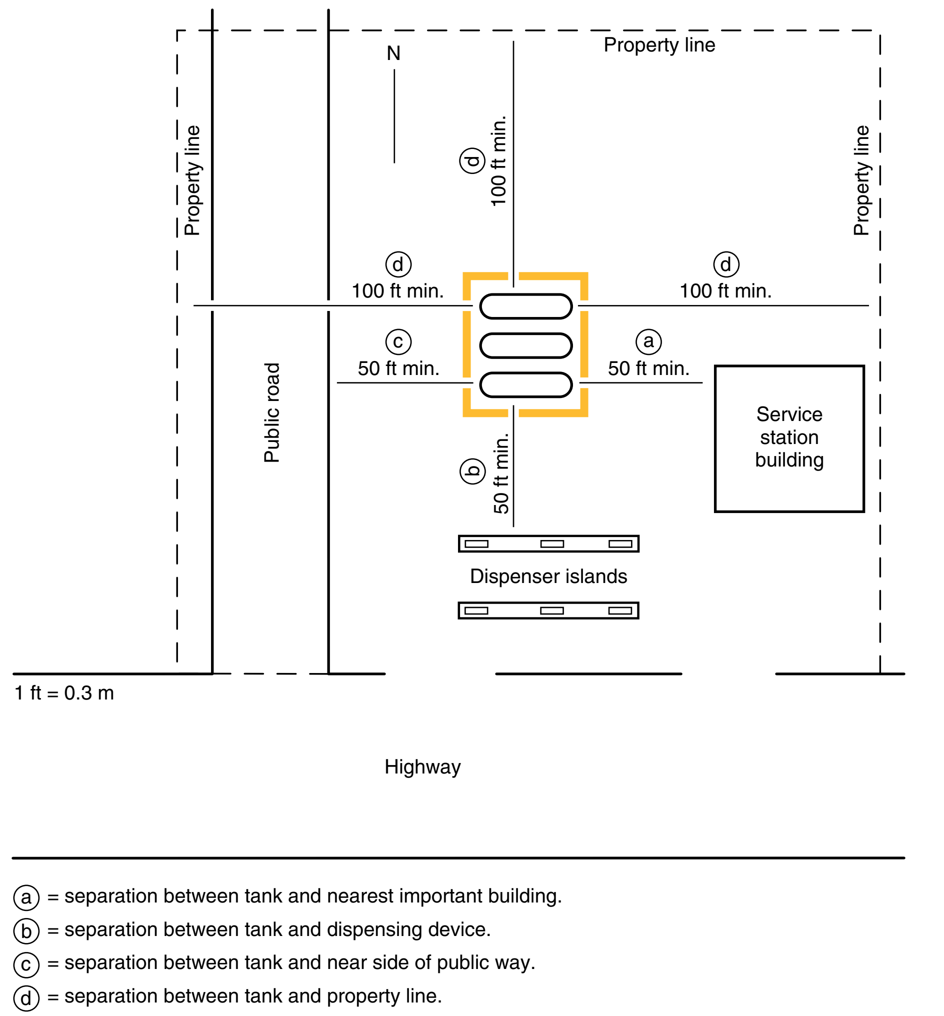
These distances were considered to be the minimum separations that could be safely used with traditional aboveground tanks in an environment where the public has ready access. These distances can be decreased only if the tanks are inherently more fire safe or are installed in a vault.

Exhibit 42.5 illustrates the separation required for bare steel tanks. Note that the 50 ft (15 m) distance required by Table 42.3.3.2.4 applies only where the near side of a public way lies inside the property line, as might arise due to a public easement through the property. In the situation depicted in Exhibit 42.5, if the west property line were on the east side of the road, the tanks would have to be situated twice as far from the road. As the diagram illustrates, use of such aboveground tanks requires a large site — at least 40,000 ft^2 (approximately 3700 m^2). Installations such as these are unlikely to be used in urban or densely populated areas.

42.3.3.2.5 The maximum individual tank capacity of 12,000 gal (45,400 L), where indicated in Table 42.3.3.2.4, shall be permitted to be increased to 20,000 gal (75,700 L) for Class II and Class III liquids at a fleet vehicle motor fuel dispensing facility and an aggregate capacity of 80,000 gal (304,000 L). [**30A:**4.3.2.5]

Note that the increased capacities in 42.3.3.2.5 apply only to fleet vehicle motor fuel dispensing facilities — that is, facilities where the vehicles and refueling systems are under common ownership or control. Aboveground fuel storage at large public truck

Exhibit 42.5



Separation distances for aboveground storage tank installation using bare steel tanks. For fire-resistant tanks, the separation distances shown can be halved.

stop facilities that would typically have storage requirements well above the 48,000 gal (181,700 L) aggregate maximum capacity specified in 42.3.3.2.3 have not been addressed. To date, no proposals have been made to amend NFPA 30A to address that situation.

42.3.3.2.6 At fleet vehicle motor fuel dispensing facilities, no minimum separation shall be required between the dispensing device and a tank in a vault, a protected aboveground tank, or a fire-resistant tank. [**30A:**4.3.2.6]

Paragraph 42.3.3.2.6 allows a fuel dispenser at a fleet fuel dispensing facility to be mounted immediately on or adjacent to the tank, if the tank is installed in a vault or the tank is a listed fire-resistant tank or protected tank. If the tank is a traditional bare steel tank, then the 15 m (50 ft) separation distance called for in Table 42.3.3.2.4 would apply. An island-type dispenser should not be located within a diked area or within a vault.

Δ **42.3.3.2.7** The provisions of this subsection shall not prohibit the dispensing of liquid motor fuels in the open from a fuel dispensing system supplied by an existing aboveground tank, not to exceed 6000 gal (22,710 L), located at commercial, industrial, government, or manufacturing establishments, and intended for fueling vehicles used in connection with their business. Such dispensing shall be permitted provided the following conditions are met:

(1) An inspection of the premises and operations has been made and approval has been granted by the AHJ.
(2) The tank is safeguarded against collision, spillage, and overfill to the satisfaction of the AHJ.
(3) The tank system is listed or approved for such aboveground use.
(4) The tank complies with requirements for emergency relief venting, the tank and dispensing system meet the electrical classification requirements of NFPA 30A, and the tank complies with the provisions of 42.3.2.4.
(5) The tank storage complies with Chapter 22 of NFPA 30.

[**30A:**4.3.2.7]

The authority having jurisdiction (AHJ) can allow two tanks if the operator requires two classes of fuel — Class I (gasoline) and Class II (diesel fuel). In addition, note that this paragraph is also applicable to the refueling of "nonregistered" vehicles that are operated only on site, such as industrial trucks. Exhibit 42.6 illustrates collision protection for an aboveground storage tank.

In the 2012 edition, 42.3.3.2.7 was revised by replacing the words "Class I and Class II liquids" in the first sentence with "liquid motor fuels" to allow the use of alternative liquid fuels that are Class III liquids.

42.3.3.2.8 Aboveground tanks shall be provided with spill control that meets the requirements of 66.21.7.1 and 66.22.11. Tank fill connections shall be provided with a noncombustible spill containment device.

*Exception: Tanks installed in vaults that meet the requirements of 42.3.3.3 need not meet this requirement. [**30A:**4.3.2.8]*

Exhibit 42.6

Collision protection for an aboveground storage tank. (Courtesy of Steel Tank Institute)

NFPA 30 provides three options for spill control: remote impounding, open diking, or closed-top diking. Of these, only the latter two are practical for a motor fuel dispensing facility. The required containment capacity is based on the volume of the largest tank and the type of material being stored in the area for which the spill control is being provided. Also note that the EPA Spill Prevention, Control, and Countermeasure (SPCC) Rule (40 CFR 112) applies to any aboveground storage tank system that exceeds 1320 gal (5000 L) aggregate capacity or any single tank that is greater than 660 gal (2500 L) capacity and that is located near surface waters, or to any underground storage exceeding 42,000 gal (159,000 L) aggregate capacity and also located near surface waters.

A storage tank vault does not have to meet this provision of NFPA 30A, because it completely encloses the tank. A secondary containment-type tank that meets the provisions of 66.22.11.4 would also not need to have separate diking provisions.

42.3.3.3 Vaults for Aboveground Tanks.

Of the types of aboveground storage systems allowed, a vaulted installation probably presents the greatest degree of equivalence to an underground buried tank in terms of both fire protection and environmental safety. The vault itself has the advantage of being located above grade, partially above and partially below grade, or completely below grade, with its top either at or below the surface. The vault provides suitable thermal protection from an exposure fire and suitable protection from impact. The tank and all piping connections can be inspected and repairs effected, as necessary.

Compliance with the ventilation requirements and the liquid and vapor detection requirements ensures rapid response to a leak or spill from the primary vessel. Most important, if a release does occur, it is totally contained, and immediate action can be taken to mitigate it. This degree of safety and the ability to detect and respond immediately to a release are the vaulted tank's most significant benefits.

42.3.3.3.1 Scope. Paragraph 42.3.3.3 shall apply to installation of aboveground tanks in vaults and design and installation of such vaults. [**30A:**4.3.3.1]

42.3.3.3.2 General. Aboveground tanks shall be permitted to be installed in vaults that meet the requirements of 42.3.3.3. Except as modified by the provisions of 42.3.3.3, vaults shall meet all other applicable provisions of NFPA 30A. Vaults shall be constructed and listed in accordance with UL 2245, *Standard for Below-Grade Vaults for Flammable Liquid Storage Tanks*. Vaults shall be permitted to be either above or below grade. [**30A:**4.3.3.2]

42.3.3.3.3* Construction and Installation of Storage Tank Vaults.

A.42.3.3.3.3 Some of the specifications for vault design and construction include the following:

(1) The walls and floor of the vault are to be constructed of reinforced concrete at least 6 in. (50 mm) thick.
(2) The top and floor of the vault and the tank foundation must be designed to withstand all anticipated loading, including loading from vehicular traffic, where applicable.
(3) The walls and floor of a belowgrade vault must be designed to withstand anticipated soil and hydrostatic loading.
(4) The vault must be liquidtight.
(5) The vault enclosure must have no openings except those necessary for access to, inspection of, and filling, emptying, and venting of the tank.
(6) The vault shall be provided with connections to permit ventilation to dilute, disperse, and remove any vapors prior to personnel entering the vault.
(7) The vault must be provided with a means for personnel entry.
(8) The vault must be provided with an approved means to admit a fire suppression agent.

[**30A:**A.4.3.3.3]

42.3.3.3.3.1 Construction Requirements. Vaults shall be designed and constructed in accordance with 42.3.3.3.3.1.1 through 42.3.3.3.3.1.4. [**30:**25.5.1]

The construction requirements for vaults are patterned after — in fact, they replaced — an old set of requirements for "special enclosures" that were part of NFPA 30A until the 2000 edition. The special enclosures were dedicated rooms within a building in which fuel storage tanks were installed. They never had wide application except for some installations in large cities. The construction requirements specified in 42.3.3.3.3.1 are intended to ensure that vaults are of substantial construction, that they are capable of withstanding any anticipated loads and stresses, and, for vaults installed at or above grade, that they can withstand the effects of an exposure fire.

Note that 42.3.3.3.3.1.1 requires that the top of an abovegrade vault be built of noncombustible material, thus allowing lightweight construction. It also requires that the top be able to vent an internal explosion, as unlikely as that might be. Paragraph 42.3.3.3.3.1.2, however, allows an option for vaults with tops that are at grade or that are entirely subterranean because they can be designed to contain an explosion. In allowing the "design to contain" option, consideration was given to the fact that many of these vaults are subject to vehicular traffic, particularly those that are used as replacements for underground tanks at small service station sites, where the vaults are located partly or completely underneath the normal path of vehicle traffic into and out of the service station. In such cases, either the top of the vault constitutes part of the service station driveway or the vault lies directly beneath the driveway. In any event, no practical means exists to vent an internal explosion, and, in fact, with all the requirements imposed on vaulted tanks, an internal explosion is unlikely.

42.3.3.3.3.1.1 The top of an abovegrade vault that contains a tank storing Class I liquid or Class II or Class III liquid stored at a temperature above its flash point shall be constructed of noncombustible material and shall be designed to be weaker than the walls of the vault to ensure that the thrust of any explosion occurring inside the vault is directed upward before destructive internal pressure develops within the vault. [**30A:**4.3.3.3.1.1]

42.3.3.3.3.1.2 The top of an at-grade or belowgrade vault that contains a tank storing Class I liquid or Class II or Class III liquid stored at a temperature above its flash point shall be designed to relieve or contain the force of any explosion occurring inside the vault. [**30A:**4.3.3.3.1.2]

To effectively vent an explosion within a belowgrade vault, the design has to incorporate a duct that extends to a safe distance above grade. This duct has to be strong enough so that it does not fail before the deflagration vent can operate. See NFPA 68, *Standard on Explosion Protection by Deflagration Venting*. Alternatively, the vault can be designed to withstand the overpressure of an explosion. This technique is known as *deflagration pressure containment* and is the option almost universally chosen. See Chapter 13 of NFPA 69, *Standard on Explosion Prevention Systems*.

42.3.3.3.3.1.3 Adjacent vaults shall be permitted to share a common wall. [**30:**25.5.1.3]

42.3.3.3.3.1.4 Where required, the vault shall be wind and earthquake resistant, in accordance with recognized engineering standards. [**30:**25.5.1.4]

42.3.3.3.3.2 Installation Requirements. Storage tank vaults shall be installed in accordance with the requirements of 42.3.3.3.3.2.1 and 42.3.3.3.3.2.2. [**30:**25.5.2]

42.3.3.3.3.2.1 Each vault and its tank shall be anchored to resist uplifting by groundwater or flooding, including when the tank is empty. [**30:**25.5.2.1]

42.3.3.3.3.2.2 Vaults that are not resistant to damage from the impact of a motor vehicle shall be protected by collision barriers. [**30:**25.5.2.2]

42.3.3.3.4 Tank Selection and Arrangement.

42.3.3.3.4.1 Tanks installed in storage tank vaults shall be listed for aboveground use. [**30:**25.3.1.4]

Even though the storage tank vault itself might be located underground, the tank within it must be an aboveground tank. An underground tank cannot be used because there is no backfill to properly support it.

42.3.3.3.4.2 Each tank shall be in its own vault and shall be completely enclosed by the vault. [**30:**25.3.1.5]

42.3.3.3.4.3 Sufficient clearance between the tank and the vault shall be provided to allow for visual inspection and maintenance of the tank and its appurtenances. [**30:**25.3.1.6]

42.3.3.3.4.4 Backfill shall not be permitted around the tank. [**30:**25.3.1.7]

42.3.3.3.5 Tank Appurtenances.

42.3.3.3.5.1 Vent pipes that are provided for normal tank venting shall terminate outside the vault and at least 12 ft (3.6 m) above ground level and shall meet the requirements of 66.27.8.1. [**30A:**4.3.3.5.1]

The requirement in 42.3.3.3.5.1 is based on a similar requirement in 66.25.13 and is intended to ensure adequate dispersal of vapors that are released through the vent whenever the tank is filled or there are increases in ambient temperature.

42.3.3.3.5.2 Emergency vents shall be vaportight and shall be permitted to discharge inside the vault. Long-bolt manhole covers shall not be permitted for this purpose. [**30A:**4.3.3.5.2]

Emergency vent devices must be vaportight to prevent the occurrence of nuisance shutdowns triggered by the vapor detection system. Long-bolt manway covers (also known as loose-bolt manhole covers) are prohibited, because they leak vapors too readily.

42.3.3.3.5.3 An approved means of overfill protection shall be provided for tanks. The use of ball float valves shall be prohibited. [**30A:**4.3.3.5.3]

42.3.3.3.5.4 Fill connections for vaults installed inside buildings shall comply with 66.22.13.4. [**30A:**4.3.3.5.4]

42.3.3.3.6 Ventilation Systems for Storage Tank Vaults.

[**30:**25.10]

The provision in 42.3.3.3.6 is a fundamental personnel safety requirement related to confined space entry rules. For further information, see 29 CFR, Part 1910.146, "Permit Required Confined Spaces."

Because some seepage of liquid at pipe joints, fittings, pump packing glands, and so forth, is anticipated, continuous ventilation is required to remove resulting vapors. If a sizable leak occurs, the concentration of vapors would likely exceed 25 percent of the lower flammable limit, and the detection system would shut down the delivery of fuel, minimizing the release of fuel while, at the same time, warning the operator of a problem. Note that fuel would probably be fed to the dispensers by a pump installed at the tank. Thus, the piping system would be pressurized and any leak that occurs would have the potential to release a large quantity of liquid, especially while the pump is running.

42.3.3.3.6.1 Vaults that contain tanks storing Class I liquids shall be ventilated at a rate of not less than 1 cfm/ft^2 of floor area (0.3 m^3/min/m^2), but not less than 150 cfm (4 m^3/min). [**30:**25.10.1]

42.3.3.3.6.2 Such ventilation shall operate continuously or shall be designed to operate upon activation of a vapor and liquid detection system. [**30:**25.10.2]

42.3.3.3.6.3 Failure of the exhaust airflow shall automatically shut down the dispensing system. [**30:**25.10.3]

42.3.3.3.6.4 The exhaust system shall be designed to provide air movement across all parts of the vault floor. [**30:**25.10.4]

42.3.3.3.6.5 Supply and exhaust ducts shall extend to within 3 in. (75 mm), but not more than 12 in. (300 mm) of the floor. [**30:**25.10.5]

Paragraphs 42.3.3.3.6.4 and 42.3.3.3.6.5 are intended to result in a "sweep" of ventilation air across the floor of the vault from one side to the other.

Δ **42.3.3.3.6.6** The exhaust system shall be installed in accordance with the provisions of NFPA 91. [**30:**25.10.6]

42.3.3.3.7 Vapor and Liquid Detection Systems.

42.3.3.3.7.1 Each vault shall be provided with an approved vapor and liquid detection system that is equipped with on-site audible and visual warning devices with battery backup. [**30:**25.15.1]

42.3.3.3.7.2 The vapor detection system shall sound an alarm when the system detects vapors that reach or exceed 25 percent of the lower flammable limit of the liquid stored. [**30:**25.15.2]

42.3.3.3.7.3 Vapor detectors shall be located no higher than 12 in. (300 mm) above the lowest point in the vault. [**30:**25.15.3]

42.3.3.3.7.4 The liquid detection systems shall sound an alarm upon detection of any liquid, including water. [**30:**25.15.4]

The liquid detection system is intended to sound an alarm not just for a spill but also for any infiltration of groundwater into the vault, which could indicate failure of the vault's floor, wall, or top or failure of a seal at the wall-to-top joint.

42.3.3.3.7.5 Liquid detectors shall be located in accordance with the manufacturer's instructions. [**30:**25.15.5]

42.3.3.3.7.6 Activation of either vapor detection system or liquid detection system shall cause a signal to be sounded at an approved, constantly attended location within the facility serving the tanks or at an approved location. [**30:**25.15.6]

Δ **42.3.3.3.8** In lieu of the separation distance requirements given in 66.22.4, separation distances between the vault and any of the following shall be permitted to be reduced to 0 ft (0 m), as measured from the outer perimeter of the vault wall:

(1) Any property line that is or can be built upon
(2) The near and far sides of a public way
(3) The nearest important building on the same property

[**30:**25.4]

42.3.3.3.9 Inspection and Maintenance of Storage Tank Vaults and Equipment. Vaults and their required equipment shall be maintained in accordance with the requirements of 42.3.3.3. [**30:**25.16]

42.3.3.4 Additional Requirements for Fire-Resistant Aboveground Storage Tanks.

42.3.3.4.1 Fire-resistant tanks shall be tested and listed in accordance with UL 2080, *Standard for Fire Resistant Tanks for Flammable and Combustible Liquids*. [**30:** 22.9.1]

Δ **42.3.3.4.2** Fire-resistant tanks shall also meet both of the following requirements:

(1) The construction that provides the required fire-resistive protection shall reduce the heat transferred to the primary tank in order to limit the temperature of the primary tank to an average maximum rise of 800°F (430°C) and a single point maximum rise of 1000°F (540°C) and to prevent release of liquid, failure of the primary tank, failure of the supporting structure, and impairment of venting for a period of not less than 2 hours when tested using the fire exposure specified in UL 2080.
(2) Reduction in sizing of the emergency vents in accordance with 22.7.3.5 of NFPA 30 shall not be permitted.

[**30:**22.9.2]

42.3.3.5 Protected Tanks. Protected aboveground tanks shall be tested and listed in accordance with ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids.* [**30:**22.10.1]

Δ **42.3.3.5.1** Protected tanks shall also meet both of the following requirements:

(1) The construction that provides the required fire-resistive protection shall reduce the heat transferred to the primary tank in order to limit the temperature of the primary tank to an average maximum rise of 260°F (144°C) and a single point maximum rise of 400°F (204°C) and to prevent release of liquid, failure of the primary tank, failure of the supporting structure, and impairment of venting for a period of not less than 2 hours when tested using the fire exposure specified in ANSI/UL 2085.
(2) Reduction in sizing of the emergency vents in accordance with 22.7.3.5 of NFPA 30 shall not be permitted.

[**30:**22.10.2]

42.3.3.6 Additional Requirements for All Aboveground Tanks.

42.3.3.6.1 All openings shall be located above the maximum liquid level. [**30A:**4.3.6.1]

The intent of this requirement is not only to reduce the chance of a spill from a broken pipe connection below the normal liquid level in the tank but also to eliminate the potential for a spill from any other opening to the tank, for example, from the connection for a liquid level gauge.

42.3.3.6.2 Means shall be provided for determining the liquid level in each tank, and this means shall be accessible to the delivery operator. [**30A:**4.3.6.2]

42.3.3.6.3 Means shall be provided to sound an audible alarm when the liquid level in the tank reaches 90 percent of capacity. Means shall also be provided either to automatically stop the flow of liquid into the tank when the liquid level in the tank reaches 98 percent capacity or to restrict the flow of liquid into the tank to a maximum flow rate of 2.5 gpm (9.5 L/min) when the liquid in the tank reaches 95 percent capacity. These provisions shall not restrict or interfere with the operation of either the normal vent or the emergency vent. [**30A:**4.3.6.3]

The requirements in 42.3.3.6.3 are intended to prevent an overfill during delivery of fuel to the tank and are consistent with federally mandated rules. As originally conceived, this provision required an alarm at 95 percent of capacity and either automatic stop of liquid flow or flow restriction to 2.5 gpm (9.5 L/min) at 98 percent of capacity, which was in accordance with the federal rules for underground storage tanks at the time. Since then, the federal rules have been changed to mandate completely stopping delivery at 98 percent of full capacity, partly because, for smaller tanks, even a reduced flow of 2.5 gpm (9.5 L/min) into a tank that was already 98 percent full did not leave much time for action to be taken to prevent an overfill. Therefore, both this paragraph and 66.21.7.1.5 were changed to be consistent with the federal rules.

42.3.3.6.4 Means shall be provided to prevent the release of liquid by siphon flow. [**30A:**4.3.6.4]

42.3.3.6.5 Shutoff and check valves shall be equipped with a pressure-relieving device that will relieve the pressure generated by thermal expansion back to the tank. [**30A:**4.3.6.5]

This provision addresses the hazards of "thermal blocking" of liquid in the piping. Liquid in any exposed portion of a pipe expands as ambient temperature increases and as a result of solar heating. Normally, thermal expansion is accommodated in the storage system. If a portion of exposed piping is "blocked in" at both ends by closed valves, however, thermal expansion results in an increase in pressure.

Thermal blocking can result in dramatic increases in pressure, with consequent leaks at fittings, joints, and seals. In extreme cases, thermal blocking has been known to cause the failure of gaskets and seals and, in some cases, the rupture of piping.

42.3.3.6.6 Fuel shall not be dispensed from the tank by either gravity flow or pressurization of the tank. [**30A:**4.3.6.6]

This requirement is intended to prevent uncontrolled flow from the tank should a break in the pipeline between the tank and the dispenser occur.

N **42.3.3.6.7** Storage tank appurtenances shall be installed and calibrated in accordance with the manufacturer's instructions, published industry practices, or equivalent methods approved by the AHJ. [**30A:**4.3.6.7]

Paragraph 42.3.3.6.7 is new to the 2018 edition of the *Code*. Its purpose is to ensure that fittings and appurtenances on storage tanks are installed in accordance with the manufacturer's instructions or recognized industry practices.

42.3.3.7 Physical Protection for All Outside Aboveground Tanks.

The intent of this paragraph is twofold: to protect the tank from being struck by a vehicle and to protect the tank from vandalism.

42.3.3.7.1 Tanks that are not enclosed in vaults shall be enclosed with a chain link fence at least 6 ft (1.8 m) high. The fence shall be separated from the tanks by at least 10 ft (3 m) and shall have a gate that is secured against unauthorized entry.

*Exception: Tanks are not required to be enclosed with a fence if the property on which the tanks are located has a perimeter security fence. [**30A:**4.3.7.1]*

Δ **42.3.3.7.2*** Guard posts or other approved means shall be provided to protect tanks that are subject to vehicular damage. When guard posts are installed, the following design shall be acceptable:

(1) They shall be constructed of steel not less than 4 in. (100 mm) in diameter and shall be filled with concrete.
(2) They shall be spaced not more than 4 ft (1.2 m) on center.
(3) They shall be set not less than 3 ft (0.9 m) deep in a concrete footing of not less than 15 in. (380 mm) diameter.

[**30A:**4.3.7.2]

A.42.3.3.7.2 The top of the posts should be set not less than 3 ft (0.9 m) above ground and should be located not less than 5 ft (1.5 m) from the tank. Other approved means to protect tanks subject to vehicular damage include vehicle impact resistance testing such as that prescribed in ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids*, for protected aboveground tanks. [**30A:**A.4.3.7.2]

42.3.3.8* Corrosion Protection. Any portion of a tank or its piping that is in contact with the soil shall have properly engineered, installed, and maintained corrosion protection that meets the requirements of 66.21.4.5. [**30A:**4.3.8]

Δ **A.42.3.3.8** Appropriate corrosion control standards include the following:

(1) STI RP 892, *Recommended Practice for Corrosion Protection of Underground Piping Networks Associated with Liquid Storage and Dispensing Systems*
(2) NACE SP0169, *Recommended Practice for Control of External Corrosion of Underground or Submerged Metallic Piping Systems*
(3) STI RP 1632, *Cathodic Protection of Underground Petroleum Storage Tanks and Piping Systems*

[**30A:**A.4.3.8]

Other means of internal corrosion protection include protective coatings and linings and cathodic protection. [**30A:**A.4.3.8]

42.3.3.9 Storage of Liquids Inside Buildings. Storage of flammable and combustible liquids in motor fuel dispensing facility buildings and in repair garage buildings shall meet the requirements of this subsection. [**30A:**4.3.9]

42.3.3.9.1 Class I, II, and IIIA Liquids in Tanks Not Exceeding 120 Gal (454 L) Capacity and in Containers.

The following example demonstrates the application of 42.3.3.9.1 through 42.3.3.9.3.

Example

The building used in this case is a traditional two-bay service station that provides motor fuel dispensing and minor repairs.

- Paragraph 42.3.3.9.1.1 limits the service station operator to 120 gal (454 L) of Class I liquids. This quantity can be stored in containers, or it can be stored in tanks, as long as the tanks do not exceed 120 gal (454 L) capacity. Regardless, the maximum allowable quantity (MAQ) is still 120 gal (454 L).
- Paragraph 42.3.3.9.1.2 allows the service station operator to store up to 120 gal (454 L) each of Class II and Class IIIA liquids. Again, this quantity can be stored in containers, or it can be stored in tanks, as long as the tanks do not exceed the specified capacity, but the MAQ is limited to 240 gal (908 L).
- In accordance with 42.3.3.9.1.3, if no Class I liquids are in the facility (which is highly unlikely), the quantity of Class II liquids permitted is allowed to be doubled to 240 gal (908 L). It should be noted that, in a typical "quick-lube" service center, if a premixed windshield washer fluid (71 percent water to 29 percent methanol would yield a Class II liquid classification) is purchased for use, application of this paragraph would be used to properly store 240 gal (908 L) of this premixed Class II liquid inside the building.
- Paragraph 42.3.3.9.2 allows a tank of greater than 120 gal (454 L) capacity to be situated inside a service station building if the tank is installed inside a vault that meets the criteria of 42.3.3.3. The vault provides a fire cutoff that separates the tank from the rest of the building.
- Paragraph 42.3.3.9.3 provides for unlimited storage of Class IIIB liquids in buildings, recognizing that these liquids are difficult to ignite and pose a low fire risk.

42.3.3.9.1.1 The aggregate quantity of Class I liquids stored in a tank that does not exceed 120 gal (454 L) capacity and in containers shall not exceed 120 gal (454 L). Liquids in storage shall be maintained in tanks or in approved containers that are closed or are fitted with an approved dispensing device that meets the requirements of 42.7.2.4.1. [**30A:**4.3.9.1.1]

42.3.3.9.1.2 Except as permitted under 42.3.3.9.1.3, the aggregate quantity of Class II and Class IIIA liquids stored in a tank that does not exceed 120 gal (454 L) capacity and in containers shall not exceed 240 gal (908 L). The quantity for each class shall not exceed 120 gal (454 L). Liquids in storage shall be maintained in tanks or in approved containers that are closed or are fitted with an approved dispensing device that meets the requirements of 42.7.2.4.1. [**30A:**4.3.9.1.2]

42.3.3.9.1.3 Where there are no Class I liquids stored, the aggregate quantities of Class II liquids shall not exceed 240 gal (908 L). [**30A:**4.3.9.1.3]

42.3.3.9.2 Class I, II, and IIIA Liquids in Tanks Exceeding 120 Gal (454 L) Capacity. Where installation of a tank that exceeds 120 gal (454 L) capacity in accordance with 42.3.3.2 is not practical because of building or property limitations, the tank shall be permitted to be installed in a building if it is enclosed as described in 42.3.3.3 and if the installation is specifically approved by the AHJ. [**30A:**4.3.9.2]

42.3.3.9.3 Class IIIB Liquids. The quantity of Class IIIB liquids in storage shall not be limited. Class IIIB liquids shall be permitted to be stored in and dispensed from tanks and containers that meet the requirements of Chapter 9 and Chapters 21 through 23 of NFPA 30 as applicable. Tanks storing Class IIIB liquids inside buildings shall be permitted to be located at, below, or above grade. Adequate drainage shall be provided. Tanks and containers that contain only crankcase drainings shall be considered as containing Class IIIB liquids. [**30A:**4.3.9.3]

As lubrication-only facilities became popular, so too did the use of tanks for dispensing fresh motor oils and lubricants and for interim storage of used motor oils. The NFPA 30A technical committee believed that some restriction should be placed on the types of containers and tanks used and did so by referencing appropriate parts of NFPA 30. Note, however, that no quantity limit is placed on Class IIIB liquids. Also, note that Chapters 21 through 23 of NFPA 30 allow the use of a tank constructed of a combustible material (e.g., glass fiber–reinforced plastic) for Class IIIB liquids if certain specific conditions are met and if allowed by the AHJ.

The last sentence of 42.3.3.9.3 clearly establishes that used motor oils are considered to be Class IIIB liquids, unless shown otherwise. This classification is based on an extensive test survey sponsored by a major franchiser of lubrication-only service centers in which samples of used motor oil from 279 franchise facilities throughout the continental United States were tested for flash point by an independent testing laboratory. Test results showed that the average flash point of the samples was 343°F (173°C). The range of flash points extended from 296°F to 424°F (147°C to 218°C), but the average was well above 300°F (149°C). The test results compared favorably with the results of earlier tests conducted by the Bartlesville (Oklahoma) Energy Research Center of the U.S. Department of Energy in 1976 and with the range of flash points of virgin motor oils, which is 350°F to 415°F (177°C to 213°C).

Paragraph 42.3.3.9.3 was added to NFPA 30A to address environmental concerns for containing spills of waste motor oil. The NFPA 30A technical committee concluded that, from an environmental viewpoint, storing Class IIIB liquids inside a building is safer than storing them outside or underground. NFPA 30A addresses the fire protection concerns, which have been minimal for Class IIIB liquids. Previous concerns that the flash point of used motor oil might be dangerously low are apparently groundless, except where raw gasoline has been added to a waste oil container. Where that situation is suspected, the AHJ can require that tests be done to determine proper classification.

Δ **42.3.3.10 Temporary Storage of Liquid Fuels.** Aboveground tanks used for dispensing of motor fuels shall not be required to be permanently installed when located on premises not normally accessible to the public provided that all of the following requirements are met:

(1) Approval of the AHJ shall be required prior to bringing the tank to a site in the jurisdiction. In reviewing a proposed installation, the condition of the tank, the site where the tank will be located, installation and testing procedures, and operational procedures shall be evaluated prior to approval.
(2) The approval shall include a definite time limit after which the tank shall be removed from the site and relocated to an approved location.
(3) The tank shall comply with 42.3.3 and all other applicable provisions of NFPA 30A and NFPA 30.
(4) A tank containing liquid shall not be moved unless it has been specifically investigated and approved for movement while full or partially full.

[**30A:**4.3.10]

The provisions of 42.3.3.10 allow for temporary storage of liquid fuels. The codes for gaseous fuels generally do not make any distinction between temporary storage and permanent storage.

42.4 Piping for Liquids

42.4.1 Scope. Section 42.4 shall apply to piping systems consisting of pipe, tubing, flanges, bolting, gaskets, valves, fittings, flexible connectors, the pressure-containing parts of other components such as expansion joints and strainers, and devices that serve such purposes as mixing, separating, snubbing, distributing, metering, controlling flow, or secondary containment of liquids and associated vapors. [**30A:**5.1]

42.4.2 General Requirements for All Piping Systems.

42.4.2.1 The design, fabrication, assembly, test, and inspection of the piping system shall meet the requirements of Section 66.27.

Exception No. 1: Where dispensing is from a floating structure or pier, approved oil-resistant flexible hose shall be permitted to be used between shore piping and the piping on the floating structure or pier and between separate sections of the floating structure to accommodate changes in water level or shoreline, provided that the hose is either resistant to or shielded from damage by fire.

*Exception No. 2: Low melting point rigid piping shall be permitted to be used between underground shore piping and a floating structure or pier and on the floating structure or pier itself, provided that the piping is protected from physical damage and stresses arising from impact, settlement, vibration, expansion, contraction, or tidal action and provided that the hose is either resistant to or shielded from damage by fire exposure. [**30A:**5.2.1]*

Requirements for the design, fabrication, assembly, testing, and inspection of piping systems at service stations are basically the same as those in Chapter 27 of NFPA 30. The major differences are the exceptions to the requirements included for marine motor fuel dispensing facilities as specified in the two exceptions to 42.4.2.1, which allow more liberal use of low melting point piping materials and hose than otherwise would be allowed by NFPA 30.

42.4.2.2 Piping shall be located so that it is protected from physical damage. Piping that passes through a dike wall shall be designed to prevent excessive stresses that could result from settlement or fire exposure. [**30A:**5.2.2]

42.4.2.3 Any portion of a piping system that is in contact with the soil shall be protected from corrosion in accordance with good engineering practice. [**30A:**5.2.3]

42.4.2.4 All piping inside buildings but outside the motor fuel dispensing area shall be enclosed within a horizontal chase or a vertical shaft used only for this piping. Vertical shafts and horizontal chases shall be constructed of materials having a fire resistance rating of not less than 2 hours. [**30A:**5.2.4]

The intent of this requirement is to preserve the isolation of the fuel dispensing operation from the rest of the building.

42.4.2.5 Each fill pipe shall be identified by color code or other marking to identify the product for which it is used. The color code or marking shall be maintained in legible condition throughout the life of the installation. [**30A:**5.2.5]

Color coding of the fill pipe or fill opening is customarily done as a convenience for delivery personnel so that the different grades of gasoline are delivered to their proper tanks. Mixing of different grades of gasoline does not constitute a hazard. However, where diesel fuel or kerosene are also stored, the inadvertent mixing of Class I and Class II liquids, which can produce serious consequences, is a definite risk. One commonly used means for identification is API RP 1637, *Using the API Color-Symbol System to Mark Equipment and Vehicles for Product Identification at Service Stations and Distribution Terminals.* Exhibit 42.7 illustrates the API 1637 color-symbol system.

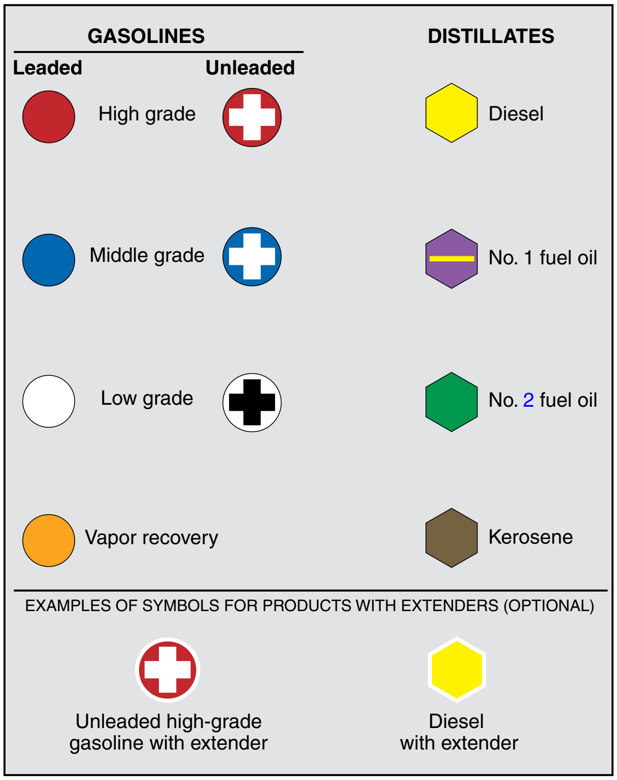
42.4.2.6 Shutoff and check valves shall be equipped with a pressure-relieving device that will relieve any pressure generated by thermal expansion of the contained liquid back to the storage tank. [**30A:**5.2.6]

Δ **42.4.2.7** Piping components made of low melting point materials shall be permitted to be used without backfill with the following sumps:

(1) Belowgrade underground tank sumps that are fitted with a cover
(2) Belowgrade piping connection sumps that are fitted with a cover
(3) Containment sumps, under the following conditions:
  (a) The sump is monitored to detect any leaks.
  (b) Any leaks can be controlled.
  (c) The components are either resistant to or shielded from damage by fire exposure.
(4) Containment sumps, provided the piping components can successfully pass the test procedures described in API 607, *Fire Test for Soft-Seated Quarter-Turn Valves*

[**30A:**5.2.7]

Exhibit 42.7



API color-symbol system for product identification at service stations. (Courtesy of American Petroleum Institute)

The use of nonmetallic piping systems for service station application has become more commonplace because nonmetallic systems provide inherent corrosion protection and are easy to install. One nonmetallic piping system uses double-walled flexible piping (see Exhibit 42.8) to minimize the number of connections needed. Concerns have been raised about the low melting point of nonmetallic piping materials, particularly where they

Exhibit 42.8

One type of double-wall flexible piping for motor fuel dispensing systems. (Courtesy of OPW) are not covered by backfill, such as the open space beneath the dispenser and the remote pump sump at the tank.

The area beneath the dispenser is subject to spills that can be ignited due to the knock-down or pull-down of the dispenser. Although the piping is equipped with an emergency shear valve that stops the flow of fuel to the dispenser (see 42.5.3.9), fire in this area would likely breach the nonmetallic piping upstream of the shear valve. If ignition were to occur while the remote pump was still operating, the outcome could be disastrous.

The same type of exposure does not exist at the remote pump sump or in belowgrade piping connection sumps. Therefore, while recognizing the obvious benefits of nonmetallic piping materials, the hazard of exposed nonmetallic piping and piping components beneath the dispenser has been determined to be severe enough to warrant the requirements imposed by 42.4.2.7(3) and (4).

42.5 Fuel Dispensing Systems

42.5.1 Scope. Section 42.5 shall apply to the system and components that dispense fuel into the tanks of motor vehicles and marine craft. [**30A:**6.1]

42.5.2 General Requirements.

Δ **42.5.2.1** Dispensing devices installed outside at motor fuel dispensing stations shall be located as follows:

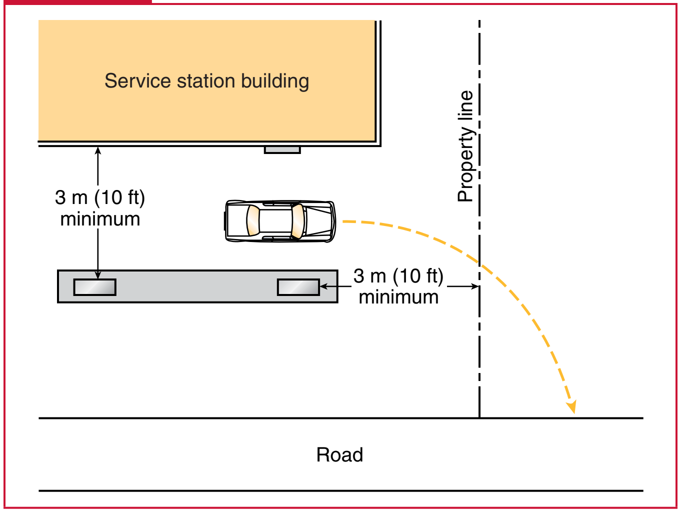
(1) 10 ft (3 m) or more from property lines
(2) 10 ft (3 m) or more from buildings, other than canopies, having combustible exterior wall surfaces or buildings having noncombustible exterior wall surfaces that are not a part of a 1 hr fire-resistive assembly
(3) Such that all parts of the vehicle being served will be on the premises of the service station
(4) Such that the nozzle, when the hose is fully extended, will not reach within 5 ft (1.5 m) of building openings

[**30A:**6.2.1]

Item (1) of 42.5.2.1 ensures that a minor spill or fire at a dispensing device (hereafter referred to as a "dispenser") will not result in a fire threat to adjacent property. Item (2) of 42.5.2.1 ensures that a fire originating at a dispenser will not threaten buildings or other structures on the same property. Both 42.5.2.1(1) and (2) ensure easy access to a dispenser fire by emergency responders and provide for sufficient clear space around dispensers for patrons to maneuver their vehicles. See Exhibit 42.9.

Item (3) of 42.5.2.1 prohibits the installation of dispensers on the sidewalk in front of a service station. The purpose of this requirement is to maintain some separation between the vehicle being fueled and vehicles traveling on the road in front of the station. Exhibit 42.10 shows two dispensers situated right next to a building on the sidewalk along a busy center-of-town road. Note the horizontal piping extending to both sides of the dispensers and the fueling hoses connected to them. The spacing allows two vehicles to be fueled at the same time — on the street.

Exhibit 42.9



Proper spacing of dispensers on a service station property.

Exhibit 42.10

Fuel dispensers situated on a sidewalk, adjacent to a (former) service station building. (Courtesy of Dedham Bike and Leather Co., Dedham, MA)

(The editor was informed by the building tenant — a high-end bicycle dealer and repair shop — that the building housed the first service station in the town, dating from the 1900s, and that the dispensers were still being used as late as 1970. The storage tanks were buried beneath the building.)

The justification for item (4) of 42.5.2.1 is to prevent a stream of fuel from being directed, either accidentally or deliberately, into the adjacent service station building.

42.5.2.2 Liquids shall not be dispensed by applying pressure to drums, barrels, and similar containers. Listed pumps taking suction through the top of the container or listed self-closing faucets shall be used. [**30A:**6.2.2]

Typical containers for liquids are not intended to be pressurized and are not tested for such handling or use. Dispensing from the typical shipping container using pressure risks failure of the container. Therefore, dispensing must be done via gravity, through a self-closing faucet, or by means of a suction pump.

42.5.2.3* Fuel dispensing systems, including dispensers, hoses, nozzles, breakaway fittings, swivels, flexible connectors, dispenser emergency shutoff valves, vapor recovery systems, and pumps that are used for alcohol-blended motor fuels shall be listed or approved for the specific purpose. [**30A:**6.2.3]

This paragraph was added in the 2012 edition of NFPA 30 to address existing dispensing equipment being used to dispense E85 fuel (85 percent ethanol/15 percent gasoline) used by so-called "flex-fuel" vehicles. Flex-fuel vehicles can operate on any mixture of gasoline and ethanol up to 85 percent ethanol by volume. (To reduce ethanol evaporative emissions and to avoid cold weather start problems in winter, the maximum percentage of ethanol allowed in motor fuels in the United States is 85 percent.) The engine of a flex-fuel vehicle has a dedicated sensor that automatically detects the percentage of ethanol in the fuel and adjusts fuel injection and spark timing accordingly, thus allowing mixing of conventional gasoline (maximum 10 percent ethanol) and E85 in any proportion.

Paragraph 42.5.2.3 was crafted to account for the potential for a wide range of ethanol concentrations and for the approval process to allow for technological advances as they emerge.

Δ **A.42.5.2.3** The following can be used to determine compliance with 42.5.2.3:

ANSI/UL 79 *Standard for Power-Operated Pumps for Petroleum Dispensing Products*

UL 87, *Standard for Power-Operated Pumps for Petroleum Dispensing Products*

UL Subject 87A, *Outline of Investigation for Power-Operated Dispensing Devices for Gasoline and Gasoline/Ethanol Blends with Nominal Ethanol Concentrations Up to 85 Percent (E0-E85)*

ANSI/UL 330, *Standard for Hose and Hose Assemblies for Dispensing Flammable Liquids*

ANSI/UL 567, *Standard for Emergency Breakaway Fittings, Swivel Connectors and Pipe-Connection Fittings for Petroleum Products and LP-Gas;*

ANSI/UL 842, *Standard for Valves for Flammable Fluids*

ANSI/UL 2586, *Standard for Hose Nozzle Valves.*

[**30A:**A.6.2.3]

42.5.3 Requirements for Dispensing Devices.

Fuel dispensing devices (dispensers) for retail application consist of a cabinet with two distinct interior sections. The lower section contains the liquid handling components and the upper section contains the electronics, such as the display panel and the point of sale (POS) components that allow the use of credit and debit cards. Exhibit 42.11 shows a modern fuel dispenser, one that is typical of the several in widespread use. This particular unit has one hose and dispensing nozzle for diesel fuel (on the left) and another set for three grades of gasoline (on the right).

Fuel enters the bottom of the cabinet from the storage tank(s) and is then pumped up the side column to a header to which are attached the dispensing hoses. In each hose, near the header, is the emergency breakaway device (to be discussed later). The dispensing nozzles are shown in their bracketed position. The upper portion of the cabinet houses the electronic components and the fuel grade selection buttons (see Exhibit 42.12).

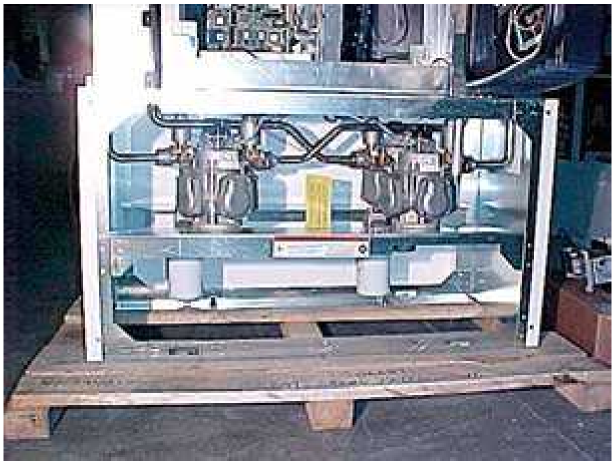
Exhibit 42.11

A modern multi-product retail fuel dispenser. (Courtesy of Bennett Pump Company, Spring Lake, MI)

Exhibit 42.12

Interior view of electronics cabinet of the fuel dispenser shown in Exhibit 42.11. (Courtesy of Bennett Pump Company, Spring Lake, MI)

Exhibit 42.13



Interior view of fuel handling components of the fuel dispenser shown in Exhibit 42.11. (Courtesy of Bennett Pump Company, Spring Lake, MI)

The lower portion contains the fuel filters and blending components for the three grades of gasoline (see Exhibit 42.13).

42.5.3.1 Class I and Class II liquids shall be transferred from tanks by means of fixed pumps designed and equipped to allow control of the flow and prevent leakage or accidental discharge. [**30A:**6.3.1]

This requirement prohibits any dispensing through a system that does not incorporate some type of variable flow valve, such as a dispensing nozzle.

42.5.3.2 Dispensing devices for Class I and II liquids shall be listed. [**30A:**6.3.2]

Dispensers are listed under UL 87, *Standard for Power-Operated Dispensing Devices for Petroleum Products.*

42.5.3.2.1 Existing listed or labeled dispensing devices shall be permitted to be modified provided that the modifications made are "Listed by Report" by an approved testing laboratory or as otherwise approved by the AHJ. Modification proposals shall contain a description of the component parts used in the modification and the recommended methods of installation on specific dispensing devices. Modification proposals shall be made available to the AHJ upon request. [**30A:**6.3.2.1]

Paragraph 42.5.3.2.1 prohibits making any modification to the dispenser that has not been either evaluated by a testing organization or approved by the AHJ. The intent is to prevent any modification that might interfere with or negate the dispenser's built-in safety features or its proper operation.

"Listed by Report," a special form of listing employed by Underwriters Laboratories Inc. (UL), covers products or construction for which no generally recognized installation requirements exist. Information concerning proper field installation is contained in a report identified by a reference number and date shown in the listing, copies of which can be obtained from UL.

42.5.3.3 A control shall be provided that will permit the pump to operate only when a dispensing nozzle is removed from its bracket or normal position with respect to the dispensing device and the switch on this dispensing device is manually actuated. This control shall also stop the pump when all nozzles have been returned to their brackets or to their normal nondispensing position. [**30A:**6.3.3]

42.5.3.4 Dispensing devices shall be mounted on a concrete island or shall otherwise be protected against collision damage by means acceptable to the AHJ. Dispensing devices shall be securely bolted in place. If located indoors, dispensing devices shall also be located in a position where they cannot be struck by a vehicle that is out of control descending a ramp or other slope. Dispensing devices shall be installed in accordance with the manufacturers' instructions. [**30A:**6.3.4]

42.5.3.5 Dispensing devices used to fill portable containers with home heating fuels shall be located at least 20 ft (6 m) from any dispensing devices for motor fuels. [**30A:**6.3.5]

This provision of NFPA 30A is intended to prevent inadvertent dispensing of gasoline into a container used to fill portable kerosene heaters. This mistake has caused numerous fires.

42.5.3.6 Inspections. Dispensing equipment shall be periodically inspected by a person who is knowledgeable in the operation of the equipment to verify that it is in proper working order and is not leaking. [**30A:**6.3.6]

The requirements of 42.5.3.6 through 42.5.3.6.2 were added to the 2012 edition to fill a void in NFPA 30A. In earlier editions, NFPA 30A had not addressed inspection of dispensing systems. With the recent use of E85 fuel in so-called legacy dispensing systems (systems originally evaluated for gasoline service and not for high percentages of alcohol oxygenates) and the anticipation of a future increase in the allowable percentage of ethanol in motor gasoline to 15 percent, the need for a formal inspection program by a qualified individual to identify unexpected deterioration of any components of the dispensing system was acknowledged. Note the emphasis on inspection of fuel handling components in 42.5.3.6.2.

42.5.3.6.1* Exterior Inspection. A visual inspection of the fuel dispenser and its associated hanging hardware (hose nozzle valve, hose, breakaway valve, and hose swivel) shall be conducted at least weekly and shall be documented. Documentation shall be available for review by the AHJ upon request. [**30A:**6.3.6.1]

A.42.5.3.6.1 Useful forms for documentation can be found in PEI/RP500-05, *Recommended Practices for Inspection and Maintenance of Motor Fuel Dispensing Equipment*, and are available at www.pei.org/rp500. [**30A:**A.6.3.6.1]

42.5.3.6.2* Internal Dispenser Cabinet Inspection. An inspection of the fuel dispensing equipment that is located inside the dispenser cabinet shall be conducted. The interior of the fuel dispenser cabinet shall be inspected for signs of leaks, damage, corrosion, or weathering, with particular attention to the sump area and joints and castings of fluid handling components. The inspection shall be conducted at least monthly and shall be documented. Documentation shall be available for review by the AHJ upon request. [**30A:**6.3.6.2]

A.42.5.3.6.2 See A.42.5.3.6.1. [**30A:**A.6.3.6.2]

Δ **42.5.3.6.3 Maintenance.** When maintenance to dispensing devices is necessary and such maintenance is capable of causing accidental release or ignition of liquid, the following precautions shall be taken before such maintenance is begun:

(1) Only persons knowledgeable in performing the required maintenance shall perform the work.
(2) All electrical power to the dispensing devices, to the pump serving the dispensing devices, and to all associated control circuits shall be shut off at the main electrical disconnect panel.
(3) The emergency shutoff valve at the dispenser, if installed, shall be closed.
(4) All vehicular traffic and unauthorized persons shall be prevented from coming within 20 ft (6 m) of the dispensing device.

[**30A:**6.3.6.3]

A fire at a Florida self-serve service station is the basis for the requirements in 42.5.3.6.3. The fire occurred when an attendant attempted to change a fuel filter in the supply line of one of the dispensers without shutting off power to the remote pump. (In a remote pumping system, the pump pressurizes the lines to all dispensers simultaneously.) A customer at an adjacent island began pumping fuel into his vehicle just as the attendant removed the filter from the pipe supplying a dispenser on the same system. The results were predictable and catastrophic — gasoline spewed out of the open supply pipe, causing a sizable spill and fire that resulted in the death of a customer.

42.5.3.7 Motor vehicle traffic patterns at motor fuel dispensing facilities shall be designed to inhibit movement of vehicles that are not being fueled from passing through the dispensing area. [**30A:**6.3.7]

Almost all new motor fuel dispensing facilities have some type of convenience store. Exhibit 42.14 shows one such service station and convenience store that has angled parking between the store and the dispensers. The increased vehicle and pedestrian traffic in these types of facilities makes control of vehicles an important safety concern.

42.5.3.8 At unattended self-serve motor fuel dispensing facilities, coin- and currency–type devices shall be permitted only with the approval of the AHJ. [**30A:**6.3.8]

This requirement intends to restrict dispensing devices at unattended self-serve facilities to those that accept only credit or debit cards or are key-operated.

42.5.3.9 Where liquid is supplied to the dispensing device under pressure, a listed, rigidly anchored, double-poppet type emergency shutoff valve incorporating a fusible link or other thermally actuated device, designed to close automatically in the event of severe

Exhibit 42.14

Typical service station and convenience store.

impact or fire exposure, shall be installed in the supply line at the base of each individual island-type dispenser or at the inlet of each overhead dispensing device. The emergency shutoff valve shall be installed in accordance with the manufacturer's instructions. The emergency shutoff valve shall not incorporate a slip-joint feature.

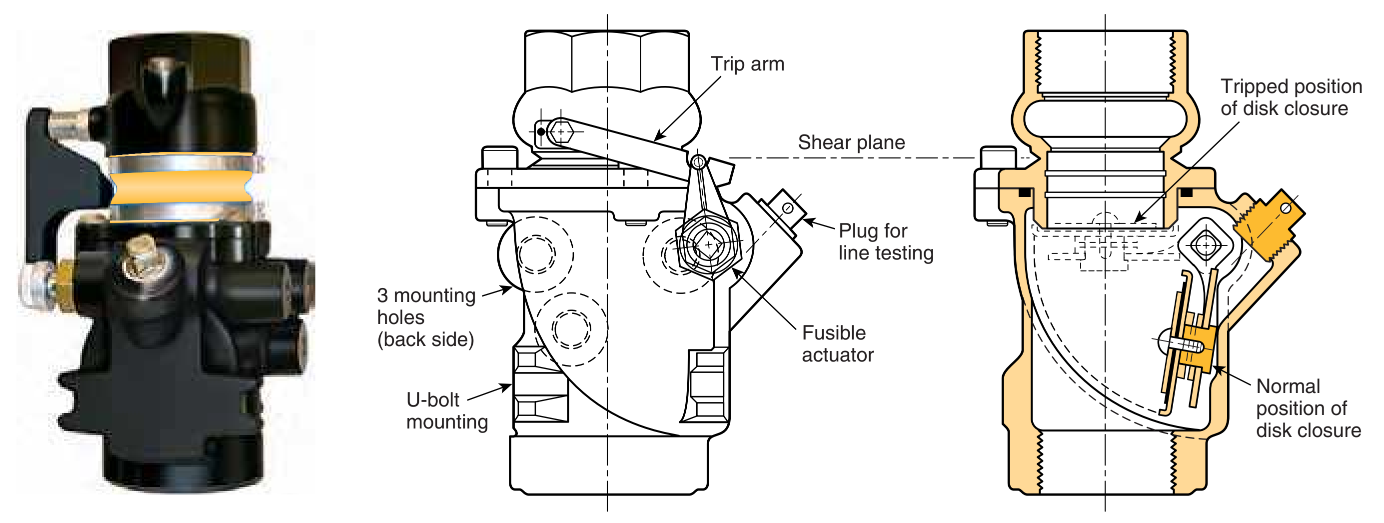
*Exception: As provided for in 42.5.3.10. [**30A:**6.3.9]*

The purpose of the shutoff valve (often referred to as a shear valve) required by 42.5.3.9 is to stop the flow of fuel from the piping that supplies the dispenser if the dispenser is hit or knocked over by a vehicle or if the dispenser is pulled over by a vehicle driving away with the dispensing nozzle still in its tank fill tube. A photo and cutaway drawings of an emergency shutoff valve are shown in Exhibit 42.15. If the dispenser is knocked or pulled over, an internal spring-loaded mechanism closes the valve. Additional protection is provided by a shear section in the valve body that breaks upon impact or severe stress. In addition, a thermally actuated device, such as the fusible actuator shown in Exhibit 42.16, trips the valve if a fire occurs within the dispenser housing.

The shear section of the valve must be installed level with the top of the dispenser island, and the entire assembly must be rigidly anchored to the island to ensure that the piping breaks at the shear section. Alternatively, the valve can be fastened to the dispenser mounting frame as long as the frame is rigidly secured to the island and that it remains in place if the dispenser is displaced. Slip-joint features are not allowed because they are prone to failure. Double backup protection is provided by the breakaway coupling required in 42.5.5.2 and by a shear point on the spout of the dispensing nozzle, both of which are intended to function if a vehicle drives away with the nozzle still inserted in its filler tube.

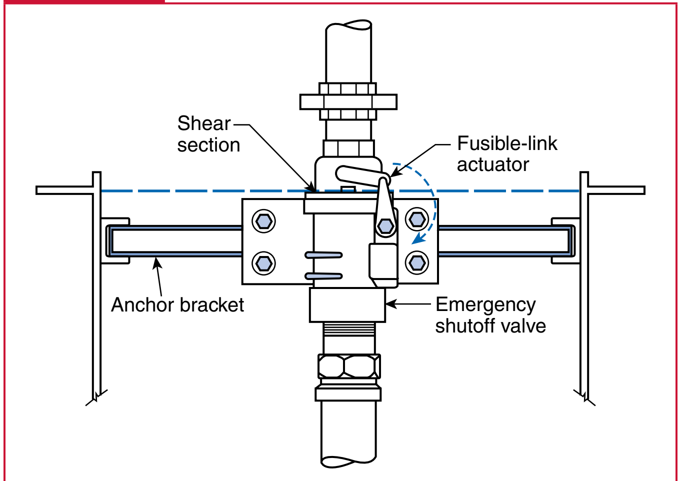
The Technical Committee on Automotive and Marine Service Stations has discussed several times whether the emergency shutoff valve should be of the double-poppet type. A double-poppet shear valve behaves like a dry-break coupling:

Exhibit 42.15



(Left) Photo of a double-poppet type emergency shutoff valve. (Center and right) Line diagram and cutaway of a double-poppet type emergency shutoff valve. (Courtesy of OPW)

Exhibit 42.16



Proper attachment of emergency shutoff valve to fuel dispenser mounting bracket. (from PEI RP100, Recommended Practices for Installation of Underground Liquid Storage Systems. Courtesy of Petroleum Equipment Institute)

a spring-loaded closure is provided on both sides of the shear section, so that liquid is retained on both sides when the valve breaks. Thus, not only will liquid be confined in the supply piping, it will also be prevented from draining from the piping inside the dislodged part of the dispenser.

Two divergent opinions are held among fire safety professionals and the fire service. Some believe that a double-poppet design limits the amount of fuel involved in an accident because the fuel contained in the dispenser itself doesn't spill. Others are of the opinion that, if a fire does occur, it will heat the trapped liquid in the dispenser, possibly to the point where the internal piping will forcefully rupture and result in injuries to emergency response personnel. This issue was discussed again in preparation for the 2018 edition of NFPA 30, and it was decided to require that the shear valve be of a double-poppet type. It is this double-poppet type that is shown in Exhibit 42.15.

42.5.3.9.1 The automatic-closing feature of this valve shall be tested at the time of installation and at least once a year thereafter by manually tripping the hold-open linkage. Records of such tests shall be kept at the premises or shall be made available for inspection by the AHJ within 24 hours of a verbal or written request. [**30A:**6.3.9.1]

42.5.3.10 Where a suction-type dispensing system includes a booster pump or where a suction-type dispensing system is supplied by a tank in a manner that produces a gravity head on the dispensing device, a vacuum-actuated shutoff valve with a shear section or equivalent-type valve listed and labeled in accordance with UL 842, *Standard for Valves for Flammable Fluids*, shall be installed directly under the dispensing device. [**30A:**6.3.10]

42.5.4 Requirements for Remote/Submersible Pumps. Subsection 42.5.4 shall apply to systems for dispensing Class I and Class II liquids where the liquids are transferred from storage to individual or multiple dispensing devices by pumps located other than at the dispensing devices. [**30A:**6.4]

Years ago, fuel dispensers had a single hose that dispensed a single grade of fuel. The pump was located within the dispenser housing, and fuel was pulled from the tank under suction. As fuels with higher vapor pressures became common, suction systems experienced problems due to "vapor locking" and cavitation. This led to the development of the remote pumping system, which pushes fuel to the dispenser rather than pulling it from the storage tank.

Almost all service stations now use remote pumping systems. The pump is located at the tank, almost always installed in the tank itself (it is submersible), occasionally mounted in a separate enclosure, and supplies several dispensers with the same grade of fuel. In many cases, the three grades of fuel are provided with just two tanks and two pumps, the middle grade being a blend of the high and regular octane grades. The supply piping between the tank and the dispensers operates under pressure, and the entire piping system and all the dispensers are pressurized whenever the pump is operating, even if only a single dispenser is actually being used. Remote pumping systems are easier and less expensive to install and maintain. The piping for such systems is also simplified and is less expensive to install. The capital cost does not increase greatly as more dispensers are added to the system, because, instead of a single pump for every dispenser, only one pump per storage tank is needed.

Remote pumping systems have some disadvantages. Because the piping system is under pressure, small leaks in the system can release sizable quantities of liquid. This problem is addressed by the requirement of 42.5.4.2. Also, careless operating procedures can lead to catastrophes, as already described in the commentary to 42.5.3.6.3.

42.5.4.1 Pumps shall be listed and shall be designed or equipped so that no part of the system will be subjected to pressures above its allowable working pressure. [**30A:**6.4.1]

42.5.4.2 Each pump shall have installed on the discharge side a listed leak detection device that restricts or shuts off the flow of product if the piping or a dispenser is leaking. Each leak-detecting device shall be checked and tested at least annually according to the manufacturers' specifications to ensure proper installation and operation.

*Exception: A leak detection device shall not be required if all piping is visible. [**30A:**6.4.2]*

42.5.4.3 Pumps installed above grade outside of buildings shall be located not less than 10 ft (3 m) from lines of adjoining property that can be built upon and not less than 5 ft (1.5 m) from any building opening. Where an outside pump location is impractical, pumps shall be permitted to be installed inside buildings as provided for dispensers in 42.5.3.4 or in sumps as provided in 42.5.4.4. Pumps shall be anchored and protected against physical damage. [**30A:**6.4.3]

The requirements in 42.5.4.3 are intended to prevent the vapors from minor leaks in the packing gland or seal from reaching an ignition source either in an adjacent building or on adjacent property.

42.5.4.4 Sumps for subsurface pumps or piping manifolds of submersible pumps shall withstand the external forces to which they can be subjected without damage to the pump, tank, or piping. The sump shall be no larger than necessary for inspection and maintenance and shall be provided with a fitted cover. [**30A:**6.4.4]

42.5.5 Requirements for Dispensing Hose.

42.5.5.1 Listed hose assemblies shall be used to dispense fuel. Hose length at automotive motor fuel dispensing facilities shall not exceed 18 ft (5.5 m). Where hose length at marine motor fuel dispensing facilities exceeds 18 ft (5.5 m), the hose shall be secured so as to protect it from damage. [**30A:**6.5.1]

The maximum hose length of 18 ft (5.5 m) is identical to the requirements of the Office of Weights and Measures of the U.S. Department of Commerce, as published in NIST *Handbook 44, Specifications, Tolerances, and Other Technical Requirements for Weighing and Measuring Devices*. The purpose of the requirement is to ensure accuracy of the dispenser totalizer and to minimize the effect of thermal expansion of any liquid remaining in the hose. These same regulations allow hose length at marine motor fuel dispensing facilities to be 50 ft (15 m) long.

42.5.5.2 A listed emergency breakaway device designed to retain liquid on both sides of the breakaway point shall be installed on each hose dispensing Class I and II liquids. Such devices shall be installed and maintained in accordance with the manufacturer's instructions. [**30A:**6.5.2]

The requirement for an emergency breakaway device was added to NFPA 30A in response to numerous incidents in which dispensers were pulled over when patrons drove away from the island with the nozzle still in the automobile's filler tube, in some cases, while the pump was still delivering fuel to the vehicle. Almost all the incidents occurred at self-serve islands. In several cases, the shear valve did not function properly and serious fires occurred. In at least one case, an attendant was seriously burned.

An emergency breakaway device is a two-part device installed in the dispenser hose, close to the dispenser, and is designed to come apart when subjected to a specified tension force. If a vehicle drives off with the dispenser nozzle still in its fuel fill tube, the two parts of the breakaway device will separate before enough force is developed to pull the dispenser off its mounting bracket. As mentioned in previous commentary, in a drive-off situation, it is a backup to the shear valve at the base of the dispenser. A cutaway view of an emergency breakaway device is shown in Exhibit 42.17.

42.5.5.3 Where hose are attached to a hose-retrieving mechanism, the listed emergency breakaway device shall be installed between

Exhibit 42.17

Cutaway of emergency breakaway coupling. (Courtesy of Husky Corporation) the point of attachment of the hose-retrieving mechanism to the hose and the hose nozzle valve.

*Exception: Such devices shall not be required at marine motor fuel dispensing facilities. [**30A:**6.5.3]*

The breakaway device is intended to separate before any significant force is transmitted to the dispenser via tension on the hose. If the hose is connected to a retrieving mechanism, the breakaway device must be installed downstream of the point where the retrieving cable is attached to the hose. Otherwise, any tension on the hose will be transmitted to the dispenser via the retrieving cable and not to the breakaway device, as intended.

42.5.6 Requirements for Fuel Delivery Nozzles.

Exhibit 42.18 illustrates the basic components of a fuel delivery nozzle. The spout of the nozzle is sized for the type of fuel to be dispensed: A nozzle for dispensing diesel fuel has a larger spout that is too large to fit into the fuel filler tube of a vehicle that uses gasoline. The nozzle shown has a flexible rubber vapor seal surrounding the spout to prevent the release of vapors and to ensure that vapors are captured by the vapor recovery system.

42.5.6.1 An automatic closing–type hose nozzle valve, with a latch-open device and listed and labeled in accordance with ANSI/UL 842, *Standard for Valves for Flammable Fluids*, or ANSI/UL 2586, *Standard for Hose Nozzle Valves*, shall be provided on island-type dispensing devices used to dispense Class I or Class II liquids. [**30A:**6.6.1]

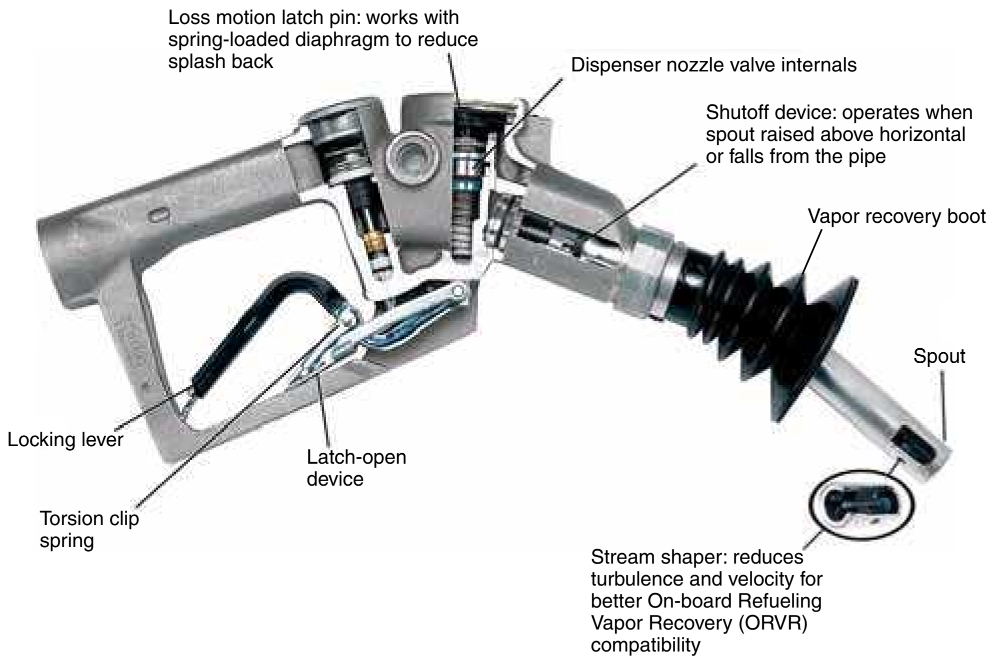
Originally, the requirement for an automatic-closing fuel delivery nozzle applied only to nozzles that dispensed Class I liquids (gasoline). The hazards inherent in refueling were determined to be independent of the class of liquid being dispensed, and a decision was made to broaden the application of the requirement to all refueling nozzles, regardless of the fuel handled.

Prior to 1981, latch-open devices were not permitted on dispenser nozzles unless the dispensing was performed by an attendant (i.e., full service was provided). Use of the latch-open device on a self-service dispensing nozzle was prohibited; the patron had to manually hold the nozzle trigger until dispensing was finished. Enforcing authorities soon began complaining that the prohibition was unenforceable and was even leading to more dangerous situations, because customers would chock open the nozzle with whatever device was at hand, including the automobile's gas cap. Enterprising individuals even marketed combination key holder/latch-open devices for personal use, some of which have even been patented.

The problem was that chocking open the dispenser nozzle sometimes inadvertently defeated its automatic-closing feature, and it would not shut off, leading to a spill. Many fire officials also pointed out that prohibiting the latch-open device inconvenienced consumers, questioned their intelligence, and gave more credit for common sense and concern for safety to the service station attendant than to the public at large.

Enforcement of the ban on latch-open devices proved difficult to justify and the apparent safety problem could not be ignored. With the 1981 edition of NFPA 30, the technical committee decided to make the use of the latch-open device an option to be decided by the local fire official. (At the time, service stations were covered in Chapter 7 of NFPA 30.) With the 2015

Exhibit 42.18



Typical fuel delivery nozzle. (Courtesy of Husky Corporation) edition of NFPA 30A, the Technical Committee on Automotive and Marine Service Stations decided that the safer approach would be to mandate the use of the latch-open device in all cases, except for marine fueling.

Note that, until the 2008 edition, NFPA 30A included the following provision:

> **6.6.2** If a hose nozzle valve is provided with a latch-open device other than the one recommended by the valve manufacturer, the latch-open device shall be an integral part of the valve assembly and such valve/latch-open device combination shall meet all applicable requirements of Section 19A of UL 842, *Standard for Valves for Flammable Fluids*.

The original intent of that paragraph was to prevent the use of makeshift devices as latch-open mechanisms where latch-open devices were not allowed. It required any after-market device to be permanently attached to the dispenser nozzle and to be evaluated to ensure that it would not interfere with any of the safety features of any nozzle with which it was likely to be used. Although many of these after-market products have appeared over the years, whether any have actually been evaluated is doubtful. Therefore, the technical committee decided to remove the requirement.

42.5.6.1.1 Any modification of the dispensing nozzle shall be listed or approved by the manufacturer of the nozzle. [**30A:**6.6.1.1]

42.5.6.2* At any installation where an automatic closing–type dispensing nozzle is used, the nozzle valve shall include a feature that causes or requires the closing of the hose nozzle valve before product flow can be resumed or before the hose nozzle valve can be replaced in its normal position in the dispenser. [**30A:**6.6.2]

A.42.5.6.2 The flow of fuel can be stopped by dispensers used in self-serve motor fuel dispensing facilities. The nozzle can be returned to the dispenser in the latched-open position. Subsequent activation of the dispenser would then immediately release fuel from the latched-open nozzle, creating a hazardous situation. [**30A:**A.6.6.2]

The purpose of 42.5.6.2 is to eliminate the possibility of spills that might occur when a customer pulls the nozzle from its bracket after the previous patron has left it in the latch-open position.

42.5.6.3 Overhead-type dispensing devices shall be provided with a listed, automatic closing–type hose nozzle valve without a latch-open device.

*Exception: A listed, automatic closing–type hose nozzle valve with a latch-open device shall be permitted to be used if the hose nozzle valve will close automatically in the event the valve is released from a fill opening or upon impact. [**30A:**6.6.3]*

42.5.6.4 Dispensing nozzles used at marine motor fuel dispensing facilities shall be of the listed automatic closing–type hose nozzle valve without a latch-open device. [**30A:**6.6.4]

The fuel fill port on a pleasure boat is typically larger than that on a motor vehicle; consequently, the fit of the nozzle spout into the fill port is looser. Therefore, the back pressure from the fill tube is not always great enough to trigger the automatic-closing feature when the tank is near full and an overfill can occur. This can lead to a spill, with spilled fuel draining to the bilge or the interior cabin of the boat. This condition is much more hazardous than a similar spill on the ground. Vapors are more confined, and dispersal takes a longer period of time and requires mechanical ventilation. Control of sources of ignition is also more difficult. Prohibiting the latch-open device means the person dispensing the fuel cannot move away from the boat and might pay greater attention to the task at hand.

42.5.7 Emergency Electrical Disconnects. Fuel dispensing systems shall be provided with one or more clearly identified emergency shutoff devices or electrical disconnects. Such devices or disconnects shall be installed in approved locations but not less than 20 ft (6 m) or more than 100 ft (30 m) from the fuel dispensing devices that they serve. Emergency shutoff devices or electrical disconnects shall disconnect power to all dispensing devices; to all remote pumps serving the dispensing devices; to all associated power, control, and signal circuits; and to all other electrical equipment in the hazardous (classified) locations surrounding the fuel dispensing devices and shall mechanically or electrically isolate other fluid transfer systems serving the fuel dispensing area. When more than one emergency shutoff device or electrical disconnect is provided, all devices shall be interconnected. Resetting from an emergency shutoff condition shall require manual intervention and the manner of resetting shall be approved by the AHJ.

*Exception: Intrinsically safe electrical equipment need not meet this requirement. [**30A:**6.7]*

Subsection 42.5.7 places special significance on the location of emergency power disconnects. They must be close enough to the dispensing island to be quickly accessible to a patron or an attendant, but not so close as to be directly involved in, or blocked by, a fire at the island or to place anyone in jeopardy while trying to access them. Manual reset ensures that operation of the station cannot be resumed automatically. Operations should not be resumed until the person responsible for the facility has rectified whatever emergency condition might exist.

The phrase "clearly identified" means that a sign is to be posted indicating where the disconnects are located. The emergency disconnect should be readily accessible and not blocked by storage of such items as tires or cases of lubricating oil. All service station operators, as well as responding fire fighters, should know the location of the disconnects. Locating the disconnects at least 20 ft (6 m) from the dispenser ensures that no person will be near any danger zone and that the patron or the attendant can reach the disconnects safely.

In this edition of the *Code*, text was modified to require that other electrical utilization equipment, including vacuum cleaners, windshield washer fluid dispensing systems, and compressed air pumps, that is sometimes installed at fuel islands be disconnected from power during emergency stop.

42.5.7.1 At attended motor fuel dispensing facilities, the devices or disconnects shall be readily accessible to the attendant and labeled with an approved sign stating "EMERGENCY FUEL SHUTOFF" or equivalent language. [**30A:**6.7.1]

42.5.7.2 At unattended motor fuel dispensing facilities, the devices or disconnects shall be readily accessible to patrons and at least one additional device or disconnect shall be readily accessible to each group of dispensing devices on an individual island. The device(s) or disconnect(s) shall be labeled with an approved sign stating "EMERGENCY FUEL SHUTOFF" or equivalent language. [**30A:**6.7.2]

42.5.8 Vapor Recovery Systems.

42.5.8.1 Dispensing devices that incorporate vapor recovery shall be listed. [**30A:**6.8.1]

The requirement that vapor recovery systems be listed prevents the use of modified or "home-built" devices or systems that are not specifically intended to provide vapor recovery functions.

42.5.8.2 Hose nozzle valves used on vapor recovery systems shall be listed for the purpose. [**30A:**6.8.2]

42.5.8.3 Means shall be provided in the vapor return path from each dispensing outlet to prevent the discharge of vapors when the hose nozzle valve is in its normal nondispensing position. [**30A:**6.8.3]

This requirement prevents vapors from reaching the interior of the dispenser housing. The interior of the housing is a relatively tight enclosure where vapors can accumulate to ignitible concentration.

42.6 Building Construction Requirements

The construction of buildings and portions of buildings that are motor fuel dispensing facilities or repair garages shall comply with Chapter 30.

42.7 Operational Requirements

Section 42.7 covers the operations associated with motor fuel dispensing facilities and repair garages. The checklist in Exhibit 42.19 is intended to remind users and enforcers of key features that need to be evaluated.

42.7.1 Scope. Section 42.7 shall apply to those requirements that relate to the operation of motor fuel dispensing facilities and fuel dispensing systems. [**30A:**9.1]

42.7.2 Basic Requirements.

42.7.2.1* Inventory Control. Accurate daily inventory records shall be maintained and reconciled for all liquid fuel storage tanks for indication of possible leakage from tanks or piping. The records shall be kept on the premises or shall be made available to the AHJ for inspection within 24 hours of a written or verbal request. The records shall include, as a minimum and by product, daily reconciliation between sales, use, receipts, and inventory on hand. If there is more than one storage system serving an individual pump or dispensing device for any product, the reconciliation shall be maintained separately for each system. [**30A:**9.2.1]

A.42.7.2.1 API RP 1621, *Recommended Practice for Bulk Liquid Stock Control at Retail Outlets*, provides information on this subject. [**30A:**A.9.2.1]

Leaks from underground storage tanks and piping systems present a distinct threat of fire and explosion, especially if the released liquid reaches subterranean or belowgrade structures. At the least, such releases contribute to groundwater contamination that is difficult to identify, isolate, and control. Small leaks can go undetected for months or even years, and identifying the source of a release can be difficult if several tanks are on nearby sites or if the release has spread from its point of origin.

Because of these problems, 42.7.2.1 requires a program of daily inventory reconciliation. If inventory records are maintained and discrepancies reconciled, leaks can often be discovered and corrected before they constitute a major hazard. API RP 1621, *Recommended Practice for Bulk Liquid Stock Control at Retail Outlets,* is the industry standard for maintaining a successful inventory control system and has been in use for years.

The requirement for daily inventory reconciliation is in addition to the leak detection rules established by the EPA in 40 CFR 280, "Technical Standards and Corrective Action Requirements for Owners and Operators of Underground Storage Tanks (UST)". The EPA's stated goal is that every underground tank system eventually will have a leak monitoring system using one or a combination of the following:

1. Groundwater monitoring systems
2. Soil vapor monitoring
3. Secondary containment with monitoring of the interstitial space
4. Automatic tank gauging systems

To ease the transition for facility operators, the EPA allows the use of inventory reconciliation combined with periodic tank tightness testing for a 10-year period after installation. Tightness testing can be performed in a number of ways, but all involve rigorous and time-consuming procedures. Any tightness test used must meet the federally mandated performance criteria for detecting a release of 0.1 gal/hr (0.38 L/hr) with a 95 percent probability of accuracy and a ±5 percent probability of error. For further information on the EPA's leak detection requirements, see *Straight Talk on Tanks: A Summary of Leak Detection Methods for Petroleum Underground Storage Tank Systems* (http://www.epa.gov/oust/pubs/straight.htm). State underground storage tank programs can be downloaded from www.epa.gov/oust/states/statcon1.htm.

In cases where a leak is suspected or confirmed, refer to NFPA 329, *Recommended Practice for Handling Releases of*

Exhibit 42.19

SERVICE STATION INSPECTION CHECKLIST

	Dispensing System	Tank	Repair Work Area
Are hoses listed for use?			
Are pumps and nozzles listed for use?			
Are emergency shutoff devices installed correctly?			
Are ignition sources controlled?			
Are emergency shutoff switches present and properly located?			
Are required operating procedures and warnings posted?			
Is electrically safe equipment being used in areas classified for type of electrical equipment?			
Is physical protection in place for pumps and piping?			
Do tanks have adequate spill control?			
Are proper separation distances being followed for operations involving ignition sources and Class I liquids?			
Is housekeeping adequate?			
Is cleanup routinely performed after operations?			
Are flammable liquids stored properly?			
Are other hazardous materials stored in proximity to flammable liquids?			
Are required communication devices working properly?			
Is required egress obstructed?			
Are required fire extinguishers present and properly located?			
For larger repair garages, is sprinkler protection installed?			
Is piping properly color coded?			
Are belowgrade work areas properly ventilated?			
Are fuel dispensing devices in buildings properly located?			
Is any flammable liquid waste properly stored and labeled?			
Are work areas free of combustible waste material?			
Are containers listed for use and properly labeled?			

Recommended inspection checklist for motor fuel dispensing facilities.

Flammable and Combustible Liquids and Gases. NFPA 329 provides guidance in determining the source of a leak, as well as procedures for testing tanks and removing liquids that are trapped underground.

42.7.2.2 Tank Filling and Bulk Delivery.

42.7.2.2.1 Delivery operations shall meet all applicable requirements of NFPA 385 and the requirements of 42.7.2.2.3 through 42.7.2.2.6. [**30A:**9.2.2.1]

N **42.7.2.2.2** No separation shall be required between the delivery vehicle and the fill connection of an underground storage tank. [**30A:**9.2.2.2]

It was not the intent of previous editions of NFPA 30A and this *Code* to impose separation distance between the delivery vehicle and the fill point for an underground tank. However, this was never explicitly stated. Paragraph 42.7.2.2.2 is new to this edition of the *Code* and rectifies that oversight.

42.7.2.2.3 The delivery vehicle shall be separated from any aboveground tank in accordance with Table 42.7.2.2.3.

Originally, a 25 ft (7.6 m) separation was required between the delivery vehicle and any aboveground storage tanks, with exceptions for tanks filled by gravity and for delivery of Class II and Class III liquids. Table 42.7.2.2.3 replaces the previous text and exceptions with separation distances that recognize the reduced risk of tanks that are inherently safer.

N **42.7.2.2.3.1** Separation distances shall be imposed by the use of curbing, guard posts, or other approved methods. [**30A:**9.2.2.3.1]

N **42.7.2.2.3.2*** Means shall be provided to prevent an accidental release originating from the delivery vehicle from flowing under the aboveground tank. [**30A:**9.2.2.3.2]

N ***TABLE 42.7.2.2.3*** *Minimum Separation Distances Between Delivery Vehicles and Aboveground Tanks*

Aboveground Tank Type	Separation Distance Between Delivery Vehicle and Aboveground Tank (ft)
Protected aboveground tanks	0
Tanks in abovegrade vaults (measured from vault wall)	0
Tanks filled by gravity	0
Fire-resistant tanks	15
Other tanks meeting the requirements of NFPA 30 storing Class II or Class III liquids	15
Other tanks meeting the requirements of NFPA 30 storing Class I liquids	25

[**30A:**9.2.2.3]

N **A.42.7.2.2.3.2** If the tank is situated in a dike, the dike wall meets this requirement. For secondary containment-type tanks, drainage, curbing, or other approved means can be used. [**30A:**A.9.2.2.3.2]

42.7.2.2.4 The delivery vehicle shall be located so that all parts of the vehicle are on the premises when delivery is made.

*Exception: This requirement shall not apply to existing fuel dispensing facilities and fuel dispensing facilities inside buildings. [**30A:**9.2.2.4]*

42.7.2.2.5 Tank filling shall not begin until the delivery operator has determined that the tank has sufficient available capacity (i.e., ullage). [**30A:**9.2.2.5]

42.7.2.2.6 Tanks shall be filled through a liquidtight connection. [**30A:**9.2.2.5]

42.7.2.2.6.1 Where an aboveground tank is filled by means of fixed piping, either a check valve and shutoff valve with a quick-connect coupling or a check valve with a dry-break coupling shall be installed in the piping at a point where connection and disconnection is made between the tank and the delivery vehicle. This device shall be protected from tampering and physical damage. [**30A:**9.2.2.5.1]

42.7.2.2.6.2 Underground tanks and tanks in belowgrade vaults shall be filled through a liquidtight connection within a spill container. [**30A:**9.2.2.5.2]

42.7.2.3 Dispensing into Containers.

The provisions of 42.7.2.3 are intended to provide safety not only while the fuel is being dispensed into a portable container, but also while it is being transported to its point of use. The latter operation is addressed by the provisions of 42.7.2.3.1 and 42.7.2.3.2. Portable containers are subject to physical abuse simply because of their portability. If not handled properly and not tightly capped, they are prone to leakage and escape of vapors.

Because the entire contents of a portable container might not be used at the time of purchase, it is important that the container be clearly marked with the name of the contents in order to prevent accidental misuse at a later date. Note that the attendant or operator is permitted to refuse the dispensing of fuel into an unsuitable container.

42.7.2.3.1* Class I or Class II liquids shall not be dispensed into portable containers unless the container is constructed of metal or is approved by the AHJ, has a tight closure, and is fitted with a spout or so designed that the contents can be poured without spilling. The hose nozzle valve shall be manually held open during the dispensing operation. [**30A:**9.2.3.1]

A.42.7.2.3.1 See Chapter 9 of NFPA 30 for further information. [**30A:**A.9.2.3.1]

42.7.2.3.2 No sale or purchase of any Class I, Class II, or Class III liquids shall be made in containers unless such containers are clearly marked with the name of the product contained therein. [**30A:**9.2.3.2]

42.7.2.3.3 Portable containers of 12 gal (45 L) capacity or less shall not be filled while they are in or on a motor vehicle or marine craft. [**30A:**9.2.3.3]

Prior to the 1993 edition, the prohibition in 42.7.2.3.3 applied to filling portable containers that were in the trunk or the passenger compartment of a vehicle for the obvious reason that it would allow vapors to accumulate in a confined space that might contain an ignition source, usually the vehicle's electrical system. In 1993, the prohibition was extended to filling containers that are "on" the vehicle. The amendment is based on dozens of fire incidents identified by the Petroleum Equipment Institute that involved filling containers while they were sitting on plastic-lined beds of pickup trucks. Apparently, containers accumulate a static electric charge (several mechanisms are possible) that cannot be dissipated because the plastic liner insulates the container from ground. Contact between the container and the grounded dispenser nozzle results in an electrostatic discharge that ignites any vapors that are present.

42.7.2.4 Dispensing from a Tank That Does Not Exceed 120 Gal (454 L) and from Containers Inside Buildings. Dispensing of flammable and combustible liquids from a tank not exceeding 120 gal (454 L) capacity and from containers in a motor fuel dispensing facility or in a repair garage building shall meet the requirements of 42.7.2.4.1 and 42.7.2.4.2. *(See 42.3.3.9 for storage quantity limitations.)* [**30A:**9.2.4]

42.7.2.4.1 Not more than one container of Class I liquid shall be permitted to be provided with a dispensing pump inside a building at any one time. The number of tanks or containers of Class II or Class IIIA liquids fitted for dispensing at any one time shall not be limited, except as provided for in 42.3.3.9.2. The number of tanks or containers of Class IIIB liquids fitted for dispensing at any one time shall not be limited. [**30A:**9.2.4.1]

Paragraph 42.3.3.9.1.1 permits storage of Class I liquid up to an aggregate capacity of 120 gal (454 L). This quantity can be stored as follows:

1. In a single 120 gal (454 L) tank
2. In more than one tank (presumably with capacities smaller than 120 gal (454 L)
3. In containers that do not exceed 60 gal (227 L)
4. In some combination of these storage methods

At first glance, there appears to be a discrepancy of 1 gal (3.8 L). However, the 120 gal (454 L) permitted by 42.3.3.9.1.1 is an *aggregate* amount of two or more containers. While the DOT does recognize containers up to 119 gal (450 L), those with a capacity above 60 gal (227 L) are used as recovery drums for leaking shipping containers, not for basic shipping and storage. Paragraph 42.7.2.4.1 adds the additional restriction that only one container or tank of Class I liquid can be provided with a dispensing pump at any one time.

For dispensing of Class II or Class IIIA liquids, 42.7.2.4.1, in combination with 42.3.3.9.1.2, permits storage of an aggregate quantity of 240 gal (908 L). If stored in tanks, the tanks cannot exceed 120 gal (454 L) capacity. If stored in containers, the containers cannot exceed 119 gal (450 L), but practicality dictates that the containers not exceed 60 gal (227 L) for the reasons discussed in the preceding paragraph of this commentary. Note that each class of liquid is restricted to a 120 gal (454 L) upper limit.

No restrictions are placed on storing and dispensing of Class IIIB liquids due to their low fire risk.

42.7.2.4.2 Class I, Class II, and Class IIIA liquids shall not be dispensed by applying pressure to tanks or containers. Listed pumps that take suction through the top of the tank or container or listed self-closing faucets shall be used. [**30A:**9.2.4.2]

This provision prohibits the use of the facility's compressed air system to dispense liquids from containers or tanks.

N **42.7.2.5* Display of Materials.** The storage or placement for display or sale of products shall be prohibited within 20 ft of any fuel dispenser. [**30A:**9.2.5.5]

N **A.42.7.2.5** Many fuel stations display items such as wood, bagged ground cover, cartons of consumable products, and other combustibles that create vision obstructions, excessive fire load, and other hazards in and around dispensing islands and pumps. [**30A:**A.9.2.5.5]

42.7.2.6 Basic Fire Control.

42.7.2.6.1 Sources of Ignition. Smoking materials, including matches and lighters, shall not be used within 20 ft (6 m) of areas used for fueling, servicing fuel systems of internal combustion engines, or receiving or dispensing of Class I and Class II liquids. The motors of all equipment being fueled shall be shut off during the fueling operation except for emergency generators, pumps, and so forth, where continuing operation is essential. [**30A:**9.2.5.1]

The 20 ft (6 m) separation distance is based on the extent of the hazardous (classified) location around a fuel dispenser and can be considered applicable to any source of ignition.

42.7.2.6.2 Fire Extinguishers. Each motor fuel dispensing facility or repair garage shall be provided with fire extinguishers installed, inspected, and maintained as required by Section 13.6. Extinguishers for outside motor fuel dispensing areas shall be provided according to the extra (high) hazard requirements for Class B hazards, except that the maximum travel distance to an 80 B:C extinguisher shall be permitted to be 100 ft (30.48 m). [**30A:**9.2.5.2]

Table 6.3.1.1 of NFPA 10, *Standard for Portable Fire Extinguishers*, calls for a maximum 50 ft (15.25 m) travel distance for an extinguisher having an 80 B:C rating. However, 42.7.2.6.2 allows 100 ft (30.48 m). There is no conflict with NFPA 10, nor does 42.7.2.6.2 violate the provisions of NFPA 10. Table 6.3.1.1 of NFPA 10 provides maximum travel distances for various sizes of fire extinguishers for light (low), ordinary (moderate), and extra (high) hazard *occupancies*, which implies the extinguishers are being installed inside a building. The 100 ft (30.48 m) travel distance allowed in 42.7.2.6.2 applies to an outside motor fuel dispensing facility and applies only to an 80 B:C unit. Because the travel distances specified in NFPA 10 are for indoor application, NFPA 30A can establish its own maximum travel distance for an outdoor application.

42.7.2.6.3 Fire Suppression Systems. Where required, automatic fire suppression systems shall be installed in accordance with the appropriate NFPA standard, manufacturers' instructions, and the listing requirements of the systems. [**30A:**9.2.5.3]

Note that this *Code* does not mandate a fire protection system for a motor fuel dispensing area. This matter should be left to the AHJ.

42.7.2.6.4* Signs. Warning signs shall be conspicuously posted in the dispensing area and shall incorporate the following or equivalent wording:

WARNING:
It is unlawful and dangerous to dispense gasoline into unapproved containers.
No smoking.
Stop motor.
No filling of portable containers in or on a motor vehicle.
Place container on ground before filling.
Discharge your static electricity before fueling by touching a metal surface away from the nozzle.
Do not re-enter your vehicle while gasoline is pumping.
If a fire starts, **do not** remove nozzle — back away immediately.
Do not allow individuals under licensed age to use the pump.

[**30A:**9.2.5.4]

A.42.7.2.6.4 The following language includes both the mandatory requirements and some optional text that could be used to comply with the requirements in 42.7.2.6.4:

WARNING
It is unlawful and dangerous to dispense gasoline into unapproved containers.
No smoking.
Stop motor.
No filling of portable containers in or on a motor vehicle.
Place container on ground before filling.
Discharge your static electricity before fueling by touching a metal surface away from the nozzle.
Before using pump, touch any metal on the car away from your vehicle's fuel filler with bare hand. This will discharge static electricity on your body. Failure to fully discharge may ignite gasoline vapors.
Do not re-enter your vehicle while gasoline is pumping. This can re-charge your body with static electricity. If you must re-enter your vehicle, discharge static electricity again before touching the pump nozzle.
If a fire starts, **do not** remove nozzle — back away immediately and tell attendant. If no attendant is on site, use the emergency shut-off button to stop pump.
Do not allow individuals under licensed age to use the pump.
Only persons of licensed age should use pump.
Keep children away from the pump area.
Do not allow children to use pump.

[**30A:**A.9.2.5.4]

42.7.2.7 Waste Handling.

42.7.2.7.1 Crankcase drainings and waste liquids shall not be dumped into sewers, into streams, or on the ground. They shall be stored in approved tanks or containers outside any building, or in tanks installed in accordance with Chapters 4 and 5 of NFPA 30A, until removed from the premises.

*Exception: As provided for in 42.3.3.9.3. [**30A:**9.2.6.1]*

Small tanks or drums are often used for the storage of crankcase drainings and similar liquids. These waste oils might be contaminated with lower flash point flammable liquids. Thus, waste oils are not to be overlooked when applying regulations. For environmental and safety reasons, crankcase drainings must not be dumped into sewers. The words "or in tanks installed in accordance with Chapters 4 and 5 of NFPA 30A" in 42.7.2.7.1 effectively allow the storage of used motor oils in tanks inside a building. Used motor oil has been determined to be no more hazardous than virgin oil unless contaminated with a low flash point liquid.

Inside storage offers a more secure situation and allows the operator to address some environmental regulations for storing used motor oil now being set by local and state authorities. Fixed piping and stationary storage tanks, as commonly used in "quick-lube" facilities, provide a more effective and secure storage arrangement, from the standpoint of both fire protection and environmental protection, than outside drum storage.

Note that the EPA publication *Restricting Service Station Wastes in Shallow Injection Wells* recommends that motor fuel dispensing facilities and repair garages abandon the practice of disposing waste liquids in septic system drain fields, drywells, or cesspools, even if the waste stream first flows through an oil–water separator, because many of the components of the waste fluids are water soluble and will pass through the separator. This practice leads to groundwater contamination. The EPA urges disposal by safer means.

42.7.2.7.2 The contents of oil separators and traps of floor drainage systems shall be collected at sufficiently frequent intervals to prevent oil from being carried into sewers. [**30A:**9.2.6.2]

42.7.2.8 Housekeeping. The dispensing area and the area within any dike shall be kept free of vegetation, debris, and any other material that is not necessary to the proper operation of the motor fuel dispensing facility. [**30A:**9.2.7]

Although 42.7.2.8 sets requirements restricting the storage of materials not required for dispensing, many facilities still

Exhibit 42.20

Items for sale stacked next to fuel dispensers. (Courtesy of Wisconsin Commerce Department)

stockpile items for sale close to the dispenser. Exhibit 42.20 illustrates an all-too-common situation that is prohibited by 42.7.2.8.

42.7.2.9 Fire Doors. Fire doors shall be kept unobstructed at all times. Appropriate signs and markings shall be used. [**30A:**9.2.8]

N **42.7.2.10 Maintenance of Aboveground Storage Tank Appurtenances.** Storage tank appurtenances shall be maintained and operated in accordance with manufacturer's instructions, published industry practices, or equivalent methods approved by the AHJ. [**30A:**9.2.9]

42.7.3 Operating Requirements for Full-Service Motor Fuel Dispensing Facilities. Each motor fuel dispensing facility shall have an attendant or supervisor on duty whenever the facility is open for business. The attendant or supervisor shall dispense liquids into fuel tanks or into containers, except as covered in 42.7.4 and 42.7.5. [**30A:**9.3]

42.7.4 Operating Requirements for Attended Self-Service Motor Fuel Dispensing Facilities.

42.7.4.1 "Self-service motor fuel dispensing facility" shall mean that portion of a property where liquids used as motor fuels are stored and dispensed from fixed, approved dispensing equipment into the fuel tanks of motor vehicles by persons other than the facility attendant and shall also include, where provided, facilities for the sale of other retail products. [**30A:**9.4.1]

The concept of self-service motor fuel dispensing facilities has almost universal acceptance by both the public and the fire service, with the exceptions of New Jersey and Oregon. For many years, self-service dispensing without an attendant were permitted only at "private" or "not-open-to-the-public" stations. Eventually, requirements were established for self-service fueling and, not long after, for unattended self-service stations.

Based on the fire incident data accumulated over the years, determining the difference in relative safety between full-service and self-service is not possible. Some jurisdictions require self-service facilities to have one set of dispensers dedicated to full-service use for the benefit of those patrons who do not wish to use, or are physically incapable of using, the self-service dispensers. The dispenser at which an incident occurs is often not identified, so it cannot be stated that one is more hazardous than the other. In addition, the nature of the fire problem is very much the same for both. For example, a full-service dispenser can be knocked over by a vehicle just as easily as can a self-service dispenser.

42.7.4.2 There shall be at least one attendant on duty while the self-service facility is open for business. The attendant's primary function shall be to supervise, observe, and control the dispensing of motor fuels. [**30A:**9.4.2]

Compliance with the requirement that the attendant "observe" dispensing has led, in some cases, to the use of closed-circuit video cameras. Communication with the patron is also being provided by intercoms mounted in the dispenser.

In previous editions of the *Code*, this provision applied only to the dispensing of Class I liquids (i.e., gasoline). The technical committee recognized that this provision should apply equally to any motor fuel, especially since retailing of alternative fuels at the same facilities as liquid fuels is becoming more common.

Δ **42.7.4.3** The responsibility of the attendant shall be as follows:

(1) Prevent the dispensing of Class I liquids into portable containers not in compliance with 42.7.2.3.1
(2) Prevent the use of hose nozzle valve latch-open devices that do not comply with 42.5.6.1
(3) Control sources of ignition
(4) Immediately activate emergency controls and notify the fire department of any fire or other emergency
(5) Handle accidental spills and fire extinguishers if needed

[**30A:**9.4.3]

42.7.4.3.1 The attendant or supervisor on duty shall be mentally and physically capable of performing the functions and assuming the responsibility prescribed in 42.7.4. [**30A:**9.4.3.1]

42.7.4.4 Operating instructions shall be conspicuously posted in the dispensing area. [**30A:**9.4.4]

42.7.5 Operating Requirements for Unattended Self-Service Motor Fuel Dispensing Facilities.

Changes in the marketing of motor fuels have led to confusion about what is meant by "open to the public" versus "not open to the public," occasionally leading to a legal dispute between the AHJ and the facility owner or operator. Once unattended self-service motor fuel dispensing was recognized and addressed in NFPA 30A, the ambiguity needed to be addressed. It was decided that by eliminating the phrases "open to the public," "not open to the public," and "private," it could clarify the intended requirements for all types of service station operations. Thus, the addition of 42.7.5 on unattended self-service stations has resulted in small but important changes in 42.7.3 and 42.7.4.

42.7.5.1 Unattended self-service facilities shall be permitted, where approved by the AHJ. [**30A:**9.5.1]

42.7.5.2 Operating instructions shall be conspicuously posted in the dispensing area. The instructions shall include location of emergency controls and a requirement that the user stay outside of his/her vehicle and in view of the fueling nozzle during dispensing. [**30A:**9.5.2]

42.7.5.3 In addition to the warning signs specified in 42.7.2.6.4, emergency instructions shall be conspicuously posted in the dispenser area. The instructions shall incorporate the following or equivalent wording:

Emergency Instructions

In case of fire or spill

(1) Use emergency stop button.

(2) Report accident by calling (*specify local fire number*). Report location.

[**30A:**9.5.3]

42.7.5.4 A listed, automatic closing–type hose nozzle valve with latch-open device shall be provided. The hose nozzle valve shall meet the requirements of 42.5.6.2. [**30A:**9.5.4]

42.7.5.5 A telephone or other approved, clearly identified means to notify the fire department shall be provided on the site in a location approved by the AHJ. [**30A:**9.5.5]

42.7.5.6* Additional fire protection shall be provided where required by the AHJ. [**30A:**9.5.6]

A.42.7.5.6 Additional fire protection considerations can include fixed suppression systems, automatic fire detection, manual fire alarm stations, transmission of alarms to off-site locations, and limitation of the quantity of motor fuel delivered per transaction. [**30A:**A.9.5.6]

42.7.6 Refueling from Tank Vehicles. The dispensing of Class I and Class II liquids in the open from a tank vehicle to a motor vehicle located at commercial, industrial, governmental, or manufacturing establishments and intended for fueling vehicles used in connection with their businesses shall be permitted only if all of the requirements of 42.7.6.1 through 42.7.6.9 have been met. [**30A:**9.6]

Originally, the requirements in 42.7.6 were intended to allow fueling of construction vehicles and equipment at isolated construction sites. Over the years, however, many new types of motorized construction equipment have been developed, and refueling these from a tank vehicle is common at construction sites, whether urban, suburban, or rural. Also, these requirements have been interpreted as allowing the fueling of motor vehicles from a tank vehicle in a parking lot, access to which is limited to employees of the user or owner of the lot.

Because of the ambiguity involving the phrase "open to the public," the NFPA 30A technical committee added the words "located at commercial, industrial, governmental, or manufacturing establishments" to define the facilities covered by these requirements. The phrase "intended for fueling vehicles used in connection with their businesses" further clarifies the intent of this subsection to apply only to vehicles directly related to the function of the facility.

If the vehicles being refueled are connected with the operation of the establishment, they are allowed to be refueled from a tank vehicle, as long as all the conditions of 42.7.6 are met. Also, the vehicles are not restricted to operating only on the site on which they are refueled. Note, however, that this requirement would also apply to refueling of nonregistered vehicles that can be operated only on-site, such as industrial trucks.

42.7.6.1 An inspection of the premises and operations shall be made and operations shall not be conducted unless approved by the AHJ. [**30A:**9.6.1]

42.7.6.2 The tank vehicle shall comply with the requirements of NFPA 385. [**30A:**9.6.2]

42.7.6.3 The dispensing hose shall not exceed 50 ft (15 m) in length. [**30A:**9.6.3]

42.7.6.4 The dispensing nozzle shall be a listed, automatic closing–type without a latch-open device. [**30A:**9.6.4]

42.7.6.5 Nighttime deliveries shall only be made in areas deemed adequately lighted by the AHJ. [**30A:**9.6.5]

42.7.6.6 The tank vehicle flasher lights shall be in operation while dispensing operations are in progress. [**30A:**9.6.6]

42.7.6.7 Expansion space shall be left in each fuel tank to prevent overflow in the event of temperature increase. [**30A:**9.6.7]

N **42.7.6.8** A means for bonding the tank vehicle to the motor vehicle shall be provided. Such bonding means shall be employed during fueling operations. [**30A:**9.6.8]

N **42.7.6.9** A spill kit designed for motor vehicle fuels shall be carried on the tank vehicle and employed in case of a fuel spill. [**30A:**9.6.9]

42.8 Additional Requirements for CNG, LNG, Hydrogen, and LPG

Section 42.8 sets requirements for motor fuel dispensing facilities that handle both gaseous and liquid fuels. For the most part, this section refers back to the fuel-specific codes for safety requirements, including NFPA 2 for hydrogen, NFPA 52 for natural gas, and NFPA 58 for propane.

42.8.1 Scope. Section 42.8 shall apply where CNG, LNG, compressed or liquefied hydrogen, or LP-Gas, or combinations of these, are dispensed as motor vehicle fuels along with Class I or Class II liquids that are also dispensed as motor vehicle fuels. [**30A:**12.1]

Exhibit 42.21

A CNG fuel dispenser at a retail motor fuel dispensing facility. (Courtesy of cleanenergyfuels.com)

Exhibit 42.22

A residential CNG refueling system. (Courtesy of cleanenergyfuels .com)

Chapter 12 of NFPA 30A includes requirements for vehicular hydrogen fueling. The refueling facility shown in Exhibit 42.21 dispenses both liquid and gaseous fuels. Exhibit 42.22 shows a type of gaseous fueling installation — a dedicated home refueling system — that is outside the scope of NFPA 30A. A dedicated home refueling system allows refueling of the vehicle conveniently overnight. The system safely compresses natural gas from the household line to the needed vehicle pressure using a relatively slow (time-fill) refueling rate.

42.8.2 General Requirements.

42.8.2.1 The installation and use of CNG and LNG systems shall meet the requirements of NFPA 52 except as modified by Section 42.8. The installation and use of hydrogen systems shall meet the requirements of NFPA 2 except as modified by Section 42.8. The installation and use of LP-Gas systems shall meet the requirements of NFPA 58 except as modified by Section 42.8. [**30A:**12.2.1]

42.8.2.2 A means shall be provided that connects to the dispenser supply piping and that prevents flow in the event that the dispenser is displaced from its mounting. [**30A:**12.2.2]

42.8.2.3* Dispensing devices for CNG, LNG, hydrogen, and LP-Gas shall be listed or approved. [**30A:**12.2.3]

N **A.42.8.2.3** Not all fuels have equipment that is currently listed. As technology develops, this provision will allow the authorities having jurisdiction (AHJ) the latitude to approve systems and equipment that cannot be currently listed. [**30A:**A.12.2.3]

42.8.2.4* Listed or approved hose assemblies shall be used to dispense fuel. Hose length at automotive motor fuel dispensing facilities shall not exceed 18 ft (5.5 m). [**30A:**12.2.4]

N **A.42.8.2.4** See A.12.2.3. [**30A:**A.12.2.4]

42.8.3 Fuel Storage.

Responsibility for establishing installation criteria for storage of gaseous fuels rests primarily with the codes that are specific to the respective fuels, not with NFPA 30A. NFPA 30A does, however, establish tank-to-tank separation, as indicated in 42.8.3.3, because these criteria are lacking in NFPA 52 and NFPA 58.

42.8.3.1 Aboveground tanks storing CNG or LNG shall be separated from any adjacent property line that is or can be built upon, any public way, and the nearest important building on the same property by not less than the distances given in Section 8.4 of NFPA 52. [**30A:**12.3.1]

42.8.3.2 Aboveground tanks storing hydrogen shall be separated from any adjacent property line that is or can be built upon, any public way, and the nearest important building on the same property by not less than the distances given in NFPA 2. [**30A:**12.3.2]

Exhibit 42.23 shows a propane tank and dispenser for vehicle fueling. The vertical configuration of the propane storage tank allows this system to be installed in a relatively small area. The propane tank separation distances from exposures, such as property lines and important buildings, are given in NFPA 58.

42.8.3.3 Aboveground tanks storing LP-Gas shall be separated from any adjacent property line that is or can be built upon, any public way, and the nearest important building on the same property by not less than the distances given in Section 6.3 of NFPA 58. [**30A:**12.3.3]

Exhibit 42.23

Typical propane storage and dispensing system for fueling vehicles. (Photo: Warren Gretz; Courtesy of DOE/NERL)

42.8.3.4* Aboveground tanks storing CNG, LNG, or LP-Gas shall be separated from each other by at least 20 ft (6 m) and from dispensing devices that dispense liquid or gaseous motor vehicle fuels by at least 20 ft (6 m).

Exception No. 1: This required separation shall not apply to tanks storing or handling fuels of the same chemical composition.

*Exception No. 2: When both the gaseous fuel storage and dispensing equipment are at least 50 ft (15 m) from any other aboveground motor fuel storage or dispensing equipment, the requirements of NFPA 52 or NFPA 58, whichever is applicable, shall apply. [**30A:**12.3.4]*

A.42.8.3.4 The selection of the 20 ft (6 m) separation distance between storage containers of different gaseous fuels is based on long-standing requirements in NFPA 2, NFPA 52, and NFPA 58. The separation distance between containers storing gaseous fuels and liquid motor fuel dispensers is based on the maximum 18-foot length of dispenser hose attached to the liquid fuel dispenser and the potential for a liquid pool fire to affect the gaseous fuel storage containers. [**30A:**A.12.3.4]

42.8.3.5 Aboveground storage tanks for the storage of CNG, LNG, or LP-Gas shall be provided with physical protection in accordance with 42.3.3.7. [**30A:**12.3.5]

42.8.3.6 Horizontal separation shall not be required between aboveground tanks storing CNG, LNG, or LP-Gas and underground tanks containing Class I or Class II liquids, provided the structural limitations of the underground tanks are not exceeded. [**30A:**12.3.6]

42.8.4 Dispenser Installations Beneath Canopies. Where CNG or LNG dispensers are installed beneath a canopy or enclosure, either the canopy or enclosure shall be designed to prevent accumulation or entrapment of ignitable vapors or all electrical equipment installed beneath the canopy or enclosure shall be suitable for Class I, Division 2 hazardous (classified) locations. [**30A:**12.4]

Unlike most other flammable gases and flammable and combustible liquids, whose vapors are more dense than air and tend to hug the ground, natural gas vapors are less dense than air and will rise. If an unexpected release of CNG or LNG occurs, vapors collect beneath the dispensing area canopy or at the top of any enclosure.

42.8.5 Specific Requirements for LP-Gas Dispensing Devices.

42.8.5.1 Dispensing devices for LP-Gas shall meet all applicable requirements of Chapter 69 and NFPA 58. [**30A:**12.5.1]

42.8.5.2 Dispensing devices for LP-Gas shall be located as follows:

(1) At least 10 ft (3 m) from any dispensing device for Class I liquids
(2) At least 5 ft (1.5 m) from any dispensing device for Class I liquids where the following conditions exist:
    (a) The LP-Gas deliver nozzle and filler valve release no more than 0.1 oz (4 cm^3) of liquid upon disconnection.
    (b) The fixed maximum liquid level gauge remains closed during the entire refueling process.

[**30A:**12.5.2]

42.8.6 Electrical Equipment.

The electrical area classification requirements in Table 42.8.6.2 are specific to gaseous fuels and differ somewhat from the criteria in Chapter 8 of NFPA 30A. For CNG and LNG, the requirements take into consideration the lighter-than-air characteristics of the gas. Unlike the requirements for liquid fuels, they establish area classification for the dispenser enclosure itself, because there is no standard equivalent to UL 87 for gaseous fuels.

42.8.6.1 All electrical wiring and electrical utilization equipment shall be of a type specified by, and shall be installed in accordance with, Section 11.1. [**30A:**12.6.1]

42.8.6.2* Table 42.8.6.2 shall be used to delineate and classify areas for the purpose of installation of electrical wiring and electrical utilization equipment. [**30A:**12.6.2]

A.42.8.6.2 The designation of classes and divisions of classified locations is defined in Article 500 of *NFPA 70*. [**30A:**A.12.6.2]

TABLE 42.8.6.2 Electrical Equipment Classified Areas for Dispensing Devices

	Extent of Classified Area	
Dispensing Device	**Class I, Division 1**	**Class I, Division 2**
Compressed natural gas (CNG)	Entire space within the dispenser enclosure	5 ft (1.5 m) in all directions from dispenser enclosure
Liquefied natural gas (LNG)	Entire space within the dispenser enclosure and 5 ft (1.5 m) in all directions from the dispenser enclosure	10 ft (3 m) in all directions from the dispenser enclosure
Liquefied petroleum gas (LP-Gas)	Entire space within the dispenser enclosure; 18 in. (46 cm) from the exterior surface of the dispenser enclosure to an elevation of 4 ft (1.22 m) above the base of the dispenser; the entire pit or open space beneath the dispenser and within 20 ft (6 m) horizontally from any edge of the dispenser when the pit or trench is not mechanically ventilated	Up to 18 in. (46 cm) above ground and within 20 ft (6 m) horizontally from any edge of the dispenser enclosure, including pits or trenches within this area when provided with adequate mechanical ventilation

[**30A:** Table 12.6.2]

42.9 Marine Fueling

42.9.1 Scope.

42.9.1.1 Section 42.9 shall apply to that portion of a property where liquids used as fuels are stored, handled, and dispensed from equipment located on shore or from equipment located on piers, wharves, or floating docks into the fuel tanks of marine craft, including incidental activity, except as covered elsewhere in NFPA 30A or in other NFPA standards. [**30A:**11.1.1]

Δ **42.9.1.2** Section 42.9 shall not apply to the following:

(1) Bulk plant or terminal loading and unloading facilities
(2) Transfer of liquids utilizing a flange-to-flange closed transfer piping system
(3) Marine motor fuel dispensing facilities where liquids used as fuels are stored and dispensed into the fuel tanks of marine craft of 300 gross tons (272 metric tons) or more

[**30A:**11.1.2]

Bulk loading and unloading of flammable and combustible liquid cargoes are covered by Chapter 28 of NFPA 30. Refueling of marine vessels of 300 gross tons (272 metric tons) or more is under the jurisdiction of the U.S. Coast Guard.

42.9.1.3 For the purpose of Section 42.9, the word *pier* shall also mean dock, floating dock, and wharf. [**30A:**11.1.3]

42.9.1.4 Permits. all comply with Section 1.12.

42.9.2 Storage.

42.9.2.1 Liquids shall be stored in tanks or containers complying with 42.3.3. [**30A:**11.2.1]

42.9.2.2* Tanks that supply marine motor fuel dispensing facilities shall be located on shore or on a pier of the solid-fill type. Pumps that are not integral with the dispensing device shall also be located on shore or on a pier of the solid-fill type.

*Exception: Tanks shall be permitted with the approval of the AHJ to be located on a pier, provided the installation meets all applicable requirements of Chapters 4 and 5 of NFPA 30A and 21.6.2 of NFPA 30 and the quantity stored does not exceed 1100 gal (4164 L) aggregate capacity. [**30A:**11.2.2]*

A.42.9.2.2 Cases where the length of the supply line to dispensing devices would result in insufficient pressure for operational purposes or would increase the potential for leakage due to the increased number of fittings or exposure of the line can warrant location of the supply on the pier. [**30A:**A.11.2.2]

Marine fuel dispensing facilities must be located where the water depth is adequate to accommodate the vessels served. Suitable locations are often near steep or rocky shores where excavation to completely bury a tank is difficult. Regardless, a tank should be located above the high water level to avoid accumulation of water in the excavation, possible corrosion, and leakage and to prevent possible dislocation or movement of the tank during a flood event.

42.9.2.3 Where a tank is at an elevation that produces a gravity head on the dispensing device, the tank outlet shall be equipped with a device, such as a normally closed solenoid valve, that will prevent gravity flow from the tank to the dispenser. This device shall be located adjacent to and downstream of the outlet valve specified by 66.22.13.1. The device shall be installed and adjusted so that liquid cannot flow by gravity from the tank to the dispenser if the piping or hose fails when the dispenser is not in use. [**30A:**11.2.3]

42.9.3 Piping Systems.

42.9.3.1 Piping shall be installed in accordance with all applicable requirements of Chapter 5 of NFPA 30A. [**30A:**11.3.1]

42.9.3.2 Piping systems shall be supported and protected against physical damage and stresses arising from impact, settlement, vibration, expansion, contraction, and tidal action. [**30A:**11.3.2]

42.9.3.3 Means shall be provided to ensure flexibility of the piping system in the event of motion of the pier. Flexible piping shall be of a type designed to withstand the forces and pressures exerted upon the piping. [**30A:**11.3.3]

42.9.3.4 Where dispensing is from a floating structure or pier, approved oil-resistant flexible hose shall be permitted to be used between shore piping and the piping on a floating structure or pier and between separate sections of the floating structure to accommodate changes in water level or shoreline, provided that the hose is either resistant to or shielded from damage by fire. [**30A:**11.3.4]

Paragraphs 42.9.3.3 and 42.9.3.4 allow the use of flexible piping and flexible hose in certain applications as follows:

1. Where the fuel piping crosses from one section of floating pier to the next to accommodate the motion of the sections relative to each other due to tide and wave action
2. Where the fuel piping crosses from land to a floating pier

Subsection 11.3.4 of NFPA 30A cites some of the factors that must be considered in the design of piping for marine application and allows flexible hose to be used where piping transits from one section of floating pier to another, as explained therein. It does not, however, mean that flexible hose can be used for the entire run from shore to dispenser. It also does not allow secondary containment-type flexible underground piping to be substituted for flexible hose and piping. Such piping is not designed for exposure to the elements and is not approved for such use.

42.9.3.5 A valve to shut off the liquid supply from shore shall be provided in each pipeline at or near the approach to the pier and at the shore end of each marine pipeline adjacent to the point where each flexible hose is attached. [**30A:**11.3.5]

Additional control valves can be located on the pier and elsewhere in the pipeline; however, the primary shutoff valve must be located on shore, where it is immediately accessible in case of an emergency without putting anyone at risk.

42.9.4 Fuel Dispensing System.

42.9.4.1 All hose shall be listed. Where hose length exceeds 18 ft (5.5 m), the hose shall be secured so as to protect it from damage. [**30A:**11.4.1]

42.9.4.2 Dispensing nozzles shall be of the automatic-closing type without a latch-open device. [**30A:**11.4.2]

If the marine craft has its own internal permanently mounted fuel tanks (as opposed to portable tanks), the fuel filler port is typically located on the gunwale and is typically larger than that on a motor vehicle; consequently, the fit of the nozzle spout into the fill port is looser. That being the case, the back pressure from the fill tube is not always great enough to trigger the automatic closing feature when the tank is near full, which could result in an overfill. An overfill can lead to spilled fuel draining to the bilge or the interior cabin of the boat, which is a much more hazardous condition than a similar spill on the ground, since vapors are more confined, dispersal takes a longer period of time, and mechanical ventilation is required. Control of sources of ignition is also more difficult. Therefore, latch-open devices are prohibited to ensure that the person refueling the vessel does not move away from the boat and pays attention to the task at hand.

42.9.4.3 Dispensing devices shall be permitted to be located on open piers, on shore, or on piers of the solid-fill type and shall be located apart from other structures so as to provide room for safe ingress to and egress from marine craft. [**30A:**11.4.3]

42.9.4.4 Dispensing devices shall be located so that exposure to all other operational marina or pleasure boat berthing area facilities is minimized. Where tide and weather conditions permit, liquid fuel handling shall be outside the main berthing areas. Where located inside marina or pleasure craft berthing areas, fueling facilities shall be located so that, in case of fire aboard a marine craft alongside, the danger to other craft near the facility is minimized. [**30A:**11.4.4]

Refueling facilities are preferably located separately from berthing areas, but this is not always possible, due to the exposure to rough water conditions caused by inclement weather. Therefore, where refueling operations must be located within the berthing area, care must be taken to limit exposure to other vessels should a fire occur.

Evacuation of vessels from their berths cannot always be immediately accomplished, due to the need to purge the engine compartment and bilge prior to starting the engines and the time necessary to untie from the dock. For the same reasons, vessels are prohibited from being berthed at the refueling location unless they are being refueled, and then only for the time necessary to refuel.

42.9.4.5 No vessel or marine craft shall be made fast to any other vessel or marine craft occupying a berth at a fuel dispensing location during fueling operations. [**30A:**11.4.5]

42.9.4.6 A marine motor fuel dispensing facility located at a bulk plant shall be separated by a fence or other approved barrier from areas in which bulk plant operations are conducted. Dispensing devices shall not be supplied by aboveground tanks located in the bulk plant. Marine motor fuel dispensing facility storage tanks shall not be connected by piping to aboveground tanks located in the bulk plant. [**30A:**11.4.6]

42.9.4.7 Each marine motor fuel dispensing facility shall have an attendant or supervisor on duty whenever the facility is open for business. The attendant's primary function shall be to supervise, observe, and control the dispensing of liquids. [**30A:**11.4.7]

42.9.5 Sources of Ignition.

42.9.5.1 All electrical components for dispensing liquids shall be installed in accordance with Chapter 8 of NFPA 30A. [**30A:**11.5.1]

42.9.5.2 All electrical equipment shall be installed and used in accordance with the requirements of Section 11.1 as it applies to wet, damp, and hazardous locations. [**30A:**11.5.2]

42.9.5.3 Clearly identified emergency electrical disconnects that are readily accessible in case of fire or physical damage at any dispensing unit shall be provided on each marine wharf. The disconnects shall be interlocked to shut off power to all pump motors from any individual location and shall be manually reset only from a master switch. Each such disconnect shall be identified by an approved sign stating EMERGENCY PUMP SHUTOFF in 2 in. (50 mm) red capital letters. [**30A:**11.5.3]

Because travel distance to emergency electrical disconnects would likely be longer than for similar situations at a vehicle refueling facility, the requirements in 42.9.5.3 are somewhat more detailed.

42.9.5.4 All electrical wiring for power and lighting shall be installed on the side of the wharf opposite from the liquid piping system. [**30A:**11.5.4]

42.9.5.5 Smoking materials, including matches and lighters, shall not be used within 20 ft (6 m) of areas used for fueling, servicing fuel systems for internal combustion engines, or receiving or dispensing of Class I liquids. Conspicuous NO SMOKING signs shall be posted within sight of the customer being served. [**30A:**11.5.5]

42.9.5.6 The motors of all equipment being fueled shall be shut off during the fueling operation, except for emergency generators, pumps, and so forth, where continuing operation is essential. [**30A:**11.5.6]

42.9.6 Electrical Installations.

42.9.6.1 Where excessive stray currents are encountered, piping handling Class I and Class II liquids shall be electrically isolated from the shore piping. [**30A:**8.5.1]

Isolation of marine service station piping is necessary because shore-based stray currents can be transmitted through a conductive hose to the tank fill opening, which is often grounded to the vessel hull, making sparks at the fill opening possible. This requirement prevents stray currents originating in the vessel's electrical system from causing an electrical arc or spark.

42.9.6.2* Pipelines on piers shall be bonded and grounded. Bonding and grounding connections on all pipelines shall be located on the pier side of hose riser insulating flanges, if used, and shall be accessible for inspection. [**30A:**8.5.2]

A.42.9.6.2 NFPA 77 contains information on this subject. [**30A:**A.8.5.2]

42.9.6.3 The fuel delivery nozzle shall be put into contact with the vessel fill pipe before the flow of fuel commences, and this bonding contact shall be continuously maintained until fuel flow has stopped, to avoid the possibility of electrostatic discharge. [**30A:**8.5.3]

42.9.6.4* Bonding and Grounding.

A.42.9.6.4 Where excessive stray currents are encountered, piping handling Class I and Class II liquids should be electrically isolated from the shore piping. This requirement prevents stray currents originating in the vessel's electrical system from causing an electrical arc or spark. [**30A:**A.11.6]

42.9.6.4.1* Pipelines on piers shall be bonded and grounded. Bonding and grounding connections on all pipelines shall be located on the pier side of hose riser insulating flanges, if used, and shall be accessible for inspection. [**30A:**11.6.1]

A.42.9.6.4.1 NFPA 77 contains information on this subject. [**30A:**A.11.6.1]

Insulating flanges are required to prevent shoreside stray currents from reaching the vessel, where they might cause a spark.

42.9.6.4.2 The fuel delivery nozzle shall be put into contact with the vessel fill pipe before the flow of fuel commences and this bonding contact shall be continuously maintained until fuel flow has stopped to avoid possibility of electrostatic discharge. [**30A:**11.6.2]

This requirement eliminates a possible electrostatic discharge that might cause ignition of vapors in the fuel filler tube by ensuring that the nozzle and the fill pipe are at the same potential.

42.9.7 Fire Control.

42.9.7.1 Each marine motor fuel dispensing facility shall be provided with fire extinguishers installed, inspected, and maintained as required by Section 13.6. Extinguishers for marine motor fuel dispensing areas shall be provided according to the extra (high) hazard requirements for Class B hazards, except that the maximum travel distance to an 80 B:C extinguisher shall be permitted to be 100 ft (31 m). [**30A:**11.7.1]

42.9.7.2 Piers that extend more than 500 ft (152 m) in travel distance from shore shall be provided with a Class III standpipe that is installed in accordance with Section 13.2. [**30A:**11.7.2]

A Class III standpipe provides both 1 in. and 2 in. (25 mm and 50 mm) hose connections for use by marina personnel and the fire department. See NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, for additional information.

42.9.7.3 Materials shall not be placed on a pier in such a manner that they obstruct access to fire-fighting equipment or important piping system control valves. Where the pier is accessible to vehicular traffic, an unobstructed roadway to the shore end of the wharf shall be maintained for access by fire-fighting apparatus. [**30A:**11.7.3]

42.9.8 Containers and Movable Tanks.

42.9.8.1 The temporary use of movable tanks in conjunction with the dispensing of liquids into the fuel tanks of marine craft on premises not normally accessible to the public shall be permitted. Such installations shall only be made with the approval of the AHJ. [**30A:**11.8.1]

Paragraph 42.9.8.1 allows fueling of vehicles by temporary use of a tank that can be moved from site to site. Such practices might be allowed at shoreside construction or earth-moving sites or dredging operations, for example.

42.9.8.2* Class I or Class II liquids shall not be dispensed into a portable container unless the container is constructed of metal or is approved by the AHJ, has a tight closure, and is fitted with a spout or is so designed that the contents can be dispensed without spilling. [**30A:**11.8.2]

A.42.9.8.2 See Section 9.4 of NFPA 30 for further information. [**30A:**A.11.8.2]

• **42.9.8.3** Portable containers of 12 gal (45 L) capacity or less shall not be filled while they are in or on a marine craft. [**30A:**11.8.3]

42.9.9 Cargo Tank Fueling Facilities. The provisions of 42.9.2 shall not prohibit the dispensing of Class II liquids in the open from a tank vehicle to a marine craft located at commercial, industrial, governmental, or manufacturing establishments when the liquid is intended for fueling marine craft used in connection with those establishments' businesses if the requirements of 42.9.9.1 through 42.9.9.7 are met. [**30A:**11.9]

As stated previously, in some areas, refueling larger vessels from a tank vehicle is common practice. However, 42.9.9 limits this practice to situations where the refueling site is not accessible to the general public and access is controlled. Refueling from a tank vehicle at a public marina, for example, is prohibited by this requirement.

42.9.9.1 An inspection of the premises and operations shall be made and approval granted by the AHJ. [**30A:**11.9.1]

42.9.9.2 The tank vehicle shall comply with the requirements of NFPA 385. [**30A:**11.9.2]

42.9.9.3 The dispensing hose shall not exceed 50 ft (15 m) in length. [**30A:**11.9.3]

42.9.9.4 The dispensing nozzle shall be a listed, automatic-closing type without a latch-open device. [**30A:**11.9.4]

42.9.9.5 Nighttime deliveries shall only be made in areas deemed adequately lighted by the AHJ. [**30A:**11.9.5]

42.9.9.6 The tank vehicle flasher lights shall be in operation while dispensing. [**30A:**11.9.6]

42.9.9.7 Fuel expansion space shall be left in each fuel tank to prevent overflow in the event of temperature increase. [**30A:**11.9.7]

42.9.10 Operating Requirements.

Δ **42.9.10.1** The following shall be the responsibilities of the attendant:

(1) Prevent the dispensing of Class I liquids into portable containers that do not comply with 42.9.8.2
(2) Be familiar with the dispensing system and emergency shutoff controls
(3) Ensure that the vessel is properly moored and that all connections are made
(4) Be within 15 ft (4.6 m) of the dispensing controls during the fueling operation and maintain a direct, clear, unobstructed view of both the vessel fuel filler neck and the emergency fuel shutoff control

[**30A:**11.10.1]

This provision establishes the basic responsibilities of the attendant. Note that 42.9.10.1(4) requires that the attendant be in a position to oversee the refueling operation and be within close proximity of the dispensing controls, even if he or she is not personally conducting the refueling.

42.9.10.2 Fueling shall not be undertaken at night except under well-lighted conditions. [**30A:**11.10.2]

42.9.10.3 During fueling operations, smoking shall be forbidden on board the vessel or marine craft and in the dispensing area. [**30A:**11.10.3]

Δ **42.9.10.4** Before opening the tanks of the vessel to be fueled, the following precautions shall be taken:

(1) All engines, motors, fans, and bilge blowers shall be shut down.
(2) All open flames and smoking material shall be extinguished and all exposed heating elements shall be turned off.
(3) Galley stoves shall be extinguished.
(4) All ports, windows, doors, and hatches shall be closed.

[**30A:**11.10.4]

Δ **42.9.10.5** After the flow of fuel has stopped, the following shall occur:

(1) The fill cap shall be tightly secured.
(2) Any spillage shall be wiped up immediately.
(3) If Class I liquid has been delivered, the entire vessel or marine craft shall remain open.

(4) Bilge blowers shall be turned on and allowed to run for at least 5 minutes before starting any engines or lighting galley fires. If bilge blowers are not available, 10 minutes of ventilation shall be required.

[**30A:**11.10.5]

42.9.10.6 No Class I liquids shall be delivered to any vessel having its tanks located below deck unless each tank is equipped with a separate fill pipe, the receiving end of which shall be securely connected to a deck plate and fitted with a screw cap. Such pipe shall extend into the tank. Vessels receiving Class II or Class IIIA liquids shall have the receiving end of the fill pipe securely connected to a deck plate and fitted with a screw cap. Such pipe shall be permitted to connect to a manifold system that extends into each separate tank. Each tank shall be provided with a suitable vent pipe that shall extend from the tank to the outside of the coaming or enclosed rails so that the vapors will dissipate away from the vessel. [**30A:**11.10.6]

Δ **42.9.10.7** Owners or operators shall not offer their vessel or marine craft for fueling unless the following conditions exist:

(1) The tanks being filled are properly vented to dissipate vapors to the outside atmosphere, and the fuel systems are liquidtight and vaportight with respect to all interiors.
(2) All fuel systems are designed, installed, and maintained in compliance with the specifications of the manufacturer of the vessel or marine craft.
(3) Communication has been established between the fueling attendant and the person in control of the vessel or craft receiving the fuel so as to determine the vessel's fuel capacity, the amount of fuel on board, and the amount of fuel to be taken on board.
(4) The electrical bonding and grounding systems of the vessel or craft have been maintained in accordance with the manufacturer's specifications.

[**30A:**11.10.7]

42.9.10.8 A sign with the following legends printed in 2 in. (50 mm) red capital letters on a white background shall be conspicuously posted at the dispensing area:

Before Fueling:

(1) Stop all engines and auxiliaries.

(2) Shut off all electricity, open flames, and heat sources.

(3) Check all bilges for fuel vapors.

(4) Extinguish all smoking materials.

(5) Close access fittings and openings that could allow fuel vapors to enter enclosed spaces of the vessel.

During Fueling:

(1) Maintain nozzle contact with fill pipe.

(2) Wipe up spills immediately.

(3) Avoid overfilling.

(4) Fuel filling nozzle must be attended at all times.

After Fueling:

(1) Inspect bilges for leakage and fuel odors.

(2) Ventilate until odors are removed.

[**30A:**11.10.8]

42.10 Aircraft Fuel Servicing

NFPA 407, *Standard for Aircraft Fuel Servicing*, applies to the fuel servicing of all types of aircraft using liquid petroleum fuel. The standard does not apply to any of the following:

1. In-flight fueling
2. Fuel servicing of flying boats or amphibious aircraft on water
3. Draining or filling of aircraft fuel tanks incidental to aircraft fuel system maintenance operations or manufacturing

Fire prevention provisions for aircraft fuel servicing are directed principally toward the prevention of fuel spillage and the elimination or control of potential ignition sources.

Δ **42.10.1 Application.** Section 42.10 applies to the fuel servicing of all types of aircraft using liquid petroleum fuel in accordance with NFPA 407.

NFPA 407 is not intended to be used as the sole standard for design, construction, operation, and maintenance of aircraft fuel storage and transfer facilities, because it does not address requirements for environmental protection, fuel quality, or other issues not directly related to fire safety. Additional guidance can be obtained from other documents, including, but not limited to, the following: A4A Spec 103, *Standard for Jet Fuel Quality Control at Airports*; ASTM MNL5, *Aviation Fuel Quality Control* Procedures; API 607, *Fire Test for Quarter-turn Valves and Valves Equipped with Nonmetallic Seats*; API RP 1595, *Design, Construction, Operation, Maintenance, and Inspection of Aviation Pre-Airfield Storage Terminals*; API RP 2003, *Protection Against Ignitions Arising out of Static, Lightning, and Stray Currents*; EI 1529, *Aviation fueling hose and hose assemblies*; EI 1540, *Design, construction, commissioning, maintenance and testing of aviation fuelling facilities*; EI 1550, *Handbook on equipment used for the maintenance and delivery of clean aviation fuel*; EI 1581, *Specifications and laboratory qualification procedures for aviation fuel filter/water separators*; EI 1583, *Laboratory tests and minimum performance levels for aviation fuel filter monitors*; EI 1590, *Specifications and qualification procedures for aviation fuel microfilters*; EI 1596, *Design and construction of aviation fuel filter vessels*; JIG 4, *Aviation Fuel Quality Control and Operating Standards for Smaller Airports*; *NATA Refueling and Quality Control Procedures for Airport Service and Support Operations*; NIST Handbook 44; PEI RP100, *Recommended Practices for Installation of Underground Liquid Storage Systems*; PEI RP200, *Recommended Practices for Installation of Aboveground Storage Systems for Motor Vehicle Fueling*; PEI RP800, *Recommended Practices for Installation* *of Bulk Storage Plants*; PEI RP-1300, *Recommended Practices for the Design, Installation, Service, Repair and Maintenance of Aviation Fueling Systems*; FAA AC-150-5230, *Aircraft Fuel Storage, Handling, Training, and Dispensing on Airports*; OSHA regulations in 29 CFR 1910; and/or EPA regulations in 40 CFR 112 (Oil Pollution Prevention) and 40 CFR 280 (Underground Tanks).

Aircraft fuel servicing involves the transfer of a flammable or combustible liquid fuel between a bulk storage system and the fuel tanks of an aircraft. It includes both fueling and defueling. The transfer is usually accomplished by using a tank vehicle, a hydrant vehicle, a hydrant cart, a fuel servicing cabinet, or a fueling pit. Drums and pumps sometimes are used. The movement of the fuel through the pumps, piping, and filters of the transfer system causes the fuel to be charged electrostatically. If the charge on the fuel is sufficiently high when it arrives at the fuel tank, a static spark could occur that can ignite the fuel vapor.

During overwing fueling, the fuel is discharged into an opening in the aircraft fuel tank using a hose with a handheld nozzle. The flow and splashing of fuel causes the generation of static electricity and the production of flammable mists and vapors. Top loading of tank vehicles creates similar hazards.

Underwing servicing, hydrant servicing, and bottom loading of tank vehicles use hoses or flexible connections of metal tubing or piping, as well as devices to allow temporary connection of fuel transfer lines. These methods minimize the charge generation and misting hazards associated with overwing fueling and top loading.

Other potential sources of ignition that could present a hazard during aircraft fuel servicing include the following:

1. Operating aircraft engines, auxiliary power units, and heaters
2. Operating automotive or other internal combustion engine servicing equipment in the vicinity
3. Arcing of electrical circuits
4. Open flames
5. Energy from energized radar equipment
6. Lightning

The autoignition temperatures of turbine fuels are such that the residual heat of aircraft turbine engines after shutdown or the residual heat of turbine aircraft brakes following hard use can ignite such fuels if they are spilled or sprayed on those surfaces before they have cooled below the autoignition temperatures of the fuels.

Aircraft fuel tank vents usually are located some distance above ground level. Under normal conditions, fuel vapors from the vents are quickly dissipated and diluted safely. Fuel spilling from the vents of an overfilled tank is a much more serious hazard. Spills resulting from leaks or equipment failure also are a hazard.

Fire prevention measures in aircraft fuel servicing are directed principally toward the following:

1. Prevention of fuel spillage
2. Elimination or control of potential ignition sources

The purpose of NFPA 407 is to establish reasonable minimum fire safety requirements for procedures, equipment, and installations for the protection of persons, aircraft, and other property during ground fuel servicing of aircraft using liquid petroleum fuels. These requirements are based upon sound engineering principles, test data, and field experience.

The fire hazard properties of aviation fuels vary; however, the same fire safety precautions are specified for all fuel types.

The provisions of NFPA 407 reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in the standard at the time it was issued. Unless otherwise specified, the design and installation provisions of NFPA 407 are not intended to apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Unless otherwise specified, operations and maintenance activities must meet the current standard. The retroactive requirements of NFPA 407 are permitted to be modified if their application clearly would be impractical in the judgment of the AHJ and only where it is clearly evident that a reasonable degree of safety is provided. In those cases where the AHJ determines that the existing situation presents an unacceptable degree of risk, the AHJ is permitted to apply retroactively any portions of NFPA 407 deemed appropriate.

Δ **42.10.1.1** Section 42.10 does not apply to any of the following:

(1) In-flight fueling
(2) Fuel servicing of flying boats or amphibious aircraft on water

NFPA 30A covers the fuel servicing of flying boats or amphibious aircraft on water.

(3) Draining or filling of aircraft fuel tanks incidental to aircraft fuel system maintenance operations or manufacturing

[**407:**1.1.1]

NFPA 410, *Standard on Aircraft Maintenance*, covers the draining or filling of aircraft fuel tanks incidental to aircraft fuel system maintenance.

42.10.1.2 Permits. Permits, where required, shall comply with Section 1.12.

• *N* **42.10.2 General Requirements.**

N **42.10.2.1 Design and Construction.**

N **42.10.2.1.1 General Requirements.**

N **42.10.2.1.1.1** The requirements of 42.10.2 shall apply to all aviation fueling facilities, aircraft fueling vehicles, rooftop heliport fueling facilities, and self-service aviation fueling facilities. [**407:**4.1.1.1]

N **42.10.2.1.1.2** Aviation fueling facilities shall also comply with the requirements of 42.10.3. [**407:**4.1.1.2]

N **42.10.2.1.1.3** Aircraft fueling vehicles and carts shall also comply with the requirements of 42.10.4. [**407:**4.1.1.3]

N **42.10.2.1.1.4** Rooftop heliport fueling facilities shall also comply with the requirements of 42.10.3 and 42.10.5. [**407:**4.1.1.4]

N **42.10.2.1.1.5** Self-service aviation fueling facilities shall also comply with the requirements of 42.10.3 and 42.10.6. [**407:**4.1.1.5]

For the 2017 edition, NFPA 407 was completely restructured to improve the usability of the standard. Requirements that apply universally to all equipment, facilities, and operations within the scope of NFPA 407 are now contained in Chapter 4 of that standard (42.10.2 in this *Code*). Chapter 5 (42.10.3) contains the requirements that apply to all fixed fueling facilities, including airport fueling systems, rooftop heliport fueling systems, and self-service aviation fueling systems. Any additional requirements that apply only to rooftop heliport fueling systems or self-service aviation fueling systems are now contained in Chapter 7 (42.10.5) and Chapter 8 (42.10.6), respectively. Requirements pertaining to aircraft fueling vehicles are contained in Chapter 6 (42.10.4).

Chapters 4 through 8 of NFPA 407 are each split into two sections: "Design and Construction" and "Operations." The sections use a common subsection structure to simplify navigation of the requirements. This structure as it pertains to this *Code* is illustrated in Commentary Table 42.1.

For example, fire extinguishers at a self-service aviation fueling station must comply with 42.10.2.1.10 (general requirements for fire extinguishers), 42.10.3.1.10 (requirements for fire extinguishers at fixed fueling facilities), and 42.10.6.1.10 (requirements for fire extinguishers at self-service aviation fueling facilities).

Subsections with no requirements are reserved in order to maintain the document structure. One example is 42.10.2.1.2 because there are no requirements that pertain to both fixed storage tanks and tanks on vehicles.

N **42.10.2.1.2 Fuel Storage Tanks. (Reserved)**

N **42.10.2.1.3 Fuel Dispensing Systems.**

N **42.10.2.1.3.1** Any valve that controls the flow of fuel into or from an aircraft fuel servicing vehicle or cart, or into or from an aircraft shall have a deadman control(s). [**407:**4.1.3.1]

NFPA 407 defines a *deadman control* as a device that requires a positive continuing action of a person to allow the flow of fuel.

N **42.10.2.1.3.2** The deadman flow control in the nozzle shall be permitted for overwing fueling. [**407:**4.1.3.2]

COMMENTARY TABLE 42.1 *Topical Structure of Requirements Pertaining to Aircraft Fuel Servicing in 42.10.2 through 42.10.6.*

Section/Subsection Number	*Section/Subsection Topic*
42.10.X.1	**DESIGN AND CONSTRUCTION**
42.10.X.1.1	General Requirements
42.10.X.1.2	Fuel Storage Tanks/Tanks on Vehicles
42.10.X.1.3	Fuel Dispensing Systems/Pumps and Piping Systems
42.10.X.1.4	Fueling Hose and Nozzles
42.10.X.1.5	Electrostatic Hazards and Bonding
42.10.X.1.6	Electrical Systems
42.10.X.1.7	Control of Fuel Flow
42.10.X.1.8	Filters and Ancillary Equipment
42.10.X.1.9	Emergency Fuel Shutoff Systems
42.10.X.1.10	Fire Extinguishers/Fire Protection
42.10.X.1.11	Marking and Labeling
42.10.X.1.12 and greater	[Miscellaneous topics]
42.10.X.2	**OPERATIONS**
42.10.X.2.1	Security
42.10.X.2.2	Training
42.10.X.2.3	Prevention and Control of Spills
42.10.X.2.4	Emergency Fuel Shutoff
42.10.X.2.5	Bonding
42.10.X.2.6	Control and Monitoring of Fuel Flow
42.10.X.2.7	Fire Protection
42.10.X.2.8	Maintenance
42.10.X.2.9	Aircraft Fueling Hose/Occupancy (Chapter 8 only)
42.10.X.2.10 and greater	[Miscellaneous topics]

N **42.10.2.1.3.3** Notches or latches in the handle of an overwing nozzle that could allow the valve to be locked open shall be prohibited. [**407:**4.1.3.3]

N **42.10.2.1.3.4** Nozzles for underwing fueling shall be designed to be attached securely to the aircraft adapter before the nozzle can be opened. [**407:**4.1.3.4]

N **42.10.2.1.3.5** Disengaging the nozzle from the aircraft adapter shall not be possible until the nozzle is fully closed. [**407:**4.1.3.5]

N **42.10.2.1.3.6** Fuel servicing pump mechanisms shall be designed and arranged so that failure or seizure does not cause rupture of the pump housing, of a tank, or of any component containing fuel. [**407:**4.1.3.6]

N **42.10.2.1.3.7** Fuel pressure shall be controlled within the stress limits of the hose and plumbing by means of either an in-line pressure controller or, a system pressure relief valve, or other suitable means. [**407:**4.1.3.7]

N **42.10.2.1.3.8** The working pressure of any system component shall equal or exceed any pressure to which it could be subjected. [**407:**4.1.3.8]

N **42.10.2.1.4* Fueling Hose.**

N **A.42.10.2.1.4** The section on aircraft refueling hose has been altered extensively by referencing EI 1529. NFPA 407 formerly contained many requirements for hose, but these were intended to address only those features that could be related to a fire or the results of a fire. It was not until 1982 that a comprehensive aircraft refueling hose specification was published by the American Petroleum Institute (API). Prior to that time, NFPA 407 was the only document in existence that addressed this subject. In 2010, the API transferred responsibility for aviation fuel-handling standards to the Energy Institute (EI). [**407:**A.4.1.4]

EI 1529 deals with all aspects of hose safety, including the couplings that are acceptable. [**407:**A.4.1.4]

NFPA 407 recognizes the need for an extensive document such as EI 1529 and requires hoses that meet that standard. However, it is important to recognize that EI does not perform testing and that it does not regulate those manufacturers who claim to sell hose that meets EI 1529. The hose user and the cognizant authority having jurisdiction could find it prudent to require hose manufacturers to produce copies of test reports or documents that certify that hoses of identical construction and compounds have been tested and have passed all requirements of EI 1529 satisfactorily. [**407:**A.4.1.4]

N **42.10.2.1.4.1 Performance Requirements.** Hose and couplings shall comply with the requirements of EI 1529. [**407:**4.1.4.1]

N **42.10.2.1.4.2 Fueling Hose Apparatus.** Nozzle receptacles and hose storage shall be arranged to avoid kinks and maintain the hose bend radius within the requirements of EI 1529 and EI 1540. [**407:**4.1.4.2]

N **42.10.2.1.4.3 Additional Requirements.**

N **42.10.2.1.4.3.1** Each coupled length of hose shall be tested at the same minimum proof pressure rating for that grade of hose as defined in EI 1529. [**407:**4.1.4.3.1]

N **42.10.2.1.4.3.2** A test certificate shall be provided for each coupled length of hose and shall state the following:

(1) Manufacturer's name of hose
(2) Manufacturer's name of couplings
(3) Hose type
(4) Hose grade
(5) Size and length of hose
(6) Serial number or reference number of hose
(7) Quarter and year of manufacture of hose
(8) Model number of couplings
(9) Sizes of coupling ferrules
(10) Hydrostatic test pressures
(11) Coupled length serial number
(12) Identification of individual responsible for coupling the hose
(13) Name and address of company responsible for coupling the hose
(14) Date of certification

[**407:**4.1.4.3.2]

N **42.10.2.1.4.3.3** The coupling tests as specified in EI 1529 shall be performed for each hose grade, type, and manufacturer. [**407:**4.1.4.3.3]

N **42.10.2.1.4.3.4** Each coupling of a coupled length of hose shall be permanently marked with a serial number corresponding to its hydrostatic test certificate. [**407:**4.1.4.3.4]

N **42.10.2.1.4.3.5** The hose at the end of each coupling ferrule shall be permanently marked prior to hydrostatic testing to serve as a reference to determine whether a coupling has slipped during testing or while in service. [**407:**4.1.4.3.5]

N **42.10.2.1.4.3.6*** Lengths of hose shall not be spliced together. [**407:**4.1.4.3.6]

A.42.10.2.1.4.3.6 Splicing of a hose with couplings alters the design bend radius of the hose, creating two kinks when the hose is wound on a drum. [**407:**A.4.1.4.3.6]

N **42.10.2.1.4.3.7 Hydrostatic Testing.** Hydrostatic testing shall be in accordance with ASTM D380. [**407:**4.1.4.3.7]

N **42.10.2.1.4.3.7.1** Following a hydrostatic test, all the water shall be drained and the hose shall be dried internally. [**407:**4.1.4.3.7.1]

N **42.10.2.1.4.3.7.2** Following a hydrostatic test, the open ends of the hose, including the threads of the couplings, shall be suitably covered to protect the threads and to prevent contamination. [**407:**4.1.4.3.7.2]

N **42.10.2.1.4.3.7.3** A hose that is recoupled for any reason shall be hydrostatically tested and recertified to the same criteria as a newly coupled hose. [**407:**4.1.4.3.7.3]

N **42.10.2.1.4.3.8** Hose shall be connected to rigid piping or coupled to a hose reel in a manner that prevents kinks or undue bending action or mechanical stress on the hose or hose couplings. [**407:**4.1.4.3.8]

N **42.10.2.1.5 Electrostatic Hazards and Bonding.**

N **42.10.2.1.5.1** A provision for bonding shall be incorporated in the design of fuel servicing vehicles or carts and airport fueling systems to prevent differences in electrostatic potential. [**407:**4.1.5.1]

N **42.10.2.1.5.2** The maximum resistance between the bonding cable clip and the fueling system framework shall not exceed 25 ohms. [**407:**4.1.5.2]

N **42.10.2.1.5.3** Bonding cables shall be constructed of conductive, durable, and flexible material. [**407:**4.1.5.3]

N **42.10.2.1.5.4** Bonding connections shall be electrically and mechanically firm. [**407:**4.1.5.4]

N **42.10.2.1.5.5** Jacks, plugs, clamps, and connecting points shall be clean, unpainted metal to provide a positive electrical connection. [**407:**4.1.5.5]

N **42.10.2.1.5.6** EI 1529 Type C hose (semiconductive) shall be used to prevent electrostatic discharges but shall not be used to accomplish required bonding. [**407:**4.1.5.6]

N **42.10.2.1.5.7** EI 1529 Type A hose that does not have a semiconductive cover shall not be used. [**407:**4.1.5.7]

N **42.10.2.1.5.8** EI 1529 Type F hose (hard wall) and EI 1529 Type CT hose (cold temperature) shall be permitted because they have semiconductive covers. [**407:**4.1.5.8]

N **42.10.2.1.5.9*** The design of airport fueling systems shall incorporate the provision of a 30-second relaxation period following the filter separator, monitors, or other filtration devices discharging into tanks. [**407:**4.1.5.9]

N **A.42.10.2.1.5.9** The charge on the fuel can be reduced by the use of a static dissipater additive that increases the electrical conductivity of the fuel and thereby allows the charge to relax or dissipate more quickly, or by the use of a relaxation chamber that increases the residence time of the fuel downstream of the filter to at least 30 seconds, thereby allowing most of the charge to dissipate before the fuel arrives at the receiving tank. [**407:**A.4.1.5.9]

API RP 2003 recommends a 30-second relaxation time for loading tank trucks and refuelers. However, it has not been a common practice to require a similar relaxation time for aircraft refueling, primarily because of the relatively few electrostatic incidents that have occurred during aircraft fueling. (For additional information on this topic, see CRC Report No. 583.) [**407:**A.4.1.5.9]

In filling tank trucks or storage tanks, API RP 2003 recommends that at least 30 seconds of residence time be provided downstream of a filter in order to allow static charges generated in flowing fuel to relax before fuel enters the tank. [**407:**A.4.1.5.9]

The reason it is possible to fuel aircraft safely with low conductivity fuel without providing 30 seconds of relaxation time is due primarily to the difference in the geometry of aircraft tanks as compared with tank truck compartments. Flow into the aircraft normally is subdivided into several tanks simultaneously and also distributed into adjoining compartments of each tank by a multi-hole inlet. Bachman and Dukek (1972) conducted full-scale research using a simulated large aircraft tank and concluded that none of the tanks or compartments hold sufficient fuel to allow enough charges to accumulate and create large surface voltages. Slower fill rates per compartment also allow more charge to relax. [**407:**A.4.1.5.9]

Additionally, the inlet system of most aircraft tanks directs fuel toward the bottom of the tank to avoid splashing that generates more charge. Finally, while the hoses that connect the fueler to the aircraft provide only a few seconds of residence time for charge relaxation at high rates of flow, the actual relaxation volume in the system is significantly greater where a coated screen is used as a second stage water barrier. In this case, the vessel's volume after the first stage filter coalescer could represent an additional 15 seconds of residence time for charge relaxation. (The coated screen, unlike other water barriers, does not generate charge.) [**407:**A.4.1.5.9]

A flammable vapor space in the tank due to the presence of JET B or JP-4 fuels still constitutes a potential hazard. Therefore, to minimize the chance for static ignition, FAA regulations require that fueling be conducted at half of the rated flow where civil aircraft have used such fuels. [**407:**A.4.1.5.9]

N **42.10.2.1.5.9.1** The relaxation period required by 42.10.2.1.5.9 shall not apply to the actual refueling of an aircraft. [**407:**4.1.5.9.1]

N **42.10.2.1.5.9.2** The relaxation period required by 42.10.2.1.5.9 shall not apply to fuels with static dissipater additives. [**407:**4.1.5.9.2]

N **42.10.2.1.6 Electrical Systems. (Reserved)**

N **42.10.2.1.7 Control of Fuel Flow. (Reserved)**

N **42.10.2.1.8 Filters and Ancillary Equipment.**

N **42.10.2.1.8.1** Filter vessels used in aviation fuel service shall have a functional automatic air vent (AAV) or automatic air eliminator (AAE). [**407:**4.1.8.1]

N **42.10.2.1.8.2** The AAV or AAE shall discharge to a closed system. [**407:**4.1.8.2]

N **42.10.2.1.9 Emergency Fuel Shutoff Systems. (Reserved)**

N **42.10.2.1.10 Fire Extinguishers.**

N **42.10.2.1.10.1** During fueling operations, fire extinguishers shall be available on aircraft servicing ramps or aprons, in accordance with NFPA 410. [**407:**4.1.10.1]

A.42.10.2.1.10.1 Carbon dioxide extinguishers should not be selected due to their limited range and effectiveness in windy conditions. [**407:**A.4.1.6.1]

N **42.10.2.1.10.2** All fire extinguishers shall conform to the requirements of NFPA 10. [**407:**4.1.10.2]

Distribution of portable fire extinguishers must be in accordance with Section 13.6 and NFPA 407.

N **42.10.2.1.10.3*** ABC multipurpose dry chemical fire extinguishers (ammonium phosphate) shall not be placed on aircraft fueling vehicles, airport fuel servicing ramps or aprons, or at airport fuel facilities that are located within 150 m (500 ft) of aircraft operating areas. [**407:**4.1.10.3]

• *N* **A.42.10.2.1.10.3** Multipurpose dry chemical (ammonium phosphate) fire extinguishing agent is known to cause corrosion to aluminum aircraft components. Although the agent is capable of extinguishing fires on or near aircraft, it is likely that the agent will spread to other, uninvolved aircraft, causing damage from corrosion. [**407:**A.42.10.2.1.7.3]

NFPA 407 is the only aviation-related NFPA standard that restricts the use of ABC multipurpose dry chemical fire extinguishers at airport facilities. NFPA 409, *Standard on Aircraft Hangars*; NFPA 410; NFPA 415, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*; and NFPA 418, *Standard for Heliports* permit the use of multipurpose dry chemical to protect the facilities and operations that are within their respective scopes. However, fire extinguishers used to protect aircraft fuel servicing facilities within 500 ft (150 m) of aircraft operating areas must be charged with BC-rated dry chemical, such as sodium bicarbonate or potassium carbonate (Purple K). This requirement is intended to apply to new installations only. In accordance with the new retroactivity clause in NFPA 407, it is the intent of the technical committee that existing multipurpose fire extinguishers that were approved for installation before this requirement was adopted can remain in service.

N **42.10.2.1.11 Marking and Labeling.**

N **42.10.2.1.11.1** Each emergency fuel shutoff station location shall be placarded EMERGENCY FUEL SHUTOFF in letters at least 50 mm (2 in.) high. [**407:**4.1.11.1]

N **42.10.2.1.11.2** The method of operation shall be indicated by an arrow or by the word PUSH or PULL, as appropriate. [**407:**4.1.11.2]

N **42.10.2.1.11.3** Any action necessary to gain access to the shutoff device (e.g., BREAK GLASS) shall be shown clearly. [**407:**4.1.11.3]

N **42.10.2.1.11.4** Lettering shall be of a color contrasting sharply with the placard background for visibility. [**407:**4.1.11.4]

N **42.10.2.1.11.5** Placards shall be weather resistant. [**407:**4.1.11.5]

N **42.10.2.1.12 Aircraft Fueling Ramps.**

N **42.10.2.1.12.1 Aircraft Radar Equipment.**

N **42.10.2.1.12.1.1** Surveillance radar equipment in aircraft shall not be operated within 90 m (300 ft) of any fueling, servicing, or other operation in which flammable liquids, vapors, or mist could be present. [**407:**4.1.12.1.1]

N **42.10.2.1.12.1.2** Weather-mapping radar equipment in aircraft shall not be operated while the aircraft in which it is mounted is undergoing fuel servicing. [**407:**4.1.12.1.2]

N **42.10.2.1.12.2* Ground Radar Equipment.**

N **A.42.10.2.1.12.2** The beam of radar equipment has been known to cause ignition of flammable vapor–air mixtures from inductive electric heating of solid materials or from electrical arcs or sparks from chance resonant conditions. The ability of an arc to ignite flammable vapor–air mixtures depends on the total energy of the arc and the time lapse involved in the arc's duration, which is related to the dissipation characteristics of the energy involved. The intensity or peak power output of the radar unit, therefore, is a key factor in establishing safe distances between the radar antenna and fueling operations, fuel storage or fuel loading rack areas, fuel tank truck operations, or any operations where flammable liquids and vapors could be present or created. [**407:**A.4.1.12.2]

Most commercially available weather-mapping airborne radar equipment operates at peak power outputs, varying from 25 kW to 90 kW. Normally this equipment should not be operated on the ground. Tests have shown that the beam of this equipment can induce energy capable of firing flash bulbs at considerable distances. If the equipment is operated on the ground for service checking or for any other reason, the beam should not be directed toward any of the hazards described in the previous paragraph that are located within 30 m (100 ft). Higher power radar equipment can require greater distances. [**407:**A.4.1.12.2]

Airport surface detection radar operates under a peak power output of 50 kW. It is fixed rather than airborne equipment. [**407:**A.4.1.12.2]

Airborne surveillance radar of the type currently carried on military aircraft has a high peak power output. Aircraft carrying this type of radar can be readily distinguished by radomes atop or below the fuselage, or both. [**407:**A.4.1.12.2]

Aircraft warning radar installations are the most powerful. Most of these installations are, however, remotely located from the hazards specified in the first paragraph and therefore are not covered herein. Ground radar for approach control or traffic pattern surveillance is considered the most fire hazardous type of radar normally operating at an airport. The latter type of equipment has a peak power output of 5 MW. Where possible, new installations of this type of equipment should be located at least 150 m (500 ft) from any of the hazards described in the first paragraph. [**407:**A.4.1.12.2]

N **42.10.2.1.12.2.1** Antennas of airport flight traffic surveillance radar equipment shall be located so that the beam will not be directed toward any fuel storage or loading racks within 90 m (300 ft). [**407:**4.1.12.2.1]

N **42.10.2.1.12.2.2** Aircraft fuel servicing shall not be conducted within the 90 m (300 ft) distance established by 42.10.2.1.12.2.1. [**407:**4.1.12.2.2]

N **42.10.2.1.12.2.3** Antennas of airport ground traffic surveillance radar equipment shall be located so that the beam will not be directed toward any fuel storage or loading racks within 30 m (100 ft). [**407:**4.1.12.2.3]

N **42.10.2.1.12.2.4** Aircraft fuel servicing or any other operations involving flammable liquids or vapors shall not be conducted within 30 m (100 ft) of antennas of airport ground traffic surveillance radar equipment. [**407:**4.1.12.2.4]

N **42.10.2.1.12.3 Emergency Fire Equipment Accessibility.** Accessibility to aircraft by emergency fire equipment shall be considered in establishing aircraft fuel servicing positions. [**407:**4.1.12.3]

N **42.10.2.1.12.4 Ramp and Apron Drainage.** Aircraft servicing ramps or aprons shall be sloped and drained in accordance with NFPA 415. [**407:**4.1.12.4]

N **42.10.2.1.12.4.1** The ramp or apron shall slope away from the rim or edge of fueling hydrants or fueling pits to prevent flooding. [**407:**4.1.12.4.1]

N **42.10.2.1.12.4.2** Fueling hydrant boxes or fueling pits that are connected to a ramp drainage system shall be fitted with vaporsealing traps. [**407:**4.1.12.4.2]

N **42.10.2.2 Operations.**

N **42.10.2.2.1 Security. (Reserved)**

N **42.10.2.2.2 Training.**

N **42.10.2.2.2.1*** Only personnel trained in the safe operation of the equipment and the fuels they use, the operation of emergency controls, and the procedures to be followed in an emergency shall be permitted to handle fuel. [**407:**4.2.2.1]

N **A.42.10.2.2.2.1** Records should be kept of personnel training. These records should be made available to the authority having jurisdiction upon request. [**407:**A.4.2.2.1]

N **42.10.2.2.2.2*** Fuel servicing personnel shall be trained in the use of the available fire-extinguishing equipment they could be expected to use. [**407:**4.2.2.2]

N **A.42.10.2.2.2.2** Fuel servicing personnel should be given adequate training with extinguishers so that such equipment is used effectively in an emergency. Such training should be given on fires of the type that could be encountered on the job. To ensure prompt action in the event of a spill or other hazardous condition developing during fueling operations, aircraft servicing personnel also should be trained in the operation of emergency fuel shutoff controls. Each new fuel servicing employee should be given indoctrination training covering these and similar safety essentials that are related to the job. Follow-up and advanced training should be given as soon as the employee is sufficiently acquainted with the work to benefit from such training. Supervisors should be given training in the more technical aspects of fire safety so that they understand the reason for these and similar requirements and have an appreciation for the responsibility of a supervisor and the safety of an operation. [**407:**A.4.2.2.2]

N **42.10.2.2.3* Prevention and Control of Spills.**

N **A.42.10.2.2.3** The following actions are appropriate in the event of a fuel spill, although each spill should be treated as an individual case due to such variables as the size of the spill, type of flammable or combustible liquid involved, wind and weather conditions, equipment arrangement, aircraft occupancy, emergency equipment, and personnel available:

(1) The flow of fuel should be stopped, if possible. If the fuel is discovered leaking or spilling from fuel servicing equipment or hoses, the emergency fuel shutoff should be operated at once. If the fuel is discovered leaking or spilling from the aircraft at the filler opening, vent line, or tank seams during fueling operations, fueling should be stopped immediately. Evacuation of the aircraft should be ordered when necessary. The aircraft then should be thoroughly checked for damage or entrance of flammable liquid or vapors into any concealed wing or fuselage area, and corrective action should be taken as necessary before it is returned to normal operational service.
(2) The airport fire crew should be notified if the spill presents a fire hazard. The only routine exceptions are for small spills. Supervisory personnel should be notified to ensure that operations in progress can be continued safely or halted until the emergency is past and that corrective measures can be taken to prevent recurrence of a similar accident.
(3) It could be necessary to evacuate the aircraft if the spill poses a serious fire exposure to the aircraft or its occupants. Walking through the liquid area of the fuel spill should not be permitted. Persons who have been sprayed with fuel or had their clothing soaked with fuel should go to a place of refuge, remove their clothing, and wash. Individuals whose clothing has been ignited should be wrapped in blankets, coats, or other items or should be told to or forced to roll on the ground.
(4) Mobile fueling equipment and all other mobile equipment should be withdrawn from the area or left as is until the spilled fuel is removed or made safe. No fixed rule can be made as fire safety varies with circumstances. Shutting down equipment or moving vehicles can provide a source of ignition if no fire immediately results from the spillage.
(5) Aircraft, automotive, or spark-producing equipment in the area should not be started before the spilled fuel is removed or made safe. If a vehicle or cart engine is running at the time of the spill, it normally is good practice to drive the vehicle away from the hazard area unless the hazard to personnel is judged too severe. Fuel servicing vehicles or carts in operation at the time of the spill should not be moved until a check is made to verify that any fuel hose that could have been in use or connected between the vehicle and the aircraft is safely stowed.
(6) If any aircraft engine is operating at the time of the spill, it normally is good practice to move the aircraft away from the hazard area unless air currents set up by operating power plants would aggravate the extent or the nature of the existing vapor hazard.
(7) If circumstances dictate that operating internal combustion engine equipment within a spill area that has not ignited should be shut down, engine speeds should be reduced to idle prior to cutting ignition in order to prevent backfire.
(8) The volatility of the fuel can be a major factor in the initial severity of the hazard created by a spill. Gasoline and other low flash point fuels at normal temperatures and pressures produce vapors that are capable of forming ignitable mixtures with the air near the surface of the liquid, whereas this condition does not normally exist with kerosene fuels (JET A or JET A-1) except where ambient temperatures are 38°C (100°F) or above or where the liquid has been heated to a similar temperature.
(9) Spills of gasoline and low flash point turbine fuels (JET B) greater than 3 m (10 ft) in any dimension and covering an area of over 5 m^2 (50 ft^2) or that are of an ongoing nature should be blanketed or covered with foam. The nature of the ground surface and the existing exposure conditions dictate the exact

method to be followed. Such fuels should not be washed down sewers or drains. The decision to use a sewer or drain should be made only by the chief of the airport fire brigade or the fire department. If fuels do enter sewers, either intentionally or unintentionally, large volumes of water should be introduced to flush such sewers or drains as quickly as possible to dilute the flammable liquid content of the sewer or drain to the maximum possible extent. Normal operations involving ignition sources (including aircraft and vehicle operations) should be prohibited on surface areas adjacent to open drains or manholes from which flammable vapors could issue due to the introduction of liquids into the sewer system until it can be established that no flammable vapor–air mixture is present in the proximity. (NOTE: NFPA 415 provides further information on aircraft fueling ramp drainage designs to control the flow of fuel that could be spilled on a ramp and to minimize the resulting possible danger.)

(10) Spills of kerosene grades of aviation fuels (JET A or JET A-1) greater than 3 m (10 ft) in any dimension and covering an area of over 5 m^2 (50 ft^2) or that are of an ongoing nature and that have not ignited should be blanketed or covered with foam if there is danger of ignition. If there is no danger of ignition, an absorbent compound or an emulsion-type cleaner can be used to clean the area. Kerosene does not evaporate readily at normal temperatures and should be cleaned up. Smaller spills can be cleaned up using an approved, mineral type, oil absorbent.

(11) Aircraft on which fuel has been spilled should be inspected thoroughly to ensure that no fuel or fuel vapors have accumulated in flap well areas or internal wing sections not designed for fuel tankage. Any cargo, baggage, express, mail sacks, or similar items that have been wetted by fuel should be decontaminated before being placed aboard any aircraft.

[**407:**A.4.2.3]

N **42.10.2.2.3.1** Following fueling of an aircraft or fuel servicing vehicle, all hoses shall be removed, including those from hydrant systems if applicable. [**407:**4.2.3.1]

N **42.10.2.2.3.2** All hoses shall also be properly stowed. [**407:**4.2.3.2]

N **42.10.2.2.3.3** Fuel nozzles shall not be dragged along the ground. [**407:**4.2.3.3]

N **42.10.2.2.3.4** Approved pumps, either hand operated or power operated, shall be used where aircraft are fueled from drums. [**407:**4.2.3.4]

N **42.10.2.2.3.4.1** Pouring or gravity flow shall not be permitted from a container with a capacity of more than 19 L (5 gal). [**407:**4.2.3.4.1]

N **42.10.2.2.3.5 Fuel Spill Procedures.**

N **42.10.2.2.3.5.1** Where a spill is observed, the fuel servicing shall be stopped immediately by release of the deadman controls. [**407:**4.2.3.5.1]

N **42.10.2.2.3.5.2** In the event that a spill continues, the equipment emergency fuel shutoff shall be actuated. [**407:**4.2.3.5.2]

N **42.10.2.2.3.5.3** In the event that a spill continues from a hydrant system, the system emergency fuel shutoff shall be actuated. [**407:**4.2.3.5.3]

N **42.10.2.2.3.5.4** The supervisor shall be notified immediately. [**407:**4.2.3.5.4]

N **42.10.2.2.3.5.5** Cleaning operations shall be performed by personnel trained in accordance with 42.10.2.2.2.1. [**407:**4.2.3.5.5]

The use of properly trained personnel to conduct cleaning operations is essential. Paragraph 42.10.2.2.2.1 provides additional information on the training of personnel.

N **42.10.2.2.3.5.6** Operation shall not be resumed until the spill has been cleared and conditions are determined to be safe. [**407:**4.2.3.5.6]

N **42.10.2.2.3.5.7** The airport fire crew, if established, or the local fire department serving the airport shall be notified if a spill covers over 3 m (10 ft) in any direction or is over 5 m^2 (50 ft^2) in area, continues to flow, or is otherwise a hazard to persons or property. [**407:**4.2.3.5.7]

There are many smaller municipal airports and small private airports and landing strips where no official airport fire crew has been established or is present. In those cases, the local fire department serving the airport area must be notified.

N **42.10.2.2.3.5.8** The spill shall be investigated to determine the cause, to determine whether emergency procedures were properly carried out, and to determine the necessary corrective measures. [**407:**4.2.3.5.8]

N **42.10.2.2.3.5.9** Corrective measures identified by the spill investigation shall be implemented as required by the authority having jurisdiction. [**407:**4.2.3.5.9]

N **42.10.2.2.3.6** Transferring fuel by pumping from one tank vehicle to another tank vehicle within 61 m (200 ft) of an aircraft shall not be permitted. [**407:**4.2.3.6]

N **42.10.2.2.3.7** Not more than one tank vehicle shall be permitted to be connected to the same aircraft fueling manifold, unless means are provided to prevent fuel from flowing back into a tank vehicle due to a difference in pumping pressure. [**407:**4.2.3.7]

N **42.10.2.2.4 Emergency Fuel Shutoff.**

N **42.10.2.2.4.1** Emergency fuel shutoff control stations shall be accessible at all times. [**407:**4.2.4.1]

N **42.10.2.2.4.2** A procedure shall be established to notify the fire department serving the airport in the event of a control station activation. [**407:**4.2.4.2]

N **42.10.2.2.4.3** If the fuel flow stops for an unknown reason, the emergency fuel shutoff system shall be checked first. [**407:**4.2.4.3]

N **42.10.2.2.4.4** The cause of the shutoff shall be identified and corrected before fuel flow is resumed. [**407:**4.2.4.4]

N **42.10.2.2.4.5** Emergency fuel shutoff systems shall be operationally checked at intervals not exceeding 6 months. [**407:**4.2.4.5]

N **42.10.2.2.4.6** Each individual device shall be checked at least once during every 12-month period. [**407:**4.2.4.6]

N **42.10.2.2.4.7** Suitable records shall be kept of tests required by this section. [**407:**4.2.4.7]

N **42.10.2.2.5* Bonding.**

The following information is from the annex material associated with the "Bonding" section in NFPA 407.

Hydrocarbon fuels, such as aviation gasoline and JET A, generate electrostatic charge when passing through the pumps, filters, and piping of a fuel transfer system. (The primary electrostatic generator is the filter/separator that increases the level of charge on a fuel by a factor of 100 or more as compared with pipe flow.) Splashing, spraying, or freefalling of the fuel further enhances the charge. When charged fuel arrives at the receiving tank (cargo tank or aircraft fuel tank), one of two possible events will occur:

(1) The charge will relax harmlessly to ground.
(2) If the charge or the fuel is sufficiently high, a spark discharge can occur. Whether or not an ignition follows depends on the energy (and duration) of the discharge and the composition of the fuel-air mixture in the vapor space (i.e., whether or not it is in the flammable range).

The amount of charge on a fuel when it arrives at the receiving tank, and hence its tendency to cause a spark discharge, depends on the nature and amount of impurities in the fuel, its electrical conductivity, the nature of the filter media (if present), and the relaxation time of the system [i.e., the residence time of the fuel in the system between the filter (separator) and the receiving tank]. The time needed for this charge to dissipate is dependent upon the conductivity of the fuels; it could be a fraction of a second or several minutes.

No amount of bonding or grounding prevents discharges from occurring inside a fuel tank. Bonding ensures that the fueling equipment and the receiving tank (aircraft or fueler) are at the same potential and provides a path for the charges separated in the fuel transfer system (primarily the filter/separator) to combine with and neutralize the charges in the fuel. Also, in overwing fueling and in top loading of cargo tanks, bonding ensures that the fuel nozzle or the fill pipe is at the same potential as the receiving tank, so that a spark does not occur when the nozzle or fill pipe is inserted into the tank opening. For this reason, the bonding wire has to be connected before the tank is opened.

Grounding during aircraft fueling or fuel servicing vehicle loading is no longer required because of the following:

(1) Grounding does not prevent sparking at the fuel surface *(see NFPA 77)*.
(2) Grounding is not required by NFPA 77.
(3) The static wire might not be able to conduct the current in the event of an electrical fault in the ground support equipment connected to the aircraft and could constitute an ignition source if the wire fuses. If ground support equipment is connected to the aircraft or if other operations are being conducted that necessitate electrical earthing, separate connections should be made for this purpose. Static electrical grounding points can have high resistance and, therefore, are unsuitable for grounding. For a more complete discussion of static electricity in fuels, see NFPA 77.

N **42.10.2.2.5.1** Prior to making any fueling connection to an aircraft or fuel servicing vehicle, the fueling equipment shall be bonded to the aircraft or fuel servicing vehicle by use of a cable, thus providing a conductive path to equalize the potential between the fueling equipment and the aircraft. [**407:**4.2.5.1]

N **42.10.2.2.5.1.1** The electrical bond shall be maintained until fueling connections have been removed, thus allowing separated charges that could be generated during the fueling operation to reunite. [**407:**4.2.5.1.1]

N **42.10.2.2.5.1.2** Grounding for the sole purpose of aircraft fueling shall not be permitted. [**407:**4.2.5.1.2]

The requirement in 42.10.2.2.5.1.2 was revised to permit grounding during aircraft fueling only if grounding is necessary for another purpose. As explained in A.42.10.2.2.5, static discharges are prevented through direct bonding of the fuel system components to the aircraft, rather than connecting each one to ground. Prior editions of NFPA 407 expressly forbid grounding during fueling. However, this created a conflict with standard operating procedures for hot-fueling rotary-wing aircraft. Rotating blades can generate a significant static charge, which must be relaxed to ground. In this case, the aircraft is being grounded for a purpose other than fuel servicing, so 42.10.2.2.5.1.2 would now permit grounding during the fueling operation.

N **42.10.2.2.5.2 Bonding for Overwing Fueling.** In addition to the requirements in 42.10.2.2.5.1, where fueling overwing, the nozzle shall be bonded to a metallic component of the aircraft that is metallically connected to the tank filler port. [**407:**4.2.5.2]

Paragraph 42.10.2.2.5.2 requires bonding with the nozzle to ensure that a spark does not occur after the filler cap is removed. If a bond cable and connection point are provided, their use is mandatory. If they are not provided, it is permitted to equalize the potential between the nozzle and the filler port by touching the nozzle to the filler cap before removing the filler cap. The nozzle should be placed in contact with the filler neck prior to commencing fueling and should remain in contact with the filler neck until fueling is completed.

N **42.10.2.2.5.2.1** The bond connection shall be made before the filler cap is removed. [**407:**4.2.5.2.1]

N **42.10.2.2.5.2.2** If a nozzle bond cable and plug receptacle or means for attaching a clip is available, the operator shall attach the nozzle bond cable before removing the cap in order to equalize the potential between the nozzle and the filler port. [**407:**4.2.5.2.2]

N **42.10.2.2.5.2.3** If no plug receptacle or means for attaching a clip is available, the operator shall touch the filler cap with the nozzle spout before removing the cap in order to equalize the potential between the nozzle and the filler port. [**407:**4.2.5.2.3]

N **42.10.2.2.5.2.4** The nozzle spout shall be kept in contact with the filler neck until the fueling is completed. [**407:**4.2.5.2.4]

N **42.10.2.2.5.3** Where a funnel is used in aircraft fueling, it shall be kept in contact with the filler neck as well as the fueling nozzle spout or the supply container to avoid the possibility of a spark at the fill opening. [**407:**4.2.5.3]

N **42.10.2.2.5.3.1*** Only metal funnels shall be used. [**407:**4.2.5.3.1]

N **A.42.10.2.2.5.3.1** Ordinary plastic funnels or other nonconducting materials can increase static generation. The use of chamois as a filter is extremely hazardous. [**407:**A.4.2.5.3.1]

N **42.10.2.2.5.4** Where a hydrant servicer or cart is used for fueling, the hydrant coupler shall be connected to the hydrant system prior to bonding the fuel equipment to the aircraft. [**407:**4.2.5.4]

The intent of 42.10.2.2.5.4 is to prevent a spark caused by a static charge on the aircraft from being produced at the hydrant coupler connection where fuel vapors might be present.

N **42.10.2.2.5.5** Bonding and fueling connections shall be disconnected in the reverse order of connection. [**407:**4.2.5.5]

The fueling connection from a hydrant servicer or truck to the aircraft should always be removed prior to removal of the bonding cable. In the case of a hydrant servicer, the hydrant coupler should be removed last.

N **42.10.2.2.5.6** Conductive hose shall be used to prevent electrostatic discharge but shall not be used to accomplish required bonding. [**407:**4.2.5.6]

N **42.10.2.2.6 Control of Fuel Flow.**

N **42.10.2.2.6.1** Fuel flow shall be controlled by use of a dead-man control device. [**407:**4.2.6.1]

N **42.10.2.2.6.2** The use of any means that defeats the dead-man control shall be prohibited. [**407:**4.2.6.2]

N **42.10.2.2.7 Fire Protection.**

N **42.10.2.2.7.1*** During fueling operations, fire extinguishers shall be available on aircraft servicing ramps or aprons, in accordance with NFPA 410. [**407:**4.2.7.1]

N **A.42.10.2.2.7.1** Portable fire extinguishers for ramps where fueling operations are conducted are intended to provide an immediate means of fire protection in an area likely to contain a high concentration of personnel and valuable equipment. The prominent and strategic positioning of portable fire extinguishers is essential for them to be of maximum value in the event of an emergency. Extinguishers should not be located in probable spill areas. For normal single parking configurations, extinguishers specified for protection of fuel servicing operations should be located along the fence, at terminal building egress points, or at emergency remote control stations of airport fixed-fuel systems. To provide accessibility from adjoining gates, particularly where more than one unit is specified, extinguishers can be permitted to be located approximately midway between gate positions. Where this is done, the maximum distance between extinguishers should not be over 60 m (200 ft). Where the specified extinguishers are not located along the fence but are brought into the servicing area prior to the fueling operation, they should be located upwind not over 30 m (100 ft) from the aircraft being serviced. For protection of fuel servicing of aircraft that are double parked or triple parked, extinguishers should be located upwind not over 30 m (100 ft) from the aircraft being serviced. [**407:**A.4.2.7.1]

Distribution, selection, installation, and servicing of portable or wheeled fire extinguishers must be in accordance with Section 13.6 and Section 42.10.

N **42.10.2.2.7.2*** Extinguishers shall be kept clear of elements such as ice and snow. [**407:**4.2.7.2]

N **A.42.10.2.2.7.2** During inclement weather, extinguishers not in enclosed compartments can be permitted to be protected by canvas or plastic covers. [**407:**A.4.2.7.2]

N **42.10.2.2.7.3** Extinguishers located in enclosed compartments shall be readily accessible, and their location shall be marked clearly in letters at least 50 mm (2 in.) high. [**407:**4.2.7.3]

N **42.10.2.2.7.4** Fuel servicing personnel shall be trained in the use of the available fire-extinguishing equipment they could be expected to use. *(See A.42.10.2.2.2.2.)* [**407:**4.2.7.4]

N **42.10.2.2.8 Maintenance.**

N **42.10.2.2.8.1** Fuel servicing equipment shall be maintained in safe operating condition. [**407:**4.2.8.1]

N **42.10.2.2.8.2** Malfunctioning equipment shall be removed from service. [**407:**4.2.8.2]

N **42.10.2.2.8.3** Where a valve or electrical device is used for isolation during maintenance or modification of a fuel system, it shall be tagged and locked out. [**407:**4.2.8.3]

N **42.10.2.2.8.4** The tag/lock shall not be removed until the operation is completed. [**407:**4.2.8.4]

N **42.10.2.2.8.5** All inspection and maintenance activities shall be recorded. [**407:**4.2.8.5]

N **42.10.2.2.8.6** Inspection and maintenance records shall be retained for a minimum of 12 months. [**407:**4.2.8.6]

N **42.10.2.2.9* Aircraft Fueling Hose.** Any hose found to be defective, in accordance with 42.10.2.2.9.1 through 42.10.2.2.9.4, shall be removed from service. [**407:**4.2.9]

N **A.42.10.2.2.9** Failure of an aircraft fueling hose in service is a potential source of fuel spillage and a potential fire hazard. The principal reasons for failure of aircraft fueling hoses include the following:

(1) Using damaged hoses
(2) Using aged hoses
(3) Exceeding hose pressure limits
(4) Installing hoses improperly
[**407:**A.4.2.9]

N **42.10.2.2.9.1** Suitable records shall be kept of required inspections and hydrostatic tests. [**407:**4.2.9.1]

N **42.10.2.2.9.2** Aircraft fueling hose shall be removed from service after 10 years from the date of manufacture. [**407:**4.2.9.2]

The maximum service life for fuel hose aligns with the requirements of A4A Specification 103.

N **42.10.2.2.9.3** Aircraft fueling hose not placed into service within 2 years of the date of manufacture shall not be used. [**407:**4.2.9.3]

The maximum age for fuel hose being placed into service aligns with the requirements of A4A Specification 103.

N **42.10.2.2.9.4 Daily Inspection.** Aircraft fueling hose shall be inspected before use each day. [**407:**4.2.9.4]

N **42.10.2.2.9.4.1** The hose shall be extended as it normally would be for fueling. [**407:**4.2.9.4.1]

N **42.10.2.2.9.4.2** The hose shall be checked for evidence of any of the following defects:

(1) Blistering
(2) Carcass saturation or separation
(3) Exposure of the reinforcement material
(4) Slippage, misalignment, or leaks at couplings
[**407:**4.2.9.4.2]

N **42.10.2.2.9.5 Monthly Inspection.** At least once each month the hose shall be completely extended and inspected as required in 42.10.2.2.9.4 and 42.10.2.2.9.5. [**407:**4.2.9.5]

N **42.10.2.2.9.5.1*** The hose couplings and the hose shall be examined for structural weakness or soft spots. [**407:**4.2.9.5.1]

N **A.42.10.2.2.9.5.1** Particular attention should be paid to the 305 mm (12 in.) adjacent to the couplings. These areas are prone to premature failure. [**407:**A.4.2.9.5.1]

N **42.10.2.2.9.5.2** With the hose completely extended, it shall be pressurized to the working pressure of the fueling equipment to which it is attached and checked for defects, such as abnormal twisting or blistering. [**407:**4.2.9.5.2]

N **42.10.2.2.9.6 Quarterly Inspection.**

N **42.10.2.2.9.6.1** The nozzle screens shall be examined for evidence of hose deterioration. [**407:**4.2.9.6.1]

N **42.10.2.2.9.7** Kinks or short loops in fueling hose shall be avoided. [**407:**4.2.9.7]

N **42.10.2.2.10* Lightning.** A written procedure shall be established to set the criteria for when and where fueling operations are to be suspended at each airport as approved by the fueling agent and the airport authority. [**407:**4.2.10]

N **A.42.10.2.2.10** Establishing precise rules for fueling is impossible when the electrical storms are in the vicinity of the airport. The distance of the storm from the airport, the direction in which it is traveling, and its intensity are all factors to be weighed in making the decision to suspend fueling operations temporarily. Experience and good judgment are the best guides. Sound travels approximately 322 m/sec (⅕ mi/sec). The approximate number of miles to the storm can be determined by counting the seconds between a flash of lightning and the sound of thunder and dividing by 5. [**407:**A.4.2.10]

Previous editions of NFPA 407 required fuel servicing operations to be suspended "where lightning flashes are in the immediate vicinity of the airport." This requirement was deleted because the criterion was vague and unenforceable. The revised requirement requires the airport to develop appropriate policies.

N **42.10.2.2.11 Aircraft Fuel Servicing.**

N **42.10.2.2.11.1 Location of Aircraft During Fuel Servicing.**

N **42.10.2.2.11.1.1** Aircraft fuel servicing shall be performed outdoors. [**407:**4.2.11.1.1]

N **42.10.2.2.11.1.2** Aircraft fuel servicing incidental to aircraft fuel system maintenance operations shall comply with the requirements of NFPA 410. [**407:**4.2.11.1.2]

N **42.10.2.2.11.1.3*** Aircraft being fueled shall be positioned so that aircraft fuel system vents or fuel tank openings are not closer than 7.6 m (25 ft) to any terminal building, hangar, service building, or enclosed passenger concourse other than a loading walkway. [**407:**4.2.11.1.3]

N **A.42.10.2.2.11.1.3** The precautions in 42.10.2.2.11.1.3 and 42.10.2.2.11.1.4 are intended to minimize the danger of the ignition of any flammable vapors discharged during fueling and of fuel spills by sources of ignition likely to be present in airport terminal buildings. [**407:**A.4.2.11.1.3]

N **42.10.2.2.11.1.4** Aircraft being fueled shall be positioned so that the vent or tank openings are not closer than 15 m (50 ft) of any combustion and ventilation air intake to any boiler, heater, or incinerator room. [**407:**4.2.11.1.4]

N **42.10.2.2.11.1.5** Accessibility to aircraft by emergency fire equipment shall be maintained for aircraft fuel servicing positions. [**407:**4.2.11.1.5]

N **42.10.2.2.11.2 Aircraft Occupancy During Fuel Servicing.**

N **42.10.2.2.11.2.1** If passengers remain on board an aircraft during fuel servicing, at least one qualified person trained in emergency evacuation procedures shall be in the aircraft at or near a door at which there is a passenger loading walkway, integral stairs that lead downward, or a passenger loading stair or stand. [**407:**4.2.11.2.1]

N **42.10.2.2.11.2.1.1** A clear area for emergency evacuation of the aircraft shall be maintained at not less than one additional exit. [**407:**4.2.11.2.1.1]

N **42.10.2.2.11.2.1.2** Where fueling operations take place with passengers on board away from the terminal building, and stairways are not provided, such as during inclement weather (diversions), all slides shall be armed and the aircraft rescue and fire fighting (ARFF) services shall be notified to respond in standby position in the vicinity of the fueling activity with at least one vehicle. [**407:**4.2.11.2.1.2]

N **42.10.2.2.11.2.1.3** Aircraft operators shall establish specific procedures covering emergency evacuation under such conditions for each type of aircraft they operate. [**407:**4.2.11.2.1.3]

N **42.10.2.2.11.2.1.4** All "no smoking" signs shall be displayed in the cabin(s), and the no smoking rule shall be enforced. [**407:**4.2.11.2.1.4]

N **42.10.2.2.11.2.2** For each aircraft type, aircraft operators shall determine the areas through which it could be hazardous for boarding or deplaning passengers to pass while the aircraft is being fueled. [**407:**4.2.11.2.2]

N **42.10.2.2.11.2.2.1** Controls shall be established so that passengers avoid such areas. [**407:**4.2.11.2.2.1]

N **42.10.2.2.12 Fire Hazards on Aircraft Fuel Servicing Ramps.**

Aircraft fuel vent openings are a source of flammable vapors during the fuel servicing operation and can discharge liquid fuel in the event of an accidental overflow. To avoid ignition of the vapors or liquid fuel, NFPA 407 sets limitations on possible ignition sources, such as equipment and vehicles.

N **42.10.2.2.12.1* Electrical Equipment Operated on Aircraft Fuel Servicing Ramps or Aprons.**

N **A.42.10.2.2.12.1** Electric hand lamps used in the immediate proximity of the fueling operation should be of the type approved for use in *NFPA 70*, Class I, Division 1, Group D hazardous locations. No supportable basis exists for requiring, in the petroleum industry, the use of approved, listed, or permitted two- or three-cell flashlights to avoid igniting Class I, Group D vapors. [**407:**A.4.2.12.1]

N **42.10.2.2.12.1.1** Battery chargers on any fueling equipment shall not be connected or disconnected while fuel servicing is performed on an aircraft. [**407:**4.2.12.1.1]

Battery chargers are permitted to be used or present during the fuel servicing operation, but it is not permitted to make or break the electrical connection during the fuel servicing operation.

N **42.10.2.2.12.1.2*** Aircraft ground-power generators or other electrical ground-power supplies shall not be connected or disconnected while fuel servicing is performed on the aircraft. [**407:**4.2.12.1.2]

N **A.42.10.2.2.12.1.2** Aircraft ground-power generators should be located as far as practical from aircraft fueling points and tank vents to reduce the danger of igniting flammable vapors that could be discharged during fueling operations at sparking contacts or on hot surfaces of the generators. [**407:**A.4.2.12.1.2]

Aircraft ground-power generators or other electrical ground-power supplies are permitted to be used or present during the fuel servicing operation, but it is not permitted to make or break the electrical connection during the fuel servicing operation.

N **42.10.2.2.12.1.3** Electric tools or similar tools likely to produce sparks or arcs shall not be used while fuel servicing is performed on an aircraft. [**407:**4.2.12.1.3]

N **42.10.2.2.12.1.4** Other than aircraft fuel servicing vehicles, battery-powered vehicles that do not comply with the provisions of this standard shall not be operated within 3 m (10 ft) of fueling equipment or spills. [**407:**4.2.12.1.4]

N **42.10.2.2.12.1.5*** Communication equipment located outside of the cab of fuel servicing vehicles and used during aircraft fuel servicing operations within 3 m (10 ft) of the fill or vent points of aircraft fuel systems shall be listed as intrinsically safe for Class I, Division 1, Group D hazardous (classified) locations in accordance with ANSI/UL 913. [**407:**4.2.12.1.5]

N **A.42.10.2.2.12.1.5** For further information on intrinsically safe apparatus, see ANSI/UL 913, FM Class 3610, or ANSI/UL 60079-11. [**407:**A.4.2.12.1.5]

N **42.10.2.2.12.2 Open Flames on Aircraft Fuel Servicing Ramps.**

N **42.10.2.2.12.2.1** Entrances to fueling areas shall be posted with "no smoking" signs. [**407:**4.2.12.2.1]

N **42.10.2.2.12.2.2** Open flames on aircraft fuel servicing ramps or aprons within 15 m (50 ft) of any aircraft fuel servicing operation or fueling equipment shall be prohibited. [**407:**4.2.12.2.2]

N **42.10.2.2.12.2.3** The category of open flames and lighted open flame devices shall include, but shall not be limited to, the following:

(1) Lighted cigarettes, cigars, or pipes
(2) Electronic cigarettes (e.g., personal vaporizers or electronic nicotine delivery systems)
(3) Exposed flame heaters, liquid, solid, or gaseous devices, including portable and wheeled gasoline or kerosene heaters
(4) Heat-producing welding or cutting devices and blowtorches
(5) Flare pots or other open-flame lights

[**407:**4.2.12.2.3]

NFPA 407 treats electronic cigarettes the same as traditional cigarettes because it is unknown whether these units are capable of igniting fuel vapors.

N **42.10.2.2.12.2.4** The authority having jurisdiction can establish other locations where open flames and open-flame devices shall not be permitted. [**407:**4.2.12.2.4]

N **42.10.2.2.12.2.5** Personnel shall not carry lighters, matches, or electronic cigarettes on their person while engaged in fuel servicing operations. [**407:**4.2.12.2.5]

N **42.10.2.2.12.2.6** Lighters, matches, or electronic cigarettes shall not be permitted on or in fueling equipment. [**407:**4.2.12.2.6]

N **42.10.2.2.12.2.7** Equipment performing aircraft servicing functions shall not be positioned within a 3 m (10 ft) radius of aircraft fuel system vent openings. [**407:**4.2.12.2.7]

Equipment used for baggage handling, galley restocking, lavatory servicing, or other aircraft preparation is permitted to be used during aircraft fuel servicing, as long as it is located at least 3 m (10 ft) from the vent openings.

N **42.10.2.2.12.3 Operation of Aircraft Engines and Heaters.**

Minimizing possible sources of ignition during a fuel servicing operation is important. Paragraphs 42.10.2.2.12.3.1 through 42.10.2.2.12.3.3 address the control of ignition sources on the aircraft itself. Explosions can occur when fuel from an accidental spill or from equipment failure is sprayed or misted onto heated surfaces.

N **42.10.2.2.12.3.1** Fuel servicing shall not be performed on a fixed wing aircraft while an onboard engine is operating, except as permitted by 42.10.2.2.12.3.2 or 42.10.2.2.14. [**407:**4.2.12.3.1]

N **42.10.2.2.12.3.2** Aircraft auxiliary power units (APUs) that direct exhaust away from the fueling operation shall be permitted to operate during fuel servicing. [**407:**4.2.12.3.2]

Aircraft auxiliary power units (APUs) are commonly operated at airports where ground-provided electrical and heating/air conditioning are not available. The exhausts of these units are generally directed away from fueling operations. At locations where quick-turnarounds of aircraft take place, APUs are necessary to provide lighting and environmental controls inside the cabin of the aircraft to allow passenger boarding/deboarding and cabin cleaning, which generally take place coincidentally with fueling.

N **42.10.2.2.12.3.3** Combustion heaters on aircraft (e.g., wing and tail surface heaters, integral cabin heaters) shall not be operated during fueling operations. [**407:**4.2.12.3.3]

N **42.10.2.2.13 Defueling of Aircraft.**

Paragraphs 42.10.2.2.13.1 and 42.10.2.2.13.2 apply to the removal of fuel from an aircraft as a routine procedure for storage. As specified in 42.10.1.1(3), the removal of fuel for the purpose of aircraft fuel system maintenance or manufacturing is not within the scope of NFPA 407 or 42.10.2.2.13.1 and 42.10.2.2.13.2. Aircraft maintenance operations are covered under NFPA 410.

N **42.10.2.2.13.1** All requirements of this standard shall apply to defueling operations. [**407:**4.2.13.1]

N **42.10.2.2.13.2** Each operator shall establish procedures to prevent the overfilling of the tank vehicle, which is a special hazard when defueling. [**407:**4.2.13.2]

N **42.10.2.2.14 Rapid Refueling.**

Rapid refueling is the practice of refueling an aircraft while the engines are running. This is generally used in operations where the required cycle time for stopping and restarting the aircraft engines cannot be tolerated. Since rapid refueling involves certain additional risks, compared to the standard fueling procedures, NFPA 407 places strict limitations on its use and conditions.

N **42.10.2.2.14.1** Rapid refueling of aircraft shall be limited to the following aircraft types:

(1) Helicopters
(2) Agricultural aircraft actively engaged in aerial application duties
(3) Medical aircraft actively engaged in the transport of medical patients
(4) Fire-fighting and search-and-rescue aircraft actively engaged in emergency operations

[**407:**4.2.14.1]

N **42.10.2.2.14.2** Only turbine engine aircraft fueled with JET A or JET A-1 fuels shall be permitted to be fueled while an onboard engine is operating. [**407:**4.2.14.2]

N **42.10.2.2.14.3** Aircraft permitted to be fueled while an onboard engine is operating shall have all sources of ignition of potential fuel spills located above the fuel inlet port(s) and above the vents or tank openings, including but not limited to the following:

(1) Engines
(2) Exhausts
(3) Auxiliary power units (APUs)
(4) Combustion-type cabin heater

[**407:**4.2.14.3]

N **42.10.2.2.14.4** Aircraft fueling while onboard engines are operating shall be permitted only under the following conditions:

(1) A pilot licensed by the appropriate governmental body shall be at the aircraft controls during the entire fueling operation.
(2) All passengers shall be deboarded to a safe location prior to rapid refueling operations, except as permitted in 42.10.2.2.14.3(3).
(3) Patients on board medical transport aircraft shall be permitted to remain on board the aircraft with medical personnel during rapid refueling operations if, in the opinion of the medical provider, removal from the aircraft would be detrimental to the patient's condition.
(4) Passengers shall not board or deboard during rapid refueling operations.
(5) Only designated personnel, properly trained in rapid refueling operations, shall operate the equipment. Written procedures shall include the safe handling of the fuel and equipment.
(6) All doors, windows, and access points allowing entry to the interior of the aircraft that are adjacent to, or in the immediate vicinity of, the fuel inlet ports shall be closed and shall remain closed during refueling operations.
(7) Fuel shall be permitted to be dispensed by one of the following methods:
    (a) Into an open port from approved deadman-type nozzles with a flow rate not to exceed 227 L/min (60 gpm)
    (b) Through close-coupled pressure fueling ports
(8) Where fuel is dispensed from fixed piping systems, the hose cabinet shall not extend into the rotor space.

(9) Clearance between aircraft fuel servicing vehicles and rotating components shall be maintained by one of the following methods:
  (a) A curb or other approved barrier shall be provided to restrict the fuel servicing vehicle from coming within 3 m (10 ft) of any aircraft rotating components.
  (b) Fuel servicing vehicles shall be kept 6 m (20 ft) away from any aircraft rotating components, and a trained person shall direct fuel servicing vehicle approach and departure.

[**407:**4.2.14.4]

N **42.10.3 Aviation Fueling Facilities.**

Subsection 42.10.3 applies to all fixed fueling facilities, including piping, hydrants, loading racks, self-service fueling stations, rooftop heliport fueling stations, and other aircraft fuel servicing infrastructure. It does not apply to airport fueling vehicles (see 42.10.4).

N **42.10.3.1 Design and Construction.**

N **42.10.3.1.1 General Requirements.**

N **42.10.3.1.1.1** Each installation shall be designed and installed in conformity with the requirements of this standard and with any additional fire safety measures deemed necessary by the authority having jurisdiction. [**407:**5.1.1.1]

It is not possible for this *Code* to address every possible scenario in airport design. The AHJ is permitted to establish additional requirements to address the unique characteristics of an installation.

N **42.10.3.1.1.2** The system and each of its components shall be designed for the working pressure of the system. [**407:**5.1.1.2]

N **42.10.3.1.1.3** The emergency fuel shutoff system shall be designed and installed as an integral part of the airport fuel system. [**407:**5.1.1.3]

N **42.10.3.1.1.4** Operating controls for emergency fuel shutoff of the system shall be located to be readily accessible in the event of an accident or spill. [**407:**5.1.1.4]

N **42.10.3.1.1.5** In establishing each aircraft fuel dispensing location, consideration shall be given to the accessibility of the location in an emergency by fire-fighting personnel and equipment. [**407:**5.1.1.5]

N **42.10.3.1.1.6 System Design and Approval.**

N **42.10.3.1.1.6.1 Design Approval.** Work shall not be started on the construction or alteration of an airport fuel system until the design, plans, and specifications have been approved by the authority having jurisdiction. [**407:**5.1.1.6.1]

This provision allows the AHJ to ensure that all work on airport fuel systems is performed by engineers and contractors qualified to perform the work and to ensure that all requirements of the AHJ are met.

N **42.10.3.1.1.6.2 System Approval.** The authority having jurisdiction shall inspect and approve the completed system before it is put into service. [**407:**5.1.1.6.2]

N **42.10.3.1.1.6.3 Hydrostatic Test.**

N **42.10.3.1.1.6.3.1** After completion of the installation (including fill and paving), new airport fuel piping systems shall be subjected to a temperature-compensated hydrostatic test pressure equal to 150 percent of the system working pressure for at least 4 hours and shall be proven tight before the system is placed into service. [**407:**5.1.1.6.3.1]

N **42.10.3.1.1.6.3.2** For additions or modifications to existing airport fuel piping systems, hydrostatic testing of new piping prior to final tie-in to existing piping shall be permitted, with final closure (tie-in) welds examined in-process in accordance with ASME B31.3. [**407:**5.1.1.6.3.2]

ASME B31.3, *Process Piping*, permits alternative means of testing, such as radiographic or ultrasonic examination, dye penetrant, or magnetic particle. With limited allowable downtime of airport fueling operations (typically overnight), pressure testing of the combined new and existing piping system is not always practical or possible.

N **42.10.3.1.2 Fuel Storage Tanks.**

N **42.10.3.1.2.1*** Fuel storage tanks shall conform to the applicable requirements of NFPA 30. [**407:**5.1.2.1]

N **A.42.10.3.1.2.1** Where pressure tanks are used, details on construction, spacing, and location should be in accordance with industry good practice and approved by the authority having jurisdiction. When AVGAS, MOGAS, or JET B turbine fuels are stored in bulk quantities in aboveground tanks, they should be stored in floating roof-type tanks. Covered floating roof tanks minimize the hazardous flammable vapor–air space above the liquid level. The vapor spaces of underground tanks storing fuels should not be interconnected. [**407:**A.5.1.2.1]

N **42.10.3.1.2.2** The authority having jurisdiction shall determine the clearances required from runways, taxiways, and other aircraft movement and servicing areas to any aboveground fuel storage structure or fuel transfer equipment, with due recognition given to national and international standards establishing clearances from obstructions. [**407:**5.1.2.2]

One possible resource is FAA AC 150/5300, *Airport Design*.

N **42.10.3.1.3 Pumps and Piping Systems.**

N **42.10.3.1.3.1** Underground piping or impact-protected aboveground piping shall be used in the vicinity of aircraft operating areas. [**407:**5.1.3.1]

N **42.10.3.1.3.2** Piping shall be laid on firm supports using clean, noncorrosive backfill. [**407:**5.1.3.2]

N **42.10.3.1.3.3** Transfer piping located within buildings not specifically designed for the purpose of fuel transfer shall be located within a steel casing of a pressure rating equal to that of the carrier pipe. [**407:**5.1.3.3]

N **42.10.3.1.3.3.1** The casing shall extend beyond the building. [**407:**5.1.3.3.1]

N **42.10.3.1.3.3.2** The casing shall terminate at a low point(s) with an automatic leak detection system. [**407:**5.1.3.3.2]

N **42.10.3.1.3.3.3** The casing shall be capable of being drained to a safe location. [**407:**5.1.3.3.3]

N **42.10.3.1.3.4** Piping, valves, and fittings shall be of steel or stainless steel, suitable for aviation fuel service and designed for the working pressure and mechanically and thermally produced structural stresses to which they could be subjected and shall comply with ASME B31.3. [**407:**5.1.3.4]

Deviations from ASME B31.3 should be approved by the AHJ, in accordance with the equivalency clause in 1.4.1.

N **42.10.3.1.3.5** Cast-iron, copper, copper alloy, and galvanized steel piping, valves, and fittings shall not be permitted. [**407:**5.1.3.5]

N **42.10.3.1.3.6** Ductile iron valves shall be permitted. [**407:**5.1.3.6]

N **42.10.3.1.3.7** Aluminum piping, valves, and fittings shall be used only where specifically approved by the authority having jurisdiction. [**407:**5.1.3.7]

N **42.10.3.1.3.8** In the selection of pipe, valves, and fittings, the following shall be considered:

(1) Working pressure
(2) Bending and mechanical strength requirements (including settlement)
(3) Internal and external corrosion
(4) Impact stresses
(5) Method of system fabrication and assembly
(6) Location of piping and accessibility for repair or replacement
(7) Exposure to mechanical, atmospheric, or fire damage
(8) Expected period of service and effect of future operations

[**407:**5.1.3.8]

N **42.10.3.1.3.9** Gaskets in flanged connections shall resist fire temperatures for a duration comparable to the temperature resistance of the flange and bolts. [**407:**5.1.3.9]

N **42.10.3.1.3.10** Flanges and their associated bolts shall be steel or stainless steel. [**407:**5.1.3.10]

N **42.10.3.1.3.10.1** Flanges shall be rated to the ANSI pressure class suitable to the fuel system working pressures but in no cases shall be less than Class 150. [**407:**5.1.3.10.1]

N **42.10.3.1.3.10.2** Joints [and flanges] shall be installed so that the mechanical strength of the joint will not be impaired if exposed to fire. [**30:**27.5.1.2]

N **42.10.3.1.3.11** Allowances shall be made for thermal expansion and contraction by the use of pipe bends, welded elbows, or other flexible design. [**407:**5.1.3.11]

N **42.10.3.1.3.12** Pressure relief valves shall be provided in lines that can be isolated. [**407:**5.1.3.12]

N **42.10.3.1.3.13** Welded joints shall be made by qualified welders in accordance with the standards of the American Welding Society and ANSI/ASME B31.3. [**407:**5.1.3.13]

N **42.10.3.1.3.14*** Isolation valves or devices shall be provided to facilitate dismantling portions of the fueling system. [**407:**5.1.3.14]

N **A.42.10.3.1.3.14** Flanged connections should be provided for ease of dismantling and to avoid cutting and welding after the system has been placed in service. The location of these isolation devices depends upon the size and character of each system, but the following locations generally apply *(see Figure A.42.10.3.1.3.14)*:

(1) At each storage tank
(2) At each pump
(3) At each filter separator
(4) At each hydrant or on each hydrant lateral
(5) At each flow regulator or pressure control valve

[**407:**A.5.1.3.14]

N **42.10.3.1.3.15** Isolation valves shall be capable of being locked closed. [**407:**5.1.3.15]

N **42.10.3.1.3.16** Buried flanges and valves shall not be permitted. [**407:**5.1.3.16]

N **42.10.3.1.3.17*** All fueling systems with underground piping shall have cathodic protection to mitigate corrosion. [**407:**5.1.3.17]

N **A.42.10.3.1.3.17** Cathodic protection is recommended for metal components of airport fueling systems and fuel storage facilities that are in contact with the ground. The two types of cathodic protection are as follows:

(1) Galvanic anode method, which generates its own current
(2) Impressed current method, which has an external current source

[**407:**A.5.1.3.17]

N **42.10.3.1.3.18** A heat-actuated shutoff valve shall be provided in the piping immediately upstream of loading hoses or swing arm connections. [**407:**5.1.3.18]

N **42.10.3.1.4 Hose and Nozzles. (Reserved)**

N **42.10.3.1.5 Bonding. (Reserved)**

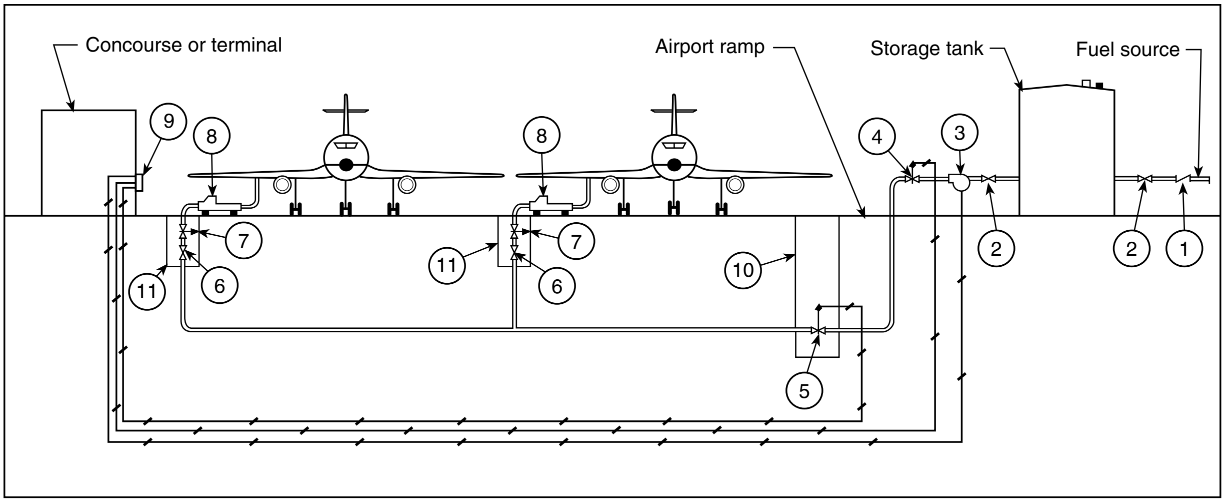
N **42.10.3.1.6 Electrical Systems.**

N **42.10.3.1.6.1 Electrical Equipment.** All electrical equipment and wiring shall comply with the requirements of *NFPA 70*, Article 515, utilizing the Class I liquids requirements for all applications. [**407:**5.1.6.1]

N **42.10.3.1.7 Control of Fuel Flow.**

N **42.10.3.1.7.1* Deadman Controls.**

N **A.42.10.3.1.7.1** Deadman controls should be designed so that the operator can use them comfortably while wearing gloves



Note: No dimensional relationship exists between elements in this figure. Refer to this standard; NFPA 30, *Flammable and Combustible Liquids Code*; *NFPA 70*, *National Electrical Code;* and FAA Regulations for separations and clearances.

Key:
1. Check valve at tank inlet
2. Isolation valve at tank inlet/outlet
3. Pumping system
4. Pump discharge control valve or hydrant system shutoff valve (alternate location)
5. Hydrant system shutoff valve (alternate location)
6. Hydrant shutoff valve
7. Hydrant pit valve
8. Hydrant fueling servicing vehicle
9. Emergency fuel shutoff station
10. Valve box
11. Hydrant pit

FIGURE A.42.10.3.1.3.14 *Typical Fixed Airport Fueling System Isolation Valving Operating and Emergency Controls.*

and hold them for the time needed to complete the operation. A pistol grip deadman device that is squeezed to operate is preferable to a small button that needs to be held by a thumb or finger. [**407:**A.5.1.7.1]

N **42.10.3.1.7.1.1** The valve that controls the flow of fuel to an aircraft or fueling vehicle shall have a deadman control. [**407:**5.1.7.1.1]

N **42.10.3.1.7.1.2** The fuel flow control means shall be one of the following:

(1) The hydrant pit valve
(2) At the feed-side of the fueling hose
(3) A separate valve on the fuel piping system
(4) On the hose nozzle for overwing servicing
(5) An electronic control to stop the pump

[**407:**5.1.7.1.2]

N **42.10.3.1.7.1.3** Deadman controls shall be designed to preclude defeating their intended purpose. [**407:**5.1.7.1.3]

N **42.10.3.1.7.2 Pressure Fuel Servicing System Controls.**

N **42.10.3.1.7.2.1** The system shall be designed to minimize surge pressure. [**407:**5.1.7.2.1]

N **42.10.3.1.7.2.2*** The overshoot shall not exceed 5 percent of actual flow rate in L/min (gal/min) at the time the deadman is released. [**407:**5.1.7.2.2]

N **A.42.10.3.1.7.2.2** The overshoot of pressure control release, *V* max, should be calculated by the following equation:

$$V_{max} = Q \times 1 \text{ min} \times 0.05$$

[A.42.10.3.1.7.2.2]

where:

Q = actual fuel flow rate, L/min (gal/min)

Example

If the actual fuel flow rate at the time of deadman control release is 1500 L/min (400 gpm), total overshoot must not exceed 75 L/min (20 gal/min). [**407:**A.5.1.7.2.2]

N **42.10.3.1.7.2.3** The control valve shall be located and designed so that it will not be rendered inoperative by a surface accident, power failure, or spill. [**407:**5.1.7.2.3]

N **42.10.3.1.7.2.4** The control valve shall be fail-safe by closing completely in the event of control power loss. [**407:**5.1.7.2.4]

N **42.10.3.1.7.3* Hydrant Valves.** Hydrant valves shall be designed so that the flow of fuel shall shut off when the hydrant coupler is closed. [**407:**5.1.7.3]

N **A.42.10.3.1.7.3** Hydrant valves and couplers should be in accordance with EI 1584. [**407:**A.5.1.7.3]

N **42.10.3.1.7.3.1** Hydrant valves shall be of the self-closing, dry-break type. [**407:**5.1.7.3.1]

N **42.10.3.1.7.4 Flow Control Valves.** The flow control valve shall be an integral part of the hydrant valve or coupler. [**407:**5.1.7.4]

N **42.10.3.1.7.4.1** The fuel control valve shall be arranged so that it is not rendered inoperative by a surface accident, spill, or malfunction and shall shut off the flow of fuel if the operating energy fails. [**407:**5.1.7.4.1]

N **42.10.3.1.7.4.2** The fuel control system shall be designed to minimize overshoot. [**407:**5.1.7.4.2]

N **42.10.3.1.7.4.3** The system shall be designed to shut off fuel flow quickly and effectively, even if there is a reduction of pressure downstream of the flow control valve such as could result from a major line or hose break. [**407:**5.1.7.4.3]

N **42.10.3.1.7.4.4** A screen shall be provided ahead of the valve to trap foreign material that could interfere with complete closure of the valve. [**407:**5.1.7.4.4]

N **42.10.3.1.7.4.5** The hydrant valve that allows the flow of fuel to the aircraft shall have a deadman control. [**407:**5.1.7.4.5]

N **42.10.3.1.7.4.6** The use of any means that allows fuel to flow without the operator activating the deadman shall not be permitted. [**407:**5.1.7.4.6]

N **42.10.3.1.7.4.7** The deadman control shall be arranged so that the fueling operator can observe the operation while activating the control. [**407:**5.1.7.4.7]

N **42.10.3.1.7.4.8** Wireless deadman controls shall be permitted. [**407:**5.1.7.4.8]

N **42.10.3.1.7.5* Fuel Pressure.** The pressure of the fuel delivered to the aircraft shall be automatically controlled so that it is not higher than that specified by the manufacturer of the aircraft being serviced. [**407:**5.1.7.5]

N **A.42.10.3.1.7.5** Where surge suppressors are necessary, they should be located so that exposure to vehicular traffic, weather conditions, and the result of accidental rupture is minimized. [**407:**A.5.1.7.5]

N **42.10.3.1.8 Filters and Ancillary Equipment.**

N **42.10.3.1.8.1** All sections of the filtering system shall have electrical continuity with adjoining piping and equipment. [**407:**5.1.8.1]

N **42.10.3.1.8.2** In freezing climates, filter separator sumps and associated piping that could contain water shall be protected to prevent freezing and bursting. [**407:**5.1.8.2]

N **42.10.3.1.8.3** Heaters shall be constructed of noncorrosive materials. [**407:**5.1.8.3]

N **42.10.3.1.8.4** Piping, valves, meters, filters, air eliminators, connections, outlets, fittings, and other components shall be designed to meet the working pressure requirements of the system. [**407:**5.1.8.4]

N **42.10.3.1.9 Emergency Fuel Shutoff Systems.**

N **42.10.3.1.9.1** Each tank vehicle loading station shall be provided with an emergency fuel shutoff system, in addition to the deadman control required by 42.10.3.1.7.4. [**407:**5.1.9.1]

N **42.10.3.1.9.2** The emergency fuel shutoff system shall shut down the flow of fuel in the entire system or in sections of the system. [**407:**5.1.9.2]

N **42.10.3.1.9.3** The emergency fuel shutoff system shall be of a fail-safe design. [**407:**5.1.9.3]

N **42.10.3.1.9.4*** The method of fuel transfer (gravity, pumping, or use of hydraulic or inert gas pressure) shall be considered in the design of the emergency fuel shutoff system and the location of the emergency fuel shutoff valve. [**407:**5.1.9.4]

N **A.42.10.3.1.9.4** Fuel transfer by pumping is the more common procedure and normally is preferred from a fire protection standpoint, since it allows rapid shutdown of fuel flow through pump shutdown. Gravity transfer is the simplest method but normally is limited to relatively low flow rates. Because the static head does exert some pressure in the system, a safety shutdown should include a valve or valves located as close to the tank as practicable. [**407:**A.5.1.9.4]

N **42.10.3.1.9.5** The emergency fuel shutoff system shall include shutoff stations located outside of probable spill areas and near the route that normally is used to leave the spill area or to reach the fire extinguishers provided for the protection of the area. [**407:**5.1.9.5]

N **42.10.3.1.9.6*** At least one emergency shutoff control station shall be accessible to each fueling vehicle loading position or aircraft fueling position. [**407:**5.1.9.6]

N **A.42.10.3.1.9.6** The operation of the emergency shutoff control should sound an alarm at the airport fire crew station and at the fuel storage facility. [**407:**A.5.1.9.6]

N **42.10.3.1.9.7** The emergency fuel shutoff system shall be designed so that operation of a station shuts off fuel flow to all hydrants that have a common exposure. [**407:**5.1.9.7]

N **42.10.3.1.9.8** Emergency fuel shutoff systems shall be designed so that they shut off the flow of fuel if the operating power fails. [**407:**5.1.9.8]

N **42.10.3.1.9.9** Emergency fuel shutoffs shall not be located beneath piping, pumps, vents, or other components containing fuel or fuel vapors. [**407:**5.1.9.9]

N **42.10.3.1.10 Fire Protection.** At least one fire extinguisher, with a minimum rating of 80-B:C, shall be provided at each fueling vehicle loading position or rack. [**407:**5.1.10]

A minimum rating of 80-B:C is typically satisfied by an extinguisher with 10 to 20 lb (4.54 to 9.07 kg) of dry chemical. In accordance with 42.10.2.1.10.3, multipurpose (ABC) dry chemical is not permitted.

N **42.10.3.1.11 Marking and Labeling.**

N **42.10.3.1.11.1** Emergency fuel shutoff signs shall be located at least 2.1 m (7 ft) above grade, measured to the bottom of the placard. [**407:**5.1.11.1]

N **42.10.3.1.11.2** Emergency fuel shutoff signs shall be positioned so that they can be seen readily from a distance of at least 15.2 m (50 ft). [**407:**5.1.11.2]

To ensure that the operator can locate the emergency fuel shutoff, the sign must be visible from the location of the fueling equipment, which typically will be at least 50 ft (15.2 m) from the emergency fuel shutoff. Paragraph 42.10.3.1.13.2 requires fueling hydrants, cabinets, and pits to be located at least 50 ft (15.2 m) from terminal buildings, hangars, service buildings, or enclosed concourses; most emergency fuel shutoff stations are mounted on the building adjacent to the fueling cabinet or hydrant.

N **42.10.3.1.11.3** Systems provided with impressed current cathodic protection shall have appropriate signs, located at points of entry, warning against separation of units without prior deenergization or without proper jumpers across the sections to be disconnected. [**407:**5.1.11.3]

N **42.10.3.1.11.4** Fuel storage tanks shall be labelled in accordance with the requirements of NFPA 704. [**407:**5.1.11.4]

N **42.10.3.1.11.5** Fuel transfer piping shall be marked in accordance with EI 1542 as to the product type conveyed through the pipe and the proper direction of flow of the product. [**407:**5.1.11.5]

N **42.10.3.1.12 Aircraft Fuel Servicing Vehicle Loading and Unloading Racks.**

N **42.10.3.1.12.1** The loading rack shall be equipped with an automatic shutdown system that stops the tank loading operation when the fuel servicing vehicle tank is full. [**407:**5.1.12.1]

N **42.10.3.1.12.2** All fuel servicing tank vehicle primary shutdown systems shall be compatible with the system utilized at the loading rack. [**407:**5.1.12.2]

N **42.10.3.1.12.3** The automatic secondary shutoff control shall not be used for normal filling control. [**407:**5.1.12.3]

N **42.10.3.1.12.4** New and existing loading systems shall comply with 42.10.3.1.12.1 through 42.10.3.1.12.3 within 5 years of the effective date of this edition. [**407:**5.1.12.4]

N **42.10.3.1.13 Fuel Servicing Hydrants, Pits, and Cabinets.**

N **42.10.3.1.13.1** Fueling hydrants and fueling pits that are recessed below a ramp or apron surface and are subject to vehicle or aircraft traffic shall be fitted with a cover designed to sustain the load of vehicles or aircraft that taxi over all or part of them. [**407:**5.1.13.1]

N **42.10.3.1.13.2** Fueling hydrants, cabinets, and pits shall be located at least 15.2 m (50 ft) from any terminal building, hangar, service building, or enclosed passenger concourse (other than loading bridges). [**407:**5.1.13.2]

N **42.10.3.2 Operations.**

N **42.10.3.2.1* Security.** Access to fuel storage and fuel vehicle loading areas shall be secured. [**407:**5.2.1]

N **A.42.10.3.2.1** The airport perimeter fence can be sufficient to meet this requirement. [**407:**A.5.2.1]

N **42.10.3.2.2 Personnel. (Reserved)**

N **42.10.3.2.3 Prevention and Control of Spills. (Reserved)**

N **42.10.3.2.4 Emergency Fuel Shutoff. (Reserved)**

N **42.10.3.2.5 Bonding. (Reserved)**

N **42.10.3.2.6 Control of Fuel Flow.** If a wireless deadman control is used, the operator shall be located at the fueling point during the fueling operation. [**407:**5.2.6]

N **42.10.3.2.7 Fire Protection.** During fueling operations, fire extinguishers shall be available on aircraft servicing ramps or aprons, in accordance with NFPA 410. [**407:**5.2.7]

N **42.10.3.2.8 Maintenance. (Reserved)**

N **42.10.3.2.9 Aircraft Fueling Hose. (Reserved)**

N **42.10.4 Airport Fueling Vehicles.**

This subsection applies to airport fueling vehicles, including aviation fuel tank trucks, hydrant fueling trucks, and hydrant fueling carts. It does not apply to fixed facilities or infrastructure.

N **42.10.4.1 Design and Construction.**

N **42.10.4.1.1 General Requirements.**

N **42.10.4.1.1.1** Aircraft fuel servicing tank vehicles that are operated on public roadways shall comply with the requirements of NFPA 385. [**407:**6.1.1.1]

N **42.10.4.1.1.2** In addition to any specific requirements in this chapter, only materials safe for use in the service intended and compatible with fuel applications shall be used in the construction of aircraft fuel servicing vehicles and hydrant fuel service carts. [**407:**6.1.1.2]

N **42.10.4.1.1.3** Magnesium shall not be used in the construction of any portion of an aircraft fuel servicing vehicle or cart. [**407:**6.1.1.3]

N **42.10.4.1.1.4** Trailer connections shall be designed to secure the trailer firmly and to prevent the towed vehicle from swerving from side to side at the speeds anticipated so that the trailer essentially remains in the path of the towing vehicle. [**407:**6.1.1.4]

N **42.10.4.1.2 Tanks.**

N **42.10.4.1.2.1** Every cargo tank shall be supported by and attached to, or shall be a part of, the tank vehicle upon which it is carried in accordance with NFPA 385. [**407:**6.1.2.1]

N **42.10.4.1.2.2** Cargo tanks shall be constructed in accordance with 49 CFR 178.345, DOT 406, or other equivalent standard for international application. [**407:**6.1.2.2]

N **42.10.4.1.2.3** Aluminum alloys for high-strength welded construction shall be joined by an inert gas arc welding process using filler metals R-GR40A, E-GR40A (5154 alloy), R-GM50A, and EGM50A (5356 alloy) in accordance with AWS A5.10. [**407:**6.1.2.3]

N **42.10.4.1.2.4** Tank outlets shall be of substantial construction. [**407:**6.1.2.4]

N **42.10.4.1.2.5** Tank outlets shall be attached securely to the tank. [**407:**6.1.2.5]

N **42.10.4.1.2.6 Baffles.** Every cargo tank or compartment over 2.3 m (7.5 ft) long shall be provided with baffles, the total number of which shall be such that the distance between any two adjacent baffles, or between any tank head or bulkhead and the baffle closest to it, shall in no case exceed 1.5 m (5 ft). [**407:**6.1.2.6]

N **42.10.4.1.2.6.1** The cross-sectional area of each baffle shall be not less than 80 percent of the cross-sectional area of the tank. [**407:**6.1.2.6.1]

N **42.10.4.1.2.6.2** The thickness of a baffle shall be not less than that required for the heads and bulkheads of the cargo tank in which it is installed. [**407:**6.1.2.6.2]

N **42.10.4.1.2.7** Venting shall be in accordance with 49 CFR, DOT 406. [**407:**6.1.2.7]

N **42.10.4.1.2.8** Cargo draw-off valves or faucets projecting beyond the frame of a tank vehicle shall be protected against damage. [**407:**6.1.2.8]

N **42.10.4.1.2.9 Fill Openings and Top Flashings.**

N **42.10.4.1.2.9.1** Dome covers shall be provided with a forward mounted hinge and self-latching catches and shall be fitted with watertight fuel-resistant seals or gaskets designed to prevent spillage or leakage from overturn and to prevent water entry. [**407:**6.1.2.9.1]

N **42.10.4.1.2.9.2** Dome covers shall automatically close and latch with the forward motion of the vehicle. [**407:**6.1.2.9.2]

N **42.10.4.1.2.9.3** Drains from top flashing shall divert spilled fuel from possible sources of ignition, including the engine, the engine exhaust system, the electrical equipment, or an auxiliary equipment enclosure. [**407:**6.1.2.9.3]

N **42.10.4.1.2.9.4** The tank fill openings shall be protected against overturn damage by a rigid member(s) fixed to the tank and extending a minimum of 25 mm (1 in.) above any dome cover, handle, vent opening, or projection of the unit. [**407:**6.1.2.9.4]

N **42.10.4.1.2.9.5** Overturn protection shall be braced adequately to prevent collapse. [**407:**6.1.2.9.5]

N **42.10.4.1.2.9.6** Overturn protection shall be designed to channel rainwater, snow, or fuel to the exterior of the cargo tank and away from vehicle exhaust components. [**407:**6.1.2.9.6]

N **42.10.4.1.2.10 Tanks for Flammable Liquids Other than Fuel.** Vehicle or cart fuel tanks and containers for other flammable liquids shall be made of metal and shall be designed, constructed, and located in a manner that precludes hazardous arrangements. [**407:**6.1.2.10]

N **42.10.4.1.2.10.1** Tanks shall be substantially protected by their location. [**407:**6.1.2.10.1]

N **42.10.4.1.2.10.2** Fill pipes shall not project beyond the vehicle profile. [**407:**6.1.2.10.2]

N **42.10.4.1.2.10.3** Tanks and containers shall vent away from sources of ignition during filling. [**407:**6.1.2.10.3]

N **42.10.4.1.2.10.4** Any arrangement not protected by location shall be listed for such use. [**407:**6.1.2.10.4]

N **42.10.4.1.2.10.5** The fuel tank arrangement shall allow for drainage without the tank's removal from its mountings. [**407:**6.1.2.10.5]

N **42.10.4.1.2.11 Tests.** Cargo tanks, at the time of manufacture, shall be tested by a minimum air or hydrostatic pressure of 24.4 kg/m^2 (5 psi) applied to the whole tank (or each compartment thereof if the tanks are compartmented) for a period of at least 5 minutes. [**407:**6.1.2.11]

N **42.10.4.1.2.11.1** If the test is by air pressure, the entire exterior surface of all joints shall be coated with a solution of soap and water, heavy oil, or other substance that causes foaming or bubbling that indicates the presence of leaks. [**407:**6.1.2.11.1]

N **42.10.4.1.2.11.2** If the test is by hydrostatic pressure, it shall be gauged at the top of the tank, and the tank shall be inspected at the joints for the issuance of liquid to indicate leaks. [**407:**6.1.2.11.2]

N **42.10.4.1.2.11.3** Any leakage discovered by either of the methods described in 42.10.4.1.2.11.1 and 42.10.4.1.2.11.2, or by any other method, shall be considered evidence of failure to meet these requirements. [**407:**6.1.2.11.3]

N **42.10.4.1.3 Pumps and Piping System.**

N **42.10.4.1.3.1** All portions of the flammable liquid feed system shall be constructed and located to minimize the fire hazard. [**407:**6.1.3.1]

N **42.10.4.1.3.2** Piping and plumbing shall be made of materials not adversely affected by the fluid or by other materials likely to be encountered. [**407:**6.1.3.2]

N **42.10.4.1.3.3** Piping and plumbing shall be of adequate strength for the purpose. [**407:**6.1.3.3]

N **42.10.4.1.3.4** Piping and plumbing shall be secured to avoid chafing or undue vibration. [**407:**6.1.3.4]

N **42.10.4.1.3.5** Piping and plumbing shall be supported adequately. [**407:**6.1.3.5]

N **42.10.4.1.3.6** Product piping shall be metal and rated for the system working pressure or at least 1030 kPa (150 psi), whichever is greater. [**407:**6.1.3.6]

N **42.10.4.1.3.7** Except as provided in 42.10.4.1.3.8, all joints shall be welded. [**407:**6.1.3.7]

N **42.10.4.1.3.8** Flanged connections or approved couplings shall be provided to avoid the need for cutting and welding where components are serviced or replaced. [**407:**6.1.3.8]

N **42.10.4.1.3.9** Gaskets in flanged connections shall be of a material and design that resist fire exposure for a time comparable to the flange and bolts. [**407:**6.1.3.9]

N **42.10.4.1.3.10** Gravity feed systems shall not be used. [**407:**6.1.3.10]

N **42.10.4.1.3.11** At the time of manufacture, the section of the fuel dispensing system that is under pressure during service shall be subjected to a hydrostatic test pressure equal to 150 percent of the working pressure of the system for at least 30 minutes and shall be proven tight before it is placed in service. [**407:**6.1.3.11]

N **42.10.4.1.3.11.1** Hose connections shall be permitted to be plugged during this test. [**407:**6.1.3.11.1]

N **42.10.4.1.3.12 Loading System.**

N **42.10.4.1.3.12.1 Top Loading.**

N **42.10.4.1.3.12.1.1** Drop tubes shall be used. [**407:**6.1.3.12.1.1]

N **42.10.4.1.3.12.1.2** Splash filling shall be prohibited. [**407:** 6.1.3.12.1.2]

N **42.10.4.1.3.12.1.3** Drop tubes used in top loading or overhead loading of tank vehicles shall be designed to minimize turbulence. [**407:**6.1.3.12.1.3]

N **42.10.4.1.3.12.1.4** Drop tubes shall be metallic. [**407:**6.1.3.12.1.4]

N **42.10.4.1.3.12.1.5** Drop tubes shall extend to the bottom of the tank or to the inside of the sump to maintain submerged loading and to avoid splashing of the fuel. [**407:**6.1.3.12.1.5]

N **42.10.4.1.3.12.2 Bottom Loading.**

N **42.10.4.1.3.12.2.1** The bottom-loading connection of a tank truck shall be a dry-break coupler that cannot be opened until it is engaged to the vehicle tank adapter. [**407:**6.1.3.12.2.1]

N **42.10.4.1.3.12.2.2** It shall not be possible to disconnect the hose coupler from the tank vehicle until the coupler valve is fully closed. [**407:**6.1.3.12.2.2]

N **42.10.4.1.3.12.2.3*** The bottom loading fitting of the tank vehicle shall be a spring-loaded check valve that remains in a closed position until opened by connecting the coupler. [**407:**6.1.3.12.2.3]

N **A.42.10.4.1.3.12.2.3** An optional precaution against misfueling of aircraft fuel servicing tank vehicles is to equip the coupler and truck fitting with coded lugs or a mechanical device to ensure product selection and to prevent mixing of products. This might not be feasible on over-the-road-type tank vehicles. [**407:**A.6.1.3.12.2.3]

N **42.10.4.1.3.12.2.4** A float-actuated shutoff or other automatic sensing device shall be provided to close the bottom-loading valve when the tank is filled. [**407:**6.1.3.12.2.4]

N **42.10.4.1.3.12.2.5** Any liquid bled from a sensing device during loading shall be piped to the bottom of the cargo tank. [**407:**6.1.3.12.2.5]

N **42.10.4.1.3.12.2.6** The fill pipe and valving on bottom-loaded tank vehicles shall be arranged to prevent fuel spray and turbulence in the cargo tank. [**407:**6.1.3.12.2.6]

N **42.10.4.1.3.12.2.7** The cargo tank vehicle shall be equipped with an automatic primary shutdown system that stops the tank loading operation when the tank is full, unless an automatic shutdown is provided on the loading rack in accordance with 42.10.3.1.2.1. [**407:**6.1.3.12.2.7]

N **42.10.4.1.3.12.2.8** The cargo tank vehicle shall be equipped with an automatic secondary shutdown system that stops the tank loading operation when the tank is full. [**407:**6.1.3.12.2.8]

This requirement is intended to align with NFPA 30, which requires both a primary and a secondary automatic shutdown for bulk loading of tank vehicles.

N **42.10.4.1.3.12.2.9** The automatic secondary shutoff control shall not be used for normal filling control. [**407:**6.1.3.12.2.9]

N **42.10.4.1.3.13** Each outlet valve shall be provided with a fusible device that causes the valve to close automatically in case of fire. [**407:**6.1.3.13]

N **42.10.4.1.3.14** A shear section shall be provided between shutoff valve seats and discharge outlets that breaks under strain, unless the discharge piping is arranged to afford the same protection and leave the shutoff valve seat intact. [**407:**6.1.3.14]

N **42.10.4.1.3.15** Openings in cargo tank compartments that are connected to pipe or tubing shall be fitted with a spring-loaded check valve, a self-closing valve, or a similar device to prevent the accidental discharge of fuel in case of equipment malfunction or line breakage. [**407:**6.1.3.15]

N **42.10.4.1.3.15.1** Unless the valves required in 42.10.4.1.3.15 are located inside the tank, they shall be equipped with a shear section as described in 42.10.4.1.3.14. [**407:**6.1.3.15.1]

N **42.10.4.1.3.16** The operating mechanism for each tank outlet valve shall be adjacent to the fuel delivery system operating controls. [**407:**6.1.3.16]
