
N **42.10.4.1.3.16.1** The operating mechanism for each tank outlet valve shall be arranged so that the outlet valve(s) can be closed simultaneously and instantly in the event of a fire or other emergency. [**407:**6.1.3.16.1]

N **42.10.4.1.3.16.2** A means shall be provided to assure proper operation. [**407:**6.1.3.16.2]

N **42.10.4.1.4 Hose and Nozzles. (Reserved)**

N **42.10.4.1.5 Bonding.**

N **42.10.4.1.5.1** All metallic components and vehicle or cart chassis shall be electrically bonded to prevent a difference in their electrostatic potential. [**407:**6.1.5.1]

N **42.10.4.1.5.2** Such bonding shall be inherent to the installation or by physical application of a suitable bonding mechanism. [**407:**6.1.5.2]

N **42.10.4.1.5.3** A provision shall be provided on the vehicle to bond the tank to a fill pipe or loading rack as specified in 42.10.4.2.11.10.1. [**407:**6.1.5.3]

N **42.10.4.1.5.4** Cables shall be provided on the vehicle or cart to allow the bonding operations specified in 42.10.2.2.5. [**407:**6.1.5.4]

N **42.10.4.1.6 Electrical System.**

N **42.10.4.1.6.1 Battery Compartments.** Batteries that are not in engine compartments shall be securely mounted in compartments to prevent accidental arcing. [**407:**6.1.6.1]

N **42.10.4.1.6.1.1** The compartment shall be separate from fueling equipment. [**407:**6.1.6.1.1]

N **42.10.4.1.6.1.2** Suitable shielding shall be provided to drain possible fuel spillage or leakage away from the compartment. [**407:**6.1.6.1.2]

N **42.10.4.1.6.1.3** The compartment shall be provided with a vent at the top of the compartment. [**407:**6.1.6.1.3]

N **42.10.4.1.6.2 Wiring.** Wiring shall be of adequate size to provide the required current-carrying capacity and mechanical strength. [**407:**6.1.6.2]

N **42.10.4.1.6.2.1** Wiring shall be installed to provide protection from physical damage and from contact with spilled fuel either by its location or by enclosing it in metal conduit or other oil-resistant protective covering. [**407:**6.1.6.2.1]

N **42.10.4.1.6.2.2** All circuits shall have overcurrent protection. [**407:**6.1.6.2.2]

N **42.10.4.1.6.2.3** Junction boxes shall be weatherproofed. [**407:**6.1.6.2.3]

N **42.10.4.1.6.2.4** The vehicle shall be equipped with a battery disconnect switch. [**407:**6.1.6.2.4]

The intent of the battery disconnect switch is to provide a means to remove power in the event of an emergency.

N **42.10.4.1.6.3** Spark plugs and other exposed terminal connections shall be insulated to prevent sparking in the event of contact with conductive materials. [**407:**6.1.6.3]

N **42.10.4.1.6.4*** Motors, alternators, generators, and their associated control equipment located outside of the engine compartment or vehicle cab shall be of a type listed for use in accordance with *NFPA 70*, Class I, Division 1, Group D locations. [**407:**6.1.6.4]

N **A.42.10.4.1.6.4** Electrical equipment contained in aircraft fuel servicing vehicles or cart engine compartments and located 460 mm (18 in.) or more above ground can be permitted to be of the general-purpose type. [**407:**A.6.1.6.4]

N **42.10.4.1.6.5** Electrical equipment and wiring located within a closed compartment shall be of a type listed for use in accordance with *NFPA 70*, Class I, Division 1, Group D locations. [**407:**6.1.6.5]

N **42.10.4.1.6.6** Lamps, switching devices, and electronic controls, other than those covered in 42.10.4.1.6.4 and 42.10.4.1.6.5, shall be of the enclosed, gasketed, weatherproof type. [**407:**6.1.6.6]

Electronic controls could include electronic gauges, monitoring devices, and the like.

N **42.10.4.1.6.7** Other electrical components not covered in 42.10.4.1.6.4 through 42.10.4.1.6.6 shall be of a type listed for use in accordance with *NFPA 70*, Class I, Division 2, Group D locations. [**407:**6.1.6.7]

N **42.10.4.1.6.8** Electronic equipment shall not be installed in compartments with other equipment that can produce flammable vapors, unless permitted by *NFPA 70*. [**407:**6.1.6.8]

N **42.10.4.1.6.9 Tractor Trailer Wiring.** Electrical service wiring between a tractor and trailer shall be designed for heavy-duty service. [**407:**6.1.6.9]

N **42.10.4.1.6.9.1** The connector shall be of the positive-engaging type. [**407:**6.1.6.9.1]

N **42.10.4.1.6.9.2** The trailer receptacle shall be mounted securely. [**407:**6.1.6.9.2]

N **42.10.4.1.7 Control of Fuel Flow.**

N **42.10.4.1.7.1*** The valve that controls the flow of fuel to an aircraft shall have a deadman control. [**407:**6.1.7.1]

N **A.42.10.4.1.7.1** See A.42.10.3.1.7.1. [**407:**A.6.1.7.1]

N **42.10.4.1.7.2** The fuel flow control valve shall be one of the following:

(1) The hydrant pit valve
(2) At the tank outlet on a tank vehicle
(3) A separate valve on the tank vehicle
(4) On the hose nozzle for overwing servicing

[**407:**6.1.7.2]

N **42.10.4.1.7.3** Deadman controls shall be designed to preclude defeating their intended purpose. [**407:**6.1.7.3]

N **42.10.4.1.7.4 Pressure Fuel Servicing System Controls.**

N **42.10.4.1.7.4.1** The system shall be designed to minimize surge pressure. [**407:**6.1.7.4.1]

N **42.10.4.1.7.4.2*** The overshoot shall not exceed 5 percent of actual flow rate in L/min (gal/min) at the time the deadman is released. [**407:**6.1.7.4.2]

N **A.42.10.4.1.7.4.2** See A.42.10.3.1.7.2.2. [**407:**A.6.1.7.4.2]

N **42.10.4.1.7.4.3** The control valve shall be located and designed so that it will not be rendered inoperative by a surface accident, power failure, or spill. [**407:**6.1.7.4.3]

N **42.10.4.1.7.4.4** The control valve shall be fail-safe by closing completely in the event of control power loss. [**407:**6.1.7.4.4]

N **42.10.4.1.7.5** On tank full trailer or tank semitrailer vehicles, the use of a pump in the tractor unit with flexible connections to the trailer shall be prohibited unless one of the following conditions exists:

(1) Flexible connections are arranged above the liquid level of the tank in order to prevent gravity or siphon discharge in case of a break in the connection or piping.
(2) The cargo tank discharge valves required by 42.10.4.1.7.1 are arranged to be normally closed and to open only when the brakes are set and the pump is engaged.

[**407:**6.1.7.5]

N **42.10.4.1.7.6 Air Elimination.** Aircraft fuel servicing tank vehicles having a positive displacement product pump shall be equipped with a product tank low-level shutdown system that prevents air from being ingested into the fueling system. [**407:**6.1.7.6]

This paragraph applies only to aircraft fuel servicing tank vehicles that have a positive displacement product pump. A low-level shutdown system is not required for tank vehicles that have a centrifugal pump. Unlike positive displacement pumps, centrifugal pumps lose prime and cavitate when the tank is emptied of product. As air enters the suction port, pump output effectively stops, thus presenting no threat of dispensing air, in lieu of fuel, into the aircraft.

N **42.10.4.1.8 Filters and Ancillary Equipment.**

N **42.10.4.1.8.1 Cabinets.**

N **42.10.4.1.8.1.1** All cabinets, other than those housing electronic equipment, shall be vented to prevent the accumulation of fuel vapors. *(See 42.10.4.1.6.)* [**407:**6.1.8.1.1]

N **42.10.4.1.8.1.2** All cabinets, other than those housing electronic equipment, shall be constructed of noncombustible materials. *(See 42.10.4.1.6.)* [**407:**6.1.8.1.2]

N **42.10.4.1.8.2 Product Recovery Tanks.** The refueling system product recovery tank shall be equipped with a control that shuts down the vehicle's fuel dispensing system when the refueling system product recovery tank is three-quarters full. [**407:**6.1.8.2]

N **42.10.4.1.9 Emergency Fuel Shutoff Systems.**

N **42.10.4.1.9.1** The vehicle shall have at least two emergency shutoff controls, one mounted on each side of the vehicle. [**407:**6.1.9.1]

N **42.10.4.1.9.2** The emergency fuel shutoff controls shall be quick-acting to close the outlet valve in case of emergency. [**407:**6.1.9.2]

N **42.10.4.1.9.3** The emergency fuel shutoff controls shall be remote from the fill openings and discharge outlets and shall be operable from a ground level standing position. [**407:**6.1.9.3]

N **42.10.4.1.9.4** All vehicles or carts equipped with a top deck or elevating platform shall have an additional emergency shutoff control operable from the deck or platform. [**407:**6.1.9.4]

N **42.10.4.1.10 Fire Protection.**

N **42.10.4.1.10.1** Each aircraft fuel servicing tank vehicle shall have two listed fire extinguishers, each having a rating of at least 80-B:C, with one extinguisher mounted on each side of the vehicle. [**407:**6.1.10.1]

N **42.10.4.1.10.2** One listed fire extinguisher having a rating of at least 80-B:C shall be installed on each hydrant fuel servicing vehicle or cart. [**407:**6.1.10.2]

N **42.10.4.1.10.3** Extinguishers shall be readily accessible from the ground. [**407:**6.1.10.3]

N **42.10.4.1.10.4** The area of the paneling or tank adjacent to or immediately behind the extinguisher(s) on fueling vehicles or carts shall be painted a color contrasting with that of the extinguisher. [**407:**6.1.10.4]

N **42.10.4.1.10.5** Extinguishers shall be kept clear of elements such as ice and snow. [**407:**6.1.10.5]

N **42.10.4.1.10.6** Extinguishers located in enclosed compartments shall be readily accessible. [**407:**6.1.10.6]

N **42.10.4.1.10.7** The locations of extinguishers in enclosed compartments shall be marked clearly in letters of a contrasting color at least 50 mm (2 in.) high. [**407:**6.1.10.7]

N **42.10.4.1.10.8 Smoking Equipment.**

N **42.10.4.1.10.8.1*** Smoking equipment, such as cigarette lighter elements and ashtrays, shall not be provided. [**407:**6.1.10.8.1]

N **A.42.10.4.1.10.8.1** It is not the intent of 42.10.4.1.10.8.1 to prohibit 12 V power outlets. The intent is to prohibit glowing elements. [**407:**A.6.1.10.8.1]

N **42.10.4.1.10.8.2** If a vehicle includes smoking equipment, it shall be removed or rendered inoperable. [**407:**6.1.10.8.2]

N **42.10.4.1.10.8.3** Subsection 42.10.4.1.10.8.2 shall be retroactive to existing vehicles. [**407:**6.1.10.8.3]

See the commentary that follows 42.10.1 regarding retroactive requirements.

N **42.10.4.1.11 Marking and Labeling.**

N **42.10.4.1.11.1** Aircraft fueling vehicles shall be marked with the name of the operator or the responsible organization. [**407:**6.1.11.1]

N **42.10.4.1.11.2** The marking shall be approved, legible signs on both sides of the exterior of the vehicle. [**407:**6.1.11.2]

N **42.10.4.1.11.3 Signage.** Each aircraft fuel servicing vehicle or cart shall have a signage viewable from all sides of the vehicle. [**407:**6.1.11.3]

N **42.10.4.1.11.3.1** Signs shall have letters at least 75 mm (3 in.) high. [**407:**6.1.11.3.1]

N **42.10.4.1.11.3.2** Signs shall be of a color contrasting sharply with the sign background for visibility. [**407:**6.1.11.3.2]

N **42.10.4.1.11.3.3** The words "FLAMMABLE," "NO SMOKING," and the name of the product carried, such as JET A, JET B, GASOLINE, or AVGAS, shall appear on each sign. [**407:**6.1.11.3.3]

N **42.10.4.1.11.4 Emergency Fuel Shutoff Signs.**

N **42.10.4.1.11.4.1** Each emergency fuel shutoff station location shall be placarded EMERGENCY FUEL SHUTOFF in letters at least 50 mm (2 in.) high. [**407:**6.1.11.4]

N **42.10.4.1.11.4.2** The method of operation shall be indicated by an arrow or by the word PUSH or PULL, as appropriate. [**407:**6.1.11.4.2]

N **42.10.4.1.11.4.3** Any action necessary to gain access to the shutoff device (e.g., BREAK GLASS) shall be shown clearly. [**407:**6.1.11.4.3]

N **42.10.4.1.11.4.4** Lettering shall be of a color contrasting sharply with the placard background for visibility. [**407:**6.1.11.4.4]

N **42.10.4.1.11.4.5** Placards shall be weather resistant. [**407:**6.1.11.4.5]

N **42.10.4.1.11.5** A "NO SMOKING" sign shall be posted prominently in the cab of every aircraft fuel servicing vehicle. [**407:**6.1.11.5]

N **42.10.4.1.11.6** Hazardous material placards meeting the requirements of 49 CFR 172.504 or equivalent shall be displayed on all four sides of fuel servicing tank vehicles. [**407:**6.1.11.6]

Vehicles that operate only on private property are not usually subject to the requirements of 49 CFR. However, it is accepted industry practice to provide hazardous material placards for the benefit of first responders.

N **42.10.4.1.12 Drive Train.**

N **42.10.4.1.12.1** Propulsion or power engine equipment shall be in a compartment housing that shall minimize the hazard of fire in the event of leakage or spillage of fuel during the servicing of an aircraft. [**407:**6.1.12.1]

N **42.10.4.1.12.2** The engine air intake shall retain the manufacturer's configuration to prevent the emission of flame in case of backfiring. [**407:**6.1.12.2]

N **42.10.4.1.12.3** Where provided, the sediment bowl in the fuel supply line shall be of steel or material of equivalent fire resistance. [**407:**6.1.12.3]

N **42.10.4.1.12.4** Full trailers and semitrailers, except tow carts with a gross vehicle weight rating (GVWR) under 1360 kg (3000 lb), shall be equipped with service brakes on all wheels. [**407:**6.1.12.4]

N **42.10.4.1.12.5** All full trailers and semitrailers, including tow carts with a GVWR under 1360 kg (3000 lb), shall be equipped with parking brakes. [**407:**6.1.12.5]

N **42.10.4.1.12.6** Self-propelled aircraft fuel servicing vehicles shall have an integral system or device that prevents the vehicle from being moved unless all of the following conditions are met:

(1) All fueling nozzles and hydrant couplers are properly stowed.
(2) All mechanical lifts are lowered to their stowed position.
(3) Bottom-loading couplers have been disconnected from the vehicle.

[**407:**6.1.12.6]

N **42.10.4.1.12.7** The vehicle shall have a means to override the system or device required by 42.10.4.1.12.6 so that the vehicle can be moved during an emergency. [**407:**6.1.12.7]

N **42.10.4.1.12.7.1** The override control shall be clearly marked and accessible. [**407:**6.1.12.7.1]

N **42.10.4.1.12.7.2** A light to indicate activation of the override shall be located in the cabin and visible outside. [**407:**6.1.12.7.2]

N **42.10.4.1.12.7.3** The override control shall be secured in the normal position with a breakaway seal. [**407:**6.1.12.7.3]

N **42.10.4.1.12.7.4** The override control shall deactivate the fueling system. [**407:**6.1.12.7.4]

N **42.10.4.1.13 Exhaust System.**

N **42.10.4.1.13.1*** The engine exhaust system shall be designed, located, and installed to minimize the hazard of fire in the event of any of the following:

(1) Leakage of fuel from the vehicle or cart (where applicable) fuel tank or fuel system
(2) Leakage from the fuel dispensing system of the vehicle or cart
(3) Spillage or overflow of fuel from the vehicle or cart (if applicable) fuel tank or the cargo tank
(4) Spillage of fuel during the servicing of an aircraft

[**407:**6.1.13.1]

N **A.42.10.4.1.13.1** Wherever possible, flexible engine exhaust pipe should be avoided due to the potential of breaking. Where used, stainless steel is preferable, and the length should be limited to approximately 460 mm (18 in.). [**407:**A.6.1.13.1]

N **42.10.4.1.13.2** Exhaust system components shall be secured and located clear of components carrying flammable liquids and separated from any combustible materials used in the construction of the vehicle. [**407:**6.1.13.2]

N **42.10.4.1.13.3** Suitable shielding shall be provided to drain possible fuel spillage or leakage away from exhaust system components safely. [**407:**6.1.13.3]

N **42.10.4.1.13.3.1** Diesel particulate filter (DPF) regeneration system piping shall be shielded from the engine discharge manifold to the outlet at the tailpipe. [**407:**6.1.13.3.1]

N **42.10.4.1.13.3.2** DPF regeneration–equipped vehicles shall have a listed diffuser installed at the outlet of the exhaust tailpipe. [**407:**6.1.13.3.2]

N **42.10.4.1.13.4** Exhaust gases shall not be discharged where they could ignite fuel vapors that could be released during normal operations or by accidental spillage or by leakage of fuel. [**407:**6.1.13.4]

N **42.10.4.1.13.4.1** DPF regeneration–equipped vehicles shall have a lockout mode that will prevent automatic regeneration when these vehicles are operated within 30 m (100 ft) of aircraft parking areas. [**407:**6.1.13.4.1]

N **42.10.4.1.13.5** A muffler (or silencer) cutout shall not be provided. [**407:**6.1.13.5]

N **42.10.4.1.13.6** Carbureted gasoline-powered engines on fuel servicing vehicles shall be provided with flame- and spark-arresting exhaust systems. [**407:**6.1.13.6]

N **42.10.4.1.13.7*** Non-turbo-charged diesel engines on fuel servicing vehicles shall be equipped with flame- and spark-arresting exhaust systems. [**407:**6.1.13.7]

N **A.42.10.4.1.13.7** The requirement for spark-arresting exhaust systems is not intended to extend to diesel engines equipped with turbochargers. The USDA Forest Service, the governmental body that regulates the spark arrester standard, clearly identifies that all diesel engines with a turbocharger and no waste gate (also clearly identified therein) are exempt from the requirements to have an additional spark-arresting device. [**407:**A.6.1.13.7]

N **42.10.4.2 Operations.**

N **42.10.4.2.1 Security.**

N **42.10.4.2.1.1 Parking of Aircraft Fuel Servicing Tank Vehicles.** Parking areas for unattended aircraft fuel servicing tank vehicles shall be arranged to provide the following:

(1) Dispersal of the vehicles in the event of an emergency
(2) A minimum of 3 m (10 ft) of clear space between parked vehicles for accessibility for fire control purposes
(3) Prevention of any leakage from draining to an adjacent building or storm drain that is not suitably designed to handle fuel
(4) A minimum of 15 m (50 ft) from any parked aircraft and buildings other than maintenance facilities and garages for fuel servicing tank vehicles

[**407:**6.2.1.1]

N **42.10.4.2.1.2 Parking of Aircraft Fuel Servicing Hydrant Vehicles and Carts.** Parking areas for unattended aircraft fuel servicing hydrant vehicles or carts shall be arranged to provide the following:

(1) Dispersal of the vehicles in the event of an emergency
(2) Prevention of any leakage from draining to an adjacent building or storm drain that is not suitably designed to handle fuel

[**407:**6.2.1.2]

N **42.10.4.2.1.3*** The authority having jurisdiction shall determine the suitability of tunnels, enclosed roadways, or other limited access areas for use by fuel servicing vehicles. [**407:**6.2.1.3]

N **A.42.10.4.2.1.3** The use of tunnels or enclosed roadways is discouraged. Where there is no alternate route, and the fuel servicing vehicle requires the use of a tunnel or enclosed roadway, the authority having jurisdiction should examine the following considerations:

(1) Length
(2) Clearances
(3) Fixed fire suppression or extinguishing systems
(4) Frequency of use
(5) Ventilation
(6) Overlying structures and operations
(7) Other traffic
(8) Fire department access
(9) Emergency egress
(10) Drainage
(11) Other conditions

[**407:**A.6.2.1.3]

With the growth of airports, traffic, and roadways, safeguards are needed to protect the public and airport operations from potential hazards due to an incident involving a fuel servicing vehicle in a tunnel, such as a spill or a fire. The use of tunnels or enclosed roadways is necessary at certain times and locations; however, the AHJ should determine the suitability of using such tunnels, based on various risk factors.

N **42.10.4.2.2 Training. (Reserved)**

N **42.10.4.2.3 Prevention and Control of Spills. (Reserved)**

N **42.10.4.2.4 Emergency Fuel Shutoff. (Reserved)**

N **42.10.4.2.5 Bonding. (Reserved)**

N **42.10.4.2.6 Control of Fuel Flow.**

N **42.10.4.2.6.1** The fueling operator shall monitor the fueling operation. [**407:**6.2.6.1]

N **42.10.4.2.6.2** During overwing fueling, the operator shall monitor the fill port. [**407:**6.2.6.2]

N **42.10.4.2.7 Fire Protection. (Reserved)**

N **42.10.4.2.8 Maintenance.**

N **42.10.4.2.8.1** Aircraft fuel servicing vehicles or carts shall not be operated unless they are in proper repair and free of accumulations of grease, oil, or other combustibles. [**407:**6.2.8.1]

N **42.10.4.2.8.2** Leaking vehicles or carts shall be removed from service, defueled, and parked in a safe area until repaired. [**407:**6.2.8.2]

N **42.10.4.2.8.3** Maintenance and servicing of aircraft fuel servicing vehicles and carts shall be performed outdoors or in a building approved for the purpose. [**407:**6.2.8.3]

N **42.10.4.2.8.4** At least monthly the operator shall perform a check to ensure complete closure of the bottom-loading valve on the tank vehicle. [**407:**6.2.8.4]

N **42.10.4.2.9 Aircraft Fueling Hose. (Reserved)**

N **42.10.4.2.10 Exhaust System.**

N **42.10.4.2.10.1** All vehicles that have engines equipped with an exhaust after-treatment device, such as a DPF, that requires the filter to be cleaned at high temperature (regenerated) while installed on the vehicle shall meet the requirements of 42.10.4.2.10.2 through 42.10.4.2.10.10. [**407:**6.2.10.1]

N **42.10.4.2.10.2** DPF regeneration shall be performed only in area(s) designated by the authority having jurisdiction. [**407:**6.2.10.2]

N **42.10.4.2.10.3** DPF regeneration shall not be performed within 30 m (100 ft) of any aircraft refueling operations. [**407:**6.2.10.3]

N **42.10.4.2.10.4* Vehicle Regeneration Area.**

Aircraft refueling vehicles with diesel particulate filter (DPF) regeneration are being used on airfields. The language addresses the operational issues with the regeneration sequence that will provide a measure of safety for the fuel handlers, as well as the airfields on which they operate. These units have the potential for introducing an ignition source due to the extremely high temperatures generated by the exhaust system. Exhaust gas temperatures, when in the regeneration mode, reach over 1200°F (649°C) inside the system, and exhaust gases are over 700°F (371°C). Both of these temperatures are hot enough to ignite Jet-A vapors or fuel (if dripped onto exhaust system components).

N **A.42.10.4.2.10.4** The size of the DPF regeneration area depends on the equipment being used (fleet size). The authority having jurisdiction should designate the size and number of DPF regeneration pads and determine whether a centralized facility is advantageous. [**407:**A.6.2.10.4]

N **42.10.4.2.10.4.1** The immediate area surrounding the DPF exhaust outlet shall be concrete or other high temperature–resistant material and shall be clear of any grass, soil, or flammable materials. [**407:**6.2.10.4.1]

N **42.10.4.2.10.4.2** The area shall be in a remote location that is a minimum of 30 m (100 ft) from the nearest aircraft parking location, airport terminal, or flammable storage or a minimum of 15 m (50 ft) from any other building. [**407:**6.2.10.4.2]

N **42.10.4.2.10.4.3** The area shall be clearly marked with a minimum 61 cm by 30 cm (2 ft by 1 ft) sign reading “Vehicle DPF Regeneration Area,” which shall have letters at least 75 mm (3 in.) high and shall be of a color contrasting sharply with the sign background for visibility. [**407:**6.2.10.4.3]

N **42.10.4.2.10.5** The regeneration cycle shall be performed only by trained personnel, who shall remain with the vehicle until the regeneration cycle is complete. [**407:**6.2.10.5]

N **42.10.4.2.10.6** The vehicle shall be visually inspected for any signs of fluid leaks under or around the vehicle before regeneration is initiated. [**407:**6.2.10.6]

N **42.10.4.2.10.7** DPF regeneration shall not be initiated if there are any signs of any fluid leaks on or beneath the vehicle. [**407:**6.2.10.7]

N **42.10.4.2.10.8** Once a regeneration cycle is started, it shall be completed without interruption. [**407:**6.2.10.8]

N **42.10.4.2.10.9** After the regeneration process is successfully completed, the vehicle shall be permitted to return to normal service. [**407:**6.2.10.9]

N **42.10.4.2.10.10** Problems occurring during the regeneration cycle shall be corrected prior to the vehicle returning to normal service. [**407:**6.2.10.10]

N **42.10.4.2.10.11** Aircraft refueling operations shall not be initiated if the regenerative system indicates regeneration is required. [**407:**6.2.10.11]

N **42.10.4.2.11 Loading and Unloading.**

N **42.10.4.2.11.1** Aircraft fuel servicing tank vehicles shall be loaded only at an approved loading rack. [**407:**6.2.11.1]

N **42.10.4.2.11.2** Aircraft fuel servicing tank vehicles shall not be loaded from a hydrant pit, unless permitted by the authority having jurisdiction under emergency circumstances. [**407:**6.2.11.2]

N **42.10.4.2.11.3** Filling of the vehicle cargo tank shall be under the observation and control of a qualified and authorized operator at all times. [**407:**6.2.11.3]

N **42.10.4.2.11.4** The required deadman and automatic overfill controls shall be in normal operating condition during the filling operation. [**407:**6.2.11.4]

N **42.10.4.2.11.5** The controls shall not be blocked open or otherwise bypassed. [**407:**6.2.11.5]

N **42.10.4.2.11.6** The engine of the tank vehicle shall be shut off before starting to fill the tank. [**407:**6.2.11.6]

N **42.10.4.2.11.7** To prevent leakage or overflow from expansion of the contents due to a rise in atmospheric temperature or direct exposure to the sun, no cargo tank or compartment shall be loaded to the point where it is liquid full. [**407:**6.2.11.7]

N **42.10.4.2.11.7.1** No cargo tank or compartment shall be loaded above the rated net capacity, as specified by the manufacturer’s data plate. [**407:**6.2.11.7.1]

N **42.10.4.2.11.7.2** Space for thermal expansion, in no case less than 3 percent of the tank volume, shall be provided to prevent leakage. [**407:**6.2.11.7.2]

N **42.10.4.2.11.8** The driver, operator, or attendant of any tank vehicle shall not remain in the vehicle but shall not leave the vehicle unattended during the loading or unloading process. [**407:**6.2.11.8]

N **42.10.4.2.11.8.1** Delivery hose, when attached to a tank vehicle, shall be considered to be a part of the tank vehicle. [**407:**6.2.11.8.1]

N **42.10.4.2.11.9** No fuel shall be transferred to or from any tank vehicle until the parking brake and wheel chocks have been set to prevent motion of the vehicle. [**407:**6.2.11.9]

N **42.10.4.2.11.10 Top Loading.**

N **42.10.4.2.11.10.1** Where loading tank trucks through open domes, a bond shall be established between the loading piping and the cargo tank to equalize potentials. [**407:**6.2.11.10.1]

N **42.10.4.2.11.10.2** The bond connection shall be made before the dome is opened and shall be removed only after the dome is closed. [**407:**6.2.11.10.2]

N **42.10.4.2.11.10.3** Drop tubes attached to loading assemblies extending into the vehicle tank shall extend to the bottom of the tank and shall be maintained in that position until the tank is loaded to provide submerged loading and avoid splashing or free falling of fuel through the tank atmosphere. [**407:**6.2.11.10.3]

N 42.10.4.2.11.10.4 Splash filling shall be prohibited. [**407:**6.2.11.10.4]

N 42.10.4.2.11.10.5 The flow rate into the tanks shall not exceed 25 percent of the maximum flow until the outlet is fully covered. [**407:**6.2.11.10.5]

N 42.10.4.2.11.10.6 Fixed drop tubes permanently mounted in the vehicle tank shall extend to the bottom of the tank or to the inside of the sump to maintain submerged loading and to avoid splashing of the fuel. [**407:**6.2.11.10.6]

N 42.10.4.2.11.10.7 The level in the tank shall be visually monitored at all times during top loading. [**407:**6.2.11.10.7]

N 42.10.4.2.11.11 Bottom Loading.

N 42.10.4.2.11.11.1 A bonding connection shall be made between the cargo tank and the loading rack before any fuel connections are made and shall remain in place throughout the loading operation. [**407:**6.2.11.11.1]

N 42.10.4.2.11.11.2 The operator shall initiate fuel flow by means of a dead-man control device. [**407:**6.2.11.11.2]

N 42.10.4.2.11.11.3 The operator shall ensure that the automatic high-level shutoff system is functioning properly for each compartment shortly after flow has been initiated. [**407:**6.2.11.11.3]

N 42.10.4.2.12 Positioning of Aircraft Fuel Servicing Vehicles and Carts During Fueling.

N 42.10.4.2.12.1 Aircraft fuel servicing vehicles and carts shall be positioned so that a clear path of egress from the aircraft for fuel servicing vehicles shall be maintained. [**407:**6.2.12.1]

N 42.10.4.2.12.2 The propulsion or pumping engine of aircraft fuel servicing vehicles or carts shall not be positioned under the wing of the aircraft during overwing fueling or where aircraft fuel system vents are located on the upper wing surface. [**407:**6.2.12.2]

N 42.10.4.2.12.3 Aircraft fuel servicing vehicles or carts shall not be positioned within a 3 m (10 ft) radius of aircraft fuel system vent openings. [**407:**6.2.12.3]

N 42.10.4.2.12.4 Parking brakes and chocks shall be set on all fuel servicing vehicles or carts before operators begin the fueling operation. [**407:**6.2.12.4]

N 42.10.4.2.12.5 During overwing aircraft fuel servicing where aircraft fuel system vents are located on the upper wing surface, equipment shall not be positioned under the trailing edge of the wing. [**407:**6.2.12.5]

N 42.10.5 Rooftop Heliports.

This subsection, along with 42.10.2 (General Requirements) and 42.10.3 (Aviation Fueling Facilities), applies to fixed fueling facilities used to service aircraft on rooftop heliports. These facilities require special considerations due to the occupancy below the rooftop heliport and inaccessibility to fire fighters. Exhibit 42.24 shows an example of a rooftop heliport.

Exhibit 42.24

Rooftop heliport.

N 42.10.5.1 Design and Construction.

N 42.10.5.1.1 General Requirements.

N 42.10.5.1.1.1 System Design and Approval.

N 42.10.5.1.1.1.1 Fueling on rooftop heliports shall be permitted only where approved by the authority having jurisdiction. [**407:**7.1.1.1.1]

N 42.10.5.1.1.1.2 In addition to the special requirements in this chapter, the heliport shall comply with the requirements of NFPA 418. [**407:**7.1.1.1.2]

N 42.10.5.1.1.1.3 Facilities for dispensing fuel with a flash point below 37.8°C (100°F) shall not be permitted at any rooftop heliport. [**407:**7.1.1.1.3]

Minimizing the vaporization of fuels is important. When facilities that dispense fuels with flash points below 100°F (37.8°C) are exposed to the higher ambient temperatures associated with rooftop heliports, the rate of vaporization and the potential for ignition of the vapors increases.

N 42.10.5.1.1.1.4 In addition to the special requirements of this chapter, the fuel storage, piping, and dispensing system shall comply with the requirements of NFPA 30 and with applicable portions of this standard. [**407:**7.1.1.1.4]

N 42.10.5.1.1.1.5 The entire system shall be designed so that no part of the system is subjected to pressure above its working pressure. [**407:**7.1.1.1.5]

N 42.10.5.1.2 Fuel Storage Tanks.

N 42.10.5.1.2.1 Fuel storage tanks and components shall comply with the requirements of NFPA 30. [**407:**7.1.2.1]

N 42.10.5.1.2.2 The fuel storage system shall be located at or below ground level. [**407:**7.1.2.2]

The location of fuel storage is required to conform to Chapter 66 and NFPA 30. All locations must be approved by the AHJ.

N **42.10.5.1.3 Pumps and Piping Systems.**

N **42.10.5.1.3.1** Pumps and piping systems shall comply with the requirements of NFPA 30. [**407:**7.1.3.1]

N **42.10.5.1.3.2** Pumps shall be located at or below ground level. [**407:**7.1.3.2]

N **42.10.5.1.3.3** Relay pumping shall not be permitted. [**407:**7.1.3.3]

N **42.10.5.1.3.4** Pumps installed outside of buildings shall be located not less than 1.5 m (5 ft) from any building opening. [**407:**7.1.3.4]

Building openings are considered to be any breach in the building envelope that is open to the atmosphere and capable of passing air, vapor, liquid mixtures, or a combination thereof. Building openings include doors, windows, ventilation intakes and discharges, combustion air intakes, conduits, drain lines, and all other wall penetrations.

N **42.10.5.1.3.5** Pumps shall be anchored and protected against physical damage from collision. [**407:**7.1.3.5]

N **42.10.5.1.3.6** Pumps installed within a building shall be in a separate room with no opening into other portions of the building. [**407:**7.1.3.6]

N **42.10.5.1.3.7** The pump room shall be adequately ventilated. [**407:**7.1.3.7]

N **42.10.5.1.3.8** Electrical wiring and equipment in pump rooms shall conform to the requirements of *NFPA 70*, Article 515. [**407:**7.1.3.8]

N **42.10.5.1.3.9** Piping above grade shall be steel and, unless otherwise approved by the authority having jurisdiction, shall be suitably cased or shall be installed in a duct or chase. [**407:**7.1.3.9]

N **42.10.5.1.3.9.1** Such piping duct or chase shall be constructed so that a piping failure does not result in the entry of fuel liquid or vapor entering the building. [**407:**7.1.3.9.1]

N **42.10.5.1.3.9.2** All pipe casings, ducts, and chases shall be drained. [**407:**7.1.3.9.2]

N **42.10.5.1.3.10** Piping shall be anchored and shall be protected against physical damage for a height of at least 2.4 m (8 ft) above the ground. [**407:**7.1.3.10]

N **42.10.5.1.3.11** An isolation valve shall be installed on the suction and discharge piping of each pump. [**407:**7.1.3.11]

N **42.10.5.1.3.12** A check valve shall be installed at the base of each fuel piping riser to automatically prevent the reverse flow of the fuel into the pump room in the event of pump seal failure, pipe failure, or other malfunction. [**407:**7.1.3.12]

N **42.10.5.1.3.13** Piping within buildings shall comply with 42.10.3.1.3.3. [**407:**7.1.3.13]

N **42.10.5.1.4 Hose and Nozzles. (Reserved)**

N **42.10.5.1.5 Electrostatic Bonding. (Reserved)**

N **42.10.5.1.6 Electrical Systems. (Reserved)**

N **42.10.5.1.7 Control of Fuel Flow. (Reserved)**

N **42.10.5.1.8 Filters and Ancillary Equipment. (Reserved)**

N **42.10.5.1.9 Emergency Fuel Shutoff Systems.**

N **42.10.5.1.9.1** At least two emergency fuel shutoff stations located on opposite sides of the heliport at exitways or at similar locations shall be provided. [**407:**7.1.9.1]

N **42.10.5.1.9.2** An additional emergency fuel shutoff station shall be located at ground level and shall be located at least 3 m (10 ft) from the pump but no further than 6 m (20 ft). [**407:**7.1.9.2]

N **42.10.5.1.10 Fire Protection.** Fire protection shall conform to the requirements of NFPA 418. [**407:**7.1.10]

N **42.10.5.1.11 Marking and Labeling. (Reserved)**

N **42.10.5.2 Operations.**

N **42.10.5.2.1 Security. (Reserved)**

N **42.10.5.2.2 Personnel.** All heliport personnel shall be trained in the use of the available fire extinguishers and fixed extinguishing systems. [**407:**7.2.2]

N **42.10.5.2.3 Prevention and Control of Spills. (Reserved)**

N **42.10.5.2.4 Emergency Fuel Shutoff.** All heliport personnel shall be trained in the operation of emergency fuel shutoff controls. [**407:**7.2.4]

N **42.10.5.2.5 Bonding. (Reserved)**

N **42.10.5.2.6 Monitoring of Fuel Flow. (Reserved)**

N **42.10.5.2.7 Fire Protection. (Reserved)**

N **42.10.5.2.8 Maintenance. (Reserved)**

N **42.10.5.2.9 Aircraft Fueling Hose. (Reserved)**

N **42.10.6 Self-Service Aircraft Fueling.**

This section, along with 42.10.2 (General Requirements) and 42.10.3 (Aviation Fueling Facilities), applies to fixed fueling facilities used for self-service aircraft fueling. These facilities require special considerations due to the risk of accident or misuse by untrained persons. Exhibit 42.25 shows a fixed fueling facility used for self-service aircraft fueling.

N **42.10.6.1 Design and Construction.**

N **42.10.6.1.1 General Requirements.**

N **42.10.6.1.1.1 System Design and Approval.** Self-service fueling shall be permitted, subject to the approval of the authority having jurisdiction. [**407:**8.1.1.1]

N **42.10.6.1.1.2** Dispensing devices shall be located on an island to protect against collision damage or shall be protected with pipe bollards or other approved protection. [**407:**8.1.1.2]

Exhibit 42.25

Self-service aircraft fueling.

N **42.10.6.1.2 Fuel Storage Tanks.** In addition to the special requirements of this chapter, the fuel storage system shall comply with the requirements of NFPA 30. [**407:**8.1.2]

N **42.10.6.1.3 Pumps and Piping Systems.**

N **42.10.6.1.3.1** In addition to the special requirements of this chapter, the piping and dispensing system shall comply with the requirements of NFPA 30. [**407:**8.1.3.1]

N **42.10.6.1.3.2** Listed or approved dispensing devices shall be used. [**407:**8.1.3.2]

N **42.10.6.1.4 Hose and Nozzles. (Reserved)**

N **42.10.6.1.5 Electrostatic Bonding. (Reserved)**

N **42.10.6.1.6 Electrical Systems. (Reserved)**

N **42.10.6.1.7 Control of Fuel Flow. (Reserved)**

N **42.10.6.1.8 Filters and Ancillary Equipment. (Reserved)**

N **42.10.6.1.9 Emergency Fuel Shutoff Systems.**

N **42.10.6.1.9.1** The controls shall be designed to allow only authorized personnel to reset the system after an emergency fuel shutoff. [**407:**8.1.9.1]

N **42.10.6.1.9.2** The emergency fuel shutoff controls shall be installed in a location acceptable to the authority having jurisdiction and shall be more than 6 m (20 ft) but less than 30 m (100 ft) from the dispensers. [**407:**8.1.9.2]

Prior to the 2017 edition of NFPA 407, the emergency fuel shutoff controls (EFSO) were required to be "near" the fuel pump. This was revised to specify both a minimum and a maximum distance from the fuel dispensers to ensure that the EFSO is located away from the potential spill location but within a maximum travel distance.

See the commentary that follows 42.10.1 regarding retroactivity of requirements.

N **42.10.6.1.9.3** A clearly identified means to notify the fire department shall be provided and shall be located in the immediate vicinity of each emergency fuel shutoff control. [**407:**8.1.9.3.]

N **42.10.6.1.9.4** Dispensing devices shall have a listed or approved emergency shutoff valve, incorporating a fusible link or other thermally actuated device designed to close automatically in case of fire. [**407:**8.1.9.4]

N **42.10.6.1.9.5** The emergency shutoff valve also shall incorporate a shear section that automatically shuts off the flow of fuel due to severe impact. [**407:**8.1.9.5]

N **42.10.6.1.9.6** The emergency shutoff valve shall be rigidly mounted at the base of the dispenser in accordance with the manufacturer's instructions. [**407:**8.1.9.6]

N **42.10.6.1.10 Fire Protection.**

N **42.10.6.1.10.1** Each facility shall have a minimum of one fire extinguisher with a rating of at least 80-B:C located at the dispenser. [**407:**8.1.10.1]

N **42.10.6.1.10.2** At least one fire extinguisher with a rating of at least 80-B:C shall be provided at each emergency fuel shutoff control. [**407:**8.1.10.2]

N **42.10.6.1.11 Marking and Labeling.**

N **42.10.6.1.11.1** Emergency instructions shall be conspicuously posted in the dispensing area and at the emergency fuel shutoff control. [**407:**8.1.11.1]

N **42.10.6.1.11.2** Emergency instructions shall incorporate the following or equivalent wording:

**EMERGENCY INSTRUCTIONS
IN CASE OF FIRE OR SPILL**

(1) Use emergency fuel shutoff.

(2) Report accident by calling (specify local fire emergency reporting number) on phone.

(3) Report address of site (list address of site here).

[**407:**8.1.11.2]

N **42.10.6.1.11.3 Operating Instructions.** Operating instructions shall be posted. [**407:**8.1.11.3]

N **42.10.6.1.11.4** The operating instructions shall include the following:

(1) Proper operation and use of all equipment
(2) Correct bonding procedures
(3) Procedures to be employed to dispense fuel safely
(4) Location and use of the emergency fuel shutoff controls
(5) Procedures to be used in the event of an emergency

[**407:**8.1.11.4]

N **42.10.6.2 Operations.**

N **42.10.6.2.1 Security.** Access to dispensing equipment shall be controlled by means of mechanical or electronic devices designed to resist tampering and to prevent access or use by unauthorized persons. [**407:**8.2.1]

N **42.10.6.2.2 Training. (Reserved)**

N **42.10.6.2.3 Prevention and Control of Spills. (Reserved)**

N **42.10.6.2.4 Emergency Fuel Shutoff. (Reserved)**

N **42.10.6.2.5 Bonding. (Reserved)**

N **42.10.6.2.6 Monitoring of Fuel Flow. (Reserved)**

N **42.10.6.2.7 Fire Protection. (Reserved)**

N **42.10.6.2.8 Maintenance. (Reserved)**

N **42.10.6.2.9 Occupancy.** The aircraft shall not be occupied during self-service fueling. [**407:**8.2.9]

42.11 Alternate Fuels

Section 42.11 contains provisions for refueling with alternate fuels derived from NFPA 52 and NFPA 58.

42.11.1 Compressed Natural Gas (CNG) Vehicular Fuel Systems. The design and installation of CNG engine fuel systems on vehicles of all types shall comply with NFPA 52, *Vehicular Gaseous Fuel Systems Code*, and Section 42.11.

Subsection 42.11.1 contains a reference to NFPA 52 and Section 42.11 for provisions for fueling vehicles with alternate fuels at motor fuel dispensing facilities that also dispense traditional motor fuels (Class I or Class II liquids).

Unless otherwise noted within NFPA 52, the provisions of NFPA 52 are not intended to be applied to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the document, except in those cases where the AHJ determines that the existing situation involves a distinct hazard to life or adjacent property.

42.11.1.1* Scope.

Δ **A.42.11.1.1** Natural gas is a flammable gas. It is colorless, tasteless, and nontoxic. It is a light gas, weighing about two-thirds as much as air. As used in the systems covered by this standard, it tends to rise and diffuses rapidly in air when it escapes from the system.

Natural gas burns in air with a luminous flame. At atmospheric pressure, the ignition temperature of natural gas–air mixtures has been reported to be as low as 900°F (482°C). The flammable limits of natural gas–air mixtures at atmospheric pressure are about 5 percent to 15 percent by volume natural gas. [**52:**A.1.1]

Natural gas is nontoxic but can cause anoxia (asphyxiation) when it displaces the normal 21 percent oxygen in air in a confined area without adequate ventilation. [**52:**A.1.1]

The concentrations at which flammable or explosive mixtures form are much lower than the concentration at which asphyxiation risk is significant. [**52:**A.1.1]

NFPA 704 rating is as follows:

(1) Health — 0
(2) Flammability — 4
(3) Reactivity — 0

NFPA 52 applies to the design and installation of CNG engine fuel systems on vehicles of all types, including those listed in 42.11.1.1.1(1) through (3).

(4) Special — None

[**52:**A.1.1]

Cryogenic fluids are gases that have been liquefied by having their temperature brought below –130°F (–90°C). They are typically stored at low pressures in vacuum jacketed containers. Some of the potential hazards of cryogenic fluids are the following:

(1) Extreme cold that freezes or damages human skin on contact and can embrittle metals
(2) Extreme pressure resulting from rapid vaporization of the fluid during a leak or release of the cryogenic fluid
(3) Asphyxiation resulting from a release of the cryogenic fluid that vaporizes and displaces air

[**52:**A.1.1]

Personnel handling cryogenic fluids should use the protective clothing prescribed on the material safety data sheet (MSDS). This clothing typically includes heavy leather gloves, aprons, and eye protection. [**52:**A.1.1]

Δ **42.11.1.1.1** Section 42.11 shall apply to the design, installation, operation, and maintenance of compressed natural gas (CNG) and liquefied natural gas (LNG) engine fuel systems on vehicles of all types and for fueling vehicle (dispensing) systems and associated storage, including the following:

(1) Original equipment manufacturers (OEMs)
(2) Final-stage vehicle integrator/manufacturer (FSVIM)
(3) Vehicle fueling (dispensing) systems

[**52:**1.1.1]

42.11.1.1.2 Section 42.11 shall apply to the design, installation, operation, and maintenance of liquefied natural gas (LNG) engine fuel systems on vehicles of all types, to their associated fueling (dispensing) facilities, and to LNG to CNG facilities with LNG storage in ASME containers of 70,000 gal (265 m³) or less. [**52:**1.1.2]

42.11.1.1.3* Vehicles and fuel supply containers complying with federal motor vehicle safety standards (FMVSSs) covering the installation of CNG fuel systems on vehicles and certified by the respective manufacturer as meeting these standards shall not be required to comply with Sections 4.4, 4.8, 4.9, and 4.10, and Chapter 6 of NFPA 52 (except Sections 6.9, 6.11, 6.12, 6.13, and 6.14 of NFPA 52). [**52:**1.1.3]

A.42.11.1.1.3 Current DOT and TC specifications, exemptions, and specified permits do not address the use of cylinders that are approved for the transportation of natural gas to be used in CNG service. [**52:**A.5.4.4]

The following Compressed Gas Association publications are relevant cylinder inspection standards:

(1) CGA C-6, *Standards for Visual Inspection of Steel Compressed Gas Cylinders*
(2) CGA C-6.1, *Standards for Visual Inspection of High Pressure Aluminum Compressed Gas Cylinders*
(3) CGA C-6.2, *Guidelines for Visual Inspection and Requalification of Fiber Reinforced High Pressure Cylinders*
(4) CGA C-10, *Recommended Procedures for Changes of Gas Service for Compressed Gas Cylinders*

The following Compressed Gas Association publication is specified in ANSI/ISA NGV2, *Compressed Natural Gas Vehicle (NGV) Fuel Containers*, as appropriate for CNG container inspection:

CGA C-6.4, *Methods of External Visual Inspection of Natural Gas Vehicle (NGV) Fuel Containers and Their Installations*

[**52:**A.5.4.4]

42.11.1.1.4 Section 42.11 shall include marine, highway, rail, off-road, and industrial vehicles. [**52:**1.1.4]

42.11.1.1.5 Vehicles that are required to comply with applicable federal motor vehicle safety standards covering the installation of LNG fuel systems on vehicles and that are certified by the manufacturer as meeting these standards shall not be required to comply with Chapter 9 of NFPA 52, except 9.12.8 of NFPA 52. [**52:**1.1.5]

42.11.2 Liquefied Petroleum Gas (LP-Gas).

Δ **42.11.2.1** Fuel dispensing facilities for vehicles using LP-Gas shall comply with NFPA 58 and 42.11.2.

Subsection 42.11.2 contains requirements for fuel dispensing facilities for vehicles using liquefied petroleum gases (LP-Gas). For additional requirements on the storage, use, and handling of LP-Gas, see Chapter 60 and Chapter 69 of this *Code* and NFPA 58.

42.11.2.2 Scope.

42.11.2.2.1* Chapter 11 of NFPA 58 applies to engine fuel systems installed on mobile and nonstationary engines and off-road vehicles using LP-Gas in internal combustion engines, including containers, container appurtenances, carburetion equipment, piping, hose and fittings, and their installation. Refer to Chapter 12 for on-road LP-Gas vehicle installations. [**58:**11.1.1]

Chapter 11 of NFPA 58 applies to all engine systems that use propane as a fuel for internal combustion engines, including the engine that powers the vehicle and engines that are mounted on vehicles for reasons other than propulsion. A new provision covering containers for stationary engines was added in the 2011 edition of NFPA 58 (11.15.2). Although not included in the scope, parts of Chapter 11 of NFPA 58 may also apply to fuel cells on vehicles powered by propane.

General-purpose vehicles and industrial trucks are the two categories of vehicles that use propane engines for their propulsion. General-purpose vehicles include most non-industrial trucks using internal combustion engines. Most general-purpose vehicles are used in fleet operations serviced from central sources of supply that are not available to the public. Propane is not readily available in large enough quantities to accommodate masses of individual private vehicle owners. All over-the-road general-purpose vehicles powered by LP-Gas must be labeled by a diamond-shaped marking. (See Figure A.11.12.2.2 of NFPA 58.)

Note that NFPA 58 covers only vehicles operating on land. NFPA 302, *Fire Protection Standard for Pleasure and Commercial Motor Craft*, addresses vessels that use propane. Propane has not been known to be used as an engine fuel for vessels. Propane is also not currently used as an aviation fuel, except for hot-air balloons. In the United States, the Federal Aviation Administration (FAA), an agency of the U.S. Department of Transportation (DOT), regulates the use of propane in hot-air balloons.

A.42.11.2.2.1 Chapter 11 of NFPA 58 covers engine fuel systems for engines installed on vehicles for any purpose, as well as fuel systems for stationary and portable engines. [**58:**A.11.1.1]

42.11.2.2.2* Chapter 11 of NFPA 58 applies to the installation of fuel systems supplying engines used to propel motorized vehicles as defined in 42.11.2.2.1. [**58:**11.1.2]

A.42.11.2.2.2 Containers for engine fuel systems can be of the permanently installed or exchange type. [**58:**A.11.1.2]

42.11.2.2.3 Chapter 11 of NFPA 58 applies to garaging of vehicles where such systems are installed. [**58:**11.1.3]

42.11.2.2.4 Permits. Permits, where required, shall comply with Section 1.12.

42.11.2.3 Training. Each person engaged in installing, repairing, filling, or otherwise servicing an LP-Gas engine fuel system shall be trained. [**58:**11.2]

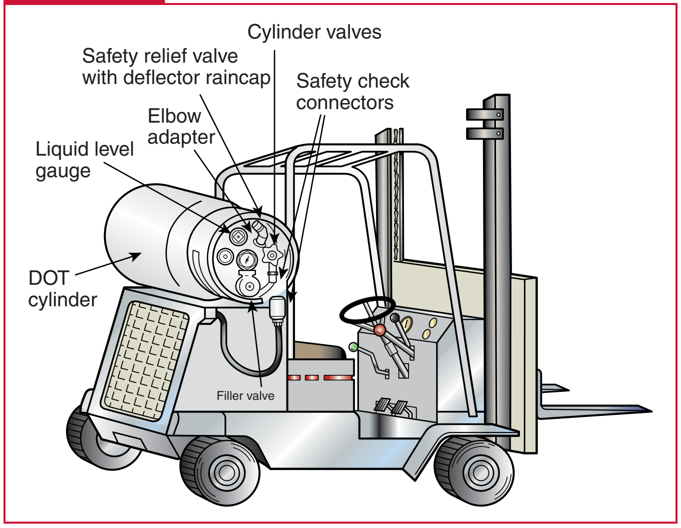
• **42.11.2.4 Industrial (and Forklift) Trucks Powered by LP-Gas.**

42.11.2.4.1 Scope. Paragraph 42.11.2.4 applies to LP-Gas installation on industrial trucks (including forklift trucks), both to propel them and to provide the energy for their materials-handling attachments. [**58:**11.13.1]

NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations*, and NFPA 58 contain requirements for LP-Gas–fueled industrial trucks. While NFPA 58 sets forth installation provisions and certain conditions for their use, NFPA 505 sets forth type designations, areas containing flammables in which the truck can be used, dual-fuel trucks, truck maintenance, and fuel handling and storage. Exhibit 42.26 shows a typical LP-Gas–powered industrial truck.

The basic provisions for engine fuel systems on general-purpose vehicles also apply to those for industrial truck engines, except for some differences that are based on the extensive use of such engines inside buildings.

Exhibit 42.26



Typical LP-Gas–powered industrial truck (forklift truck). (Courtesy of RegO® Products)

Exhibit 42.27

Floor maintenance machine. (Courtesy of Amano Pioneer Eclipse Corp.)

42.11.2.4.2 Operations. The operation of industrial trucks (including forklift trucks) powered by LP-Gas engine fuel systems shall comply with 42.11.2.4.2.1 through 42.11.2.4.2.3. [**58:**11.13.4]

42.11.2.4.2.1 Industrial trucks shall be refueled outdoors. [**58:** 11.13.4.1]

42.11.2.4.2.2 Where cylinders are exchanged indoors, the fuel piping system shall be equipped to minimize the release of fuel when cylinders are exchanged, in accordance with either of the following:

(1) Using an approved quick-closing coupling in the fuel line
(2) Closing the shutoff valve at the fuel cylinder and allowing the engine to run until the fuel in the line is exhausted [**58:**11.13.4.2]

42.11.2.4.2.3 Where LP-Gas–fueled industrial trucks are used in buildings or structures, the following shall apply:

(1) The number of fuel cylinders on such a truck shall not exceed two.
(2) The use of industrial trucks in buildings frequented by the public, including those times when such buildings are occupied by the public, shall require the approval of the AHJ.
(3) The total water capacity of the fuel cylinders on an individual truck shall not exceed 105 lb (48 kg) [nominal 45 lb (20 kg) propane capacity].
(4) Trucks shall not be parked and left unattended in areas occupied by or frequented by the public without the approval of the AHJ. If left unattended with approval, the cylinder shutoff valve shall be closed.
(5) In no case shall trucks be parked and left unattended in areas of excessive heat or near sources of ignition. [**58:**11.13.4.3]

42.11.2.5 General Provisions for Vehicles Having Engines Mounted on Them (Including Floor Maintenance Machines).

42.11.2.5.1 Scope.

Section 11.14 of NFPA 58 includes coverage of floor maintenance machines, such as the one shown in Exhibit 42.27. Use of these propane-powered floor buffers has grown since their introduction into NFPA 58 in 1989. Their widespread use has resulted in specific coverage in NFPA 58 for the benefit of users of this equipment and enforcers of that code.

42.11.2.5.1.1 Paragraph 42.11.2.5 applies to the installation of equipment on vehicles that supply LP-Gas as a fuel for engines installed on these vehicles. [**58:**11.14.1.1]

42.11.2.5.1.2 Vehicles include floor maintenance and any other portable mobile unit, whether the engine is used to propel the vehicle or is mounted on it for other purposes. [**58:**11.14.1.2]

42.11.2.5.2 General Requirements.

42.11.2.5.2.1 Industrial trucks (including forklift trucks) and other engines on vehicles operating in buildings other than those used exclusively to house engines shall have an approved automatic shutoff valve installed in the fuel system. [**58:**11.14.2.1]

Although approved automatic shutoff valves are required by 42.11.2.5.2.1, the use of atmospheric-type regulators (zero governors) recognized for this purpose, with portable engines of 12 horsepower or less and having magneto ignition used exclusively outdoors, is acceptable.

An atmospheric-type regulator, as its name implies, depends on the atmospheric pressure for its control. The regulator is not an approved vacuum lock-off, which is considered an approved automatic shutoff valve. The regulator operates on the principle that, when the carburetor venturi is without vacuum, the regulator shuts off the flow of fuel. Atmospheric-type regulators have been used for many years on outdoor engine applications.

42.11.2.5.2.2 The source of air for combustion shall be isolated from the driver and passenger compartment, ventilating system, or air-conditioning system on the vehicle. [**58:**11.14.2.2]

42.11.2.5.2.3 Non–self-propelled floor maintenance machinery (floor polishers, scrubbers, buffers) and other similar portable equipment shall be listed. [**58:**11.14.2.3]

42.11.2.5.2.3.1 A label shall be affixed to the machinery or equipment, with the label facing the operator, with the text denoting that the cylinder or portion of the machinery or equipment containing the cylinder shall be stored in accordance with Chapter 8 of NFPA 58. [**58:**11.14.2.3(A)]

42.11.2.5.2.3.2 The use of floor maintenance machines in buildings frequented by the public, including the times when such buildings are occupied by the public, shall require the approval of the AHJ. [**58:**11.14.2.3(B)]

Great concern exists that a propane-powered floor buffer, with its 20 lb (9 kg) LP-Gas cylinder, will be stored inside buildings in concealed areas, such as closets. The technical committee, consistent with its long prohibition (with certain exceptions) of LP-Gas cylinders larger than 1 lb (0.5 kg) in buildings, reinforced its intent that cylinders be stored properly in accordance with Chapter 8 of NFPA 58. The technical committee was especially concerned that the introduction of engine fuel cylinders would lead to improper storage and therefore require specific labeling.

Propane-powered floor buffers and forklift trucks are both categorized as industrial trucks. It is highly improbable, however, that a forklift truck will be left in a closet. If a floor buffer and its 20 lb (9 kg) LP-Gas cylinder were stored in a closet and a fire occurred, the propane in the cylinder could be a threat to fire fighters due to the storage of a fuel that can accelerate a fire. Recognition of this threat to fire fighters is especially important when one considers that the nature of the floor buffer requires that it be used in buildings such as offices, malls, schools, and other nonindustrial areas where the storage of propane cylinders is not anticipated.

Propane-powered floor buffers have been found in storage closets and backrooms of a variety of stores, such as clothing stores and big box stores. They have also been found in the areas under the seating in large arenas, such as college basketball venues. In many cases the label required in 42.11.2.5.2.3.1 has come off, been removed, or been ignored. In a few instances, these machines have been found with improperly installed cylinders, so the relief valve would not be communicating with the vapor space if the cylinder were more than half full. Sometimes this is due to a broken locating pin on the machine, thus not "requiring" the cylinder to be properly installed.

Another issue is the apparent lack of awareness of the requirements of 42.11.2.5.2.3.2. Floor maintenance machines may be brought into a building by cleaning contractors and stored in the building, or they may be purchased by building owners for staff use. Both of these groups of people may be unaware of building and fire codes. Building inspectors who inadvertently find these machines in closets or storage rooms also may not be aware of these rules.

42.11.2.6 Garaging of Vehicles. Where vehicles with LP-Gas engine fuel systems mounted on them, and general-purpose vehicles propelled by LP-Gas engines, are stored or serviced inside garages, the following conditions shall apply:

(1) The fuel system shall be leak-free.
(2) The container shall not be filled beyond the limits specified in Chapter 7 of NFPA 58.
(3) The container shutoff valve shall be closed when the vehicle or the engine is being repaired, except when the engine is required to operate. Containers equipped with an automatic shutoff valve as specified in 11.4.1.8 of NFPA 58 satisfy this requirement.
(4) The vehicle shall not be parked near sources of heat, open flames, or similar sources of ignition or near inadequately ventilated pits. [**58:**11.16]

42.11.3* Liquefied Natural Gas (LNG). Fuel dispensing facilities for marine, highway, rail, off-road, and industrial vehicles using LNG and LNG storage in ASME containers of 70,000 gal (265 m^3) or less shall comply with NFPA 52.

• Δ **A.42.11.3** For information on on-site storage of LNG in ASME tanks larger than 70,000 gal (265 m^3) and in tanks built to API or other standards, see NFPA 59A.

Prior to the time NFPA 52 was developed, the use of LNG as an aviation fuel, fueling site liquefaction facilities, and the use of residential LNG fueling facilities were not being considered actively. The NFPA 52 committee intends to provide coverage for these applications at the appropriate time.

NFPA 57, *Liquefied Natural Gas (LNG) Vehicular Fuel Systems Code*, was incorporated into the 2006 edition of NFPA 52. Additionally, the scope of the Technical Committee on Vehicular Alternative Fuel Systems has been expanded to include hydrogen, and new chapters have been added that address general gaseous hydrogen requirements and equipment qualifications; service and maintenance of gaseous hydrogen engine fuel systems; gaseous hydrogen compression systems; gas processing, storage, and dispensing systems; and liquefied hydrogen fueling facilities.

42.11.3.1 Permits. Permits, where required, shall comply with Section 1.12.

Table 1.12.8(a) requires a permit to display, compete, or demonstrate liquid- or gas-fueled vehicles or equipment in assembly buildings.

Spraying, Dipping, and Coating Using Flammable or Combustible Materials

43

Chapter 43 addresses spraying, dipping, and coating using flammable or combustible materials, including automated powder and liquid application; solvent distillation equipment; drying, curing, or fusion processes; and miscellaneous spray operations. Chapter 43 is based on the 2016 edition of NFPA 33, *Standard for Spray Application Using Flammable or Combustible Materials*, and the 2015 edition of NFPA 34, *Standard for Dipping, Coating, and Printing Processes Using Flammable or Combustible Liquids*. NFPA 33 and NFPA 34 are the primary NFPA standards governing the regulation of spraying, dipping, and coating operations using flammable and combustible materials, and they are extracted into Chapter 43 of this *Code*. The commentary in this chapter has been edited and revised to reflect substantive amendments incorporated in the source documents since the previous edition of this Handbook.

43.1 Application

Δ **43.1.1*** Operations involving the spray application of flammable and combustible materials shall comply with NFPA 33 and Section 43.1.

A.43.1.1 The risk to life and property because of the fire and explosion hazards of spray application of flammable and combustible materials varies depending on the arrangement and operation of the particular process and on the nature of the material being sprayed. The principal hazards addressed in this *Code* are those of the materials being sprayed: flammable and combustible liquids and combustible powders, as well as their vapors, mists, and dusts, and the highly combustible deposits and residues that result from their use. Properly designed, constructed, and ventilated spray areas are able to confine and control combustible residues, dusts, or deposits and to remove vapors and mists from the spray area and discharge them to a safe location, thus reducing the likelihood of fire or explosion. Likewise, accumulations of overspray residues, some of which are not only highly combustible but also subject to spontaneous ignition, can be controlled. [**33:**A.1.1]

The control of sources of ignition in spray areas and in areas where flammable and combustible liquids or powders are handled, together with constant supervision and maintenance, is essential to safe spray application operations. The human element requires careful consideration of the location of spray application operations and the installation of fire extinguishing systems so that the potential for spread of fire to other property and damage to property by extinguishing agent discharge is reduced. [**33:**A.1.1]

NFPA 33 applies to the spray application of flammable or combustible materials (either continuously or intermittently) by any of the following methods:

1. Compressed air atomization
2. Airless or hydraulic atomization
3. Electrostatic application methods
4. Other means of atomized application

It also applies to the application of flammable or combustible materials (either continuously or intermittently) by any of the following methods:

1. Fluidized bed application methods
2. Electrostatic fluidized bed application methods
3. Other means of fluidized application

NFPA 33 also applies to spray application of water-borne, water-based, and water-reducible materials that contain flammable or combustible liquids or that produce combustible deposits or residues.

Finally, NFPA 33 contains provisions for organic peroxide–catalyzed coatings, other coatings using plural component chemistry, and manufacture of glass fiber–reinforced composites using styrene/unsaturated polyester resins.

NFPA 33 provides requirements for fire safety for spray application of flammable or combustible materials. It anticipates conditions of average use. Where unusual industrial processes are involved, the authority having jurisdiction (AHJ) is permitted to require additional safeguards or modifications to the requirements of NFPA 33, provided equivalent safety is achieved. Only the fire and explosion hazards of spray application processes and operations are addressed. NFPA 33 does not address toxicity or industrial health and hygiene. From the standpoint of personnel safety, it should be recognized that the materials used in these processes could be present in concentrations that present a health hazard, even if the concentrations do not present a fire or explosion hazard.

Some paints, varnishes, lacquers, and other coating materials contain volatile flammable solvents. In addition, such solvents are often added as "thinners." When exposed to the atmosphere, these solvents give off vapors that mix with the surrounding air, and, if the concentration reaches as much as approximately 1 percent solvent in air, the vapor-air mixtures can be ignited and an explosion might occur. Spray applications using only liquids that have relatively high flash points, although less likely to produce ignitible atmospheres than those using low flash point liquids, can nevertheless result in mists that are capable of propagating a flame in a manner similar to combustible particulate solids in dust explosions.

The provisions of this chapter also apply to cleaning or removal of overspray (sprayed material that does not reach the workpiece but accumulates on adjacent surfaces), cleaning of tools and equipment used, and safely storing flammable or combustible liquids used in the spraying process.

Δ **43.1.1.1*** Section 43.1 shall apply to the spray application of flammable or combustible materials, as herein defined, either continuously or intermittently by any of the following methods:

(1) Compressed air atomization
(2) Airless or hydraulic atomization
(3) Electrostatic application methods
(4) Other means of atomized application

[**33:**1.1.1]

Note that "other means of atomized application" includes fluidized bed processes, as noted in the commentary to A.43.1.1.

A.43.1.1.1 Refer to Figure A.43.1.1.1 for assistance in determining whether Chapter 43 applies to a particular spray application process. [**33:**A.1.1.1]

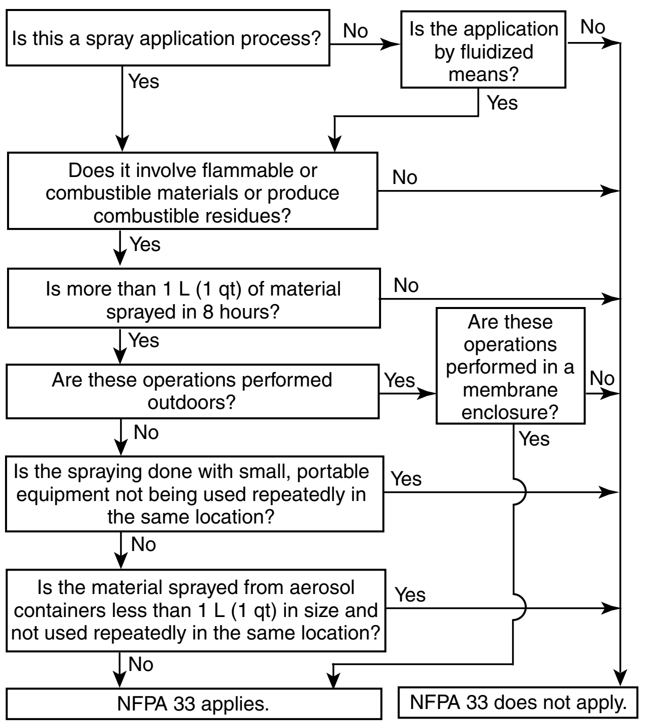
Figure A.43.1.1.1 has been amended to incorporate a decision point for spray processes in membrane enclosure, as covered in Chapter 18 of NFPA 33.

43.1.1.2 Section 43.1 shall also apply to spray application of water-borne, water-based, and water-reducible materials that contain flammable or combustible liquids or that produce combustible deposits or residues. [**33:**1.1.3]

Although these materials comprise a substantial portion of water, they are still of an organic nature, and the dried overspray or residue might present a fire hazard. A fire hazard assessment is warranted.

43.1.1.3 Section 43.1 shall not apply to the following:

(1)* Spray operations that use less than 1 L (33.8 fl oz) of flammable or combustible liquid in any 8-hour period [**33:**1.1.4]



Δ ***FIGURE A.43.1.1.1*** *Decision Tree — Does Chapter 43 Apply? [**33:**Figure A.1.1.1]*

A.43.1.1.3(1) There are many industrial applications that involve routine use of small quantities of flammable or combustible liquids (e.g., coatings, lubricants, adhesives) on a regular or periodic basis. An example would be touch-up of manufactured articles using aerosol containers or small, portable spray application equipment. The intent of this provision is to allow such use without having to comply with the requirements of Chapter 43. [**33:**A.1.1.4]

(2)* Spray application processes or operations that are conducted outdoors [**33:**1.1.6]

A.43.1.1.3(2) Chapter 43 does not cover spray application operations that are conducted outdoors on buildings, bridges, tanks, or similar structures. These situations occur only occasionally for any given structure and overspray deposits are not likely to present a hazardous condition. Also, the space where there might be an ignitible vapor–air or dust–air mixture is very limited due to atmospheric dilution. [**33:**A.1.1.6]

(3)* Portable spraying equipment that is not used repeatedly in the same location [**33:**1.1.7]

Δ **A.43.1.1.3(3)** The occasional use of portable spray equipment or aerosol spray containers is not likely to result in hazardous accumulations of overspray. Therefore, such operations are not within the scope of this *Code*. The following safeguards, however, should be observed:

(1) Adequate ventilation should be provided at all times, particularly where spray application is conducted in relatively small rooms or enclosures.

(2) Spray application should not be conducted in the vicinity of open flames or other sources of ignition. Either the spray operation should be relocated or the source of ignition should be removed or turned off.
(3) Containers of coating materials, thinners, or other hazardous materials should be kept tightly closed when not actually being used.
(4) Oily or coating-laden rags or waste should be disposed of promptly and in a safe manner at the end of each day's operations, due to the potential for spontaneous ignition
(5) The same fundamental rules for area cleanliness and housekeeping that are required for industrial spray application operations should be observed.

[**33:**A.1.1.7]

(4) Use of aerosol products in containers up to and including 1 L (33.8 oz) capacity that are not used repeatedly in the same location [**33:**1.1.8]
(5) Spray application of noncombustible materials [**33:**1.1.9]
(6) The hazards of toxicity or to industrial health and hygiene [**33:**1.1.10]

[**33:**1.1]

43.1.1.4 Permits. Permits, where required, shall comply with Section 1.12.

Table 1.12.8(a) requires that a permit be obtained to store, use, or handle Class I, Class II, or Class IIIA flammable or combustible liquids. A permit is also required for conducting a spraying or dipping operation that uses flammable or combustible liquids or combustible powders, as well as for the installation or modification of any spray room, spray booth, or preparation workstation.

43.1.2 Location of Spray Application Operations.

Δ **43.1.2.1* General.** Spray application operations and processes shall be located in industrial occupancies as defined by *NFPA 5000* and shall be confined to spray booths, spray rooms, spray areas, or in temporary membrane enclosures as defined in this *Code*. [**33:**4.1]

Prior to the 2018 edition of NFPA 1, spray application was not limited to industrial occupancies, simply by omission. Indeed, there was no mention of any particular occupancy. Paragraph 43.1.2.2 did address spray application operations in "other occupancies" but specifically cited only assembly, educational, institutional, and residential occupancies and ignored all others. The 2016 edition of NFPA 33 rectified this oversight by limiting general use of spray application processes to industrial occupancies and expanding application of the special provisions given in 43.1.2.2 to all other occupancy classes.

Temporary membrane enclosures were first addressed in (new) Chapter 18 of the 2016 edition of NFPA 33. They are used for spraying workpieces that are too large or too cumbersome to be enclosed in traditional spray booths or spray rooms. The primary example of such use is spray painting of the hull and superstructure of large luxury marine yachts and similar marine vessels. See Exhibit 43.1.

Exhibit 43.1

Temporary membrane enclosures surrounding motor yachts. (Courtesy of Global Finishing Solutions)

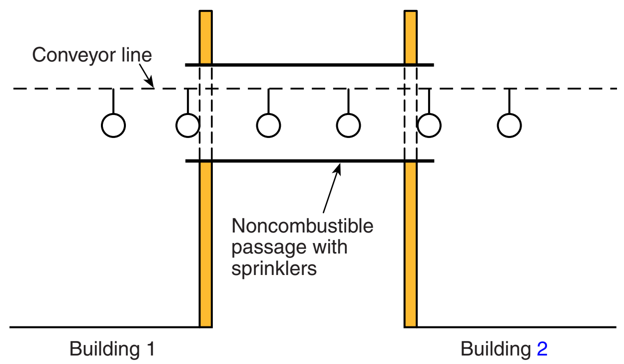
See Section 4.3 of NFPA 33 and its annex material for provisions and a discussion of spray processes located in basement areas.

A.43.1.2.1 Fires involving spray application operations and processes can be expected to develop rapidly and to generate copious quantities of heat and smoke. In sprinklered buildings, such fires can also result in the operation of a greater-than-normal number of sprinklers. Operations and equipment should be arranged and located so that there is adequate egress for personnel and adequate access for fire-fighting operations. Where spray application operations are extensive, they should be located in a separate building or in an area that is separated by fire-rated construction from all other operations or storage. [**33:**A.4.1]

Spray application operations that incorporate assembly lines or conveyor systems present special problems. If the conveyor systems extend between separate buildings, a noncombustible or limited-combustible sprinkler-protected enclosure or sprinkler-protected passageway, as illustrated in Exhibit 43.2, is recommended.

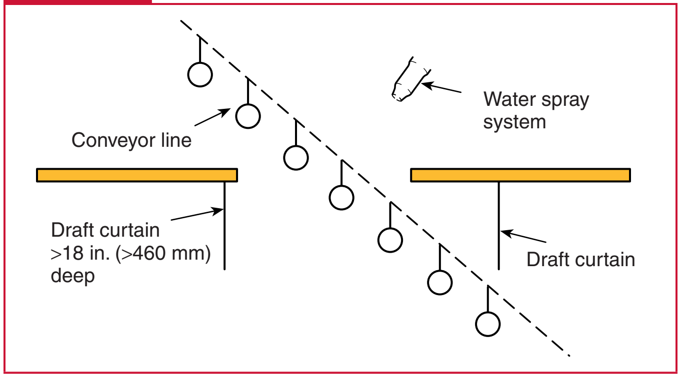
If the conveyor systems pass through floors, the openings should be surrounded by deep draft curtains [greater than 18 in. (460 mm)] on the underside of the floor deck, as illustrated in Exhibit 43.3. Draft curtains extending down from the ceiling

Exhibit 43.2



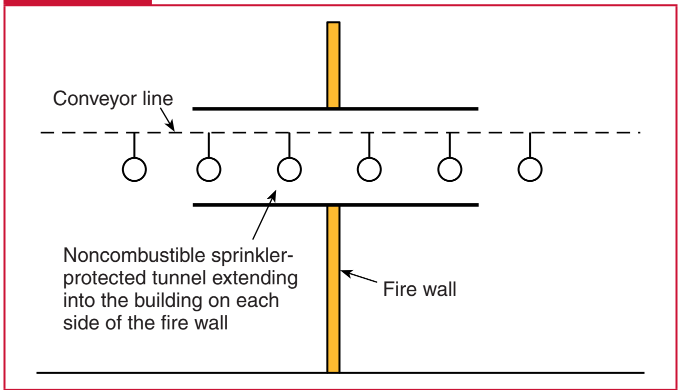
Conveyor line passing between separate buildings.

Exhibit 43.3



Draft curtains surrounding a conveyor line passing through a floor.

Exhibit 43.4



Conveyor line passing through a common building wall.

around spraying operations, along with smoke and heat vents, will slow the "mushrooming" of hot combustion gases along the ceiling and, thus, limit the number of sprinklers that will activate. The use of heat and smoke vents also aids fire control. Another safety precaution is the use of automatic high-velocity spray nozzles arranged to create a counterdraft.

If conveyor systems pass through fire walls or fire partitions, it is difficult to reliably protect the openings with automatic-closing fire doors. One alternative to an automatic fire door system is a noncombustible or limited-combustible, sprinkler-protected tunnel on both sides of the opening, as illustrated in Exhibit 43.4.

43.1.2.2* Locations in Other Occupancies. Spray application operations and processes shall not be conducted in any building that is classified as an assembly, educational, day care, health care, ambulatory health care, detention/correctional, residential, mercantile, business, or storage occupancy, unless the following requirements are met:

(1) The spraying is located in a room that is separated both vertically and horizontally from all surrounding areas by construction having a fire resistance rating of not less than 2 hours.
(2) The room is protected by an approved automatic sprinkler system designed and installed in accordance with Section 13.313.3.

[**33:**4.1.1]

See commentary to 43.1.2.1.

N **A.43.1.2.2** Spray application operations that incorporate assembly lines or conveyor systems present special problems. If conveyor systems extend between separate buildings, sprinklered, noncombustible, connecting passageway is advisable. If conveyor systems pass through floors, the openings should be surrounded by deep [greater than 18 in. (460 mm)] draft curtains on the underside of the floor deck and should be provided with automatic high-velocity spray nozzles arranged to create a counterdraft. If conveyor systems pass through fire walls or fire barrier walls, it is most desirable to provide a short gap in the conveyor to allow automatic fire doors to close. Interlocks might be necessary to stop conveyors moving toward the fire walls and clear the conveyors moving away from the fire walls in order to prevent fire doors from dropping on conveyed materials and thereby preventing complete closure. Another option is to provide a noncombustible or limited-combustible, sprinkler-protected tunnel on both sides of the opening. [**33:**A.4.2]

Rooms that house spray application operations should be separated from other occupancies or operations by construction that meets the requirements of 43.1.3. [**33:**A.4.2]

In sprinklered buildings where spray application operations occupy one portion of an open area, the spray application operations should be surrounded by noncombustible or limited-combustible draft curtains extending downward at least 18 in. (460 mm) from the ceiling, but deeper if practical. The draft curtains aid in preventing the activation of sprinklers outside the area enclosed by the curtains and tend to confine the discharge of water to the immediate area of the fire. Additional consideration might be given to the use of heat and smoke vents to aid in fire control. [**33:**A.4.2]

Sprinkler discharge should be drained to the outside of the building, to an internal drain system, or to some other suitable location. Properly designed and installed floor drains and scuppers of sufficient number and size to handle expected sprinkler discharge should be provided. Where spray application operations are located on an upper floor, they should not be located directly above goods or equipment that are subject to water damage. In addition, the floor should be made watertight and means should be provided to drain sprinkler discharge directly from the area. [**33:**A.4.2]

43.1.3 Construction and Design of Spray Areas, Spray Rooms, and Spray Booths.

43.1.3.1* Walls and Ceilings. Walls, doors, and ceilings that intersect or enclose a spray area shall be constructed of noncombustible or limited-combustible materials or assemblies and shall be securely and rigidly mounted or fastened. The interior surfaces of the spray area shall be smooth, designed and installed to prevent pockets that can trap residues, and designed to facilitate ventilation and cleaning. [**33:**5.1]

A.43.1.3.1 Spray booths can be of a wide variety of shapes and sizes to accommodate the various industrial applications of spray application. Without the use of a spray booth, the spray area, as defined in 3.3.14.12, can constitute a considerable area, with all the requirements for a spray area then becoming applicable. It is important that only equipment suitable for specific purposes be utilized in connection with the handling and application of flammable or combustible liquids or powders. [**33:**A.5.1]

If spray operations are *not* confined to a spray booth, spray room, or limited finishing workstation, the definition of the term *spray area* given in 3.3.14.12 is used and all requirements of Chapter 6 of NFPA 33 apply in the spray area, as well as the electrical area classification shown in Figure 43.1.4.4.1. Also, if an enclosure that does not meet the requirements specified in Chapter 43 for a spray booth or spray room is used for spray application, then that enclosure is treated as an unconfined spray area. Special consideration is given to "limited finishing workstations" in 43.5.3, because they are limited to the use of not more than 1 gal (3.8L) of material per 8-hour shift. Any enclosure that does not comply with 43.5.3 is referred to as a "preparation workstation" and is not considered a suitable enclosure for spray operations. Instead, 43.5.2 treats them as unenclosed spray areas. Preparation workstations ("prep stations") were originally conceived for use by auto body shops as an enclosure for "prepping" vehicles for painting, that is, cleaning and sanding, and should be limited to such use.

Only equipment suitable for the handling and application of flammable or combustible liquids or powders should be used in spray areas.

43.1.3.1.1 Air intake filters that are a part of a wall or ceiling assembly shall be listed as Class 1 or Class 2, in accordance with ANSI/UL 900, *Standard for Air Filter Units*. [**33:**5.1.1]

After the publication of the 2016 edition of NFPA 33, ANSI/UL 900, *Standard for Air Filter Units*, was revised to only require the criteria for Class 2 air filters and the class designations became moot.

43.1.3.1.2 The floor of the spray area shall be constructed of noncombustible material, limited-combustible material, or combustible material that is completely covered by noncombustible material. [**33:**5.1.2]

43.1.3.1.3 Aluminum shall not be used for structural support members or the walls or ceiling of a spray booth or spray room enclosure. Aluminum also shall not be used for ventilation ductwork associated with a spray booth or spray room. Aluminum shall be permitted to be used for interior components, such as platforms, spray apparatus components, and other ancillary devices. [**33:**5.1.3]

Aluminum loses about half its structural strength at temperatures of 400 to 480°F (200 to 250°C). Its melting point ranges from about 1100 to 1200°F (600 to 650°C), depending on the alloy.

43.1.3.1.4 If walls or ceiling assemblies are constructed of sheet metal, single-skin assemblies shall be no thinner than 0.0478 in. (1.2 mm), and each sheet of double-skin assemblies shall be no thinner than 0.0359 in. (0.9 mm). [**33:**5.1.4]

These thicknesses are considered the minimum allowable in order for the booth to maintain structural stability during a fire event.

43.1.3.1.5 Structural sections of spray booths shall be permitted to be sealed with a caulk or sealant to minimize air leakage. [**33:**5.1.5]

The amounts of caulk or sealant used present as negligible fire load.

43.1.3.1.6 Spray rooms shall be constructed of and separated from surrounding areas of the building by construction assemblies that have a fire resistance rating of 1 hour. [**33:**5.1.6]

Managing the spread of a fire from the room of origin or between floors in a building is an important consideration. Managing the spread of fire using construction barriers designed to limit the transfer of heat, smoke, and, in some cases, both, is achieved by compartmentation. Requiring a 1-hour-rated enclosure of spray rooms recognizes a unique fire hazard that is present in those spaces and helps ensure that a fire that starts in a spray room will be confined to the spray room or will at least slow the spread of fire from the compartment of origin.

43.1.3.1.7 Enclosed spray booths and spray rooms shall be provided with means of egress that meet the applicable requirements of Chapter 40 of NFPA *101*. [**33:**5.1.7]

43.1.3.1.8 Spray booths that are used exclusively for powder coating shall meet the requirements of Chapter 15 of NFPA 33. They shall be permitted to be constructed of fire-retardant combustible materials where approved by the AHJ. [**33:**5.1.8]

N **43.1.3.1.8.1** Listed spray booth assemblies that are constructed of other materials shall be permitted. [**33:**5.1.8.1]

43.1.3.2 Conveyor Openings. Conveyor openings that are necessary for transporting or moving work into and out of the spray area shall be as small as practical. [**33:**5.2]

43.1.3.3* Separation from Other Occupancies. Spray booths shall be separated from other operations by a minimum distance of 3 ft (915 mm) or by a partition, wall, or floor/ceiling assembly having a minimum fire resistance rating of 1 hour. Multiple connected spray booths shall not be considered as "other operations" except as provided for in Section 13.3 of NFPA 33. [**33:**5.3]

A.43.1.3.3 The "other" operations referred to in 43.1.3.3 are those that do not involve spray application processes. [**33:**A.5.3]

43.1.3.3.1 Spray booths shall be installed so that all parts of the booth are readily accessible for cleaning. [**33:**5.3.1]

43.1.3.3.2 A clear space of not less than 3 ft (915 mm) shall be maintained on all sides and above the spray booth. This clear space shall be kept free of any storage or combustible construction.

N **43.1.3.3.2.1** This requirement shall not prohibit locating a spray booth closer than 3 ft (915 mm) to or directly against an interior partition, wall, or floor/ceiling assembly that has a fire resistance rating of not less than 1 hour, provided the spray booth can be maintained and cleaned. [**33:**5.3.2.1]

N **43.1.3.3.2.2** This requirement shall not prohibit locating a spray booth closer than 3 ft (915 mm) to an exterior wall or a roof assembly, provided the wall or roof is constructed of noncombustible material and provided the spray booth can be maintained and cleaned. [**33:**5.3.2.2]

43.1.3.4 Movement of Powered Vehicles. Powered vehicles shall not be moved into or out of a spray area or operated in a spray area unless the spray application operation or process is stopped and the ventilation system is maintained in operation.

*Exception: This requirement shall not apply to vehicles that are listed for the specific hazards of the spray area. [**33:**5.4]*

43.1.3.5 Vision and Observation Panels.

43.1.3.5.1 Panels for luminaires or observation shall be of heat-treated glass, laminated glass, wired glass, or hammered-wired glass and shall be sealed to confine vapors, mists, residues, dusts, and deposits to the spray area. [**33:**5.4.1]

N **43.1.3.5.1.1** Listed spray booth assemblies that have *observation* panels constructed of other materials shall be permitted. [**33:**5.4.1.1]

43.1.3.5.2 Panels for luminaires shall be separated from the fixture to prevent the surface temperature of the panel from exceeding 200°F (93°C). [**33:**5.4.2]

The intent here is to prevent autoignition of any overspray deposited on the panels.

43.1.3.5.3 The panel frame and method of attachment shall be designed to not fail under fire exposure before the observation panel fails. [**33:**5.4.3]

43.1.3.5.4 Observation panels for spray booths that are used exclusively for powder coating processes shall be permitted to be constructed of fire-resistant combustible materials. [**33:**5.4.4]

43.1.3.6 Ventilation. Spray areas that are equipped with ventilation distribution or baffle plates or with dry overspray collection filters shall meet the requirements of 43.1.3.6.1 through 43.1.3.6.5. [**33:**5.5]

43.1.3.6.1 Distribution plates or baffles shall be constructed of noncombustible materials and shall be readily removable or accessible for cleaning on both sides. [**33:**5.5.1]

43.1.3.6.2 Filters shall not be used when applying materials known to be highly susceptible to spontaneous heating or spontaneous ignition. [**33:**5.5.2]

43.1.3.6.3 Supports and holders for filters shall be constructed of noncombustible materials. [**33:**5.5.3]

43.1.3.6.4 Overspray collection filters shall be readily removable or accessible for cleaning or replacement. [**33:**5.5.4]

43.1.3.6.5 Filters shall not be alternately used for different types of coating materials if the combination of the materials might result in spontaneous heating or ignition. *(See also Section 10.9 of NFPA 33.)* [**33:**5.5.5]

43.1.4 Electrical and Other Sources of Ignition.

43.1.4.1* General.

A.43.1.4.1 Because of the requirements for special safeguards, electrostatic apparatus; drying, curing, and fusing apparatus; and vehicle undercoating and body lining operations are covered in other chapters of NFPA 33. [**33:**A.6.2]

43.1.4.1.1 Electrical wiring and utilization equipment shall meet all applicable requirements of Articles 500, 501, 502, 505, and 516 of *NFPA 70* and all applicable requirements of this chapter.

Exception No. 1: Powered vehicles shall meet the requirements of 43.1.3.4.

*Exception No. 2: Resin application operations shall meet the requirements of Chapter 17 of NFPA 33. [**33:**6.2.1]*

Articles 500 through 503 of the 2017 edition of *NFPA 70*®, *National Electrical Code*®, cover the requirements for electrical and electronic equipment and wiring for all voltages in Class I, Divisions 1 and 2 locations; Class II, Divisions 1 and 2 locations; and Class III, Divisions 1 and 2 locations where fire or explosion hazards might exist due to flammable gases, flammable liquid–produced vapors, combustible dusts, or ignitible fibers or flyings. Article 505 of *NFPA 70* covers the requirements for the zone classification system, as an alternative to the division classification system covered in Article 501, for electrical and electronic equipment and wiring for all voltages in Zone 0, Zone 1, and Zone 2 hazardous (classified) locations where fire or explosion hazards might exist due to flammable gases, vapors, or liquids. Similarly, Article 506 covers the requirements for the zone classification system, as an alternative to the division classification system covered in Article 502, for electrical and electronic equipment and wiring for all voltages in Zone 20, Zone 21, and Zone 22 hazardous (classified) locations where fire or explosion hazards might exist due to combustible dusts, or ignitible fibers or flyings.

Article 516 covers the regular or frequent application of flammable liquids, combustible liquids, and combustible powders by spray operations and the application of flammable liquids or combustible liquids at temperatures above their flash point by dipping, coating, or other means.

43.1.4.1.2* For the purposes of this *Code*, the Zone system of electrical area classification shall be applied as follows:

(1) The inside of open or closed containers or vessels shall be considered a Class I, Zone 0 location.
(2) A Class I, Division 1 location shall be permitted to be alternatively classified as a Class I, Zone 1 location.
(3) A Class I, Division 2 location shall be permitted to be alternatively classified as a Class I, Zone 2 location.
(4) A Class II, Division 1 location shall be permitted to be alternatively classified as a Zone 21 location.
(5) A Class II, Division 2 location shall be permitted to be alternatively classified as a Zone 22 location. [**33:**6.2.2]

A.43.1.4.1.2 In the Division system, areas are classified as either Division 1 or Division 2, depending on whether ignitible gases or vapors are always present or likely to be present (Division 1) or whether ignitible gases or vapors are not normally present (Division 2). The Zone system identifies hazardous locations as Zone 0, Zone 1, or Zone 2, depending on whether the ignitible atmosphere will always be present (Zone 0), is likely to be present (Zone 1), or is not normally present (Zone 2). The Zone system is based on

International Electrotechnical Commission (IEC) standards and was incorporated into *NFPA 70* in 1996. [**33:**A.6.2.2]

43.1.4.1.3 For the purposes of electrical area classification, the Division system and the Zone system shall not be intermixed for any given source of release. [**33:**6.2.3]

43.1.4.1.4 In instances of areas within the same facility classified separately, Class I, Zone 2 locations shall be permitted to abut, but not overlap, Class I, Division 2 locations. Class I, Zone 0 or Zone 1 locations shall not abut Class I, Division 1 or Division 2 locations. [**33:**6.2.4]

43.1.4.1.5* Open flames, spark-producing equipment or processes, and equipment whose exposed surfaces exceed the autoignition temperature of the material being sprayed shall not be located in a spray area or in any surrounding area that is classified as Division 2, Zone 2, or Zone 22.

A.43.1.4.1.5 There should be no open flames, hot surfaces, or spark-producing equipment in the spray area or in any area where they might be exposed to combustible residues. Open flames or spark-producing equipment should not be located where they can be exposed to deposits of combustible residues. Some residues can be ignited at low temperatures, such as those produced by steam pipes, incandescent luminaires, and power tools. In powder coating applications, the temperature of the object or material being coated should be maintained at least 50°F (28°C) below the autoignation temperature of the powder. [**33:**A.6.2.5]

The potential ignition sources identified in 43.1.4.1.5 should be kept outside any hazardous (classified) areas designated in Chapter 6 of NFPA 33.

The provision for limited temperature of the workpiece in powder coating processes is to prevent carbonization of the powder, which could alter the characteristics of the powder.

N **43.1.4.1.5.1** This requirement shall not apply to drying, curing, or fusing apparatus covered by Section 43.4. [**33:**6.2.5.1]

43.1.4.1.6* Any utilization equipment or apparatus that is capable of producing sparks or particles of hot metal and that is located above or adjacent to either the spray area or the surrounding Division 2, Zone 2, or Zone 22 areas shall be of the totally enclosed type or shall be constructed to prevent the escape of sparks or particles of hot metal. [**33:**6.2.6]

A.43.1.4.1.6 Areas that are above or adjacent to spray areas and where materials are located, stored, mixed, or processed should be ventilated. Equipment that is known to produce flame, sparks, or particles of hot metal, including luminaires, that are adjacent to areas that are safe under normal operating conditions but which can become dangerous due to accident or careless operation should not be installed in such areas unless the equipment is totally enclosed or is separated from the area by partitions that will prevent the sparks or particles from entering the area. [**33:**A.6.2.6]

Any electrical equipment in the spray area must be listed for use in either a Class I, Division 1 location or a Class II, Division 1 location, as applicable. If the equipment is subject to deposits of combustible residue, it also must be listed for that exposure. The equipment should be listed for all the exposures to which it is subjected.

43.1.4.2 Electrical Area Classification.

43.1.4.2.1* Class I Locations. A Class I location shall be any location where a flammable gas or vapor is present or might be present in the air in quantities sufficient to produce an explosive or ignitible mixture. [**33:**6.3.1]

A.43.1.4.2.1 See NFPA 70. [**33:**A.6.3.1]

43.1.4.2.1.1* Class I, Division 1 Locations. As defined in 500.5(B)(1) of *NFPA 70*, a Class I, Division 1 location shall be any location where one of the following conditions exists:

(1) An ignitible concentration of flammable gas or vapor can exist under normal operating conditions.
(2) An ignitible concentration of flammable gas or vapor can exist frequently because of repair or maintenance operations or because of leakage.
(3) Breakdown or faulty operation of equipment or processes might release an ignitible concentration of flammable gas or vapor and might also cause simultaneous failure of electrical equipment in such a way as to directly cause the electrical equipment to become a source of ignition. [**33:**6.3.1.1]

A.43.1.4.2.1.1 This classification usually includes the following locations:

(1) Where volatile flammable liquids or liquefied flammable gases are transferred from one container to another
(2) Interiors of spray booths and areas in the vicinity of spraying and painting operations where volatile flammable solvents are used
(3) Locations containing open tanks or vats of volatile flammable liquids
(4) Drying rooms or compartments for the evaporation of flammable solvents
(5) All other locations where ignitible concentrations of flammable vapors or gases are likely to occur in the course of normal operations

[**33:**A.6.3.1.1]

In some Division 1 locations, ignitible concentrations of flammable gases or vapors may be present continuously or for long periods of time. Examples include the following:

(1) The inside of inadequately vented enclosures containing instruments normally venting flammable gases or vapors to the interior of the enclosure
(2) Inadequately ventilated areas within spraying or coating operations using volatile flammable fluids
(3) The interior of an exhaust duct that is used to vent ignitible concentrations of vapors

[**33:**A.6.3.1.1]

43.1.4.2.1.2* Class I, Division 2 Locations. As defined in 500.5(B)(2) of *NFPA 70*, a Class I, Division 2 location shall be any location where one of the following conditions exists:

(1) A flammable gas or a volatile flammable liquid is handled, processed, or used, but any flammable gas, vapor, or liquid is confined within a closed container or a closed system from which it can escape only in case of accidental rupture or breakdown of the container or system or in case of abnormal operation of the equipment.
(2) An ignitible concentration of flammable gas or vapor is normally prevented by positive mechanical ventilation but might exist because of failure or abnormal operation of the ventilating equipment.
(3) An ignitible concentration of flammable gas or vapor might occasionally be transmitted from an adjacent Class I, Division 1 location, unless such transmission is prevented by positive pressure ventilation from a source of clean air and effective safeguards against ventilation failure are provided. [**33:**6.3.1.2]

A.43.1.4.2.1.2 This classification usually includes locations where volatile flammable liquids or ignitible vapors are used but that, in the judgment of the AHJ, would become hazardous only in case of an accident or of some unusual operating condition. The quantity of flammable material that might escape in case of accident, the adequacy of ventilating equipment, the total area involved, and the record of the industry or business with respect to explosions or fires are all factors that merit consideration in determining the classification and extent of each location. [**33:**A.6.3.1.2]

Piping without valves, checks, meters, and similar devices would not ordinarily introduce a hazardous condition even though used for flammable liquids. Depending on factors such as the quantity and size of the containers and ventilation, locations used for the storage of flammable liquids in sealed containers may be considered either hazardous (classified) or unclassified locations. See NFPA 30. [**33:**A.6.3.1.2]

43.1.4.2.1.3* Class I, Zone 0 Locations. As defined in 505.5(B)(1) of *NFPA 70*, a Class I, Zone 0 location shall be any location where an ignitible concentration of flammable gas or vapor is present either continuously or for long periods of time. [**33:**6.3.1.3]

A.43.1.4.2.1.3 This classification includes locations inside vented tanks or vessels that contain volatile flammable liquids; inside inadequately vented spraying or coating enclosures, where volatile flammable solvents are used; inside open vessels, tanks and pits containing volatile flammable liquids; and the interior of an exhaust duct that is used to vent ignitible concentrations of vapors. [**33:**A.6.3.1.3]

It is not good practice to install electrical equipment in Zone 0 locations except when the equipment is essential to the process or when other locations are not feasible. [*See NFPA 70, 505.5(A) Informational Note No. 2.*] If it is necessary to install electrical systems in a Zone 0 location, it is good practice to install intrinsically safe systems as described by *NFPA 70*, Article 504. [**33:**A.6.3.1.3]

43.1.4.2.1.4* Class I, Zone 1 Locations. As defined in 505.5(B)(2) of *NFPA 70*, a Class I, Zone 1 location shall be any location where one of the following conditions exists:

(1) An ignitible concentration of flammable gas or vapor is likely to exist under normal operating conditions.
(2) An ignitible concentration of flammable gas or vapor might exist frequently because of repair or maintenance operations or because of leakage.
(3) Breakdown or faulty operation of equipment or processes might release an ignitible concentration of flammable gas or vapor and might also cause simultaneous failure of electrical equipment in such a way as to directly cause the electrical equipment to become a source of ignition.
(4) An ignitible concentration of flammable gas or vapor might occasionally be transmitted from an adjacent Class I, Zone 0 location, unless such transmission is prevented by positive pressure ventilation from a source of clean air and effective safeguards against ventilation failure are provided. [**33:**6.3.1.4]

A.43.1.4.2.1.4 Normal operation is considered the situation when plant equipment is operating within its design parameters. Minor releases of flammable material may be part of normal operations. Minor releases include the releases from mechanical packings on pumps. Failures that involve repair or shutdown (such as the breakdown of pump seals and flange gaskets, and spillage caused by accidents) are not considered normal operation. [**33:**A.6.3.1.4]

This classification usually includes locations where volatile flammable liquids are transferred from one container to another; areas in the vicinity of spraying and painting operations where flammable solvents are used; adequately ventilated drying rooms or compartments for evaporation of flammable solvents; inadequately ventilated pump rooms for volatile flammable liquids; . . . and other locations where ignitible concentrations of flammable vapors or gases are likely to occur in the course of normal operation but not classified Zone 0. [**33:**A.6.3.1.4]

43.1.4.2.1.5 Class I, Zone 2 Locations. As defined in 505.5(B)(3) of *NFPA 70*, a Class I, Zone 2 location shall be any location where one of the following conditions exists:

(1) An ignitible concentration of a flammable gas or vapor is not likely to exist under normal operating conditions, and if an ignitible concentration does exist, will exist only for a short period of time.
(2) A flammable gas or a volatile flammable liquid is handled, processed, or used, but any flammable gas, vapor, or liquid is confined within a closed container or a closed system from which it can escape only in case of accidental rupture or breakdown of the container or system or in case of abnormal operation of the equipment.
(3) An ignitible concentration of flammable gas or vapor is normally prevented by positive mechanical ventilation but might exist because of failure or abnormal operation of the ventilating equipment.

(4) An ignitible concentration of flammable gas or vapor might occasionally be transmitted from an adjacent Class I, Zone 1 location, unless such transmission is prevented by positive pressure ventilation from a source of clean air and effective safeguards against ventilation failure are provided. *(See also A.43.1.4.2.1.2.)* [**33:**6.3.1.5]

43.1.4.2.2 Class II Locations. A Class II location shall be any location that might be hazardous because of the presence of a combustible dust. [**33:**6.3.2]

43.1.4.2.2.1* Class II, Division 1 Locations. As defined in 500.5(C)(1) of *NFPA 70*, a Class II, Division 1 location shall be any location where one of the following conditions exists:

(1) Combustible dust is in the air in quantities sufficient to produce explosive or ignitible mixtures under normal operating conditions.
(2) Mechanical failure or abnormal operation of machinery or equipment might cause an explosive or ignitible mixture of combustible dust in air and might also provide a source of ignition through simultaneous failure of electrical equipment, operation of protection devices, or from other causes.
(3) Group E combustible dusts might be present in quantities sufficient to be hazardous. [**33:**6.3.2.1]

A.43.1.4.2.2.1 Dusts containing magnesium or aluminum are particularly hazardous, and the use of extreme precaution is necessary to avoid ignition and explosion. [**33:**A.6.3.2.1]

43.1.4.2.2.2* Class II, Division 2 Locations. As defined in 500.5(C)(2) of *NFPA 70*, a Class II, Division 2 location shall be any location where one of the following conditions exists:

(1) Combustible dust due to abnormal operations might be present in the air in quantities sufficient to produce explosive or ignitible mixtures.
(2) Combustible dust accumulations are present but are normally insufficient to interfere with the normal operation of electrical equipment or other apparatus, but could as a result of infrequent malfunctioning of handling or processing equipment become suspended in the air.
(3) Combustible dust accumulations on, in, or in the vicinity of the electrical equipment could be sufficient to interfere with the safe dissipation of heat from electrical equipment, or could be ignitible by abnormal operation or failure of electrical equipment. [**33:**6.3.2.2]

A.43.1.4.2.2.2 The quantity of combustible dust that may be present and the adequacy of dust removal systems are factors that merit consideration in determining the classification and may result in an unclassified area. [**33:**A.6.3.2.2]

Where products are handled in a manner that produces low quantities of dust, the amount of dust deposited may not warrant classification. [**33:**A.6.3.2.2]

43.1.4.2.2.3* Zone 20. As defined in 506.5(B)(1) of *NFPA 70*, a Zone 20 location shall be any location where one of the following conditions exists:

(1) An ignitible concentration of combustible dust is present continuously.
(2) An ignitible concentration of combustible dust is present for long periods of time. [**33:**6.3.2.3]

A.43.1.4.2.2.3 As a guide to classification of Zone 20, 21, and 22 locations, refer to ANSI/ISA-61241 (12.10.05), *Electrical Apparatus for Use in Zone 20, Zone 21 and Zone 22 Hazardous (Classified) Locations — Classification of Zone 20, Zone 21, and Zone 22 Hazardous (Classified) Locations*. [**33:**A.6.3.2.3]

Zone 20 classification includes locations inside dust containment systems; inside hoppers, silos, cyclones and filter houses, dust transport systems, except some parts of belt and chain conveyors, and so on; inside blenders, mills, dryers, bagging equipment, and so on. [**33:**A.6.3.2.3]

43.1.4.2.2.4* Zone 21. As defined in 506.5(B)(2) of *NFPA 70*, a Zone 21 location shall be any location where one of the following conditions exists:

(1) An ignitible concentration of combustible dust is likely to exist occasionally under normal operating conditions.
(2) An ignitible concentration of combustible dust might exist frequently because of repair or maintenance operations or because of leakage.
(3) Equipment is operated or processes are carried on of such a nature that equipment breakdown or faulty operations could result in the release of an ignitible concentration of combustible dust and also cause simultaneous failure of electrical equipment in a mode to cause the electrical equipment to become a source of ignition.
(4) An ignitible concentration of combustible dust could be communicated from an adjacent Zone 20 location, unless communication is prevented by adequate positive pressure ventilation from a source of clean air and effective safeguards against ventilation failure are provided. [**33:**6.3.2.4]

A.43.1.4.2.2.4 This classification usually includes locations outside dust containment and in the immediate vicinity of access doors subject to frequent removal or opening for operation purposes when internal combustible mixtures are present; locations outside dust containment in the proximity of filling and emptying points, feed belts, sampling points, truck dump stations, belt dump over points, etc. where no measures are employed to prevent the formation of combustible mixtures; locations outside dust containment where dust accumulates and where due to process operations the dust layer is likely to be disturbed and form combustible mixtures; locations inside dust containment where explosive dust clouds are likely to occur (but neither continuously, nor for long periods, nor frequently) as, for example, silos (if filled and/or emptied only occasionally) and the dirty side of filters if large self-cleaning intervals are occurring. *(See also A.43.1.4.2.2.3.)* [**33:**A.6.3.2.4]

43.1.4.2.2.5* Zone 22. As defined in 506.5(B)(3) of *NFPA 70*, a Zone 22 location shall be any location where one of the following conditions exists:

(1) An ignitible concentration of combustible dust is not likely to occur in normal operation, and if it does occur, will only persist for a short period.
(2) A combustible dust is handled, processed, or used, but the dust is normally confined within closed containers or closed systems from which it can escape only as a result of the abnormal operation of the equipment with which the dust is handled, processed, or used.
(3) An ignitible concentration of combustible dust could be communicated from an adjacent Zone 21 location, unless communication is prevented by adequate positive pressure ventilation from a source of clean air and effective safeguards against ventilation failure are provided. [**33:**6.3.2.5]

A.43.1.4.2.2.5 Zone 22 locations usually include outlets from bag filter vents, because in the event of a malfunction there can be emission of combustible mixtures; locations near equipment that has to be opened at infrequent intervals or equipment that from experience can easily form leaks where, due to pressure above atmospheric, dust will blow out; pneumatic equipment, flexible connections that can become damaged, etc.; storage locations for bags containing dusty product, since failure of bags can occur during handling, causing dust leakage; and locations where controllable dust layers are formed that are likely to be raised into explosive dust/air mixtures. Only if the layer is removed by cleaning before hazardous dust–air mixtures can be formed is the area designated non-hazardous. [**33:**A.6.3.2.5]

Locations that normally are classified as Zone 21 can fall into Zone 22 when measures are employed to prevent the formation of explosive dust–air mixtures. Such measures include exhaust ventilation. The measures should be used in the vicinity of (bag) filling and emptying points, feed belts, sampling points, truck dump stations, belt dump over points, etc. *(See also A.43.1.4.2.2.3.)* [**33:**A.6.3.2.5]

43.1.4.3 Electrical Devices in Spray Areas.

43.1.4.3.1 The spray area as defined in NFPA 33 shall be Class I, Division 1; Class I, Zone 1; Class II, Division 1; or Zone 21, whichever is applicable. [**33:**6.4.1]

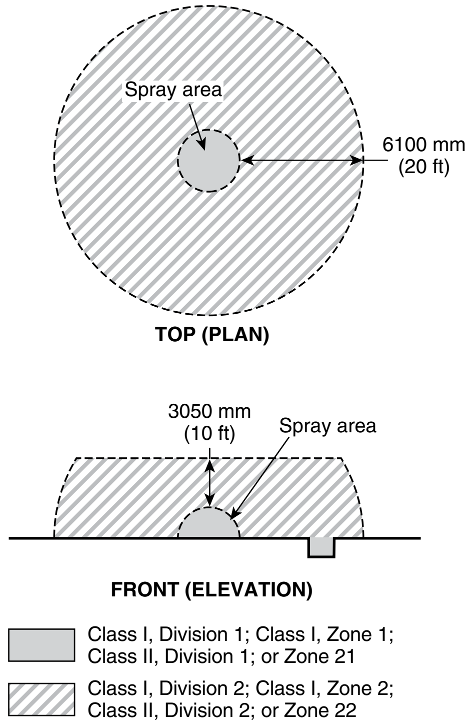
43.1.4.3.2 Electrical wiring and utilization equipment that is located in the spray area and is not subject to deposits of combustible residues shall be suitable for Class I, Division 1; Class I, Zone 1; Class II, Division 1; or Zone 21 locations, whichever is applicable. [**33:**6.4.2]

43.1.4.3.3* Electrical wiring and utilization equipment that is located in the spray area and is subject to deposits of combustible residues shall be listed for such exposure and shall be suitable for Class I, Division 1; Class I, Zone 1; Class II, Division 1; or Zone 21 locations, whichever is applicable. [**33:**6.4.3]

A.43.1.4.3.3 Equipment that is listed for both Class I, Division 1; Class I, Zone 1; Class II, Division 1; and Zone 21 locations and is also listed for accumulation of deposits of combustible residues can be installed in the spray area. *(See NFPA 70.)* [**33:**A.6.4.3]

43.1.4.4 Electrical Devices in Areas Adjacent to or Connected to Spray Areas. Electrical wiring and utilization equipment located in areas adjacent to or connected to the spray area, including but not limited to vestibules and tunnels, shall be classified in accordance with 43.1.4.4.1 through 43.1.4.4.5. [**33:**6.5]

43.1.4.4.1 Electrical wiring and utilization equipment located outside, but within 20 ft (6100 mm) horizontally and 10 ft (3050 mm) vertically, of an unenclosed spray area and not separated from the spray area by partitions extending to the boundaries of the area designated as Division 2, Zone 2; or Zone 22 in Figure 43.1.4.4.1 shall be suitable for Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable. [**33:**6.5.1]



Δ *FIGURE 43.1.4.4.1 Electrical Area Classification for Unenclosed Spray Areas. [33:Figure 6.5.1]*

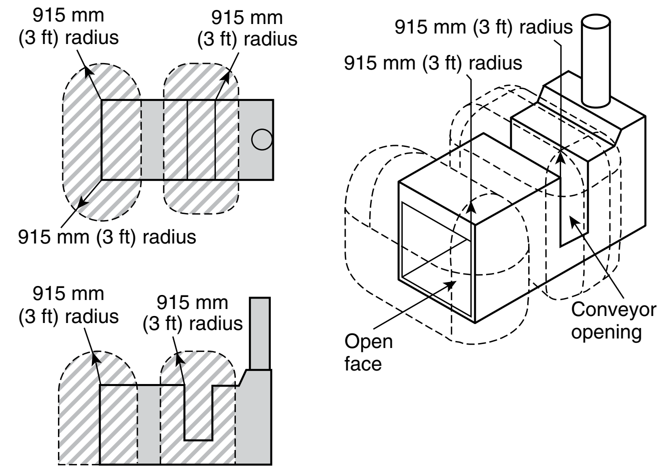
In applying Figure 43.1.4.4.1, envision the spray area as the volume occupied by the workpiece plus the surrounding volume through which the spray apparatus is moved. As an example, assume a railroad boxcar 55 ft (16.8 m) long, 11 ft (3.4 m) wide, and 11 ft (3.4 m) high that is supported 3 ft (0.9 m) above the shop floor. Assume also that the operator holds the spray gun 1.5 ft (0.5 m) from the surface being sprayed. Then the dimensions of the spray area would be as follows:

$$\begin{aligned} 55\text{ ft} + 1.5\text{ ft} + 1.5\text{ ft} &= 58\text{ ft } (16.8\text{ m} + 0.5\text{ m} + 0.5\text{ m} \\ &= 17.8\text{ m) long} \\ 11\text{ ft} + 1.5\text{ ft} + 1.5\text{ ft} &= 14\text{ ft } (3.4\text{ m} + 0.5\text{ m} + 0.5\text{ m} \\ &= 4.4\text{ m) wide} \\ 3\text{ ft} + 11\text{ ft} + 1.5\text{ ft} &= 15.5\text{ ft } (0.9\text{ m} + 3.4\text{ m} + 0.5\text{ m} \\ &= 4.8\text{ m) high} \end{aligned}$$

These are the dimensions of the spray area that must be classified as Class I, Division 1, Class I, Zone 1, Class II, Division 1, or Zone 21, whichever is applicable.

Note that Figure 43.1.4.4.1 has been redrawn for purposes of clarity and now includes a below-grade trench that is classified as Division 1/Zone 1/Zone 21.

43.1.4.4.2 If spray application operations are conducted within a closed-top, open-face or open-front booth or room, as shown in Figure 43.1.4.4.2, any electrical wiring or utilization equipment located outside the booth or room but within 3 ft (915 mm) of any opening shall be suitable for Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable. [**33:**6.5.2(a)]



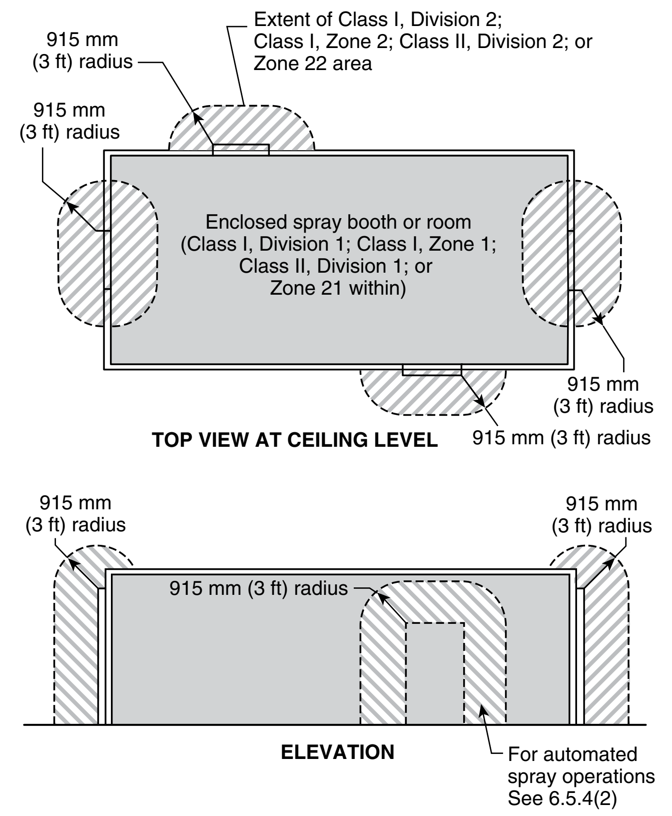
Δ *FIGURE 43.1.4.4.2 Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 Locations Adjacent to an Open-Face or Open-Front Spray Booth or Spray Room. [**33:**Figure 6.5.2]*

43.1.4.4.3 If spray application operations are conducted within an open-top booth, any electrical wiring or utilization equipment located within the space 3 ft (915 mm) vertically from the top of the booth shall be suitable for Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable. In addition, any electrical wiring or utilization equipment located within 3 ft (915 mm) in all directions of openings other than the open top also shall be suitable for Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable. [**33:**6.5.3]

43.1.4.4.4 If spray application operations are confined to an enclosed spray booth or room, electrical area classification shall be as follows:

(1) The area within 3 ft (915 mm) of any opening shall be classified as Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable, as shown in Figure 43.1.4.4.4.

(2)* Where automated spray application equipment is used, the area outside the access doors shall be unclassified provided the door interlock prevents the spray application operations when the door is open.



Δ *FIGURE 43.1.4.4.4 Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 Locations Adjacent to an Enclosed Spray Booth or Spray Room. [**33:**Figure 6.5.4]*

N **A.43.1.4.4.4(2)** Access doors into a spray area that must be closed to allow normal automated spray application operations to occur should not be considered an opening. The door should be considered a maintenance access and never open while a hazardous condition exists in the booth. Therefore, the area outside the door/maintenance access should be considered unclassified. [**33:**A.6.5.4(2)]

(3) Where exhaust air is recirculated and all requirements of 43.1.5.5 are met, both of the following shall apply:
  (a) The interior of any recirculation path downstream of the recirculation particulate filter up to and including the air supply plenum shall be classified as Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable.
  (b) The interior of fresh air supply ducts shall be unclassified.

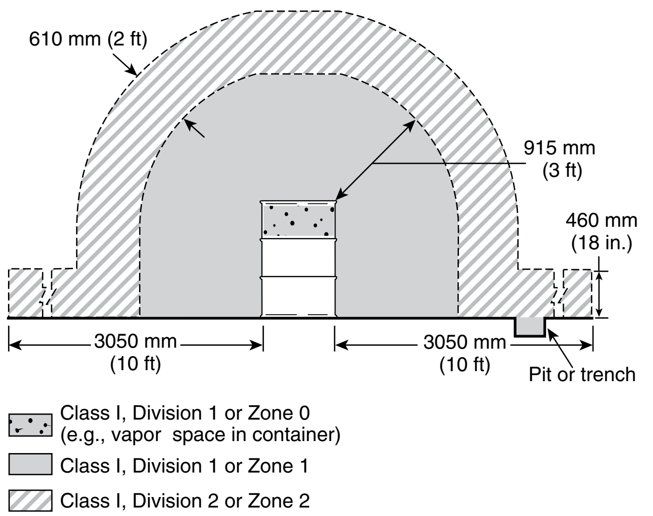
(4) Where exhaust air is not recirculated, the interior of fresh air supply ducts and fresh air supply plenums shall be unclassified. [**33:**6.5.4]

43.1.4.4.5 Open containers, supply containers, waste containers, spray gun cleaners, and solvent distillation units that contain Class I liquids shall be located in areas ventilated in accordance with applicable requirements of 43.1.5. [**33:**6.5.5]

43.1.4.4.5.1 Electrical area classification shall be as follows:

(1) The area within 3 ft (915 mm) in all directions from any such container or equipment and extending to the floor or grade level shall be classified as Class I, Division 1 or Class I, Zone 1, whichever is applicable.
(2) The area extending 2 ft (610 mm) beyond the Division 1 or Zone 1 location shall be classified as Class I, Division 2 or Class I, Zone 2, whichever is applicable.
(3) The area extending 5 ft (1525 mm) horizontally beyond the area described in 43.1.4.4.5.1(2) up to a height of 18 in. (460 mm) above the floor or grade level shall be classified as Class I, Division 2 or Class I, Zone 2, whichever is applicable.
(4) The area inside any tank or container shall be classified as Class I, Division 1 or Class I, Zone 0, whichever is applicable. [**33:**6.5.5.1]

43.1.4.4.5.2 Electrical wiring and utilization equipment installed in these areas shall be suitable for the location, as shown in Figure 43.1.4.4.5.2. [**33:**6.5.5.2]

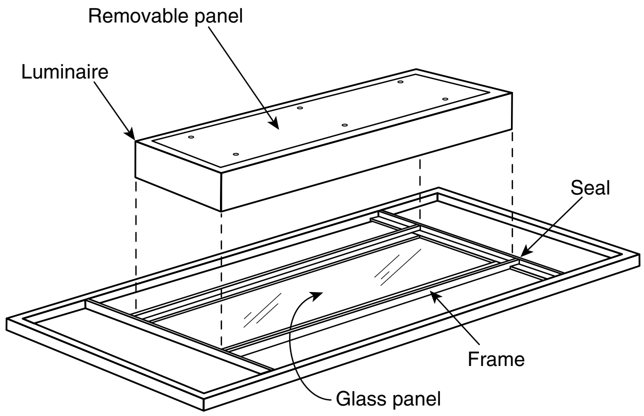


Δ *FIGURE 43.1.4.4.5.2 Electrical Area Classification for Class I Liquid Operations Around Open Containers, Supply Containers, Waste Containers, Spray Gun Cleaners, and Solvent Distillation Units. [**33:**Figure 6.5.5.2]*

43.1.4.5 Illumination.

43.1.4.5.1 Luminaires, like that shown in Figure 43.1.4.5.1, that are attached to the walls or ceiling of a spray area but that are outside any classified area and are separated from the spray area by glass panels that meet the requirements of 43.1.3.5 shall be suitable for use in unclassified locations. Such fixtures shall be serviced from outside the spray area. [**33:**6.6.1]

43.1.4.5.2 Luminaires, like that shown in Figure 43.1.4.5.1, that are attached to the walls or ceiling of a spray area; that are separated from the spray area by glass panels that meet the requirements of



Δ *FIGURE 43.1.4.5.1 Example of a Luminaire Mounted Outside of the Spray Area and Serviced from Outside the Spray Area. [**33:**Figure 6.6.1]*

43.1.3.5; and that are located within a Class I, Division 2, a Class I, Zone 2, a Class II, Division 2; or a Zone 22 location shall be suitable for such location. Such fixtures shall be serviced from outside the spray area. [**33:**6.6.2]

43.1.4.5.3 Luminaires, like that shown in Figure 43.1.4.5.3, that are an integral part of the walls or ceiling of a spray area shall be permitted to be separated from the spray area by glass panels that are an integral part of the fixture. Such fixtures shall be listed for use in Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 locations, whichever is applicable, and also shall be listed for accumulations of deposits of combustible residues. Such fixtures shall be permitted to be serviced from inside the spray area. [**33:**6.6.3]

43.1.4.5.4 Luminaires that are located inside the spray area shall meet the requirements of 43.1.4.3 and 43.1.4.6. [**33:**6.6.4]

43.1.4.6* Static Electricity. All electrically conductive objects in the spray area, except those objects required by the process to be at high voltage, shall be electrically connected to ground with a resistance of not more than 1 megohm (10^6 ohms). This requirement shall apply to containers of coating material, wash cans, guards, hose connectors, brackets, and any other electrically conductive objects or devices in the area. This requirement shall also apply to any personnel who enter the spray area. [**33:**6.7]

The 1 megohm limit cited here is an absolute maximum. Generally speaking, a good ground path, that is, the path from the object to earth, would not exceed 10,000 ohms. Resistance greater than that, while still considered safe, is indicative of a deteriorating ground path. Causes might be corroded or loose ground connections. NFPA 77, *Recommended Practice on Static Electricity*, includes useful information on the subject of proper bonding and grounding.

A.43.1.4.6 During operation of any electrostatic equipment, electrically conductive isolated objects within the process area are influenced

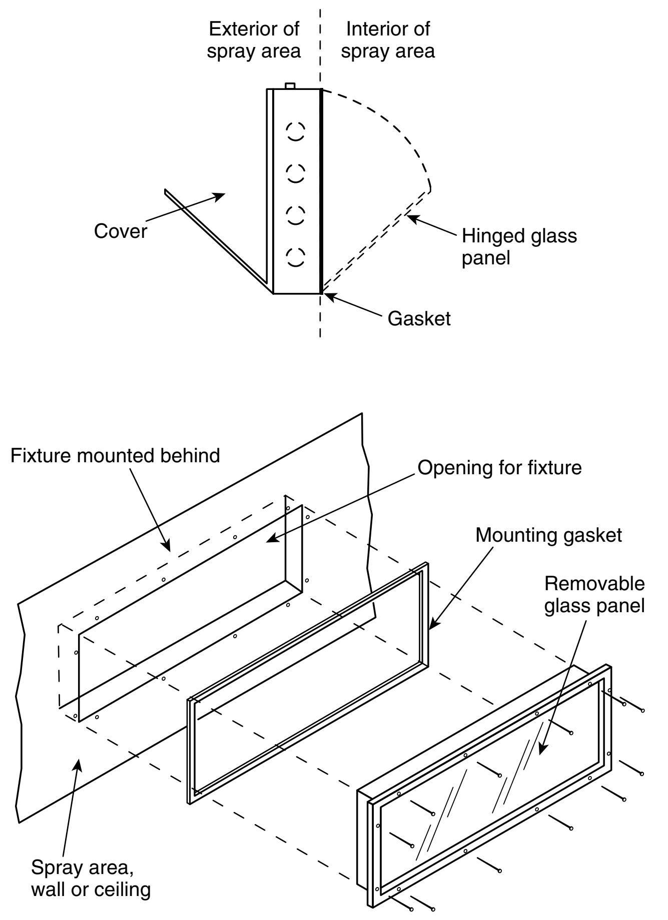


*FIGURE 43.1.4.5.3 Examples of Luminaires That Are Integral Parts of the Spray Area and That Are Serviced from Inside the Spray Area. [**33:**Figure 6.6.3]*

by the process and can become charged to voltages that result in spark discharges capable of igniting flammable or combustible substances. Objects commonly involved in such incidents include workpieces on conveyor racks that have fouled contact points; solvent containers or tools placed on nonconducting paint residues, cardboard, or wooden rests; spray booth components such as loose floor grates; and human beings insulated from ground by rubber footwear, paint residue accumulations on floors, and gloves. [**33:**A.6.7]

Even in spray painting environments where there is no electrostatic equipment in operation but where sticky, electrically nonconductive paint residues have accumulated on the floor, a significant hazard is associated with static electrification of human bodies that results from walking across such a floor. As few as two or three steps can produce sufficient voltage on the body of a worker to create an incendive spark when he or she approaches a grounded object. If this spark occurs in a flammable vapor such as is found surrounding a solvent container or a freshly painted object, a fire results. See NFPA 77 for additional information. [**33:**A.6.7]

Workers must be grounded if they work in an area where spray painting is conducted, or if they work directly with electrostatic equipment in the presence of flammable or combustible substances. Grounding can be accomplished by having the operator grip a grounded spray gun, grounded wire, or grounded metal rod with a bare hand. If the floor is grounded and clean, workers can also be grounded by wearing shoes with electrically conductive soles. To the extent possible, the number of ungrounded (isolated) conductive objects in the spray area should be kept to a minimum.

43.1.4.7 Flexible Power Cords. For automated equipment and robotic equipment, flexible power cords shall be permitted to be used in hazardous (classified) locations and shall be permitted to be connected to the fixed part of the electrical circuit, provided they meet all of the following conditions:

(1) They are approved for extra-hard usage.
(2) They are equipped with a grounding conductor that meets the requirements of Section 400.2 of *NFPA 70*.
(3) They are connected to terminals or conductors in an approved manner.
(4) They are supported by a positive mechanical clamp in such a manner that permits the cord to be readily replaced and prevents strain at the cord connections within the terminal enclosure.
(5) They are provided with explosionproof seals for liquid applications or dusttight seals for powder applications where the cord enters junction boxes, fittings, or enclosures.
(6) They are listed for deposits of combustible residues. [**33:**6.8]

43.1.4.8 Portable Electric Lights. Portable electric luminaires shall not be used in any spray area while spray application operations are being conducted.

*Exception: Where portable electric luminaires are required for use in spaces that are not illuminated by fixed luminaires within the spray area, they shall meet the requirements of 43.1.4.3.3. [**33:**6.9]*

43.1.5 Ventilation.

43.1.5.1 General. Ventilating and exhaust systems shall be designed and installed in accordance with the applicable requirements of NFPA 91 except as amended by the requirements of 43.1.5. [**33:**7.1]

43.1.5.2 Performance Requirements. Each spray area shall be provided with mechanical ventilation that is capable of confining and removing vapors and mists to a safe location and is capable of confining and controlling combustible residues, dusts, and deposits. The concentration of the vapors and mists in the exhaust stream of the ventilation system shall not exceed 25 percent of the lower flammable limit. *(See Annex B of NFPA 33 for additional guidance on determining the lower flammable limit.)* [**33:**7.2]

*Exception: In confined spaces, where ventilation might not be capable of providing the necessary ventilation, a properly applied inerting procedure shall be permitted to be used. Such procedures shall meet the applicable requirements of NFPA 69 and shall be acceptable to the AHJ. [**33:**7.2]*

The atmosphere in the direct path of the spray exceeds the lower flammable limit (LFL) of the solvent. Because the vapors from most solvents are heavier than air, even small quantities of vapor can form an ignitible mixture in low or unventilated spaces.

Instruments are not always required to determine whether the ventilation system is operating properly. A strong odor of solvent vapor evident within 3 ft (1 m) from any opening is an indication that the exhaust ventilation system is not confining vapors and mists. The presence of overspray residues on the floor outside the open front of a booth or outside a conveyor opening is an indication that the exhaust ventilation system is not confining residues, dusts, and deposits. In totally enclosed booths, such as those used in automotive body shops, visual observation can determine whether residues, dusts, and deposits are being removed from the booth.

In large spray rooms, however, such as those used for refinishing aircraft, deposits on the floor are to be expected. Air velocities of 100 ft/min (30 m/min) or greater cannot keep the overspray airborne, although solvent vapors are removed.

43.1.5.2.1* Spray areas equipped with overspray collection filters shall have an effective means to ensure that the performance requirements of 43.1.5.2 are met. [**33:**7.2.1]

A.43.1.5.2.1 Acceptable means to comply with 43.1.5.2.1 include, but are not limited to, visible gauges, audible alarms, approved interlocks, or an effective inspection program. [**33:**A.7.2.1]

43.1.5.2.2 Powder Coating Systems. Powder coating systems also shall meet the requirements of Section 15.8 of NFPA 33. [**33:**7.2.2]

43.1.5.2.3 Mechanical ventilation shall be kept in operation at all times while spray operations are being conducted and for a sufficient time thereafter to allow the vapors from drying coated objects or material and residues to be exhausted. Where spray operations are conducted automatically without an attendant constantly on duty, the operating controls of the spray apparatus shall be arranged so that the spray apparatus cannot function unless the exhaust fans are operating. [**33:**7.2.3]

Δ **43.1.5.2.4** In confined spaces, where ventilation is not capable of meeting the requirements of 43.1.5.2, an inerting procedure shall be permitted to be used. Such procedures shall meet the applicable requirements of NFPA 69 and shall be acceptable to the AHJ. [**33:**7.2.4]

43.1.5.3* Make-Up Air. Clean make-up air shall be provided to compensate for the air exhausted from spray operations. The intake for this make-up air shall be located so that the air exhausted from spray operations is not recirculated. [**33:**7.3]

A.43.1.5.3 All spray areas require make-up air, and since the air exhausted from spray application operations is normally contaminated and can be recirculated only under rigidly controlled conditions, the source of the make-up air should be given careful consideration. When the capacity of the ventilating fan is low and the area where the exhaust system is located is large, sufficient make-up air often can be provided by natural infiltration of air through building walls, windows, doors, and so forth. In general, if the volume of the room or building where the exhaust system is located is not equal to at least 20 times the volumetric capacity of the fans (three air changes per hour), then additional make-up air should be provided. Outside air should be tempered and might have to be dehumidified or chilled for proper operation of the spray application apparatus. Automatic controls, including a high temperature limit switch, fan interlocks, and safety shutoff valves, should be provided for safe operation. [**33:**A.7.3]

The method of distributing the make-up air requires careful consideration. If the velocities and distribution of air through baffles, filters, and registers have not been carefully designed, the spray application operation can be inefficient. The velocity of the air through filters, and so forth, should not exceed 200 ft/min (60 m/min). Higher velocities can disrupt spray application operations due to turbulent airflow in the vicinity of the spray apparatus. This turbulence can also cause a properly designed exhaust system to fail to confine and remove vapors or to fail to confine and control residues, dusts, and deposits. [**33:**A.7.3]

In some heating arrangements, forced make-up or replacement air directly compensating for the contaminated air exhausted from spray application operations is used in place of or to augment general area heating and ventilation. [**33:**A.7.3]

With the many variables that can be encountered in heating and ventilating systems, it generally is advisable to engage the services of a qualified ventilating engineer to obtain a safe and efficient installation. [**33:**A.7.3]

The features that should be considered include the following:

(1) Location of sources of heat to comply with 43.1.4
(2) Locating air intakes to prevent recalculation of contaminated air, and equipping air intakes with appropriate screens or filters
(3) Automatic temperature and proportioning controls, including an independent excess temperature limit control
(4) A safety system interlocked with the heater to automatically provide for its safe ignition and to minimize the hazards that might result from failure of its proper operating cycle, proper pressure of fuel supply, ventilation, and electrical power
(5) An interlock between the spray booth exhaust system and the make-up air system to ensure that both systems are operable and provide a proper balance of supply and replacement air
(6) In the case of direct-fired units, operating controls that ensure that concentrations of unburned fuel or products of combustion, if inhaled, are kept to levels that are safe for operating personnel

[**33:**A.7.3]

Δ **43.1.5.4 Routing of Exhaust Ducts.** Air exhausted from liquid spray operations shall be conducted by ducts directly to the outside of the building. Exhaust ducts shall follow the shortest route to the point of discharge and shall meet the following conditions:

(1) Exhaust ducts shall not penetrate a fire wall.
(2) Exhaust discharge shall be directed away from any fresh air intakes.
(3) Exhaust discharge point shall be at least 6 ft (1830 mm) from any exterior wall or roof.

(4) Exhaust discharge point shall be at least 10 ft (3048 mm) from openings into the building.
(5) Exhaust discharge point shall be at least 10 ft (3048 mm) above adjoining grade.
(6) Exhaust duct shall not discharge in the direction of any combustible construction that is within 25 ft (7625 mm) of the exhaust duct discharge point.
(7) Exhaust duct shall not discharge in the direction of any unprotected opening in any noncombustible or limited-combustible construction that is within 25 ft (7625 mm) of the exhaust duct discharge point.
(8) Exhaust duct shall not discharge in the direction of any exit discharge or public way that is within 25 ft (7625 mm) of the exhaust duct discharge point.

[**33:**7.4]

If a fire occurs in a spray booth or spray room, standard practice is to not shut down the exhaust system. This prevents backdraft of flame into the area where the spray booth or room is located. However, flames, heat, and products of combustion will be ejected out the exhaust stack. The provisions of 43.1.5.4 are intended to minimize damage that might result by ensuring the exhaust stack terminates far enough away from any exposures.

43.1.5.5 Recirculation of Exhaust.

43.1.5.5.1* Air exhausted from spray areas shall not be recirculated unless all of the following requirements are met:

(1) Recirculation particulate filters as defined in this *Code* shall be used to remove particulates from the recirculated air.
(2) The concentration of vapors in the exhaust airstream shall not exceed 25 percent of the lower flammable limit.
(3) Listed equipment shall be used to monitor the concentration of vapors in all exhaust airstreams.
(4) The equipment specified in 43.1.5.5.1(3) shall initiate a local alarm and shall automatically shut down the spray operation if the concentration of any vapor in the exhaust airstream exceeds 25 percent of the lower flammable limit.
(5) All equipment installed to process and remove contaminants from the air exhausted from spray operations shall be approved by the AHJ.
(6)* For occupied spray areas where a portion of the exhaust air is recirculated within the spray area, toxicity and worker exposures shall be addressed.

[**33:**7.5.1]

A.43.1.5.5.1 If air exhausted from the spray area is permitted to be recirculated, as provided for in 43.1.5.5.1, it is critical for effective monitoring that sensors be protected from obstruction and contamination. See *NFPA 72* for recommended maintenance and calibration procedures. [**33:**A.7.5.1]

N **A.43.1.5.5.1(6)** If recirculated air is used for make-up air for occupied spaces, including spray areas, spray booths, spray rooms, and other process areas, the requirements for decontamination and maximum allowable concentrations of solvents are far more stringent than those required by this standard for fire and explosion prevention. Refer to appropriate occupational safety and health and industrial hygiene standards for permissible exposure limits. One such standard is ANSI/AIHA Z9.7, *Recirculation of Air from Industrial Process Exhaust Systems*. [**33:**A.7.5(6)]

43.1.5.5.2* The provisions of 43.1.5.5.1 shall not disallow recirculation of air to occupied spaces. However, other requirements addressing the toxicity and permissible exposure limits shall also apply. *(See ANSI/AIHA Z9.7, Recirculation of Air from Industrial Process Exhaust Systems.)* [**33:**7.5.2]

A.43.1.5.5.2 If recirculated air is used for make-up air for occupied spaces, including spray areas, spray booths, spray rooms, and other process areas, the requirements for decontamination and maximum allowable concentrations of solvents are far more stringent than those required by this *Code* for fire and explosion prevention. Refer to appropriate occupational safety and health and industrial hygiene standards for permissible exposure limits. One such standard is ANSI/AIHA Z9.7, *Recirculation of Air from Industrial Process Exhaust Systems*. [**33:**A.7.5.2]

43.1.5.6* Manifolding of Exhaust Ducts. Individual spray booths shall be separately ducted to the building exterior.

Exception No. 1: Multiple cabinet spray booths whose combined frontal area does not exceed 18 ft² (1.7 m²) shall be permitted to be manifolded if the sprayed materials used will not react and cause ignition of the residue in the ducts.

Exception No. 2: Where treatment of exhaust is necessary for air pollution control or for energy conservation, ducts shall be permitted to be manifolded if all of the following conditions are met:

(1) The sprayed materials used will not react and cause ignition of the residue in the ducts.
(2) No finishing materials containing nitrocellose are used.
(3) An air-cleaning system is provided to reduce the amount of overspray carried into the duct manifold.
(4) Automatic sprinkler protection is provided at the junction of each booth exhaust with the manifold, in addition to the protection required by 43.1.7.
*(5) The installation is approved by the AHJ. [**33:**7.6]*

A.43.1.5.6 Exhaust systems should be individually ducted to the outside of the building. Where treatment of the exhaust airstream is necessary to satisfy environmental regulations or where energy conservation measures are used, this might not be practical, and manifolding of the exhaust ducts might be necessary. It should be understood that manifolding of exhaust ducts increases the fire hazard. A fire starting in one booth can spread through the exhaust system and involve other spray areas. Heat exchangers, which are sometimes used to preheat exhaust air before it enters an incinerator, are subject to fires from the spontaneous ignition of residue that collects on heat exchanger surfaces. [**33:**A.7.6]

It is critical that the provisions of 43.1.5.6, Exception No. 2, be met in order to prevent a fire in a spray booth or spray room from spreading through the exhaust ventilation system and involving other spray areas.

Where heat exchangers are used, the surfaces of the heat exchangers must be cleaned at intervals that are frequent enough to prevent a buildup of residue.

43.1.5.7* Materials of Construction. Exhaust plenums and exhaust ducts and fasteners shall be constructed of steel, except as allowed in 43.1.5.7.1, 43.1.5.7.2, and 43.1.5.7.3. [**33:**7.7]

Δ **A.43.1.5.7** For ducts for powder coating systems, the strength of the materials of construction should be considered, since the duct might have to contain the pressure of a deflagration. *(See NFPA 68.)* [**33:**A.7.7]

43.1.5.7.1 For spray booths used exclusively for powder coating, ducts shall be permitted to be constructed of fire-retardant combustible materials. [**33:**7.7.1]

43.1.5.7.2 Concrete shall be permitted to be used. The interior surfaces of the concrete exhaust plenum or exhaust duct shall be smooth and sealed to facilitate cleaning. [**33:**7.7.2]

43.1.5.7.3 Other materials of construction shall be permitted to be used in cases where the conveyed materials are not compatible with steel. [**33:**7.7.3]

43.1.5.8* Support of Exhaust Ducts. Exhaust ducts shall be supported to prevent collapse under fire conditions. [**33:**7.8]

A.43.1.5.8 The designer of the exhaust ducts and fasteners should refer to appropriate design guides, such as the SMACNA *Round Industrial Duct Construction Standards* and the SMACNA *Rectangular Industrial Duct Construction Standards*, published by the Sheet Metal and Air Conditioning Contractors National Association. [**33:**A.7.8]

43.1.5.8.1 Duct supports shall be designed to carry the weight of the duct system itself, plus the anticipated weight of any residues. If sprinkler protection is provided inside the duct system, then the duct supports also shall be designed to carry the anticipated weight of any accumulation of sprinkler discharge. [**33:**7.8.1]

Δ **43.1.5.8.2** Hangers and supports shall be fastened to the building or to the structure to minimize vibration and stress on the duct system. [**33:**7.8.2]

This provision was revised to eliminate vague and unenforceable language. The words "securely" and "avoid" were deleted. The performance expected is that hangers and supports are fastened strongly enough to minimize vibration, recognizing that it is not possible to completely eliminate it.

43.1.5.8.3 Hangers and supports shall be designed to allow for expansion and contraction. [**33:**7.8.3]

43.1.5.8.4 Exhaust ducts shall not use building walls, floors, ceilings, or roofs as component parts. [**33:**7.8.4]

43.1.5.8.5 The provisions of 43.1.5.8.4 shall not disallow the use of concrete exhaust plenums or exhaust ducts where some or all of the plenum or duct is part of the concrete floor. [**33:**7.8.5]

43.1.5.9 Exhaust Duct Access Openings. Exhaust ducts shall be provided with doors, panels, or other means to facilitate inspection, maintenance, cleaning, and access to fire protection devices. [**33:**7.9]

43.1.5.10 Exhaust Fans and Drives.

43.1.5.10.1 The rotating element of the exhaust fan shall be nonferrous, or the fan shall be constructed so that a shift of the impeller or shaft will not permit two ferrous parts of the fan to rub or strike. Necessary allowances shall be made for ordinary expansion and loading and to prevent contact between moving parts and the duct or fan housing. Fan blades shall be mounted on a shaft that is sufficiently heavy to maintain alignment even when the blades of the fan are heavily loaded. All bearings shall be of the self-lubricating type or shall be provided with accessible lubricating ports. [**33:**7.10.1]

This provision was revised to eliminate vague and unenforceable language. The second sentence was revised to remove text that was redundant to the performance requirement of the first sentence. The provision regarding lubrication points was also revised to remove unenforceable text.

43.1.5.10.2 Electric motors that drive exhaust fans shall not be placed inside any spray area unless they meet the provisions of 43.1.4.3.3. [**33:**7.10.2]

The exhaust duct is considered part of the spray area. Therefore, any electrical devices in the exhaust air stream must be suitable for a hazardous (classified) area.

43.1.5.10.3 Belts shall not enter any spray area unless the belt and pulley within the spray area are completely enclosed. [**33:**7.10.3]

Drive belts are subject to frictional heating that could lead to ignition of the belt. They must be isolated from the exhaust air stream to prevent ignition of any vapors therein or of any residues on the inside of the duct.

43.1.5.11* Drying Areas. Freshly sprayed workpieces shall be dried only in spaces that are ventilated to prevent the concentration of vapors from exceeding 25 percent of the lower flammable limit. *(See also Section 43.4.)* [**33:**7.11]

A.43.1.5.11 If there are other operations that give off ignitible vapors in the vicinity of a spray application operation, they should be provided with independent mechanical ventilation. [**33:**A.7.11]

43.1.6 Storage, Handling, and Distribution of Flammable and Combustible Liquids.

43.1.6.1* General. Storage, handling, and mixing of flammable and combustible liquids shall meet all the applicable requirements of NFPA 30 and 43.1.6. [**33:**8.1]

A.43.1.6.1 For large spray operations, coatings, thinners, and solvents can be stored in one of the following locations:

(1) Underground storage tanks
(2) Aboveground storage tanks
(3) Separate buildings
(4) Separate dedicated rooms within the facility

[**33:**A.8.1]

In some cases, liquids are pumped to a mixing room or paint kitchen, where they are mixed and then pumped to the spray area. For smaller operations, separate storage and mixing areas might not be justified. However, it is desirable to minimize the fire loading in or near the spray area by one or a combination of the following methods:

(1) Flammable liquid storage cabinets
(2) A protected enclosed metal structure
(3) Use of metal containers with limitations on the quantity of liquid located near the spray area

[**33:**A.8.1]

43.1.6.2 Storage in Process Areas.

43.1.6.2.1 The volume of Class I, Class II, and Class IIIA liquids stored in a storage cabinet shall not exceed 120 gal (454 L). [**33:**8.2.1]

Δ **43.1.6.2.1.1** The total aggregate volume of Class I, Class II, and Class IIIA liquids in a group of storage cabinets shall not exceed the maximum allowable quantity of flammable and combustible liquids per control area based on the occupancy where the cabinets are located, as set forth in Section 9.6 of NFPA 30. [**33:**8.2.1.1]

Δ **43.1.6.2.1.2** For industrial occupancies, the total aggregate volume of Class I, Class II, and Class IIIA liquids in a group of storage cabinets in a single area shall not exceed the maximum allowable quantity (MAQ) of flammable and combustible liquids per control area for industrial occupancies as set forth in Table 43.1.6.2.1.2. [**33:**8.2.1.2]

Δ ***TABLE 43.1.6.2.1.2** Maximum Allowable Quantity of Flammable and Combustible Liquids per Control Area*

	Liquid Classes	Quantity		Notes
		L	gal	
Flammable liquids	IA	115	30	1, 2
	IB & IC	460	120	1, 2
	IA, IB, IC combined	460	120	1, 2, 3
Combustible liquids	II	460	120	1, 2
	IIIA	1,265	330	1, 2

Source: Table 34.1.3.1 of *NFPA 5000, Building Construction and Safety Code*, 2009 edition.

Notes:

(1) Quantities are permitted to be increased 100 percent where all liquids are stored in approved flammable liquids storage cabinets or in safety cans. Where Note 2 also applies, the increase for both notes is permitted to be applied accumulatively.

(2) Quantities are permitted to be increased 100 percent in buildings equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13. Where Note 1 also applies, the increase for both notes is permitted to be applied accumulatively.

(3) Containing not more than the maximum allowable quantity per control area of Class IA, Class IB, or Class IC flammable liquids, individually.

[**33:** Table 8.2.1.2]

43.1.6.2.2 The quantity of liquid located in the vicinity of spraying operations but outside of identified storage areas, such as storage cabinets, an inside liquid storage area, or a warehouse or outside of other specific process areas that are cut off by at least a 2-hour fire separation from the spraying operations shall not exceed the quantity given in either of the following, whichever is greater:

(1)* The amount required to supply spraying operations for one continuous 24-hour period

A.43.1.6.2.2(1) The intent of this requirement is to allow the quantities of flammable and combustible liquids needed to safely and efficiently operate for the actual operating hours in any 24-hour period. As an example, if the facility operates only 8 hours out of 24 (i.e., a single shift) and uses 50 gal (190 L) of liquid during that time, then 50 gal (190 L) is the allowable quantity for the continuous 24-hour period. If the facility increases operations to two shifts, then the allowable quantity doubles to 100 gal (380 L). [**33:**A.8.2.2(1)]

(2) The aggregate sum of the following:
   (a) 25 gal (95 L) of Class IA liquids in containers
   (b) 120 gal (454 L) of Class IB, Class IC, Class II, or Class III liquids in containers
   (c) 1585 gal (6000 L) of either of the following:
      1. Class IB, IC, II, or IIIA liquids in metal portable tanks or metal intermediate bulk containers, each not exceeding 793 gal (3000 L)
      2. Class II or Class IIIA liquids in nonmetallic intermediate bulk containers, each not exceeding 793 gal (3000 L)
   (d) Twenty portable tanks or intermediate bulk containers, each not exceeding 793 gal (3000 L) of Class IIIB liquids [**33:**8.2.2]

It should be noted that the "aggregate sum" of 43.1.6.2.2(2)(a) through (d) is extracted from 8.2.2 of NFPA 33, which, in turn, extracts the text from the 2015 edition of NFPA 30, *Flammable and Combustible Liquids Code*. The 2018 edition of NFPA 30 does not include this text but bases all quantities on the "maximum allowable quantity." Basically, NFPA 30 allows the aggregate sum of the quantities allowed for each class of liquid, as set forth in Table 43.1.6.2.1.2 (i.e., Table 18.5.4 in NFPA 30, 2018 edition) *or* the amount required for a single continuous 24-hour period.

43.1.6.2.3 The quantity of flammable and combustible liquids located in a spray area or in a mixing room adjacent to a spray area shall meet the requirements of 43.1.6.3. [**33:**8.2.3]

43.1.6.3 Mixing.

43.1.6.3.1 Dispensing or transfer of liquids from containers and filling of containers, including portable mixing tanks and "pressure pots," shall be done only in a spray area with the ventilation in operation or in a mixing room. [**33:**8.3.1]

Pressure pots are special pressure tanks designed and outfitted specifically to feed paint or similar coatings to a manual spray gun. See Exhibit 43.5.

Exhibit 43.5

Typical paint pressure pot. (Courtesy of Carlisle Fluid Technologies)

Δ **43.1.6.3.2** Mixing rooms shall meet all of the following requirements:

(1) Mixing rooms shall meet the construction requirements of 43.1.3.
(2) The area of a mixing room shall not exceed 150 ft^2 (14 m^2).
(3) If more than one mix room is installed, the total quantity of liquids shall not exceed the limits in 43.1.6.3.4 or 43.1.6.3.5.
(4) Mixing rooms shall be designed to contain a spill of the contents in the room.
(5) Mixing rooms used for mixing and dispensing operations shall be provided with continuous mechanical ventilation capable of providing air movement of not less than 1 ft^3/min per square foot of floor area (0.3 $m^3/min/m^2$) or 150 ft^3/min (4 m^3/min), whichever is greater. The ventilation system shall be in operation at all times.

This level of exhaust ventilation provides six air changes per hour for the ventilated space, assuming a 10 foot (3 m) ceiling height. Six air changes per hour historically has been considered sufficient to prevent accumulation of fugitive vapors from normal industrial activities.

(6) The mixing room air make-up system and exhaust system shall remain functioning during any fire alarm condition in accordance with Section 9.3 of NFPA 33.

See commentary to 43.1.5.4 and to 43.1.7.3.

(7) Mixing rooms shall be classified, for purposes of electrical area classification, the same as enclosed spray booths, in accordance with 43.1.4.4.4.
(8) Mixing rooms shall be provided with an approved automatic fire protection system that meets all applicable requirements of Chapter 9 of NFPA 33.
(9) Mixing rooms shall be provided with portable fire extinguishers located in accordance with NFPA 10.

[**33:**8.3.3]

43.1.6.3.3 The amount of liquid permitted in a single spray area shall not exceed 60 gal (227 L). [**33:**8.3.4]

43.1.6.3.4 Where a separate mixing room is provided and the mixing room is located adjacent to or within 6 ft (1830 mm) of an adjacent spray area or areas, as shown in Figure 43.1.6.3.4(a) and Figure 43.1.6.3.4(b), the combined quantities of liquids located in the spray areas and the mixing room shall not exceed 120 gal (454 L). [**33:**8.3.5]

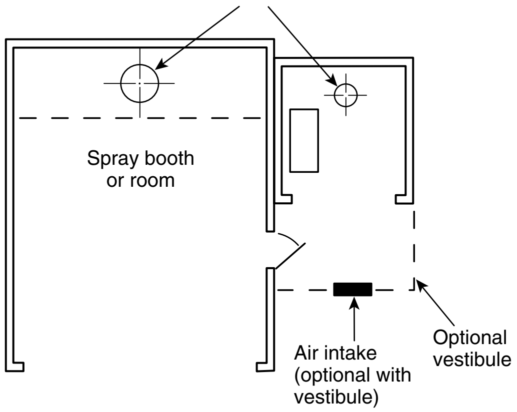

***FIGURE 43.1.6.3.4(a)** Mixing Room Within 6 ft (1830 mm) of Spray Area, Including Maximum Volume of Liquid Allowed. [**33:**Figure 8.3.5.(a)]*

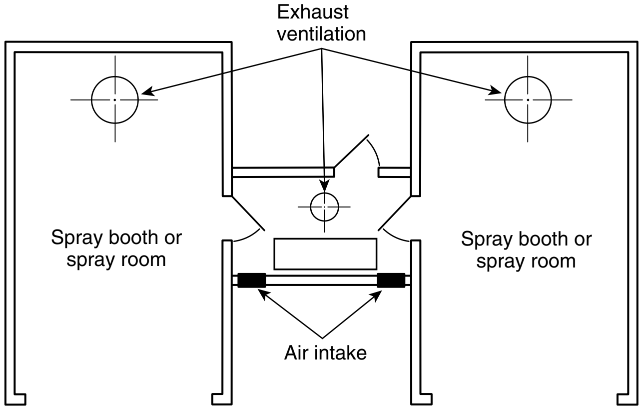

***FIGURE 43.1.6.3.4(b)** Mixing Room Within 6 ft (1830 mm) of Spray Area and with Direct Entry to Spray Area, Including Maximum Volume of Liquid Allowed. [**33:**Figure 8.3.5(b)]*

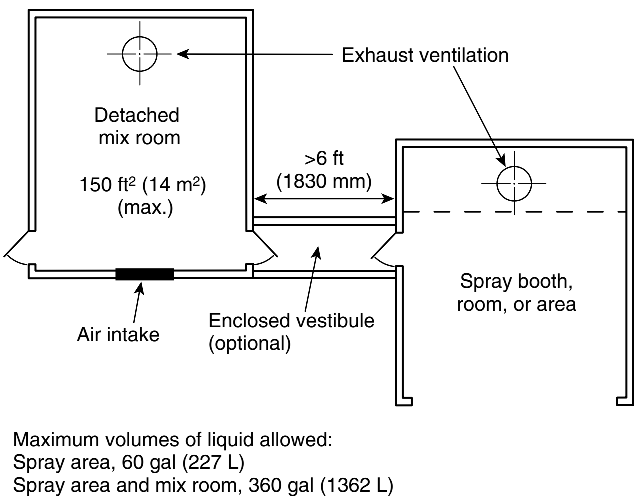

***FIGURE 43.1.6.3.5** Mixing Room More Than 6 ft (1830 mm) from Spray Area, Including Maximum Volume of Liquid Allowed. [**33:**Figure 8.3.6]*

43.1.6.3.5 Where a separate mixing room is provided and the mixing room is located more than 6 ft (1830 mm) from an adjacent spray area or areas, the quantity of liquid permitted in the mixing room shall not exceed 2 gal/ft^2 (80 L/m^2), up to a maximum of 300 gal (1135 L), as shown in Figure 43.1.6.3.5. The amount of liquid in the spray area shall not exceed 60 gal (227 L). [**33:**8.3.6]

43.1.6.4 Distribution Systems — Piping.

43.1.6.4.1* Piping systems that convey flammable or combustible liquids between storage tanks, mixing rooms (paint kitchens), and spray areas shall be of steel or other material having comparable properties of resistance to heat and physical damage. Piping systems shall be properly bonded and grounded. [**33:**8.4.1]

A.43.1.6.4.1 NFPA 77 provides information on bonding and grounding. [**33:**A.8.4.1]

43.1.6.4.2* Piping systems within the spray area shall be of steel or material having comparable heat and physical resistance where possible. Where tubing or hose is used, a shutoff valve shall be provided on the steel pipe at the connection. [**33:**8.4.2]

A.43.1.6.4.2 Valves should be kept shut when spray application operations are not being conducted, to minimize the release of coating material in the event of fire. [**33:**A.8.4.2]

43.1.6.4.3* Tubing or hose shall be inspected and replaced as necessary. Replacement tubing or hose shall be that recommended by the equipment manufacturer. [**33:**8.4.3]

A.43.1.6.4.3 If plastic tubing leaks within shielded areas, such as within color changers, the resulting spray fire will destroy all tubing, releasing large quantities of coating material in an area that cannot be reached by the booth protection system. Automatic protection systems should be provided for these areas. [**33:**A.8.4.3]

A major cause of fire in automatic electrostatic spray booths has been the replacement of original equipment plastic tubing with other types of tubing. Such replacement tubing, particularly if conductive coatings are used, is susceptible to the development of pinhole leaks. [**33:**A.8.4.3]

43.1.6.4.4 Where a pump is used to supply the liquid used in the spray application process, piping, tubing, hose, and other accessories shall be designed to withstand the maximum working pressure of the pump, or means shall be provided to limit the discharge pressure of the pump. [**33:**8.4.4]

43.1.6.4.5* Where a pump is used to supply the liquid used in the spray application process, an automatic means shall be provided to shut off the supply of liquid in event of fire. When pressurized tanks larger than 5 gal (19 L) are used to supply the liquid used in the spray application process, an automatic means shall be provided to shut off liquid flow at the tank outlet in the event of fire. [**33:**8.4.5]

A.43.1.6.4.5 The severity and extent of the many fires in spray application operations has been substantially increased when rubber or plastic supply hose were burned off, resulting in the entire contents of the supply system being added to the fire. By limiting the amount of fuel available, the magnitude of the fire can be held to more manageable limits. The shutoff should be accomplished by means of an interlock with a fire detection system or the automatic fire extinguishing system for the spray area. This shutoff is normally accomplished by shutting the distribution pumps. In some cases, it is also advisable to limit the flow from the solvent piping system. This can be accomplished with properly specified check valves in the pipe “drops.” [**33:**A.8.4.5]

43.1.6.4.6 All pressure tubing, hose, and couplings shall be inspected at regular intervals. With the hose extended, the hose and couplings shall be tested using the in-service maximum operating pressure. Any hose showing material deteriorations, signs of leakage, or weakness in its carcass or at the couplings shall be replaced. [**33:**8.4.6]

43.1.6.5 Distribution Systems — General.

43.1.6.5.1 Liquids shall be transported by means of closed containers, approved safety cans, or approved portable tanks or shall be transferred by means of a piping system. Open containers shall not be used for moving or storing liquids. [**33:**8.5.1]

43.1.6.5.2* Wherever liquids are transferred from one container to another, both containers shall be effectively bonded and grounded to dissipate static electricity. [**33:**8.5.2]

A.43.1.6.5.2 NFPA 77 provides information on static protection. [**33:**A.8.5.2]

43.1.6.5.3 Containers that supply spray nozzles shall be of the closed type or shall be provided with metal covers that are kept closed. Containers that do not rest on the floor shall have supports or shall be suspended by wire cables. Containers that supply spray nozzles by gravity flow shall not exceed 10 gal (38 L) capacity. [**33:**8.5.3]

43.1.6.5.4 Original shipping containers shall not be subjected to air pressure for supplying spray nozzles. [**33:**8.5.4]

43.1.6.5.5 Containers that are pressurized to supply spray nozzles, air storage tanks, and coolers shall comply with all applicable requirements of the ASME *Boiler and Pressure Vessel Code*, Section VIII, for construction, tests, and maintenance. [**33:**8.5.5]

N **43.1.6.5.5.1** Containers that meet the following requirements need not meet the requirements of the ASME *Boiler and Pressure Vessel Code*, Section VIII, for construction, tests, and maintenance:

(1) Pressure containers less than 6 in. (150 mm) in diameter
(2) Pressure containers that operate at less than a gauge pressure of 15 psi (1.03 kPa)
(3) Siphon-type spray cups

[**33:**8.5.5.1]

Δ **43.1.6.5.6** If a heater is used to heat the liquid being sprayed, it shall be low-pressure steam, low-pressure hot water, or electric. [**33:**8.5.6]

N **43.1.6.5.6.1** If electric heaters are used to heat the liquid being sprayed, the electric heater shall be approved and listed for the specific location in which it is used. *(See Chapter 6 of NFPA 33.)* [**33:**8.5.6.1]

N **43.1.6.5.6.2** Heaters shall not be located in spray booths or other locations subject to the accumulation of deposits of combustible residue. [**33:**8.5.6.2]

N **43.1.6.5.7** Agitators, if used, shall be driven by compressed air, water, low-pressure steam, or electricity. [**33:**8.5.7]

N **43.1.6.5.7.1** If the agitators are powered by an electric motor, the motor shall meet the requirements of Chapter 6 of NFPA 33. [**33:**8.5.7.1]

43.1.6.5.8 Methods for cleaning paint circulation systems shall meet the requirements of Chapter 18 of NFPA 30. [**33:**8.5.8]

Δ **43.1.6.5.9** Compressed air shall be permitted to be used for cleaning paint delivery hoses for individual applicators in a spray booth, provided both of the following requirements are met:

(1) The booth ventilation is operating.
(2) The maximum air pressure does not exceed the maximum working pressure of any component of the piping or hose system.

[**33:**8.5.9]

43.1.7 Protection.

Δ **43.1.7.1* General.** Spray areas, as defined in this *Code*, and mixing rooms, shall be protected with an approved automatic fire protection system. This shall apply to both manual and automated spray application processes. [**33:**9.1]

The second sentence was added to emphasize that manual and automated spray application systems are subject to the provisions of Chapter 9 of NFPA 33. Historically, there has been some misconception that only automated systems needed to be protected.

Note that 43.1.7.1 requires an automatic fire *protection* system. This does not imply that an *automatic sprinkler* system is mandated or even preferred. The type of system chosen should be based on the type of spray application system used, the characteristics of the coating(s) used, economics, and, in the case of automatic sprinklers, sufficient water flow to supply the system. See also the commentary after the last paragraph of A.43.1.7.1.

Also note that NFPA 33 incorporated new provisions for the protection of dry particulate scrubbers (Section 9.9), electrostatic precipitator scrubbers (Section 9.10), and high-capacity dry paint arrestors (Section 9.11). Those sections address new technology applications that have not been extracted into this edition of the *Code*. Therefore, the reader will have to refer to the 2016 (or later) edition of NFPA 33 for these protection requirements.

A.43.1.7.1 As indicated in 43.1.6, it is not advisable to keep large quantities of flammable or combustible liquids in areas that expose personnel or important property to injury or loss. The primary reason is that fires in flammable liquids are difficult to extinguish by the usual methods, and if large quantities are involved, they can spread the fire by flowing over large areas. For fires in small amounts of flammable or combustible liquids, hand extinguishers or large extinguishers on wheels especially designed for such fires are effective. If large quantities of liquids are to be protected, suitable automatic equipment should be provided and special attention should be given to proper dikes, curbs, and drains to prevent the flow to other property. [**33:**A.9.1]

For the extinguishment of fire in spray residues, handheld fire extinguishers suitable for fire in ordinary combustibles or hose streams are effective. [**33:**A.9.1]

Regardless of the level of filtration, residues will accumulate in the exhaust ductwork. Because the ductwork is part of the spray area, it must be protected in accordance with 43.1.7. This includes the ductwork from a water-wash booth. [**33:**A.9.1]

Water-wash spray booths use a recirculating curtain of water at the entrance to the exhaust plenum to remove overspray particles from the exhaust air stream. They are typically used where large quantities of coating are used and are very efficient at cleaning the exhaust air stream. As efficient as they are, some coating particles will still pass through the water curtain and will settle on the interior of ductwork. See Exhibit 43.6.

Because the particulate filters will accumulate paint residue, they must be protected. The solvent concentrator units, by their design, contain high concentrations of solvent, so they also must be protected. Also, the most commonly used solvent concentrators use activated carbon as the adsorption medium. This medium is highly combustible, especially with high levels of solvents absorbed. Ketone solvents pose an even greater risk. [**33:**A.9.1]

Because suppression media other than water might damage the carbon bed, water-based suppression systems (wet pipe sprinklers, preaction sprinklers, dry pipe sprinklers, and open-head deluge systems) are recommended for this application. [**33:**A.9.1]

The recirculated air supply unit must be protected because of the filter media it contains. Also, many large air supply units have gas-fired heaters to heat outside make-up air. [**33:**A.9.1]

Exhibit 43.6

Typical water-wash spray booth. (Courtesy of Global Finishing Solutions)

Air supply ducts from the particulate filter to the air supply unit and from the air supply unit to the spray booth are not normally protected, since all particulates have been filtered. [**33:**A.9.1]

The choice of the automatic fire protection system should always be based on good engineering practice. Generally, for most spray areas, automatic sprinklers are considered most appropriate *(see A.43.1.7.4)*. However, consideration must be given to how much water is likely to flow and to how much water is to be contained. [**33:**A.9.1]

Dry chemical extinguishing systems are most appropriate for small spray application operations (e.g., automotive refinishing, furniture refinishing, and similar processes) that utilize dry filters to capture overspray. These systems provide economical adequate protection. They are a viable alternative for any facility without sufficient water supply to support an automatic sprinkler system. [**33:**A.9.1]

Carbon dioxide or clean agent extinguishing systems should be used for open area protection only after careful consideration. Holding the required concentration of agent for the period of time needed for extinguishment in a spray booth environment can be difficult. In addition, total flooding with carbon dioxide in normally or potentially occupied areas presents serious health concerns. The time delay required prior to discharge can allow a fire time to grow and spread. Carbon dioxide and clean agent systems, however, are an appropriate choice for protecting electrostatic equipment enclosures inside or immediately outside the spray area. [**33:**A.9.1]

Handheld fire extinguishers or specially designed large extinguishers on wheels are effective only for fires involving small quantities of flammable or combustible liquids.

Handheld fire extinguishers suitable for fires in ordinary combustibles or hose streams are generally effective for extinguishing fires in spray residue. See Section 13.6 for issues relating to fire extinguisher selection and placement.

Δ **43.1.7.1.1** The automatic fire protection system shall be permitted to be, and shall be installed in accordance with, any of the following:

(1) An automatic water sprinkler system that meets all applicable requirements of NFPA 13
(2) An automatic foam water sprinkler system that meets all applicable requirements of NFPA 16
(3) A carbon dioxide extinguishing system that meets all applicable requirements of NFPA 12
(4) A dry chemical extinguishing system that meets all applicable requirements of NFPA 17
(5) A gaseous agent extinguishing system that meets all applicable requirements of NFPA 2001
(6) A water mist fire protection system that meets the applicable requirements of NFPA 750

[**33:**9.1.1]

43.1.7.1.2 The automatic fire protection system also shall meet all applicable requirements of 43.1.7.2 and 43.1.7.3. [**33:**9.1.2]

43.1.7.1.3 The fire alarm and fire protection system shall be supervised in accordance with *NFPA 72*. [**33:**9.1.3]

43.1.7.2 Continuous Spray Application Operations.

43.1.7.2.1 For continuous spray application operations, activation of the automatic fire protection system shall automatically accomplish all of the following:

(1) Activate a local alarm in the vicinity of the spraying operation
(2) Transmit an alarm signal to the facility's fire alarm system, if such a system is provided
(3) Shut down the coating material delivery system
(4) Shut down all spray application operations
(5) Stop any conveyors into and out of the spray area [**33:**9.2.1]

43.1.7.2.1.1 For continuous spray application operations, the additional requirements of 43.1.7.7, for automated powder application equipment, or 43.1.7.8, for automated liquid electrostatic spray application equipment, whichever is applicable, shall also apply. [**33:**9.2.1.1]

43.1.7.2.2 Emergency Shutdown. For continuous spray application operations, one or more manual emergency system shutdown stations shall be installed to serve each spray area. When activated, the stations shall accomplish at least the functions listed in 43.1.7.2.1(1) and 43.1.7.2.1(3) through 43.1.7.2.1(5). At least one such station shall be within ready access of operating personnel. If access to this station is likely to involve exposure to danger, an additional station shall be located adjacent to an exit from the area. [**33:**9.2.2]

43.1.7.3 Ventilation Systems. Air make-up systems and spray area exhaust systems shall remain functioning during any fire alarm condition. [**33:**9.3]

As explained in the commentary to 43.1.5.4, standard practice is to not shut down the exhaust system if there is a fire in the spray area, to prevent backdraft into the surrounding area. This provision disallows any interlock between the exhaust system controls and the fire alarm system that would initiate a shutdown. This is fine for spray areas protected with an automatic sprinkler system, but it might be detrimental to a gaseous or dry chemical extinguishing system. Recognizing this, 43.1.7.3.1 serves as an exception to this rule.

N **43.1.7.3.1** Where the type of automatic fire protection system requires that ventilation be discontinued, air make-up systems and spray area exhaust systems shall be permitted to be shut down and dampers shall be permitted to close. [**33:**9.3.1]

43.1.7.4* Automatic Sprinkler Systems.

A.43.1.7.4 Spray application operations should be located only in buildings that are completely protected by an approved system of automatic sprinklers. If the operations are located in unsprinklered buildings, sprinklers should be installed to protect spray application processes where practical. Because of the rapidity and intensity of fires that involve spray operations, the available water should be ample to simultaneously supply all sprinklers likely to open in one fire without depleting the available water for use by hose streams. Noncombustible draft curtains can be used to limit the number of sprinklers that will open. [**33:**A.9.4]

Even when areas adjacent to coating operations are considered under reasonably positive fire control by adequate automatic sprinkler protection, damage is possible if operations are conducted on floors above those containing contents that are highly susceptible to water damage. Waterproofing and drainage of spray room floors can assist in reducing water damage on floors below. Proper drainage of the large volume of water frequently necessary to extinguish spray finishing room fires often presents considerable difficulty. [**33:**A.9.4]

Automatic sprinklers in spray areas, including the interior of spray booths and exhaust ducts, should be wet pipe, preaction, or deluge system so that water can be placed on the fire in the shortest possible time. Automatic sprinklers in spray booths and exhaust ducts should be of the lowest practical temperature rating. The delay in application of water with ordinary dry pipe sprinklers can permit a fire to spread so rapidly that final extinguishment is difficult without extensive resulting damage. [**33:**A.9.4]

The location of the sprinklers inside spray booths should be selected with care to avoid heads being placed in the direct path of spray and yet afford protection for the entire booth interior. When sprinklers are in the direct path of spray, even one day's operation can result in deposits on the sprinklers that insulate the fusible link or choke open head orifices to the extent that sprinklers cannot operate efficiently. [**33:**A.9.4]

Automatic sprinklers should also be located so that areas subject to substantial accumulations of overspray residue are protected. Generally, sprinklers are located no more than 4 ft (1220 mm) from side walls of booths and rooms and from dry overspray collectors (where applicable). Sprinklers in booths or rooms should be on Extra Hazard occupancy spacing of 100 ft^2 (9.3 m^2). [**33:**A.9.4]

All sprinkler systems in spray areas should be controlled by an accessible indicating control valve. [**33:**A.9.4]

Use of water as the extinguishing agent for solvent and coating material fires might, in some cases, cause problems with splashing and "floating" of flaming liquids and residues. This possibility should be included with the other factors that are normally considered in the selection of an extinguishing agent. In addition, water from sprinkler or deluge systems, after coming into contact with coating materials, residues, or solvents, might have to be collected and treated as hazardous waste. [**33:**A.9.4]

Where spray application operations are located in unsprinklered buildings, sprinklers can be fed from the domestic water system, if sufficient flow and pressure are available. See NFPA 13, *Standard for the Installation of Sprinkler Systems,* for sprinkler system installation requirements from the domestic water system. This statement does not mean that an unsprinklered building must be retrofitted with automatic sprinklers only because of the presence of a spray application process. Other types of fixed fire protection systems are allowed, as required by the AHJ, to meet the protection requirements for spray operations using flammable or combustible materials.

The alternative agents permitted by 43.1.7.5 have limitations. These limitations include the size of the area or the size of the hazard that can be protected, the need for additional confinement of the area, and personnel safety issues. Also, the supply of extinguishing agent is typically limited to the amount needed to meet the anticipated demand, plus a second back-up (compared to a sprinkler system, which can be considered to have an unlimited capacity.) The AHJ should be involved in reviewing the use of alternative fire protection systems to ensure that they can provide the necessary level of protection. For the installation of these systems, see Section 13.8.

43.1.7.4.1* The automatic sprinkler system shall be a wet pipe system, a dry pipe system, a preaction system, or an open-head deluge system, whichever is most appropriate for the portion of the spray operation being protected. [**33:**9.4.1]

A.43.1.7.4.1 Paragraph 43.1.7.4.1 lists four types of automatic sprinkler systems and requires that the one "most appropriate for the portion of the spray area being protected" be used. Generally, an open-head deluge system provides the highest level of protection, given that all sprinklers in the protected area flow simultaneously. This type of system is most appropriate for large, down-draft, water-wash spray booths when protecting automatic electrostatic spray application zones. [**33:**A.9.4.1]

Wet pipe automatic sprinkler systems are appropriate for protecting spray booths that utilize nonelectrostatic application processes or operations using listed electrostatic application processes. Wet pipe systems are also generally used to protect exhaust plenums (eliminator or scrubber sections), exhaust ducts, and air recirculation filter houses. [**33:**A.9.4.1]

Dry pipe systems have been included because some exhaust duct designs include sections that are subject to freezing. [**33:**A.9.4.1]

Preaction systems have been included because some spray application processes and equipment can be damaged by unwanted water discharge. This damage can be disruptive and costly. Powder spray booths and solvent concentrator (air pollution abatement) systems are examples of systems where it is appropriate to use a preaction system. [**33:**A.9.4.1]

43.1.7.4.2 The automatic sprinkler system shall be designed as follows: for Extra Hazard (Group 2) occupancies, as defined in NFPA 13.

(1) For spray application of styrene cross-link thermoset resin application areas, sprinklers shall be designed for Ordinary Hazard (Group 2) as defined in NFPA 13.
(2) For powder coating operations, sprinklers shall be designed for Ordinary Hazard (Group 2) as defined in NFPA 13.
(3) For all other spray areas, sprinklers shall be designed for Extra Hazard (Group 2) as defined in NFPA 13.

[**33:**9.4.2]

N **43.1.7.4.2.1** The sprinkler design area shall not be required to exceed the area of the booth or room in which spraying or resin application is conducted. [**33:**9.4.2.1]

This provision recognizes that the area around the spray booth or spray room is subject to its own sprinkler design parameters, based on the occupancy of the building. Also, in cases where a spray booth or spray room is in an unprotected building and it is desirable to protect the booth or room from the domestic water system, as is allowed by 43.1.7.4.4, limiting the sprinkler design area to the area of the booth or room does not needlessly penalize the design by imposing a water demand for floor area that will not be protected.

43.1.7.4.3 The water supply shall be sufficient to supply all sprinklers likely to open in any one fire incident without depleting the available water for use in hose streams. [**33:**9.4.3]

Refer to A.9.4.3 of NFPA 33 for a thorough discussion of the protocol for calculating the anticipated water demand for a sprinkler system that protects a spray area. Included in that discussion are sample water demand calculation sheets for simple and complex situations.

43.1.7.4.4 Where sprinklers are installed to protect spray areas and mixing rooms only, water shall be permitted to be supplied from domestic water systems, provided the domestic supply can meet the demand for the design criteria of 43.1.7.4.2. [**33:**9.4.4]

43.1.7.4.5 The sprinkler system shall be controlled by a separate, listed indicating valve(s), operable from floor level. [**33:**9.4.5]

The intent of this provision is to allow shutdown of the part of the sprinkler system that protects the spray booth or room without having to impair the domestic supply or the building's automatic sprinkler system, whichever supplies the former.

43.1.7.4.6* Sprinkler systems protecting stacks or ducts shall meet all of the following requirements:

(1) One sprinkler shall be located at the top of each vertical riser and at the midpoint of each offset. Additional heads shall be spaced on 24 ft (7.3 m) centers if the rise is greater than 24 ft (7.3 m).

The first sentence of this provision was added to the 2016 edition of NFPA 33 and is based on the determination that sprinklers located as stipulated are the most effective in dealing with a duct fire. The requirement for additional heads spaced as stated was retained to deal with large duct systems.

(2) Horizontal exhaust ducts shall have sprinklers located on 12 ft (3.7 m) centers beginning no more than 6 ft (1.7 m) from the duct entrance.
(3) Where exhaust ducts are manifolded, a sprinkler shall be located in the manifold at the junction of each exhaust duct with the manifold.

The intent of this provision is to prevent a fire in one spray area from leap-frogging to an adjacent spray area.

(4) Sprinklers shall provide a minimum flow of 30 gpm (114 L/min) per head at a minimum of 15 psi (1 bar) pressure.
(5) Sprinklers shall be ordinary temperature rated, unless required to be higher due to operating temperatures measured in the ducts, in which case the operating temperature shall be at least 50°F (28°C) above the inside temperature of the duct. [**33:**9.4.6]

A.43.1.7.4.6 Water supply requirements for most industrial paint spray operations should be adequate to supply all automatic sprinklers in the spray area. Loss experience has shown that fires starting in the exhaust duct can spread to the spray booth and that fires starting in the booth can spread to the exhaust duct. [**33:**A.9.4.6]

Sprinklers or sprinkler systems protecting stacks or ducts should be of a type not subject to freezing. Automatic systems are preferred, but manual systems are also acceptable. Nonfreeze or dry-type sprinkler systems can be used in ducts subject to freezing. For some industries, such as the automotive industry, manually operated open-head systems have proved to be effective protection for ducts and stacks. [**33:**A.9.4.6]

43.1.7.4.6.1 Stacks and exhaust ducts shall be provided with access openings for inspection and cleaning of sprinklers. [**33:**9.4.6.1]

43.1.7.4.6.2 Sprinkler systems protecting stacks and ducts that are subject to freezing shall be of a nonfreezing type or be a manually controlled open-head system. [**33:**9.4.6.2]

43.1.7.4.7 Sprinklers shall be protected against overspray residue, either by location or covering, so that they will operate quickly in event of fire. [**33:**9.4.7]

43.1.7.4.7.1 Sprinklers shall be permitted to be covered only by cellophane bags having a thickness of 0.003 in. (0.08 mm) or less or by thin paper bags. These coverings shall be replaced frequently so that heavy deposits of residue do not accumulate. [**33:**9.4.7.1]

Use of other types of plastic film is not allowed. It has been found that plastic film other than cellophane has a tendency to "shrink wrap" the sprinkler when subjected to the heat from a fire, thus preventing the sprinkler from functioning.

43.1.7.4.7.2 Sprinklers that have been painted or coated by overspray or residues shall be replaced with new sprinklers. [**33:**9.4.7.2]

There is no easy way to effectively clean sprinkler heads that have been coated with overspray and be confident of reliable future functioning.

43.1.7.5* Automatic Carbon Dioxide, Dry Chemical, and Clean Agent Systems. The fire protection system shall be capable of discharging its contents into the entire protected area simultaneously, including the exhaust plenum and exhaust ductwork. [**33:**9.5]

A.43.1.7.5 This discharge is typically accomplished by means of a piping network from the fire protection system into all parts of the spray area. To avoid potential flashback of an unextinguished fire, modular fire protection units should not be used to protect areas with ducts or plenums, or areas that exceed the listing of the system. They might, however, be suited for smaller open spray areas that fall within the limits of the listing. [**33:**A.9.5]

43.1.7.6 Portable Fire Extinguishers. Portable fire extinguishers shall be provided and located in accordance with Section 13.6. [**33:**9.6]

Section 13.6 of this *Code* mandates the selection, installation, distribution, inspection, maintenance, and testing of portable fire extinguishers. In addition to being in compliance with this section, fire extinguishers must be in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

43.1.7.7* Protection for Automated Powder Application Equipment.

A.43.1.7.7 During the first few seconds in the development of a fire in a dry powder spray booth, the following observations can be made:

(1) *Conventional structure equipment (spray booth connected to enclosed collector by ductwork)*
    (a) Airborne powder in the spray plumes of the gun(s) burns vigorously as long as the gun feeder(s) continues to supply powder. Flames from about 2 ft to 6 ft (600 mm to 1800 mm) in length might extend from the guns but do not intrude into the interior of the guns. These flames do not extend into the exhaust ductwork if adequate airflow has been provided to maintain maximum powder concentration in the exhaust stream below the minimum explosive concentration (MEC). The flames are extinguished almost instantly if their supply of airborne fuel is interrupted by shutting down the gun feeders.
    (b) Deposits of powder that have accumulated on the interior surfaces of the spray enclosure are not readily ignited, even by direct exposure to flames for a few seconds.
    (c) If a fire in a powder spray booth has been sustained for an appreciable period of time (10- to 60-second delays have been observed), propagation proceeds as follows:
        i. Heat exposure effects of the fire, acting on the deposits of overspray powder that have accumulated on the interior surfaces of the spray enclosure, will modify a layer on the surface of the deposits to form an extremely fragile, tissue-thin structure of powder grains that have been softened only enough to adhere to adjacent grains but not enough to flow together and form a film. This is called a *sintered structure*. In response to the effects of vibration and rapidly fluctuating temperature (flickering of flames, etc.), this structure will break into a "mud-cracked" pattern, and individual platelets in some regions will curl up, presenting their edges to the fire-involved atmosphere. Exposure to this environment's heat and turbulence will char and dislodge platelets to form airborne glowing embers comparable to those formed by burning piles of autumn leaves. These embers, if drawn through exhaust ductwork to the powder collector, could ignite the collector, resulting in an explosion.
        ii. If this sequence is interrupted within the first few seconds of a fire's history, then ember formation and propagation by this mechanism can be stopped. The requirements of 43.1.7.7 are directed toward this result.

(2) *Integrated spray booth/"open" collector*
    (a) Fire in the spray plumes of the guns is identical to that found in A.43.1.7.7(1). Because there is no exhaust ductwork and no enclosed collector, however, the conditions necessary for generation of an explosion do not exist and the risk is confined only to conventional fire considerations. If powder feed to the spray guns is sustained after ignition and if the exhaust fan is kept in operation, enough heat can be delivered to the region of the cartridge filters to result in ignition of the filters and collected residues, which will then be sustained as a "deep-seated" fire producing large quantities of smoke but limited heat.
    (b) Attempts to extinguish "deep-seated" fires with carbon dioxide and dry chemical extinguishers have yielded disappointing results. Although flame is promptly knocked down, continued production of smoke and ultimate reflash should be expected. The most satisfactory results have been yielded by thoroughly soaking the filter cartridges and residues with water.

[**33:**A.9.7]

43.1.7.7.1 Automated powder application equipment, both listed and unlisted, shall be further protected by listed optical flame detection, installed and supervised in accordance with *NFPA 72*. The optical flame detection shall, in event of ignition, react to the presence of flame within one-half (0.5) second and shall accomplish all of the following:

(1) Stop any conveyors into and out of the spray area
(2) Shut off ventilation

(3) Shut off application, transfer, and powder collection equipment
(4) Close segregation dampers in associated ductwork to interrupt airflows from application equipment to powder collectors
(5) Disconnect power to the high-voltage elements in the spray area and de-energize the system [**33:**9.7.1]

43.1.7.7.2 Automated powder application equipment that is unlisted shall be further protected by the following:

(1) In addition to meeting the requirements in 43.1.7.2.1 and 43.1.7.7.1, the optical flame detection system shall also activate the automatic fire protection system, if provided.
(2) Automatic electrostatic equipment enclosures inside the booth shall be protected with an approved automatic fire protection system. Activation of this system shall automatically accomplish the requirements of 43.1.7.2.1 and 43.1.7.7.1.
(3) Manual activation stations shall be installed. At least one such station shall be within ready access of operating personnel. If access to this station is likely to involve exposure to danger, an additional station shall be located adjacent to an exit from the area. These devices shall activate the fire protection system as specified in 43.1.7.1.1 for the affected automated zone, if applicable, and accomplish the requirements in 43.1.7.7.1.

[**33:**9.7.2]

N **43.1.7.7.2.1** This requirement shall not apply to a closed-head wet pipe automatic sprinkler system. [**33:**9.7.2.1]

43.1.7.8* Protection for Automated Liquid Electrostatic Spray Application Equipment.

A.43.1.7.8 Unlike powder application systems, the make-up air and exhaust systems for a liquid application system have to continue to function, unless there is a compelling reason to shut them down. [**33:**A.9.8]

43.1.7.8.1 Automated liquid electrostatic spray application equipment, both listed and unlisted, shall be further protected by listed optical flame detection, installed and supervised in accordance with *NFPA 72*. The optical flame detection shall, in event of ignition, react to the presence of flame within one-half (0.5) second and shall accomplish all of the following:

(1) Meet all of the requirements of 43.1.7.2.1
(2) Disconnect power to the high-voltage elements in the spray area and de-energize the system [**33:**9.8.1]

Δ **43.1.7.8.2** Automated liquid electrostatic spray application equipment that is unlisted shall be protected further by the following:

(1) In addition to meeting the requirements in 43.1.7.8.1, the optical flame detection system shall also activate one of the following over each zone in which fire has been detected:
  (a) An open head deluge system designed to discharge a minimum density of 0.6 gpm/ft^2 (24.4 mm/min)
  (b) A carbon dioxide extinguishing system
  (c) A dry chemical extinguishing system
  (d) A gaseous agent extinguishing system
  (e) A water mist fire protection system
(2) Manual activation stations shall be installed. At least one such station shall be within ready access of operating personnel. If access to this station is likely to involve exposure to danger, an additional station shall be located adjacent to an exit from the area. These devices shall activate the fire protection system as specified in 43.1.7.8.2(1) and accomplish the requirements of 43.1.7.2.1 and 43.1.7.8.2(2).
(3) A wet pipe sprinkler system shall also be provided throughout the spray booth. This system shall meet all the applicable requirements of NFPA 13 for Extra Hazard (Group 2) occupancies.
(4) Automatic electrostatic equipment enclosures inside the booth systems shall be protected with an approved automatic fire protection system. Activation of this system shall automatically accomplish the requirements of 43.1.7.2.1 and 43.1.7.8.1(2). [**33:**9.8.2]

43.1.8 Operations and Maintenance.

43.1.8.1* General. Maintenance procedures shall be established to ensure that all spray application apparatus and processes are operated and maintained in accordance with the manufacturers' specifications and the requirements of this *Code*. Maintenance shall be the responsibility of the users of the apparatus and processes. [**33:**10.1]

A.43.1.8.1 The materials used in spray application processes can create serious fire hazards. For example, the vapors and mists created by the atomization of flammable and combustible liquids can form explosive mixtures in air. In addition, deposits of residues can ignite spontaneously or be easily ignited. Finally, fires involving flammable and combustible liquids or combustible residues can spread rapidly and can produce intense heat and smoke. Properly designed equipment can do much to lessen these hazards but cannot eliminate them. These inherent characteristics should make it obvious that supervision of operations, maintenance of equipment, and daily cleaning are essential to a safe operation. [**33:**A.10.1]

It is important that some type of periodic inspection be conducted and recorded as part of the maintenance procedures. It is also important that any inspections of spray application equipment be conducted by competent and reliable personnel who have knowledge of the equipment and the inherent characteristics of the materials used. [**33:**A.10.1]

The frequency of the inspections depends on the individual components of the spray application process. For example, it might be acceptable to check sprinkler control valves or other control mechanisms for approved fire protection systems on a weekly or even monthly basis. However, this frequency would not be acceptable for ensuring adequate airflow through collector filters of a spray booth. At a minimum, that should be done at the beginning of each operating shift. Similarly, the buildup of residues would also need to be checked on a per-shift basis. Individual plant operations might dictate that either of these items (airflow and residue buildup) be checked every few hours. [**33:**A.10.1]

43.1.8.1.1* Spray application operations shall not be conducted outside predetermined spray areas. [**33:**10.1.1]

A.43.1.8.1.1 The use of the term *predetermined* is intended to convey the idea that one cannot arbitrarily locate or conduct spray application operations without thought to the hazards and special requirements that such operations demand. Requirements regarding electrical equipment and ventilation are of primary concern. This *Code* also specifies requirements that can vary based on the type of equipment used, the type of material being spray applied, and even the type of operation. Any spray application operation should also consider the storage, handling, and distribution of the coating materials used in the process. Certainly there are other factors, but these examples should adequately explain the need for predetermining the spray area and why operations should be confined to those areas. [**33:**A.10.1.1]

43.1.8.1.2 Inspection of extinguishing systems shall be conducted to ensure that the performance of the extinguishing system components will not be affected by overspray and residues. [**33:**10.1.2]

43.1.8.2* Combustible Deposits.

A.43.1.8.2 In the spray finishing of any workpiece, there is frequently a portion of the spray that does not deposit directly on the object or material being coated but does deposit on adjacent surfaces as residue material. This is referred to as *overspray*. Many of these residues are highly combustible, igniting at very low temperatures or spontaneously, resulting in fast-spreading fires. To limit the duration and intensity of fires, the accumulation of deposits has to be minimized and controlled as much as practical. The accumulation of residues represents one of the most significant challenges to fire control. [**33:**A.10.2]

Cleaning. The interior of spray booths, exhaust fan blades, and exhaust ducts should be cleaned regularly to avoid the accumulation of residues. Either spray operators should be allowed ample time for this cleaning, or a special maintenance crew should be provided for cleaning at the close of each day's operation. If equipment is so designed that during cleanup hose streams or fixed water nozzles can be used in ducts and spray booths without water damage to building and contents, cleaning operations are greatly facilitated. Many plants have found that by coating the interior of spray booths with a suitable soap-like or water-soluble material immediately after cleaning, adhesive spray deposits can be removed on the following day with the use of water streams. Other materials, such as plastics that can be readily peeled off the interior of the spray booth, can also be used to facilitate cleaning of the overspray residue. [**33:**A.10.2]

Properly maintained water-wash booths offer lower fire loading than dry booths. To maintain this advantage, it is necessary to perform regular and scheduled maintenance. This maintenance schedule should be recorded and the records filed. When the nozzles, jets or orifices, eliminator packs, and strainer screens become fouled with accumulated sludge or overspray, combustible residues will be deposited on the interior of the exhaust duct and fan blades. The nozzles, jets, orifices, and eliminator packs should be inspected each work shift. Strainer screens should be removed and cleaned each work shift. [**33:**A.10.2]

The booth interior, exhaust stack, and fan blades should be checked periodically, and accumulations of overspray and dirt should be removed as required. Exhaust ducts or stacks should not be entered for cleaning or repairs unless they are free from flammable vapors and have been thoroughly wet down. [**33:**A.10.2]

Many fires are caused by poor maintenance and the accumulation of combustible residues. This is particularly true in spray areas, where residue accumulates in the exhaust ductwork and in the plenums behind the overspray filters. Excessive residues that are present between the overspray filters and the fan or within the ductwork must be removed. If residue has accumulated to the extent that it can be scraped off if rubbed by hand, dangerous or excessive quantities are present and the spray application must be discontinued until the accumulations have been removed.

For more information, refer to the list of NFPA codes and standards in Chapter 40 identifying the fire and explosion hazards of combustible particulate solids for more information.

43.1.8.2.1 All spray areas shall be kept free of excessive accumulation of deposits of combustible residues. [**33:**10.2.1]

43.1.8.2.2 Combustible coverings (thin paper, plastic) and strippable coatings shall be permitted to be used to facilitate cleaning operations in spray areas. [**33:**10.2.2]

43.1.8.2.2.1 Where plastic covering is used, it shall be of a static dissipative nature or shall have a maximum breakdown voltage of 4 kV to prevent accumulation of a hazardous static electric charge. [**33:**10.2.2.1]

43.1.8.2.3 If residue accumulates to excess in booths, duct or duct discharge points, or other spray areas, all spraying operations shall be discontinued until conditions have been corrected. [**33:**10.2.3]

43.1.8.3 High-Pressure Hose Lines. High-pressure hose lines that convey flammable or combustible coating material in "airless" spray application operations shall be inspected daily and shall be repaired or replaced as necessary. Hose lines and equipment shall be located so that, in the event of a leak or rupture, coating material will not be discharged into any space having a source of ignition. [**33:**10.3]

43.1.8.4 Maintenance Procedures.

Δ **43.1.8.4.1** Overspray collectors shall be inspected daily and clogged filters shall be discarded and replaced. Maintenance procedures shall be established to ensure that overspray collector filters are replaced before restriction to airflow is reduced below the minimum established by Section 7.2 of NFPA 33. [**33:**10.4.1]

43.1.8.4.2 At the close of the day's operation, all discarded overspray collector filters, residue scrapings, and debris contaminated with residue shall be removed immediately to a designated storage location, placed in a noncombustible container with a tight-fitting lid, or placed in a water-filled metal container. [**33:**10.4.2]

If overspray collector filters are bundled and compacted for disposal, fires can result from spontaneous ignition. Placing loaded filters in water-filled containers might require disposal of the water as hazardous waste. The best solution is to remove the discarded filters to a safe, well-separated location until they are removed from the facility by an appropriate hazardous waste hauler.

43.1.8.5* Waste Containers.

A.43.1.8.5 Many fires have originated from the spontaneous ignition of fabric and waste impregnated with coating materials. When sprayed articles are rubbed with rags or waste, all unclean rags and waste should be immediately placed in approved waste cans and removed from the premises at least daily at the close of each shift. When employees change clothes on plant premises, soiled clothing should be kept in metal lockers provided in a segregated dressing room. [**33:**A.10.5]

43.1.8.5.1 Approved waste containers shall be provided wherever rags or waste are impregnated with sprayed material, and all such rags or waste shall be deposited therein immediately after use. The contents of waste containers shall be placed in a designated storage location. [**33:**10.5.1]

43.1.8.5.2 Waste containers containing flammable liquids shall be located in ventilated areas that meet the requirements of 43.1.5. Such areas shall also meet the electrical area classification requirements of 43.1.4.4.5. [**33:**10.5.2]

43.1.8.5.3* Waste containers for flammable liquids shall be constructed of conductive materials and shall be bonded and grounded. [**33:**10.5.3]

A.43.1.8.5.3 See NFPA 77 for information on bonding and grounding. [**33:**A.10.5.3]

43.1.8.5.4 Waste containers for flammable liquids shall be handled and stored in accordance with 43.1.6. [**33:**10.5.4]

43.1.8.6 Clothing. Employees' clothing contaminated with sprayed material shall not be left on the premises overnight unless kept in metal lockers. [**33:**10.6]

43.1.8.7 Cleaning Operations.

43.1.8.7.1 Scope. Paragraph 43.1.8.7 shall apply to the use of flammable or combustible liquids for the flushing and cleaning of equipment. [**33:**10.7.1]

43.1.8.7.2 Liquids. Class I and Class II liquids used in cleaning operations shall be in original shipping containers or in listed safety containers. [**33:**10.7.2]

43.1.8.7.3 Location. Cleaning operations using flammable or combustible liquids shall be conducted inside a spray area with ventilating equipment operating or in ventilated areas that meet the requirements of 43.1.5. Such areas shall also meet the electrical area classification requirements of 43.1.4.4.5. [**33:**10.7.3]

Spray gun cleaning devices that are not enclosed should be used only in ventilated areas. Enclosing spray gun devices gives better control of the vapors, fumes, and excess coatings resulting from the application.

43.1.8.7.4* Equipment. Equipment using flammable or combustible liquids shall meet the requirements of 43.1.4.4.5 and shall be bonded and grounded. [**33:**10.7.4]

A.43.1.8.7.4 See NFPA 77 for information on bonding and grounding. [**33:**A.10.7.4]

43.1.8.7.5 Manual Cleaning. Individual manual cleaning operations shall be limited to not more than 1 gal (4 L) of flammable or combustible liquid for each cleaning operator. [**33:**10.7.5]

43.1.8.7.6 Liquid Storage. Flammable and combustible liquids shall be handled and stored in accordance with 43.1.6. Containers used for handling, storage, or recovery of Class I liquids shall be constructed of conductive materials and shall be bonded and grounded. [**33:**10.7.6]

43.1.8.8 Solvent Distillation Units (Solvent Recyclers).

43.1.8.8.1 Scope.

43.1.8.8.1.1 Paragraph 43.1.8.8 shall apply to solvent distillation units having distillation chambers or still pots that do not exceed 60 gal (230 L) capacity and are used to recycle Class I, Class II, and Class IIIA liquids. [**30:**19.6.1.1]

43.1.8.8.1.2 Paragraph 43.1.8.8 shall not apply to research, testing, or experimental processes; to distillation processes carried out in petroleum refineries, chemical plants, or distilleries; or to distillation equipment used in dry cleaning operations. [**30:**19.6.1.2]

43.1.8.8.2 Equipment. Solvent distillation units shall be approved or shall be listed in accordance with ANSI/UL 2208, *Standard for Solvent Distillation Units*. [**30:**19.6.2]

43.1.8.8.3 Solvents. Solvent distillation units shall only be used to distill liquids for which they have been investigated and that are listed on the unit's marking or contained within the manufacturer's literature. [**30:**19.6.3]

43.1.8.8.3.1 Unstable or reactive liquids or materials shall not be processed unless they have been specifically listed on the system's markings or contained within the manufacturer's literature. [**30:**19.6.3.1]

43.1.8.8.4 Location.

43.1.8.8.4.1 Solvent distillation units shall be located and operated in locations in accordance with their approval or listing. [**30:**19.6.4.1]

43.1.8.8.4.2 Solvent distillation units shall not be used in basements. [**30:**19.6.4.2]

43.1.8.8.4.3 Solvent distillation units shall be located away from potential sources of ignition, as indicated on the unit's marking. [**30:**19.6.4.3]

43.1.8.8.5 Liquid Storage. Distilled liquids and liquids awaiting distillation shall be stored in accordance with NFPA 30. [**33:**10.8.5]

43.1.8.9* Spontaneous Ignition Hazards. The same spray booth shall not be alternately used for different types of coating materials if the combination of the materials is conducive to spontaneous ignition, unless all deposits of the first-used coating material are removed from the booth and exhaust ducts prior to spraying with the second coating material. [**33:**10.9]

A.43.1.8.9 Bleaching compounds, such as hydrogen peroxide, hypochlorites, perchlorates, or other oxidizing compounds, can cause fires when in contact with organic finishing materials. Hence, if bleaching compounds are to be used in spray booths, the booths should be thoroughly cleaned and used only for that purpose. The alternate use of spray booths for bleaching compounds and other finishing materials or the alternate use of finishing materials containing nitrocellulose and other types of finishing materials containing drying oils, such as varnishes, oil-based stains, air-drying enamels, primers, and so forth, without first thoroughly removing all traces of deposits can result in a spontaneous ignition fire. [**33:**A.10.9]

43.1.8.10* Chlorinated Solvents. Coating materials containing chlorinated solvents shall not be used with spray application apparatus or fluid-handling equipment if the chlorinated solvent will come into contact with aluminum within a piping system, pump, enclosed container, or any enclosure that is capable of being pressurized by the potential reaction. This shall apply even if the container or system has been constructed with pressure relief devices. [**33:**10.10]

A.43.1.8.10 Stricter environmental regulation has given rise to the increased use of chlorinated solvents, such as 1,1,1-trichloroethane and methylene chloride. These solvents are not photochemically reactive and, therefore, can be useful in helping to meet standards regarding volatile organic compound emissions. However, these solvents have a well-documented characteristic of being chemically reactive with aluminum. The reaction that occurs is unpredictable both in terms of when it will occur and to what degree it will proceed. In most situations there is no apparent reaction. Other situations have noted effects ranging from simple corrosion to catastrophic explosion-like failure accompanied by considerable shrapnel and a fireball. Understanding and controlling the subsequent hazard is hindered by this unpredictability. Although there is some understanding of the actual reaction, the following factors acting as independent variables have been found to have an effect on the initiation and rate of reaction:

(1) Heat
(2) Pressure
(3) Ratio of aluminum surface area to volume of solvent, presence of moisture (condensation), aluminum alloy content, metal content of the coating, and the introduction of other solvents or materials

[**33:**A.10.10]

Therefore, the only assuredly safe condition is to keep these materials separate. [**33:**A.10.10]

It is important to realize that aluminum has been used as a primary material for spray equipment construction over many years. Incorporating these solvents into existing spray systems cannot be done safely without first determining the construction material of the equipment and then replacing those components where contact with aluminum and chlorinated solvent will occur within a pressurizable device (e.g., pumps, heaters, piping, fluid valves, and spray gun cups). [**33:**A.10.10]

43.1.8.11 Smoking. Signs stating NO SMOKING OR OPEN FLAMES in large letters on contrasting color background shall be conspicuously posted at all spray areas and paint storage rooms. [**33:**10.11]

See the smoking provisions in Section 10.9 for additional guidance. An example of a sign complying with this paragraph can be found in Exhibit 43.7.

Exhibit 43.7

Example of a warning sign in compliance with 43.1.8.11.

43.1.8.12* Hot Work. Welding, cutting, and other spark-producing operations shall not be permitted in or adjacent to spray areas until a written permit authorizing such work has been issued. The permit shall be issued by a person in authority following his or her inspection of the area to ensure that precautions have been taken and will be followed until the job is completed. [**33:**10.12]

A.43.1.8.12 If repairs or changes are to be made to equipment, care should be taken to see that all residue deposits are removed and the area wet down with water beforehand in order to avoid a fire. During such repairs, no spraying should be conducted, all flammable and combustible liquids and portable combustible material should be removed from the vicinity, and suitable fire extinguishers should be kept readily available. [**33:**A.10.12]

The use of welding or cutting torches should be prohibited except under the supervision of a competent person familiar with the fire hazards involved. *(See NFPA 51B.)* [**33:**A.10.12]

See Chapter 41 for additional guidance on precautions for the use of welding or cutting torches and other hot work activities.

43.2 Automated Electrostatic Spray Equipment

For information on the installation and use of automated electrostatic spray application apparatus, see Chapter 11 of NFPA 33.

43.3 Handheld Electrostatic Spray Equipment

For information on the installation and use of handheld electrostatic spray application apparatus, see Chapter 12 of NFPA 33.

43.4 Drying, Curing, or Fusion Processes

For information on drying, curing, or fusion apparatus used in connection with spray application of flammable and combustible materials, see Chapter 13 of NFPA 33.

43.5 Miscellaneous Spray Operations

43.5.1 Vehicle Undercoating and Body Lining.

43.5.1.1 Spray undercoating or spray body lining of vehicles that is conducted in an area that has adequate natural or mechanical ventilation shall be exempt from the provisions of this *Code*, if all of the requirements of 43.5.1.1.1 through 43.5.1.1.4 are met. [**33:**14.1.1]

43.5.1.1.1 There shall be no open flames or spark-producing equipment within 20 ft (6100 mm) of the spray operation while the spray operation is being conducted. [**33:**14.1.1.1]

Essentially, this requirement establishes a "safe zone" similar to a Class I, Division 2 hazardous (classified) location around an unenclosed spray area, as depicted in Figure 43.1.4.4.1.

43.5.1.1.2 There shall be no drying, curing, or fusion apparatus in use within 20 ft (6100 mm) of the spray operation while the spray operation is being conducted. [**33:**14.1.1.2]

43.5.1.1.3 Any solvent used for cleaning procedures shall have a flash point not less than 100°F (37.8°C). [**33:**14.1.1.3]

43.5.1.1.4 The coating or lining materials used shall meet one of the following criteria:

(1) Be no more hazardous than UL Class 30-40, when tested in accordance with ANSI/UL 340, *Test for Comparative Flammability of Liquids*
(2) Not contain any solvent or component that has a flash point below 100°F (37.8°C)
(3) Consist only of Class IIIB liquids and not include any organic peroxide catalyst [**33:**14.1.1.4]

43.5.1.2 Noncomplying Undercoating Operations. Spray undercoating operations that do not meet the requirements of 43.5.1 shall meet all applicable requirements of this *Code* pertaining to spray finishing operations. [**33:**14.1.2]

43.5.2 Preparation Workstations. If spray finishing operations are performed at or in a preparation workstation, the preparation workstation shall be considered an unenclosed spray area and shall meet all requirements of an unenclosed spray area. [**33:**14.2]

Although sometimes used for minor spray application, such as touch-up jobs, preparation workstations (prep stations) were originally not conceived of or designed for spray application processes.

N **43.5.2.1** A preparation workstation that is designed and operated in accordance with 43.5.3 shall be considered a limited finishing workstation and not an unenclosed spray area. [**33:**14.2.1]

43.5.3 Limited Finishing Workstations. A limited finishing workstation shall be designed and operated in accordance with the requirements of 43.5.3.1 through 43.5.3.9. [**33:**14.3]

An example of a limited finishing workstation is shown in Exhibit 43.8.

Exhibit 43.8

Typical limited finishing workstation. (Courtesy of Global Finishing Solutions)

43.5.3.1 A limited finishing workstation shall be designed and constructed to have all of the following:

(1) A dedicated make-up air supply and air supply plenum
(2) Curtains or partitions that are noncombustible or limited-combustible, as defined in 3.3.165 and 3.3.175.11 or that can successfully pass Test Method 2 of in Chapter 12 NFPA 701
(3) A dedicated mechanical exhaust and filtration system
(4)* An approved automatic extinguishing system that meets the requirements of 43.1.7 [**33:**14.3.1]

A.43.5.3.1(4) For dry chemical fire protection systems, it might be prudent to double the quantity of agent and its flowrate, compared to a similar size fully enclosed spray booth to achieve the desired degree of protection. This is due to the relatively unenclosed nature of a limited finishing workstation compared to a traditional spray booth. [**33:**A.14.3.1(4)]

This recommendation is based on a white paper provided by the Fire Equipment Manufacturers' Association titled "Recommendations for Protection of Curtained Limited Finishing Workstations." [**33:**A.14.3.1(4)]

43.5.3.2 The amount of material sprayed in a limited finishing workstation shall not exceed 1 gal (3.8 L) in any 8-hour period. [**33:**14.3.2]

43.5.3.3 The limited finishing workstation shall meet all applicable requirements of 43.1.2 through 43.1.8 and Section 43.10. [**33:**14.3.3]

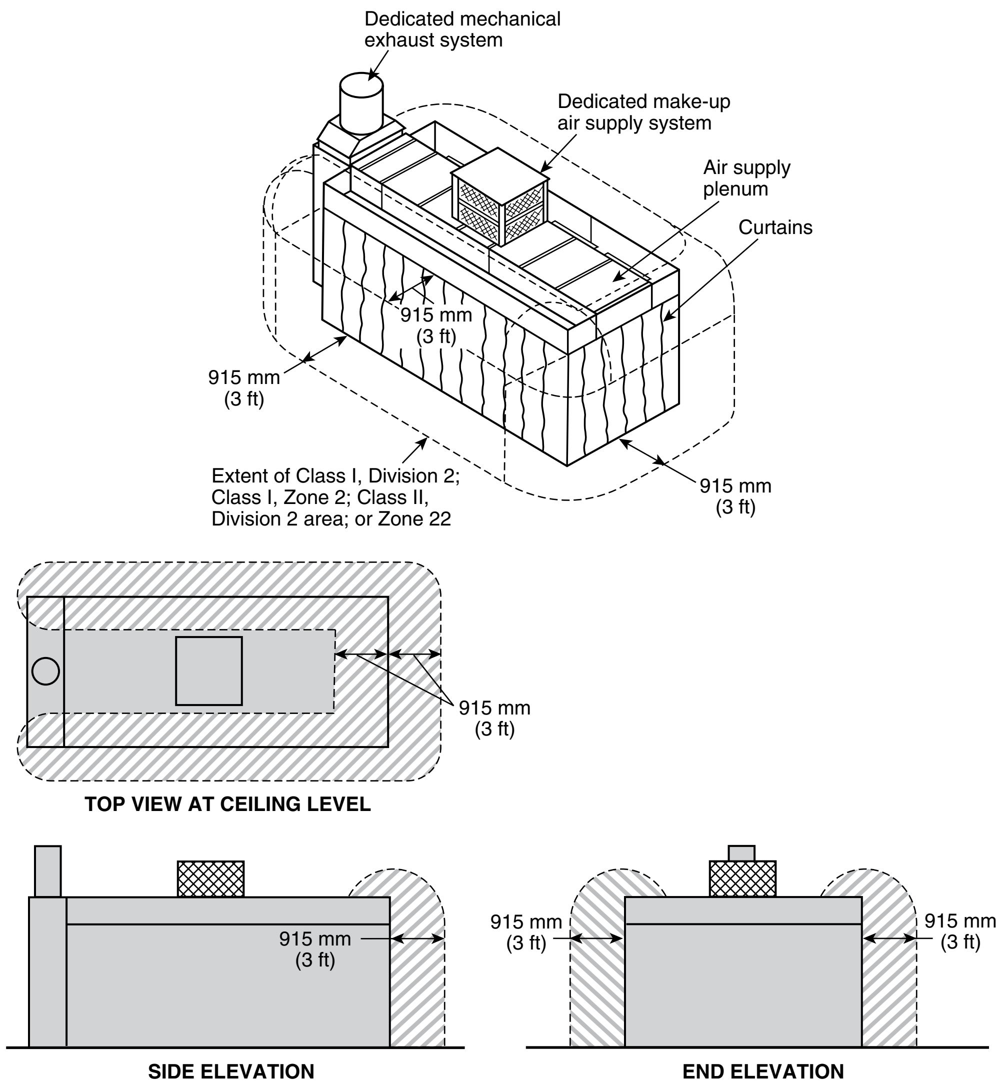
43.5.3.4 Curtains or partitions shall be fully closed during any spray application operations. [**33:**14.3.4]

43.5.3.5 The area inside the curtains or partitions shall be considered a Class I, Division 1; Class I, Zone 1; Class II, Division 1; or Zone 21 hazardous (classified) location, as defined by Article 500 of *NFPA 70*. [**33:**14.3.5]

43.5.3.5.1 A Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 hazardous (classified) location, as applicable, shall extend 3 ft (915 mm) both horizontally and vertically beyond the volume enclosed by the outside surface of the curtains or partitions as shown in Figure 43.5.3.5.1. [**33:**14.3.5.1]

43.5.3.5.2 For the purposes of this subsection, *interlocked* shall mean that the spray application equipment cannot be operated unless the exhaust ventilation system is operating and functioning properly and spray application is automatically stopped if the exhaust ventilation system fails. [**33:**14.3.5.2]

43.5.3.6 Any limited finishing workstation used for spray application operations shall not be used for any operation that is capable of producing sparks or particles of hot metal or for operations that



Δ ***FIGURE 43.5.3.5.1*** *Class I, Division 2; Class I, Zone 2; Class II, Division 2; or Zone 22 Locations Adjacent to a Limited Finishing Workstation. [**33:**Figure 14.3.5.1]* involve open flames or electrical utilization equipment capable of producing sparks or particles of hot metal. [**33:**14.3.6]

43.5.3.7 Drying, curing, or fusion apparatus shall be permitted to be used in a limited finishing workstation if they meet the requirements of Section 43.4 and the requirements of 43.5.3.7.1 through 43.5.3.7.3. [**33:**14.3.7]

43.5.3.7.1 When industrial air heaters are used to elevate the air temperature for drying, curing, or fusing operations, a high limit switch shall be provided to automatically shut off the drying apparatus if the air temperature in the limited finishing workstation exceeds the maximum discharge-air temperature allowed by the standard that the heater is listed to or 200°F (93°C), whichever is less. [**33:**14.3.7.1]

43.5.3.7.2* A means shall be provided to show that the limited finishing workstation is in the drying or curing mode of operation and that the limited finishing work station is to be unoccupied. [**33:**14.3.7.2]

A.43.5.3.7.2 A means of showing that the limited finishing workstation is in the drying or curing mode of operation can be, but is not limited to, having the lighting of the workstation go out, use of a flashing light or strobe, or use of an audible device. [**33:**A.14.3.7.2]

43.5.3.7.3 Any containers of flammable or combustible liquids shall be removed from the limited finishing workstation before the drying apparatus is energized. [**33:**14.3.7.3]

43.5.3.8 Portable spot-drying, curing, or fusion apparatus shall be permitted to be used in a limited finishing workstation, provided that it is not located within the hazardous (classified) location defined in 43.5.3.5 when spray application operations are being conducted. [**33:**14.3.8]

43.5.3.9 Recirculation of exhaust air shall be permitted only if all provisions of 43.1.5.5 are met. [**33:**14.3.9]

43.6 Powder Coating

For information on the installation and use of powder coating application apparatus, see Chapter 15 of NFPA 33.

43.7 Organic Peroxides and Plural Component Coatings

43.7.1* Scope. Section 43.7 shall apply to the spray application operations that involve the use of organic peroxide formulations and other plural component coatings.

*Exception: As covered in Section 43.8. [**33:**16.1]*

A.43.7.1 Organic peroxides are a group of chemicals that are used as catalysts (chain reaction initiators) in the polymerization of plastics monomers and resins. Commercially, they are available as numerous formulations that differ not only in chemical species but also in concentration, type, and amount of diluent. [**33:**A.16.1]

The rapidly expanding reinforced styrene–polyester composites industry is one of the larger users of organic peroxide formulations. The formulations are used to catalyze (harden) the styrene–polyester resin. Frequently, the resin mixture and the catalyst are spray-applied to the reinforcing matrix using an automatic proportioning spray applicator. The most widely used catalyst systems are formulations of methyl ethyl ketone peroxide (MEKP), in varying concentration with different diluents, usually dibutyl phthalate. For transportation purposes, the U.S. Department of Transportation classifies these formulations as "organic peroxides" or "flammable liquids." [**33:**A.16.1]

For purposes of storage and warehousing, NFPA 400 classifies these materials using a five-tiered system, depending on their relative hazard as packaged for shipment. Thus, NFPA 400 recognizes that the different formulations available differ widely in fire hazard. In many cases, the "active oxygen," a measure of the material's catalytic activity and one measure of its reactivity hazard, has been reduced, thus reducing any explosion hazard. [**33:**A.16.1]

The following precautions are recommended:

(1) Organic peroxide formulations should be stored in a cool, dry location that is separated from the work area. The formulations should not be stored with materials with which they might not be compatible. Storage quantity limitations and fire protection requirements are contained in NFPA 400.
(2) The amount of organic peroxide formulation kept in the work area should be limited to that needed for a single day's use. Any formulation remaining at the end of a workday should be returned to the storage area.
(3) All necessary precautions, as recommended by the supplier, should be taken when organic peroxide formulations are used. Good housekeeping should be strictly observed, and spills should be immediately cleaned. Spilled material or material (such as resin) that has been contaminated with organic peroxide formulations has to be properly disposed of immediately. Trained personnel and safe operating procedures are essential for safe operation. The user should refer to the material safety data sheet (MSDS) or its equivalent for safety and handling information for the specific formulation being used.

[**33:**A.16.1]

See Annex B for tabular information on typical organic peroxide formulations.

43.7.2 General. Spray application operations that involve the use of organic peroxide formulations and other plural component coatings shall be conducted in spray areas that are protected by approved automatic sprinkler systems that meet the requirements of 43.1.7. [**33:**16.2]

43.7.3 Prevention of Contamination. Measures shall be taken to prevent the contamination of organic peroxide formulations with any foreign substance. Only spray guns and related handling equipment that are specifically manufactured for use with organic peroxide formulations shall be used. Separate fluid-handling equipment shall be used for the resin and for the catalyst, and they shall not be interchanged. [**33:**16.3]

43.7.3.1 The wetted portions of equipment and apparatus that handle organic peroxide formulations shall be constructed of stainless steel (300 series), polyethylene, Teflon®, or other materials that are specifically recommended for the application. [**33:**16.3.1]

43.7.3.2* Measures shall be taken to prevent contamination of organic peroxide formulations with dusts or overspray residues resulting from the sanding or spray application of finishing materials. [**33:**16.3.2]

A.43.7.3.2 Such mixing can result in a spontaneous fire or explosion. [**33:**A.16.3.2]

43.7.3.3 Spills of organic peroxide formulations shall be promptly removed so there are no residues. Spilled material shall be permitted to be absorbed by use of a noncombustible absorbent, which is then disposed of promptly in accordance with the manufacturer's recommendations. [**33:**16.3.3]

43.7.4 Storage of Organic Peroxides. Organic peroxide formulations shall be stored in accordance with the requirements of Chapter 70 and with the manufacturers' recommendations. [**33:**16.4]

43.7.5 Handling of Organic Peroxides. Measures shall be taken to prevent handling of organic peroxide formulations to avoid shock and friction, which can cause decomposition and violent reaction. [**33:**16.5]

43.7.6* Mixing of Organic Peroxides with Promoters. Organic peroxide formulations shall not be mixed directly with any cobalt compounds or other promoters or accelerators, due to the possibility of violent decomposition or explosion. To minimize the possibility of such accidental mixing, these materials shall not be stored adjacent to each other. [**33:**16.6]

A.43.7.6 The chemical and thermal stability of organic peroxide formulations is markedly reduced by contact or contamination with strong acids or bases, sulfur compounds, amines, and reducing agents of any type. Decomposition gases or vapors produced by some organic peroxide formulations can present a fire or explosion hazard. For example, the decomposition of benzoyl peroxide produces highly flammable vapors. [**33:**A.16.6]

Heat, including heat from fire exposure, is an important factor in the decomposition of organic peroxide formulations. Some formulations decompose quietly when exposed to a slow, gradual increase in temperature. However, these same formulations can decompose violently or even explode when subjected to a rapid, excessive increase in temperature, such as from fire exposure. [**33:**A.16.6]

In general, an organic peroxide that is formulated with a diluent into a dilute solution or paste burns more slowly than the concentrated or pure material and is less sensitive to shock or impact. [**33:**A.16.6]

43.7.7 Smoking. Smoking shall be prohibited, NO SMOKING signs shall be prominently displayed, and only nonsparking tools shall be used in any area where organic peroxide formulations are stored, mixed, or applied. [**33:**16.7]

43.7.8 Trained Personnel. Only designated personnel trained to use and handle organic peroxide formulations shall be permitted to use these materials. [**33:**16.8]

43.7.9 Material Safety Data Sheets. Where organic peroxide formulations are used, the material safety data sheet (MSDS) or its equivalent shall be consulted. [**33:**16.9]

With the introduction in the United States of the United Nations *Globally Harmonized System of Classification and Labeling of Chemicals* (*GHS*), material safety data sheets are now known simply as safety data sheets (SDS). See 29, CFR, 1910.1200, "Hazard Communication."

43.8 Styrene Cross-Linked Composites Manufacturing (Glass Fiber–Reinforced Plastics)

43.8.1* Scope. Section 43.8 shall apply to manufacturing processes involving spray application of styrene cross-linked thermoset resins (commonly known as glass fiber–reinforced plastics) for hand lay-up or spray fabrication methods, that is, resin application areas, and where the processes do not produce vapors that exceed 25 percent of the lower flammable limit. [**33:**17.1]

A.43.8.1 The reinforced styrene–polyester composites industry uses a variety of fabrication techniques to manufacture a wide range of useful products. Most of these products are fabricated with polyester- or vinyl ester–based resins and a fiber reinforcement, most commonly glass fiber. The resins contain a monomer, usually styrene, and are mixed with a catalyst to initiate curing. Other volatile organic chemicals used include the organic peroxide formulations, such as methyl ethyl ketone peroxide (MEKP), used to cure the resin, and various dyes and admixtures. [**33:**A.17.1]

Open molding is the predominant molding method, with mold sizes ranging from less than 1 ft^2 (0.1 m^2) to very large structures, such as boat hulls over 100 ft (30 m) in length. The two most widely used application methods are hand lay-up and spray-up. In the hand lay-up fabrication method, a glass fiber mat is saturated with the resin by direct spray application or by manual application of the liquid resin. The spray-up fabrication method employs a "chopper gun" that simultaneously applies catalyzed resin and chopped glass fiber to a mold. In addition, many operations use a spray-applied polyester resin gelcoat, as for in-mold coating. Products produced by this industry include boats, bathtubs and shower enclosures, sinks and lavatories, underground storage tanks, auto and truck bodies, recreational vehicles, pollution control equipment, piping, and other specialized parts. [**33:**A.17.1]

43.8.2 Resin Application Equipment. The equipment and apparatus for spray application of the resin shall be installed and used in accordance with the requirements of Sections 43.7 and 43.8. [**33:**17.2]

Δ **43.8.3* Fire Protection.** Resin application areas shall be protected in accordance with 43.1.7. [**33:**17.3]

A.43.8.3 The determination by the Technical Committee on Finishing Processes that Ordinary Hazard (Group 2) sprinkler design density is sufficient for protecting spray application of styrene cross-linked thermoset resins (commonly known as glass fiber–reinforced plastics) is based on the following factors:

(1) Although the styrene monomer that is a component in unsaturated polyester resin is a Class I flammable liquid by definition, actual burn tests reveal that the resin does not readily ignite and burns slowly when it does ignite.
(2) Tests of resin application areas have shown that the processes do not produce vapors that exceed 25 percent of the lower flammable limit (LFL). Resin application tests have also indicated that the maximum levels of vapor concentrations are about 690 parts per million (ppm) for spray application. The tests were conducted in an enclosed area with no ventilation. The LFL concentration for styrene is 11,000 ppm. Twenty-five percent of the LFL is 2,750 ppm. [**33:**A.17.3]

43.8.4 Resin Storage. The quantity of flammable and combustible liquids located in the vicinity of resin application areas outside an inside storage room or storage cabinet in any one process area shall not exceed the greater of any of the following:

(1) A supply for one day
(2) The sum of 25 gal (95 L) of Class IA liquids in containers and 120 gal (454 L) of Class IB, IC, II, or III liquids in containers
(3) One approved portable tank not exceeding 660 gal (2500 L) of Class IB, IC, II, or III liquids [**33:**17.4]

43.8.5 Electrical and Other Hazards.

43.8.5.1 Electrical wiring and utilization equipment located in resin application areas that is not subject to deposits of combustible residues shall be installed in accordance with the requirements of *NFPA 70* for Ordinary Hazard locations. [**33:**17.5.1]

43.8.5.2 Electrical wiring and utilization equipment located in resin application areas that is subject to deposits of combustible residues shall be listed for such exposure and shall be suitable for Class I, Division 2 or Class I, Zone 2 locations if applicable as defined in 43.1.4.2.1.2. [**33:**17.5.2]

43.8.5.3* All metal parts of resin application areas, exhaust ducts, ventilation fans, spray application equipment, workpieces or containers that receive the spray stream, and piping that conveys flammable or combustible liquids shall be electrically grounded. [**33:**17.5.3]

A.43.8.5.3 NFPA 77 contains information on static electricity. [**33:**A.17.5.3]

43.8.5.4 Space heating appliances or other hot surfaces in resin application areas shall not be located where deposits or residues accumulate. [**33:**17.5.4]

43.8.6 Ventilation.

43.8.6.1 Mechanical ventilation shall be designed and installed throughout the resin application area in accordance with the requirements of 43.1.5.

Exception: Buildings that are not enclosed for at least three-quarters of their perimeter shall not be required to meet this requirement. [33:17.6.1]

43.8.6.2 Local ventilation shall be provided where personnel are under or inside of the workpiece being fabricated. [**33:**17.6.2]

43.8.7 Use and Handling.

43.8.7.1 The storage and use of organic peroxide formulations shall meet the requirements of Section 43.7. [**33:**17.7.1]

43.8.7.2 Excess catalyzed resin, while still in the liquid state, shall be drained into an open-top, noncombustible container. Enough water shall be added to the container to cover the contained resin by at least 2 in. (50 mm). [**33:**17.7.2]

43.8.7.3 In areas where chopper guns are used, paper, polyethylene film, or similar material shall be provided to cover the exposed surfaces of the walls and floor to allow the buildup of overchop to be removed. When the accumulated overchop has reached an average thickness of 2 in. (50 mm), it shall be disposed of after a minimum curing time of 4 hours.

Exception: A single day's accumulation of more than an average of 2 in. (50 mm) shall be permitted, provided that it is properly cured and disposed of before operations are resumed. [33:17.7.3]

43.8.7.3.1 Used paper, polyethylene film, or similar material shall be placed in a noncombustible container and disposed of when removed from the facility. [**33:**17.7.3.1]

43.9 Dipping, Coating, and Printing Processes

43.9.1 Dipping, roll coating, flow coating, curtain coating, printing, cleaning, and similar processes, hereinafter referred to as "coating processes" or "processes," in which articles or materials are passed through tanks, vats, or containers, or passed over rollers, drums, or other process equipment that contain flammable or combustible liquids shall comply with NFPA 34 and Section 43.9. [**34:**1.1.1]

Section 43.9 is based on NFPA 34, which is the primary NFPA standard governing dipping and coating operations that use flammable and combustible materials and which is extracted, in part, in this section. The commentary in this section reflects substantive amendments incorporated into the 2015 edition of NFPA 34.

NFPA 34 applies to processes in which articles or materials are passed through tanks, vats, containers, or process equipment that contain flammable or combustible liquids. Application can be direct, as in dipping the workpiece into a tank that holds the liquid (Exhibit 43.9), or indirect, as in impregnating fabric with liquid that is applied by passing the fabric through rollers that pick up the liquid from a trough. A printing press is an example of the latter application (Exhibit 43.10).

NFPA 34 addresses the fire and explosion hazards of dipping and coating processes and operations that use flammable and combustible liquids. It does not address toxicity or industrial health and hygiene. From the standpoint of personnel safety, it must be recognized that the materials used in these processes

Exhibit 43.9

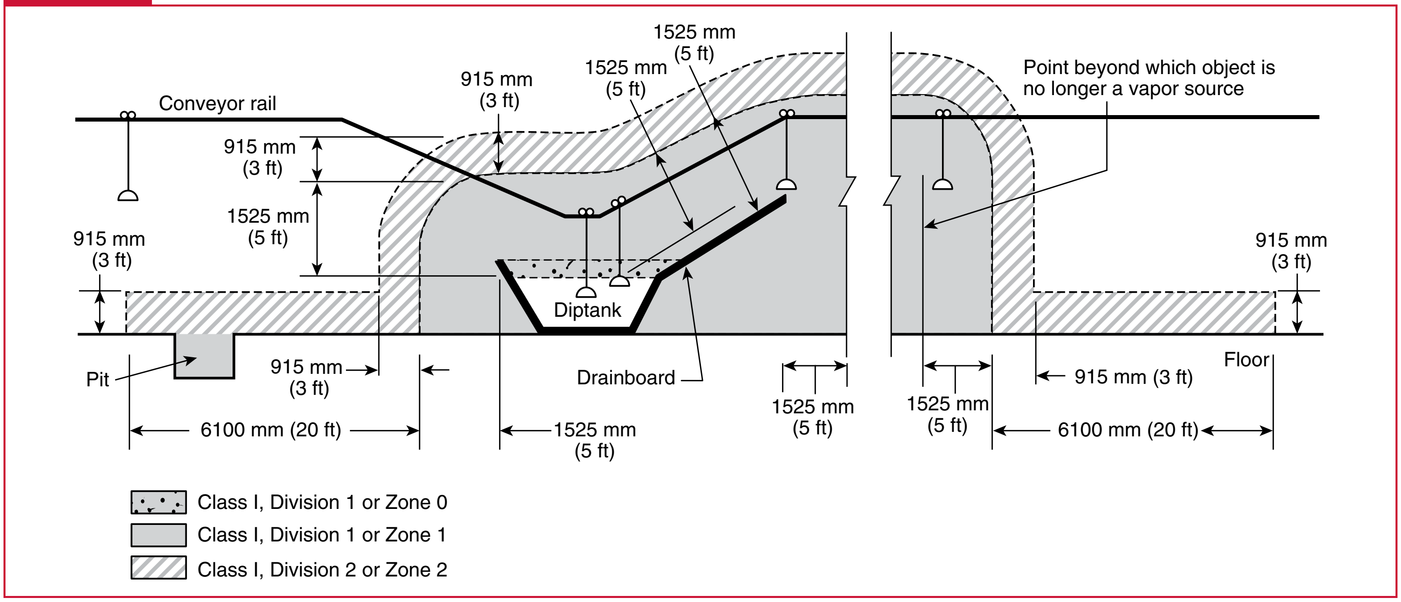


Diagram showing the hazardous (classified) areas surrounding an open dipping process. [Figure 6.4(a) from NFPA 34-2018.]

Exhibit 43.10

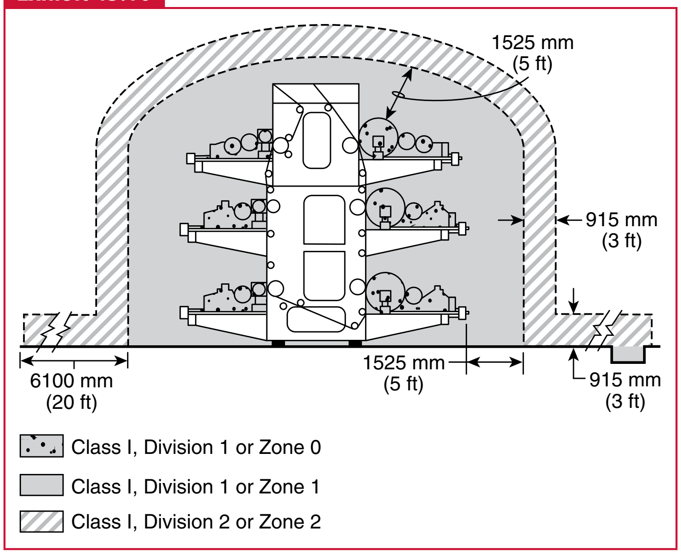

Diagram showing the hazardous (classified) areas surrounding a printing press. [Figure 6.4(d) from NFPA 34-2018.]

and operations could be present in concentrations that present a health hazard, even if the concentrations do not present a fire or explosion hazard. The requirements of NFPA 34 are intended to minimize the risk of fire and explosion; they are not intended to — and might not be adequate to — protect personnel from the toxic or negative effects from exposure to the materials used. The risk to life and property from fire or explosion as a result of dipping or coating processes varies, depending on the arrangement and operation of a particular installation. The principal hazards of such processes are fire and explosion hazards from large quantities of exposed flammable liquids. A fire, if not quickly controlled, can open sprinklers over a large area and might seriously damage building structural members. Enclosed processes, if not properly ventilated, present an explosion hazard that can result in release of coating material and could cause structural damage.

The fire hazard can be reduced by any one of several protection systems, which generally fall into the following two categories:

1. Protection system designed specifically for the process, such as a dry chemical system with an automatic-closing cover
2. Area protection system, such as an automatic sprinkler system for the room where the process is located

In some cases, a combination of the systems might be required. Protection should be chosen based on the design of the process and the properties of the coating used.

The elimination of all sources of ignition in areas where flammable or combustible liquids or combustible residues are present is essential to safe operation. Spread of fire to other property, exposure of personnel, and possibility of damage to goods in process or equipment should be considered in locating processes and installing protection systems. This consideration should be made regardless of the size of the process.

Unless otherwise noted, the provisions of NFPA 34 are not intended to be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of the standard, except in those cases where the AHJ determines that the existing situation involves a distinct hazard to life or adjacent property.

For the benefit of the user and because much of the text of NFPA 34 is not part of NFPA 1, the following is a summary of the major changes incorporated into the 2015 edition of NFPA 34:

1. Requirements were added to cover processes located in basements to ensure safe egress of personnel and safe access by emergency responders.
2. Provisions were added to address recirculation particulate filters.
3. Requirements for routing of exhaust ducts were modified to be consistent with those in NFPA 33.
4. Storage quantities for flammable and combustible liquids were modified to be consistent with both NFPA 30 and NFPA 33.
5. Water mist fire protection systems meeting the requirements of NFPA 750, *Standard on Water Mist Fire Protection Systems*, are now recognized as an acceptable means of protection.

43.9.1.1 Section 43.9 shall also apply to cleaning processes that utilize a solvent vapor, such as vapor degreasing processes. [**34:**1.1.2]

43.9.1.2 Section 43.9 shall also apply to processes that use waterborne, water-based, and water-reducible materials that contain flammable or combustible liquids or that produce combustible deposits or residues. [**34:**1.1.3]

43.9.1.3 Section 43.9 shall not apply to processes that use only noncombustible liquids for processing and cleaning. Section 43.9 shall also not apply to processes that use only Class IIIB liquids for processing or cleaning, provided the liquids or mixtures thereof maintain their Class IIIB classification at their point of use. [**34:**1.1.4]

43.9.1.4 Section 43.9 shall not apply to processes that use a liquid that does not have a fire point when tested in accordance with ASTM D92, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup*, up to the boiling point of the liquid or up to a temperature at which the sample being tested shows an obvious physical change. [**34:**1.1.5]

Δ **43.9.1.5** Section 43.9 shall not apply to fluidized bed powder application. *(See Chapter 15 of NFPA 33.)* [**34:**1.1.6]

43.9.1.6* Section 43.9 shall not apply to quench tanks that are addressed in Chapter 51 of this *Code*.

Δ **A.43.9.1.6** See NFPA 86.

See also Chapter 51 for more information on quench tanks.

43.9.2* Where unusual industrial processes are involved, the AHJ shall be permitted to require additional safeguards or modifications to the requirements of NFPA 34, provided equivalent safety is achieved.

A.43.9.2 Section 43.9 anticipates conditions of average use.

43.10 Training

Δ **43.10.1* General.** All personnel involved in the spray application processes covered by this *Code* shall be instructed in the following:

(1) Potential safety and health hazards
(2) Operational, maintenance, and emergency procedures required
(3) Importance of constant operator awareness

[**33:**19.1]

A.43.10.1 The safety of a spray application process depends on the employees who operate it and the knowledge and understanding they have of the process and equipment involved. Therefore, it is important to maintain an effective and ongoing training program for all employees involved in such work. New employees should be effectively trained before being assigned to a job. After the initial training, employees should receive periodic retraining to ensure their knowledge and understanding of normal process procedures as well as with emergency procedures or changes in procedures. Safe work habits are developed; they do not occur naturally. [**33:**A.19.1]

All training should be provided by qualified personnel knowledgeable in the processes and operations involved. Appropriate training should be provided for all employees involved in or affected by spray application processes. This includes, but is not limited to, operating, supervisory, housekeeping, and maintenance personnel. [**33:**A.19.1]

43.10.1.1 Personnel required to handle or use flammable or combustible materials shall be instructed in the safe handling, storage, and use of the materials, as well as emergency procedures. [**33:**19.1.1]

43.10.1.2* All personnel required to enter or to work within confined or enclosed spaces shall be instructed as to the nature of the hazard involved, the necessary precautions to be taken, and the use of protective and emergency equipment required. [**33:**19.1.2]

A.43.10.1.2 Any work requiring entry of employees into confined spaces should be conducted in accordance with a written procedure that is rigidly followed. This procedure should include, but not be limited to, the following:

(1) Analysis of confined space atmosphere for flammable, combustible, toxic, or oxygen-deficient conditions
(2) Rescue, fire, and emergency procedures
(3) Locking and tagging procedures for all power and process hazard sources
(4) Ventilation
(5) Personal protective equipment
(6) Proper tools and electrical equipment
(7) Written entry authorization by a qualified responsible individual

[**33:**A.19.1.2]

All confined spaces should be considered hazardous areas due to their potential for containing atmospheric hazards such as oxygen deficiency and the presence of flammable and toxic vapors.

In addition, confined spaces can also present physical hazards (e.g., slips, trips, and falls) due to the structure and configuration of the space, particularly if lockout/tagout techniques are not employed. Consequently, confined space regulations and safety practices should be followed for any work that requires personnel to enter confined spaces. Safe practices could involve testing the atmosphere in the confined space before entry and while work is being performed in the space.

Personnel assigned to work in confined spaces, as well as others who are to respond to such areas in the event of an emergency, should receive training on the safe practices to be followed. The training program should address the anticipated hazards for the area and how to eliminate or reduce their effects. For additional information and regulatory requirements, consult 29 CFR 1910.146, "Permit-Required Confined Spaces."

43.10.1.3 All personnel shall be instructed in the proper use, maintenance, and storage of all emergency, safety, or personal protective equipment that they might be required to use in their normal work performance. [**33:**19.1.3]

The safety of spray application processes and dipping and coating processes depends on the personnel who perform the work and their knowledge and understanding of the process and the equipment involved. Therefore, maintaining an effective and ongoing training program for all personnel involved in such work is important. New employees should be effectively trained before being assigned to a job. After their initial training, employees should receive periodic retraining to reinforce their knowledge and understanding of normal process procedures, as well as to ensure their knowledge of emergency procedures and changes in procedures. Maintenance personnel must be trained to use the proper tools when performing routine maintenance and to inspect enclosed areas, such as plenums and ductwork, before using torches or cutting tools on outside surfaces. Safe work habits must be developed.

All training should be provided by qualified personnel who are knowledgeable in the processes and operations involved. Appropriate training should be provided for all personnel involved in, or affected by, spray application processes. Such personnel include, but are not limited to, operating, supervisory, housekeeping, and maintenance personnel.

43.10.1.4 Documentation shall be employed to record the type and date of training provided to each individual involved in these processes. [**33:**19.1.4]

Solvent Extraction

44

Chapter 44 contains requirements for solvent extraction plants. There are some fundamental differences between the operation of solvent extraction plants and the processing of solvents in other facilities. Many extraction plants are relatively small units in isolated locations that are operated without the benefit of the overall fire protection measures customary in large solvent processing installations.

The operator of an extraction plant must establish and maintain a fire safety philosophy among a small number of employees, because they cannot rely on established fire safety programs as can be done in large-scale operations.

Certain inherent hazards that result from the combining and separating of solids and solvents are unique to this industry. Compounding the problem is the potential dust explosion hazard in some areas of a typical solvent extraction plant. Therefore, due consideration has been given to established industry practices that would apply to either potential dust-laden or flammable vapor atmospheres.

Δ 44.1 General

Solvent extraction plants shall comply with NFPA 36 and Chapter 44.

NFPA 36, *Standard for Solvent Extraction Plants*, contains requirements for the commercial-scale extraction processing of animal and vegetable oils and fats by the use of Class I flammable hydrocarbon liquids, referred to as solvents. NFPA 36 applies to the unloading, storage, and handling of solvents and applies to the means by which the material to be extracted is conveyed from the preparation process to the extraction process. In addition, it applies to the means by which extracted desolventized solids and oils are conveyed from the extraction process. NFPA 36 includes any preparation or meal-finishing processes that are connected to the solvent extraction process by a conveyor, establishing a boundary between those operations governed by NFPA 36 and those that might be governed by NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities*.

NFPA 36 contains provisions that address the following conditions:

1. Requirements for the design, construction, and operation of extraction processes that use Class I flammable hydrocarbon liquids
2. Requirements for the prevention of fire and explosions in extraction processes and in associated preparation and meal-finishing areas
3. Means by which plant fire protection and supervisory personnel can evaluate the processes and operations under their control
4. Guidance to regulatory and inspection officials in determining whether a given facility is being operated in accordance with good practice
5. A workable set of standards for the use of design engineers, architects, and others in the planning and designing of new installations

The provisions of NFPA 36 apply to all extraction plants. Existing plants that comply with the edition of NFPA 36 in effect at the time of construction are considered to be in compliance with the *Code*, provided that they do not constitute a recognized hazard to life or adjacent property, as determined by the authority having jurisdiction (AHJ).

The effective date for the edition of NFPA 36 referenced in this *Code* is December 1, 2016. However, the provisions of NFPA 36 might not be enforceable retroactively to its effective date if it has not been adopted by a separate action in the jurisdiction. The date that NFPA 1, *Fire Code*, was adopted in the jurisdiction establishes the effective date for the enforcement of not only NFPA 1 but also the other codes and standards incorporated into the *Code*.

44.2 Application

44.2.1 Chapter 44 shall apply to the following:

(1) The commercial scale extraction processing of animal and vegetable oils and fats by the use of Class I flammable hydrocarbon liquids, hereinafter referred to as “solvents” [**36:**1.1.1]
(2) Any equipment and buildings that are located within 100 ft (30 m) of the extraction process [**36:**1.1.2]

(3) The unloading, storage, and handling of solvents, regardless of distance from the extraction process [**36:**1.1.3]
(4) The means by which material to be extracted is conveyed from the preparation process to the extraction process [**36:**1.1.4]
(5) The means by which extracted desolventized solids and oil oils are conveyed from the extraction process [**36:**1.1.5]
(6) Preparation and meal finishing processes that are connected by conveyor to the extraction process, regardless of intervening distance [**36:**1.1.6]

44.2.2 Chapter 44 shall not apply to the following:

(1) The storage of raw materials or finished products [**36:**1.1.7]
(2) Extraction processes that use liquids that are miscible with water [**36:**1.1.8]
(3) Extraction processes that use flammable gases, liquefied petroleum gases, or nonflammable gases [**36:**1.1.9]

44.3 Permits

Permits, where required, shall comply with Section 1.12.

Permit requirements are listed in Table 1.12.8(a). Permits are required for the storage, use, and handling of solvents associated with a solvent extraction process.

44.4 Special Requirements

The use of processes that employ oxygen-active compounds that are heat or shock sensitive, such as certain organic peroxides, shall be prohibited within the area defined in 44.2.1(2). [**36:**1.1.10]

45 Combustible Fibers

45.1 General

45.1.1 The storage, use, and handling of combustible fibers shall comply with the requirements of Chapter 45.

Fibers are the basic components of all textiles; they can be either natural or man-made. Natural fiber sources include cellulosic materials, proteins, and minerals. Cellulosic fibers come from a variety of plants, the most common of which is cotton, while protein fibers come from a variety of animal hairs. Mineral fibers include mineral wool and fiberglass. Man-made fibers are produced by chemical processes. All fibers come in a variety of lengths. Although natural fiber length can be slightly manipulated genetically, man-made fiber can be produced in any length.

The term *combustible fiber* is defined in 3.3.59 as "any material in a fibrous or shredded form that readily ignites when heat sources are present." Combustible fibers include cotton, sisal, henequen, ixtle, jute, hemp, tow, cocoa fiber, oakum, baled waste, baled wastepaper, kapok, hay, straw, excelsior, Spanish moss, or other similar materials.

Commentary Table 45.1 provides the fire hazard properties of common textile fibers. Many fibers are spun into yarns and then woven or knitted into a variety of fabrics. Examples include plain or patterned fabrics or pile, such as flannels, terry cloth towels, artificial furs, and carpets. Fibers also can be processed directly into useful materials, such as nonwoven fabrics or battings. Fabrics are usually scoured, bleached, dyed, or finished (or undergo a combination of these processes) with chemicals that provide them with a stiffer or softer feel, with permanent-press characteristics, with luster, or with resistance to flame or weather. See Commentary Table 45.2 for more information on identification of textiles by their burning characteristics. The *NFPA Fire Protection Handbook®* contains additional information on combustible fibers.

45.1.2* Chapter 45 shall not apply to buildings completely protected by an approved automatic fire-extinguishing system; however, this exclusion does not preclude the need for good housekeeping.

A.45.1.2 The use of automatic sprinkler protection in accordance with NFPA 13 is recommended for all storage of combustible fibers.

N **45.1.3** Chapter 45 shall not apply to biomass feedstock regulated by Chapter 31.

45.1.4 Permits. Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the storage or handling of combustible fibers greater than 100 ft^3 (2.8 m^3); see Table 1.12.8(a).

45.2 Electrical Wiring

45.2.1 Electrical wiring and equipment in any combustible fiber storage room or building shall be installed in accordance with the requirements of *NFPA 70* for Class III hazardous locations.

45.2.2 The AHJ shall be responsible for designating the areas requiring hazardous location electrical classifications and shall classify the area in accordance with the classification system set forth in *NFPA 70*.

45.3 No Smoking

45.3.1 No smoking or open flame shall be permitted in any area where combustible fibers are handled or stored, nor within 50 ft (15 m) of any uncovered pile of such fibers.

45.3.2 NO SMOKING signs shall be posted.

See Section 10.9 for further information on smoking restrictions.

Δ 45.4 Vehicles and Material Handling Equipment

Trucks or automobiles, other than mechanical handling equipment and approved industrial trucks complying with NFPA 505, shall not enter any fiber storage room or building but shall be permitted to be used at loading platforms.

NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations*, applies to fork trucks, tractors, platform lift trucks, motorized hand trucks, and other specialized industrial trucks powered by electric motors or internal combustion engines.

COMMENTARY TABLE 45.1 *Fire Hazard Properties of Common Textile Fibers*

Fiber Designation	Decomp. Temp. °F (°C)	Melting Temp. °F (°C)	Ignition Temp. °F (°C)	Burning Temp. °F (°C)	Burning Behavior	End Uses
A. Natural Fibers						
Cellulosic: cotton, hemp, jute, linen, sisal, etc.	580–610 (305–320)	— —	490–750 (255–400)	1560 (850)	Chars, burns, sometimes afterglow	Apparel, furnishings, towels, cordage
Protein: wool, mohair, cashmere, camel hair, etc.	450 (230)	— —	1060–1110 (570–600)	1720 (940)	Chars, intumesces, burns less readily than cellulosics	Apparel, blankets, carpets, furniture covers
B. Manufactured Fibers						
Acetate	570 (300)	500 (260)	842 (450)	1720 (940)	Shrinks, melts, and burns	Apparel, lingerie, furnishings
Acrylic	540–590 (280–310)	420–490 (215–255)	860–1050 (460–565)	1560 (850)	Chars, intumesces, burns, and drips	Apparel, furnishings, carpets, blankets, pile fabrics
Nylon	600–790 (315–420)	420–490 (215–255)	840–1060 (450–570)	1600 (870)	Melts, ablates, burns	Apparel, lingerie, furnishings, carpets, cordage, industrial uses
Anidex	NA	NA	NA	NA	NA	Elastic fiber used in apparel, home furnishings, and laces
Aramid	660 (370–400)	3700 (2040)	800–1040 (427–560)		Does not melt	
Lyocell	350 (175)	450–500 (230–260)	860 (460)			Dresses, slacks, coats, jeans
Modacrylic	500 (287)		1025 (550)			Children's sleepwear, carpets, blankets, draperies
Novoloid		Nonmelting				Protective equipment
Rubber	200 (93)					
Triacetate	>572 (>300)	550 (288)	>842 (>450)	1560 (850)	Shrinks, melts, and burns	
Vinal	Similar to nylon					Good chemical resistance
Vinyon						Good chemical resistance
Olefin (polypropylene)	750 (400)	330 (165)	930–1060 (500–570)	1540 (840)	Melts, ablates, burns	Knitted sportswear, carpets, cordage, furniture covers, industrial uses
Polyester	680–750 (360–400)	480–570 (250–300)	840–1040 (450–560)	1290–1330 (700–720)	Melts, ablates, burns	Apparel, lingerie, furnishings, carpets, blankets, fiberfill, cordage, industrial uses
Rayon (viscose)	550 (290)	—	790 (420)	1560 (850)	Chars, burns	Apparel, lingerie, furnishings
Spandex	581–671 (305–355)	446–482 (230–250)	780 (415)	NA	Melts, burns	In apparel and lingerie where stretch is desired

NA: Not available.

Source: Table 6.5.7 of the *NFPA Fire Protection Handbook*.

COMMENTARY TABLE 45.2 *Textile Identification by Burning Characteristics*

Fiber	Burn Characteristics	Residue
Acetate	Shrinks, melts, and burns	Dark, hard, solid bead; acrid odor (hot vinegar)
Acrylic	Shrinks, melts, and burns	Hard, irregularly shaped bead; black smoke; acrid odor
Aramid	Shrinks, melts, and burns	Hard, black bead; self-extinguishing
Cotton	Burns	Fine, feathery gray ash; odor similar to burning paper
Flax, hemp, jute, ramie	Burns	Fine, feathery gray ash, odor similar to burning paper
Glass	Shrinks slowly, melts at very high temperature	Flame-resistant fiber, heat from lighter will not cause fiber to melt
Modacrylic	Shrinks, melts, and burns	Hard, black, irregular bead; self-extinguishing; acrid chemical odor
Novoloid	Shrinks, burns at high temperature	Retains shape but turns black; heat from lighter will not cause fiber to burn
Nylon	Shrinks, melts, and burns	Hard, cream-colored bead; if fibers are overheated, bead will become dark; flaming usually caused by finish present; drops of melted fiber may fall from heated portion of sample; celery odor
Olefin	Shrinks, melts, and burns	Hard, tan bead; black smoke; chemical odor
Polyester	Shrinks, melts, and burns	Hard, cream-colored bead; if fibers are overheated, bead will become dark; drops of melted fiber may fall from heated portion of sample; black smoke; chemical odor
Rayon	Burns	Fine, feathery gray ash
Rubber	Shrinks, melts, and burns rapidly	Tacky, soft black residue
Saran	Shrinks, melts, and burns	Hard, black, irregular bead; self-extinguishing; chemical odor
Silk	Shrinks and burns	Black, hollow, irregular bead that crushes easily to a gritty black powder
Spandex	Burns and melts	Soft, black ash
Triacetate	Shrinks, melts, and burns	Dark, hard, solid bead; chemical odor
Vinal	Shrinks, melts, and burns	Hard, tan bead; chemical odor
Vinyon	Shrinks, melts, and burns	Hard, black, irregular bead; acrid odor
Wool, mohair, cashmere, alpaca	Shrinks and burns	Black, hollow, irregular bead that crushes easily to a gritty black powder

Source: Table 6.5.7 of the *NFPA Fire Protection Handbook.*

45.5 Loose Storage of Combustible Fibers

45.5.1 Loose combustible fibers (not in bales or packages), whether housed or in the open, shall not be stored within 100 ft (30 m) of any building, except as hereinafter specified.

45.5.2 Quantities of loose combustible fibers up to 100 ft^3 (2.8 m^3) shall not be kept in any building unless stored in a metal or metal-lined bin that is equipped with a self-closing cover.

A summary of the loose storage of combustible fibers in rooms or buildings is provided in Commentary Table 45.3.

COMMENTARY TABLE 45.3 *Requirements for Loose Storage of Combustible Fibers*

Quantity	Storage
$\leq$100 ft^3 (2.8 m^3)	Metal or metal-lined bin with self-closing cover
$>$100 ft^3 (2.8 m^3) and $\leq$500 ft^3 (14.2 m^3)	Rooms or compartments with floors, walls, and ceilings having not less than ¾-hour fire-resistance rating; self-closing fire door
$>$500 ft^3 (2.8 m^3) and $\leq$1000 ft^3 (28.3 m^3)	Storage vaults enclosed with floors, walls, and ceilings with 2-hour fire-resistance-rated fire barriers*
$>$1000 ft^3 (28.3 m^3)	Storage vaults enclosed with floors, walls, and ceilings with 2-hour fire-resistance-rated fire barriers and protected by an approved automatic sprinkler system*

*Additional requirements may apply depending on if the storage vault is located inside or outside the building.

45.5.3 Rooms or Compartments for Quantities of Loose Combustible Fibers Ranging Between 100 ft^3 (2.8 m^3) and 500 ft^3 (14.2 m^3).

45.5.3.1 Quantities exceeding 100 ft^3 (2.8 m^3) of loose combustible fibers, but not exceeding 500 ft^3 (14.2 m^3), shall be permitted to be stored in rooms or compartments in which the floors, walls, and ceilings have a fire-resistance rating of not less than ¾ hour.

45.5.3.2 Each opening into such rooms or compartments from other parts of the building shall be equipped with an approved self-closing fire door.

45.5.4 Storage Vaults for Quantities of Loose Combustible Fibers Ranging Between 500 ft³ (14.2 m³) and 1000 ft³ (28.3 m³).

45.5.4.1 Quantities exceeding 500 ft^3 (14.2 m^3) of loose combustible fibers, but not exceeding 1000 ft^3 (28.3 m^3), shall be permitted to be stored in storage vaults enclosed with floors, walls, and ceilings that are 2-hour fire-resistance-rated fire barriers.

45.5.4.2 Such storage vaults shall be located outside of buildings or, if located inside, shall be protected with approved safety vents to the outside.

45.5.4.3 If such storage vaults are located inside a building, each opening into the storage vault from other parts of the building shall be protected on each side of the wall by an approved opening protective assembly having a fire resistance rating of 1½ hours.

45.5.4.4 If such storage vaults are located outside of buildings but have openings that expose other buildings (not sufficiently detached to be considered cutoff), each such opening shall be protected on each side of the wall by an approved opening protective assembly having a fire resistance rating of 1½ hours.

45.5.4.5 Roofs of outside vaults shall be of noncombustible material, but shall be permitted to be constructed so as to readily give way in case of an internal explosion.

45.5.5 Storage Vaults for Quantities of Loose Combustible Fibers Exceeding 1000 ft³ (28.3 m³).

45.5.5.1 Quantities exceeding 1000 ft^3 (28.3 m^3) of loose combustible fibers shall be permitted to be stored in storage vaults as indicated in 45.5.4.

45.5.5.2 The storage vault shall also be protected by an approved automatic sprinkler system designed and installed in accordance with Section 13.3.

45.5.6 Loose House.

45.5.6.1 Not more than 2500 ft^3 (71 m^3) of loose fibers shall be permitted to be stored in a detached loose house, with openings properly protected against the entrance of sparks.

45.5.6.2 The loose house shall be used for no other purpose.

45.6 Baled Storage

The main hazard of baled cotton and other fibers of vegetable origin is the multitude of exposed, minute fibers on the surfaces of the bales. Fire quickly flashes over the vertical surfaces, the loose particles on the floor, and the lint on overhead piping and structural members. Fire on one side of an automatic-closing fire door can progress through the open doorway on loose floor scraps before the door can close automatically. Therefore, proper housekeeping is especially important in areas where such fibers are present.

Fire also tends to penetrate between and into bales, requiring their removal from the building for extinguishment. Considerable smoke emission complicates fire fighting. Certain fibers, such as jute, swell when wet; therefore, the bales should be piled with careful attention to their stability during a fire and with proper clearance from walls. See NFPA 654, *Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids*, for more information on fire protection requirements that affect the fibers industry.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, and FM Global Property Loss Prevention Data Sheet 8-7, "Baled Fiber Storage," provide guidance for the protection of fibers.

45.6.1 Blocks or Piles.

45.6.1.1 No single block or pile shall contain more than 25,000 ft^3 (708 m^3) of combustible fibers, exclusive of aisles or clearances.

45.6.1.2 Blocks or piles of baled fiber shall be separated from adjacent storage by aisles not less than 5 ft (1.5 m) wide or by flash fire barriers consisting of continuous sheets of noncombustible material extending from the floor to a height of at least 1 ft (0.3 m) beyond the top of the piles and projecting not less than 1 ft (0.3 m) beyond the sides of the piles.

45.6.1.3 Baled cotton storage and combustibles shall be kept at least 4 ft (1.2 m) from fire door openings.

45.6.2 Sisal and Other Fibers.

45.6.2.1 Sisal and other fibers in bales bound with combustible tie ropes or jute and other fibers that are liable to swell when wet shall be stored in a manner that allows for expansion in any direction without endangering building walls, ceilings, or columns.

45.6.2.2 Not less than 3 ft (0.9 m) of clearance shall be left between walls and sides of piles, except that in storage compartments not more than 30 ft (9 m) in width, 1 ft (0.3 m) clearance at side walls shall be sufficient, provided that a center aisle not less than 5 ft (1.5 m) wide is maintained.

The application of water, either from a sprinkler system or from fire-fighting hose lines, causes certain fibers to swell. If baled fibers are located adjacent to the walls or the structural components of a building, the swelling can be sufficient to deform the building components, pushing out walls or displacing columns.

Waterlogged fiber bales impinging on building components can lead to structural instability. Limiting the width of piles allows the focus to remain on fire-fighting operations, but it also limits the amount of expansion due to swelling and reduces the chances for pile instability. The potential movement of unstable piles is also a hazard to fire fighters.

45.7 Storage of Hay, Straw, and Other Similar Agricultural Products

45.7.1 Hay, straw, and other similar agricultural products shall not be stored adjacent to buildings or combustible material unless a cleared horizontal distance equal to the height of pile is maintained between such storage and combustible material and buildings.

45.7.2 Storage shall be limited to stacks of 100 tons (90,720 kg) each.

Δ **45.7.3** Either an approved 1-hour fire wall installed in accordance with NFPA 221 or a clear space of 20 ft (6.1 m) shall be maintained between such stacks.

45.7.4 Unlimited quantities of hay, straw, and other agricultural products shall be permitted to be stored in or near farm buildings located outside of closely built areas.

45.8 Hazardous Materials

Combustible fibers shall not be stored in rooms or buildings with hazardous gases, flammable liquids, dangerous chemicals, or other similar materials.

- Chapter 46
- Chapter 47
- Chapter 48
- Chapter 49

Commercial Cooking

50

Fires in commercial cooking establishments are a serious concern. Many commercial cooking operations are part of assembly, educational, and health care occupancies where a fire could create a significant risk to life safety. Based on a report published by NFPA's Fire Analysis and Research Division, "Structure Fires in Eating and Drinking Establishments," between 2010 and 2014 U.S. fire departments responded to an estimated average of 7410 structure fires at eating and drinking establishments per year. Those fires caused average annual losses of three civilian deaths, 110 civilian injuries, and $165 million in direct property damage each year. Three out of five (61 percent) of the fires involved cooking equipment. The vast majority of the fires in this category were in restaurants. Of the 7410 fires, 59 percent (4380 fires) began in the kitchen or cooking area and caused 35 percent ($58 million) of the direct property damage. Leading factors contributing to the ignition of fires in restaurants were reported as failure to clean the equipment, electrical and/or mechanical failures, abandoned or discarded material or product, heat source too close to combustibles, or unattended equipment. The proper design, installation, and maintenance of a commercial cooking system are essential to the proper function of a building and the safety of its occupants.

The case studies included in the commentary in this chapter are published incidents in eating and drinking establishments where the presence of commercial cooking equipment played an important role in the fire scenario. These incidents show the importance of the proper installation, inspection, testing, and maintenance of such equipment in case of a fire event. These case studies are based on short articles from the "Firewatch" column in the *NFPA Journal* and incidents from either the large-loss fires report or the catastrophic fires report. It is important to remember that this is anecdotal information.

Case Study

Suppression Systems Control Restaurant Grease Fire, Pennsylvania

A kitchen extinguishing system and a sprinkler that activated during a fire in an Asian restaurant limited fire damage. The single-story restaurant building, which was 20 feet (6 meters) wide and 40 feet (12 meters) long, was protected by a wet-pipe sprinkler system and a kitchen hood suppression system, both of which were connected to a monitored fire alarm system. Investigators determined that the fire started in grease deposits that had formed in the bottom of smoke box cooking equipment and spread to a deep-fat fryer, causing the hood extinguishing system to activate. Additional heat fused a nearby sprinkler, which held the fire in check until the fire department arrived to extinguish the blaze. The kitchen's hood system extinguished the fire in the deep fryer.

— "Firewatch," *NFPA Journal*, May/June 2012, pp. 38–39

Suppression System Controls Kitchen Hood Fire, Utah

A fire suppression system controlled a fire that started in the hood duct of a restaurant kitchen, but the fire fed off the grease that had built up in the duct and continued to burn until firefighters extinguished it. The building was occupied when the fire broke out, but everyone had evacuated safely by the time firefighters arrived. Someone called 911 to report the blaze at 4:20 p.m., and firefighters arrived four minutes later to find smoke coming from the roof. The restaurant owner told the incident commander that the hood had caught fire after they started the grill. It looked as though the hood suppression system had put the fire out, but firefighters on the roof reported that they could still see the fire burning in the ductwork some 8 feet (2 meters) below them. When they were unable to get water on the flames from their position, they recommended an interior attack.

Interior crews advanced a hose line into the kitchen and opened the ceiling around the ductwork. Once the duct was exposed, they saw that the grease and creosote that had built up on the sides of it were still burning. Fortunately, the duct maintained its integrity, preventing the fire and heat from escaping into hidden areas before it was extinguished. Investigators noted that the hood suppression system heads did not discharge properly.

Damage to the property and its contents was estimated at $5,000. There were no injuries.

— "Firewatch," *NFPA Journal*, May/June 2012, p. 39

Kitchen Fire Damages Restaurant, Ohio

A restaurant suffered significant structural damage when a pressurized deep-fat fryer malfunctioned and ignited cooking oil, starting a fire that caused more than a million dollars in property damage. The single-story, wood-frame building covered an area of 16,625 square feet (1,545 square meters) and had a wood-frame roof covered in asphalt shingles. Smoke and heat detectors throughout the building were connected to a monitored fire alarm panel. A kitchen hood fire suppression system was installed in the kitchen, but it did not operate. There were no sprinklers.

Employees detected the fire and tried unsuccessfully to control it using portable fire extinguishers before the restaurant manager called the fire department at 9:17 a.m. The monitoring company did not report the alarm to the fire department until 20 minutes into the incident.

Firefighters arrived within four minutes of the manager's 911 call to find heavy smoke pouring from the back of the building and flames coming out the roof. First-in crews found flames from floor to ceiling at the end of the cooking line and abandoned their initial efforts to control the fire from inside, undertaking a defensive fire attack instead.

The building, valued at $2.1 million, and its contents, valued at $500,000, sustained damage estimated at $1.25 million and $250,000, respectively. There were no injuries.

— "Firewatch," *NFPA Journal*, September/October 2011, p. 14

Grease Fire Destroys Restaurant, Maryland

Employees of a take-out restaurant had begun preparing to open for the day when they discovered a fire in the ductwork over two rotisserie ovens and a deep fat fryer. They tried to put out the flames with fire extinguishers, but the fire spread through the ductwork to concealed spaces above. The single-story, wood-frame restaurant, which measured 100 by 30 feet (30 by 9 meters), was separated from adjacent stores by gypsum board walls. The restaurant had no smoke or fire detection equipment, and its kitchen hood system was not operational as heads were missing.

Approximately 30 minutes after a worker cleaned the overhead duct filters and ignited charcoal in the ovens, he noticed the fire and used several fire extinguishers in an unsuccessful effort to control the flames. After a delay of about eight minutes, a restaurant employee called 911 at 8:40 a.m.

Investigators determined that the fire began when heat from the ovens ignited a buildup of grease in the ductwork. A hole in the ductwork allowed the fire to spread into the concealed ceiling space, where it charred the combustible construction and ignited the roof assembly. The owner told investigators that the ductwork had been poorly cleaned two weeks earlier and that he had contacted another firm about future cleaning.

The structure, valued at $2 million, and its contents, valued at $500,000, were destroyed. There were no injuries.

50.1 Application

Δ **50.1.1*** The design, installation, operation, inspection, and maintenance of all public and private commercial cooking equipment and mobile and temporary cooking operations shall comply with this chapter and NFPA 96.

A.50.1.1 These requirements include, but are not limited to, all manner of cooking equipment, exhaust hoods, grease removal devices, exhaust ductwork, exhaust fans, dampers, fire-extinguishing equipment, and all other auxiliary or ancillary components or systems that are involved in the capture, containment, and control of grease-laden cooking effluent. [**96:**A.1.1.1]

The effective date for the edition of NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*, referenced in this *Code* is December 1, 2016. However, the provisions of NFPA 96 might not be enforceable retroactively to its effective date if it has not been adopted by a separate action in the jurisdiction. The date that NFPA 1, *Fire Code*, was adopted in the jurisdiction establishes the effective date for enforcement of not only NFPA 1 but also other codes and standards incorporated into this *Code*.

The 2017 edition of NFPA 96 added a new normative annex on mobile and temporary cooking operations. Section 50.7 includes provisions on mobile and temporary cooking operations that are consistent with the new guidelines in NFPA 96. See Section 50.7 for additional commentary and information on these new provisions.

50.1.2 This chapter shall apply to residential cooking equipment used for commercial cooking operations. [**96:**1.1.2]

50.1.3 This chapter shall not apply to cooking equipment located in a single dwelling unit. [**96:**1.1.3]

Δ **50.1.4*** This chapter shall not apply to facilities where all of the following are met:

(1) Only residential equipment is being used.
(2) Fire extinguishers are located in all kitchen areas in accordance with Section 13.6.

(3) The facility is not an assembly occupancy.
(4) The AHJ has approved the installation.
[**96:**1.1.4]

Δ **A.50.1.4** This judgment should take into account the type of cooking being performed, the items being cooked, and the frequency of cooking operations. Examples of operations that might not require compliance with Chapter 50 include the following:

(1) Day care centers warming bottles and lunches
(2) Therapy cooking facilities in health care occupancies
(3) Churches and meeting operations that are not cooking meals that produce grease-laden vapors
(4) Employee break rooms where food is warmed

In non-assembly occupancies where residential equipment is utilized, the AHJ may consider requiring protection of the cooking surface with a listed residential range top extinguishing unit as an alternative to no protection or requiring full protection in accordance with this standard.

[**96:**A.1.1.4]

In the past, NFPA 96 was used for commercial cooking operations, public or private. However, other operations, particularly those involving residential cooking equipment, were a source of considerable debate. NFPA 96 now clearly states that residential equipment used in commercial cooking operations is within its scope. The current text in NFPA 96 and in this *Code* establishes the following four criteria that all must be met for a facility to be considered exempt from the requirements of NFPA 96:

1. Only residential equipment is being used.
2. Fire extinguishers must be located in all kitchen areas in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.
3. The facility must not be an assembly occupancy (see 6.1.2).
4. The authority having jurisdiction (AHJ) has approved the installation.

In the past, a frequently asked question was how to apply NFPA 96 to specific pieces of equipment, such as standard pizza ovens, conveyor pizza ovens, smokers, steamers, mesquite grills, and other equipment. Much of the debate centered on the production of grease-laden vapors and on the amount of grease-laden vapor that can be produced by a given piece of equipment, because previous editions of the standard contained scope language regarding equipment that "produces grease-laden vapors." Recent editions have removed that language from the scope and, as a result, have clearly established that NFPA 96 is intended to apply to any and all commercial cooking appliances.

50.2 General Requirements

50.2.1 General.

50.2.1.1 Cooking equipment used in processes producing smoke or grease-laden vapors shall be equipped with an exhaust system that complies with all the equipment and performance requirements of this chapter. [**96:**4.1.1]

Most commercial cooking equipment produces smoke and grease-laden vapors with very few exceptions. Equipment that is being considered for qualification as an exception must be carefully evaluated before any of the requirements for ventilation and protection are modified.

The operation and protection of commercial cooking equipment have general requirements. Special attention must be given to the arrangement and protection of ventilation systems that serve multiple hoods in multiple tenancies, such as food courts in malls. Those tenancies house various arrangements that affect ventilation and fire protection system operation, as well as system maintenance. All these factors need to be considered in the design and maintenance plan to ensure that fire protection systems operate properly.

Given the requirement of 50.2.1.1, it is therefore possible to have a piece of equipment and a location that fall under the applicability of NFPA 96 but are not required to be provided with an exhaust system as the standard specifies. This will be a rare occurrence, since the vast majority of cooking operations will produce smoke or grease-laden vapors. The possibility still exists, for example, for a piece of equipment to be installed without the exhaust system, provided a policy is set that limits its use to only operations that do not produce smoke or grease-laden vapors. That is a policy that would be difficult to ensure and the final approval would need to come from the AHJ.

50.2.1.1.1* Cooking equipment that has been listed in accordance with ANSI/UL 197, *Standard for Commercial Electric Cooking Appliances*, or an equivalent standard for reduced emissions shall not be required to be provided with an exhaust system. [**96:**4.1.1.1]

ANSI/UL 197, *Standard for Commercial Electric Cooking Appliances,* addresses commercial electric cooking appliances rated 600 volts or less, intended for indoor use, and intended for use in accordance with *NFPA 70®, National Electrical Code®*. It also covers coffee makers, conductive cookers, food warmers, fryers, griddles, steam kettles, steam cookers, nut warmers, popcorn machines, ranges, utensil warmers, and other appliances found in commercial kitchens, restaurants, or other business establishments where food is dispensed.

For valid conclusions, it is imperative to conduct the evaluation while the equipment is being operated at an airflow of 500 cfm (0.236 m^3/s), since lower and higher airflow rates would likely produce unreliable results. This airflow rate was determined after a comprehensive research project conducted by ASHRAE in the early 2000s generated a report titled "Effects of Air Velocity on Grease Deposition in Exhaust Ductwork."

A.50.2.1.1.1 As referenced in ANSI/UL 197, some products evaluated using the emission test procedure EPA 202, as described in ANSI/UL 710B, are listed in the UL directory under the category KNLZ, Commercial, with Integral Systems for Limiting the Emission of Grease-laden Air. [**96:**A.4.1.1.1]

50.2.1.1.2 The listing evaluation of cooking equipment covered by 50.2.1.1.1 shall demonstrate that the grease discharge at the exhaust duct of a test hood placed over the appliance shall not exceed 0.00018 oz/ft^3 (5 mg/m^3) when operated with a total airflow of 500 cfm (0.236 m^3/s). [**96:**4.1.1.2]

50.2.1.2 All such equipment and its performance shall be maintained in accordance with the requirements of this chapter during all periods of operation of the cooking equipment. [**96:**4.1.2]

Δ **50.2.1.3** The following equipment shall be kept in working condition:

(1) Cooking equipment
(2) Hoods
(3) Ducts (if applicable)
(4) Fans
(5) Fire-extinguishing equipment
(6) Special effluent or energy control equipment

[**96:**4.1.3]

50.2.1.3.1 Maintenance and repairs shall be performed on all components at intervals necessary to maintain good working condition. [**96:**4.1.3.1]

Maintenance is performed predominantly to create an acceptable level of confidence in the performance of the equipment being maintained. Maintenance schedules often include inspection of components, which provides an opportunity to discover components needing repair. Routine maintenance and repairs keep the equipment operable in a safe and efficient manner.

50.2.1.4 All airflows shall be maintained. [**96:**4.1.4]

Airflow is important for two reasons. First, airflow is a critical component in the process of effectively filtering grease from the exhaust during cooking operations. Second, airflow provides an important cooling feature when it continues after an extinguishing agent is discharged, because it removes residual heat from the appliances and from the protected surfaces.

Most fire officials do not feel that air movement caused by the continued running of an exhaust system fan significantly affects fire behavior. The slight additional risk is far outweighed by the benefit of the additional cooling that is achieved when the exhaust fan continues to run. With modern extinguishing systems relying on no "reflash" on the cooking surfaces, shutting off fuel and removing residual heat are important evolutions.

50.2.1.5 The responsibility for inspection, testing, maintenance, and cleanliness of the ventilation control and fire protection of the commercial cooking operations, including cooking appliances, shall ultimately be that of the owner of the system, provided that this responsibility has not been transferred in written form to a management company, tenant, or other party. [**96:**4.1.5]

This requirement states that the responsibility for the systems is that of the system owner. This responsibility can only be transferred in written form to other parties, including a tenant or a management company. It is important for building owners and tenants to understand who will have this responsibility where a space with an existing kitchen exhaust system is leased.

The phrase "including cooking appliances" was added to the 2017 edition of NFPA 96 to emphasize that, in addition to the owner taking responsibility for the inspection, testing, maintenance, and cleanliness of exhaust systems and fire protection systems, the owner is responsible for maintaining the cooking appliances to comply with the standard.

50.2.1.6* All solid fuel cooking equipment are required to comply with the requirements of Chapter 14 of NFPA 96. [**96:**4.1.6]

A.50.2.1.6 When solid fuel is burned in cooking operations, increased quantities of carbon, creosote, and grease-laden vapors are produced that rapidly contaminate surfaces, produce airborne sparks and embers, and are subject to significant flare-ups. Also, solid fuel cooking requires fuel storage and handling and produces ash that requires disposal. For these reasons, solid fuel cooking operations are required to comply with Chapter 14 of NFPA 96. [**96:**A.4.1.6]

Solid fuel cooking equipment has the added consequence of creating by-products beyond grease and smoke, which might in themselves be hazards. In the case of wood fuel, an added by-product is creosote. Other solid fuels might contain other by-products, such as paraffin and tar, which might need to be addressed.

50.2.1.7 Multi-tenant applications shall require the concerted cooperation of design, installation, operation, and maintenance responsibilities by tenants and by the building owner. [**96:**4.1.7]

50.2.1.8 All interior surfaces of the exhaust system shall be accessible for cleaning and inspection purposes. [**96:**4.1.8]

Since the continued safe operation of commercial cooking depends on inspection and routine cleaning, access needs to be provided to the interior areas that require inspection and cleaning.

Δ **50.2.1.9*** Cooking equipment used in fixed, mobile, or temporary concessions, such as trucks, buses, trailers, pavilions, tents, or any form of roofed enclosure, shall comply with NFPA 96. [**96:**4.1.9]

A.50.2.1.9 The AHJ can exempt temporary facilities, such as a tent, upon evaluation for compliance to the applicable portions of NFPA 96 or this *Code*.

Although it might not be practical to enforce all requirements of NFPA 96 in temporary facilities, the AHJ should determine that all necessary provisions that affect the personal safety of the occupants are considered. [**96:**A.4.1.9]

Enforcement of the requirements for temporary installations, such as those found in pavilions, outdoor carnivals, and temporary concessions, is important. The *Code* recognizes that the criterion established has been done with much forethought and deliberation. The requirement is believed to be the most all-encompassing yet prudent means of mitigating the known hazards inherent in tents and temporary installations. Enforcing these rules in some operations but not enforcing them in others, or adopting the regulations and then not implementing them, at least in part, merely because of the untraditional arrangement and nature of temporary installations, such as those found in buses, tents, and food trucks, would not be logical.

Many AHJs have developed specific guidelines to address temporary arrangements within their jurisdictions, such as temporary venues, including carnivals and mobile street vendors. The provisions provide the AHJ with some latitude as to which provisions they require to be enforced and to what degree, based on the circumstances in each individual instance or as jurisdictional policy for all temporary cooking arrangements. See Section 50.7 for more information on mobile and temporary cooking operations.

50.2.2* Clearance.

A.50.2.2 See Figure A.50.2.2(a) through Figure A.50.2.2(h) for clarification of the appropriate clearances required in 50.2.2. [**96:**A.4.2]

The exhaust system for commercial cooking equipment is primarily composed of a hood, ductwork, and a fan; it can also include special control equipment, such as grease extraction devices and odor control devices, through which the exhaust air flows. All this equipment is subject to the requirements of 50.2.2, unless a specific listing alters the clearances.

The issue of clearance from cooking equipment to combustible material is particularly important to prevent fires from spreading. Fires that burn in ducts can reach very high temperatures. Extremely hot temperatures in a duct can create a large amount of radiant heat on the outside of the duct even where the duct is not compromised. The radiant heat has the potential to ignite combustible materials and start fires in the combustible concealed spaces of a building. Maintaining a clearance from the duct to combustible and limited-combustible materials is intended to reduce this risk. Exhibit 50.1 shows an example of a hood with near zero clearance to noncombustible construction.

Exhibit 50.1

Example of near zero clearance to noncombustible construction.

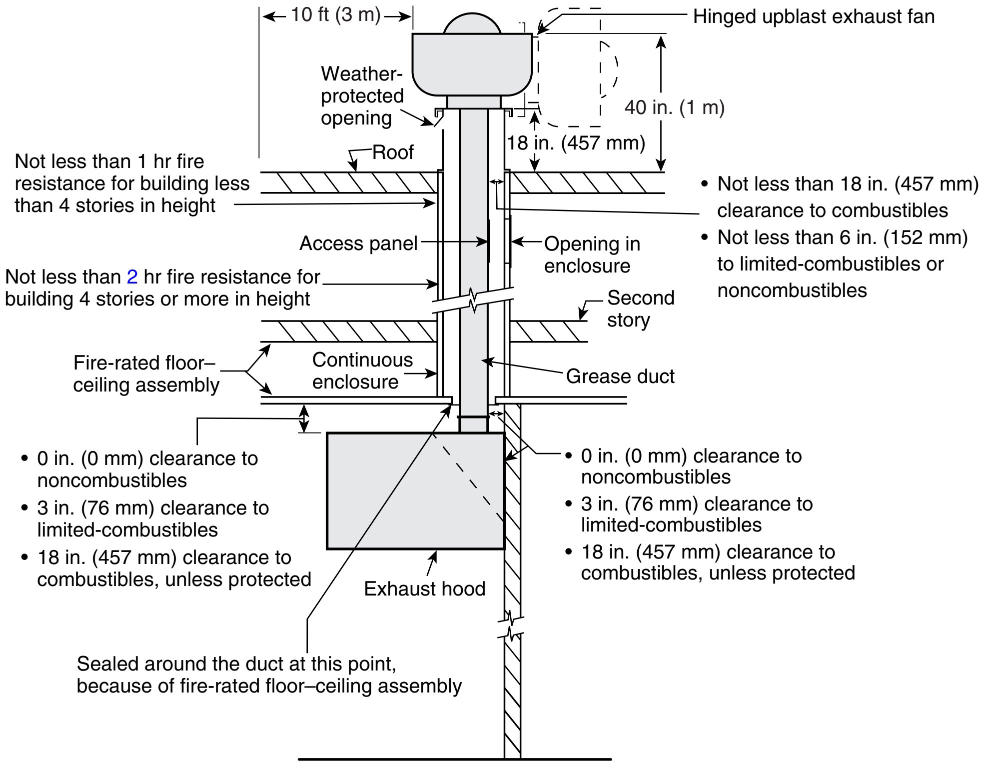

FIGURE A.50.2.2(a) *Typical Section View for Building with Two Stories or More with Fire-Rated Floor–Ceiling Assembly. [**96:**Figure A.4.2(a)]*

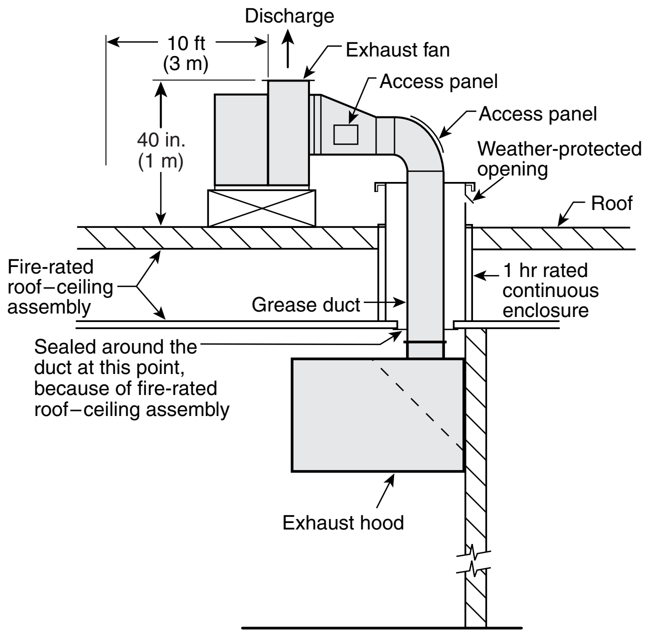

*FIGURE A.50.2.2(b) Typical Section View for One-Story Building with Fire-Rated Roof–Ceiling Assembly. [Clearances given in Figure A.50.2.2(a) apply also to this drawing.] [**96:**Figure A.4.2(b)]*

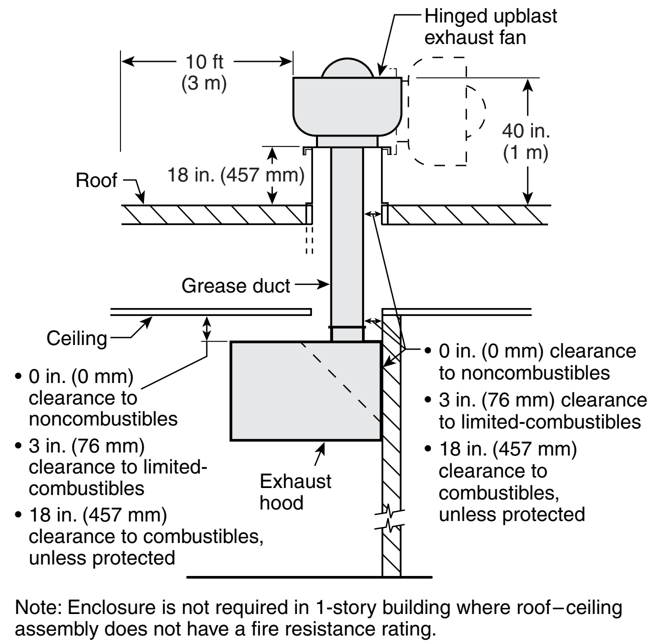

*FIGURE A.50.2.2(d) Typical Section View for One-Story Building Without Fire-Rated Roof–Ceiling Assembly. [**96:**Figure A.4.2(d)]*

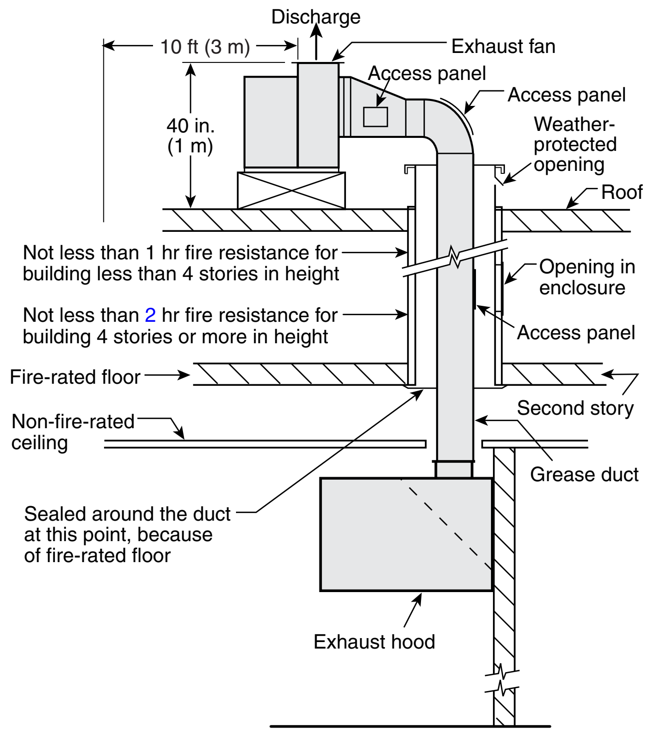

*FIGURE A.50.2.2(c) Typical Section View for Building with Two Stories or More with Non-Fire-Rated Ceiling and Fire-Rated Floor. [Clearances given in Figure A.50.2.2(a) apply also to this drawing.] [**96:**Figure A.4.2(c)]*

While the clearances specified in Section 4.2 of NFPA 96 are directly related to construction requirements, the clearances should still be observed in the ongoing operational life of the system. Placing combustible boxes on top of a hood or directly against the side of it, for instance, can present the very same hazards discussed in the preceding paragraph.

50.2.2.1* Where enclosures are not required, hoods, grease removal devices, exhaust fans, and ducts shall have a clearance of at least 18 in. (457 mm) to combustible material, 3 in. (76 mm) to limited-combustible material, and 0 in. (0 mm) to noncombustible material. [**96:**4.2.1]

N **A.50.2.2.1 Measurement of Clearance.** The measurement of clearance to combustible or limited-combustible material is intended to be measured from the closest point of the exhaust system component to that material. Example: The clearance where ceramic tile is installed over gypsum board that extends behind the hood should be measured from the hood to the gypsum board. Placing a noncombustible material over a combustible or limited-combustible material does not permit a zero clearance installation. [**96:**A.4.2.1]

For the 2017 edition of NFPA 96, new annex material was added to clarify how to measure the distances given in 50.2.2.1. In addition, it is important to recognize that the distance specified in this requirement is intended to apply in every direction from the hoods, grease removal devices, exhaust fans, and ducts to the combustible, limited-combustible, and noncombustible materials.

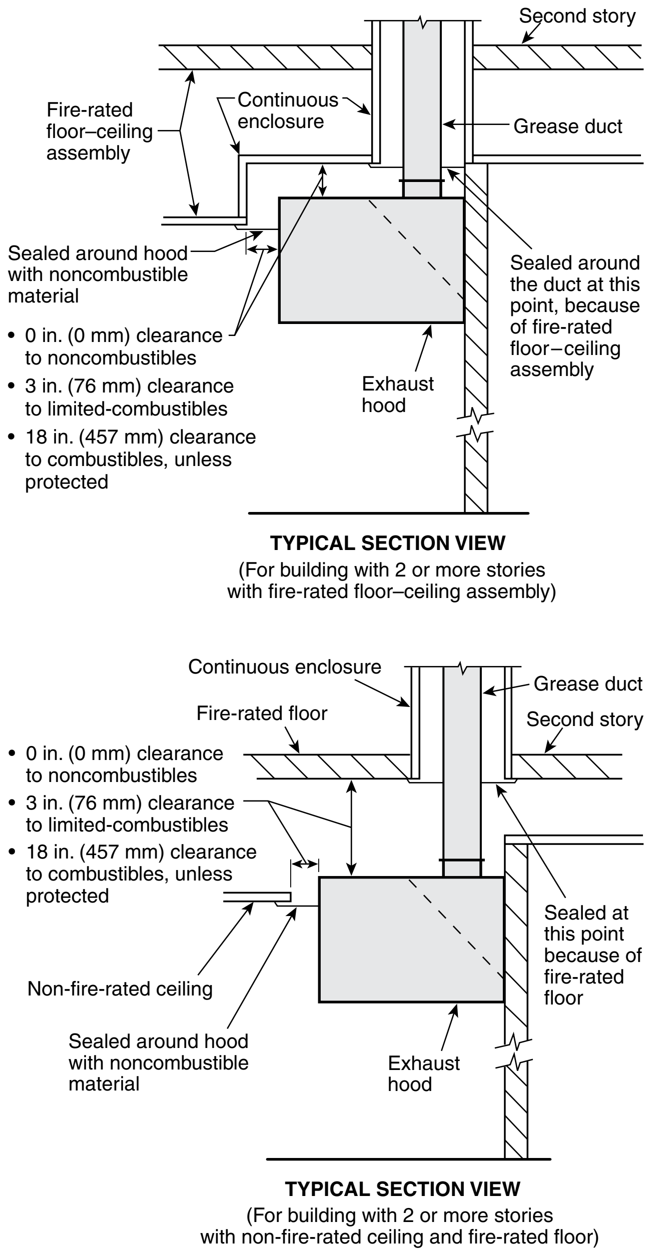

***FIGURE A.50.2.2(e)** Detail Drawings Showing Hoods Penetrating Ceilings. [**96:**Figure A.4.2(e)]*

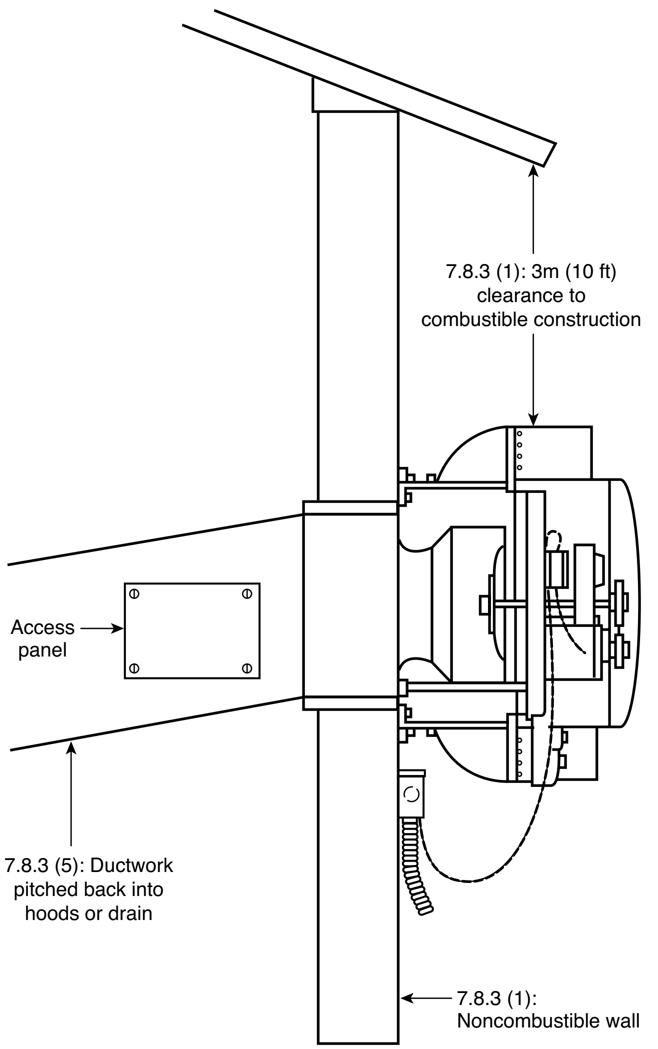


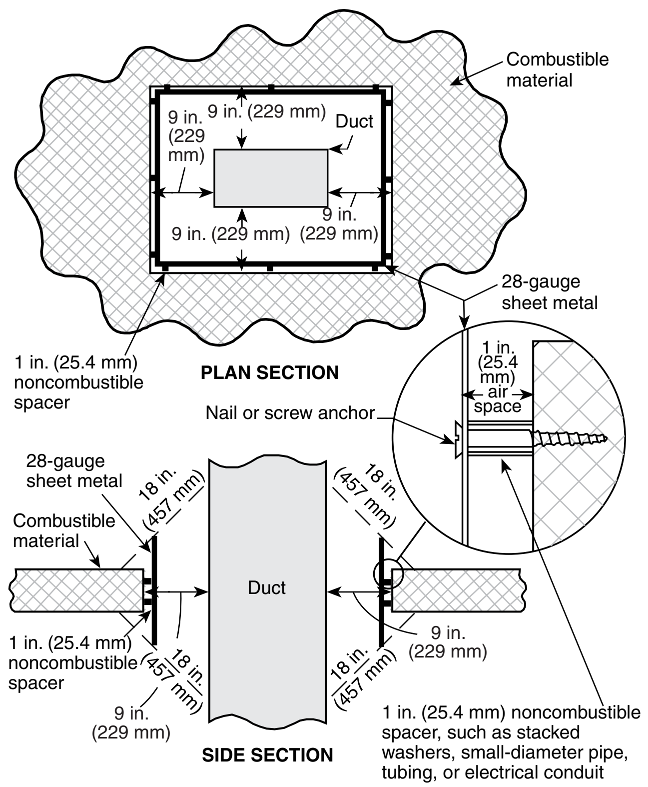
N ***FIGURE A.50.2.2(f)** Wall Mounted Fan. [**96:**Figure A.4.2(f)]*

50.2.2.2 Where a hood, duct, or grease removal device is listed for clearances less than those required in 50.2.2.1, the listing requirements shall be permitted. [**96:**4.2.2]

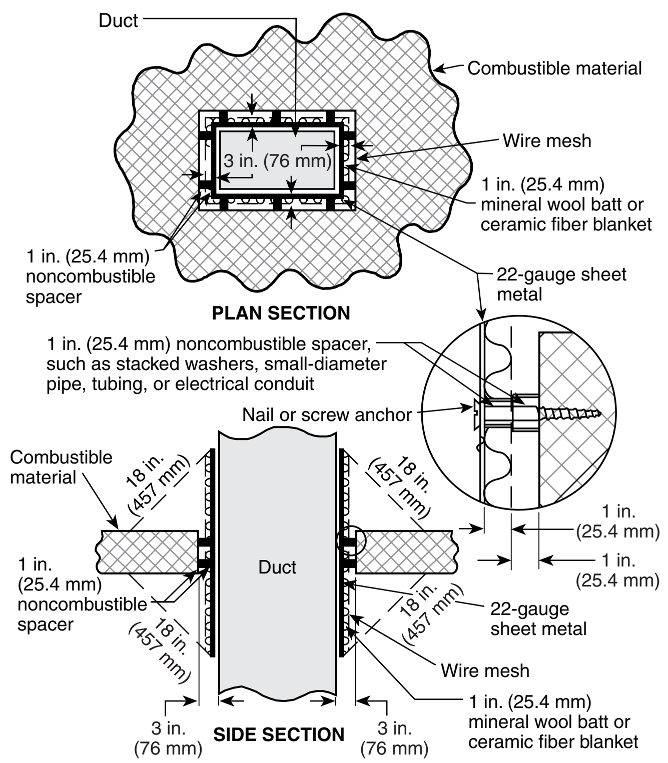
50.2.2.3 Clearance Reduction.

If the hood, duct, or grease removal equipment is not listed for a reduction of the clearances established, the clearances could still be reduced by the installation of a clearance reduction system as detailed in 50.2.2.3.

In practical terms, normally an insulating blanket is built into the back wall of the hood in a special cavity that permits the hood to be directly mounted to a combustible wall while holding the active back wall of the hood at the specified 3 in. (76 mm) clearance from the wall. Similar insulated panels are usually installed on the wall above the hood to provide the same clearance from the exhaust duct to the wall. A three-sided panel is installed around the duct and connected to the ends of the insulated wall panel to provide a decorative chase to hide the duct. Within an attic space, where a chase is not required, all combustible structural materials (joists, trusses, or rafters) within 18 in. (457 mm) of the ductwork must be protected by one of the methods for reducing clearances to combustibles. Some restaurants build kitchen walls and ceiling and roof structures with noncombustible materials, making it unnecessary to provide minimum clearances from the duct to such structures.



△ *FIGURE A.50.2.2(g) Example of Clearance Reduction System: 9 in. (229 mm) Clearance to Combustible Material. [**96:**Figure A.4.2(g)]*



△ *FIGURE A.50.2.2(h) Example of Clearance Reduction System: 3 in. (76 mm) Clearance to Combustible Material. [**96:**Figure A.4.2(h)]*

Where exposed ducts are run through an attic space (whether or not the construction is combustible) and there is any likelihood that the attic space will be used for storage, a good practice is to put a strong metal guard around all ductwork at a distance of at least 18 in. (457 mm). This guard keeps stored combustibles safely away from the ductwork while still allowing visual inspection of the ductwork.

50.2.2.3.1 Where a clearance reduction system consisting of 0.013 in. (0.33 mm) (28 gauge) sheet metal spaced out 1 in. (25 mm) on noncombustible spacers is provided, there shall be a minimum of 9 in. (229 mm) clearance to combustible material. [**96:**4.2.3.1]

50.2.2.3.2 Where a clearance reduction system consisting of 0.027 in. (0.69 mm) (22 gauge) sheet metal on 1 in. (25 mm) mineral wool batts or ceramic fiber blanket reinforced with wire mesh or equivalent spaced 1 in. (25 mm) on noncombustible spacers is provided, there shall be a minimum of 3 in. (76 mm) clearance to combustible material. [**96:**4.2.3.2]

50.2.2.3.3 Where a clearance reduction system consisting of a *listed* and *labeled* field-applied grease duct enclosure material, system, product, or method of construction specifically evaluated for such purpose in accordance with ASTM E2336, the required clearance shall be in accordance with the listing. [**96:**4.2.3.3]

Paragraph 50.2.2.3.3 clarifies that listed and labeled systems (permitted by Section 4.3 of NFPA 96), which are also tested and approved for their clearance to combustibles, can be installed in accordance with their listings.

Manufacturers of field-applied grease duct enclosure systems have, as part of their listings for each system, an allowable clearance from the outside of the enclosure system to adjacent combustibles. They achieve this clearance based on the type, quantity, and method of installation of the protective enclosure materials, and test them in accordance with ASTM E2336, *Standard Test Methods for Fire Resistive Grease Duct Enclosure Systems*. ASTM E2336 is designed to evaluate for zero clearance, and most field-applied grease duct enclosure system manufacturers have listings for zero clearance.

The materials are routinely used as an option for reducing clearances, particularly in cases where a limited amount of space is available for other means of protection. Another typical use is in a one-story restaurant where no rated wall/ceiling is being penetrated, but field-applied protection is installed because of the proximity of the grease duct to adjacent combustible construction.

50.2.2.3.4 Zero clearance to limited-combustible materials shall be permitted where protected by one of the following:

(1) Metal lath and plaster
(2) Ceramic tile
(3) Quarry tile
(4) Other noncombustible materials or assembly of noncombustible materials that are listed for the purpose of reducing clearance
(5) Other materials and products that are listed for the purpose of reducing clearance

[**96:**4.2.3.4]

The requirement in 50.2.2.3.4 permits the materials listed to be laid over the limited-combustible materials to allow for reduced clearance. The clearance reduction systems covered in 50.2.2.3.1 through 50.2.2.3.3 provide clearance reduction to combustible material.

50.2.3 Drawings. A drawing(s) of the exhaust system installation along with copies of operating instructions for subassemblies and components used in the exhaust system, including electrical schematics, shall be kept on the premises. [**96:**4.6]

50.2.4 AHJ Notification. If required by the AHJ, notification in writing shall be given of any alteration, replacement, or relocation of any exhaust or extinguishing system or part thereof or cooking equipment. [**96:**4.7]

50.3 Protection of Coverings and Enclosure Materials

50.3.1 Measures shall be taken to prevent physical damage to any covering or enclosure material. [**96:**7.7.3.1]

The primary objective is to maintain the protection afforded by the covering or enclosure by using whatever safeguards are necessary to minimize damage to enclosure materials. Where daily operations or another occurrence does cause damage to the covering, 50.3.2 requires that it be repaired or restored so as to meet its initial listing and fire resistance rating.

50.3.2 Any damage to the covering or enclosure shall be repaired, and the covering or enclosure shall be restored to meet its intended listing and fire resistance rating and to be acceptable to the AHJ. [**96:**7.7.3.2]

50.3.3 In the event of a fire within a kitchen exhaust system, the duct, the enclosure, and the covering directly applied to the duct shall be inspected by qualified personnel to determine whether the duct, the enclosure, and the covering directly applied to the duct are structurally sound, capable of maintaining their fire protection functions, suitable for continued operation, and acceptable to the AHJ. [**96:**7.7.3.3]

If a fire occurs within the kitchen exhaust system, the entire system — including the duct, its enclosure, and other items associated with the exhaust system — must be inspected by a qualified person before being returned to operation. Before permitting operation of a system that has been involved in a fire, the AHJ should review the report submitted by the qualified person for the structural soundness of the duct and enclosure and should ask questions such as the following:

1. Is the system safe for operation?
2. Has the suppression system been recharged?
3. Is the entire system capable of its original fire protection function and protection?

50.3.4 Listed grease ducts shall be installed in accordance with the terms of the listing and the manufacturer's instructions. [**96:**7.7.3.4]

50.4 Fire-Extinguishing Equipment

50.4.1 Prior to installation of any fire-extinguishing system, construction documents shall be reviewed and approved by the AHJ.

See Section 1.14 for plan review requirements.

50.4.2 Permits. Permits, where required, shall comply with Section 1.12.

See 1.12.8 for information on permits. Permits are required for installation, modification, or removal from service of any automatic fire suppression system.

50.4.3 General Requirements.

50.4.3.1 Fire-extinguishing equipment for the protection of grease removal devices, hood exhaust plenums, and exhaust duct systems shall be provided. [**96:**10.1.1]

Fire-extinguishing equipment includes both automatic fire-extinguishing systems and portable fire extinguishers. Any pre-engineered systems provided for the protection of grease removal devices, hoods, duct systems, and cooking equipment must be listed for such use.

50.4.3.2* Cooking equipment that produces grease-laden vapors and that might be a source of ignition of grease in the hood, grease removal device, or duct shall be protected by fire-extinguishing equipment. [**96:**10.1.2]

A.50.4.3.2 Examples of cooking equipment that produce grease-laden vapors include, but are not limited to, deep fat fryers, ranges, griddles, broilers, woks, tilting skillets, and braising pans. [**96:**A.10.1.2]

While 50.4.3.1 requires the protection of the exhaust system components without any stipulations, 50.4.3.2 requires the protection of cooking equipment that produces grease-laden vapors, which can be a source of ignition for grease in those exhaust system components. If the provisions of NFPA 96 have been applied to this point, based on the application requirements of Section 4.1 of NFPA 96, then the equipment is more than likely going to require protection by a fire-extinguishing system.

N **50.4.3.3** Fume incinerators, thermal recovery units, air pollution control devices, or other devices installed in the exhaust duct, shall be protected by an automatic fire-extinguishing system. [**96:**10.1.3]

50.4.4 Types of Equipment.

50.4.4.1 Fire-extinguishing equipment shall include both automatic fire-extinguishing systems as primary protection and portable fire extinguishers as secondary backup. [**96:**10.2.1]

The type of fire extinguisher selected should be compatible with the fire-extinguishing agent in the extinguishing system. Fire-extinguishing agents form a foam layer over the burning surface that can separate the fuel from the needed oxygen. If a fire extinguisher is discharged over the surface, it can have an adverse effect on the maintenance of that foam layer, causing a breakdown of the foam layer and increasing the possibility of the fuel re-igniting.

It is important to recognize that the fire suppression system built into a kitchen exhaust hood serves as the primary line of defense in the event of a fire. The required portable fire extinguisher serves as a backup to the fixed fire-extinguishing system and is not the preferred method of extinguishment. However, some history shows that the availability of a required portable fire extinguisher has led to the quick extinguishment of small fires on cooking surfaces, other than deep-fat fryers, prior to the activation of the fixed fire-extinguishing system. The following is the typical appropriate sequence of actions upon discovery of a fire in a restaurant that is beyond the incipient stage:

1. Operate the manual actuator for the hood fire suppression system; do NOT wait for automatic operation.
2. Call the fire department.
3. Evacuate the building.
4. Until the fire department arrives, a person(s) properly trained in the use and limitations of portable extinguishers should stand by with the proper portable extinguisher in the event of a reflash.

Upon activation of the fire-extinguishing system, all sources of fuel and electrical power that produce heat to all equipment requiring protection by that system are automatically shut off. If these heat-producing appliances were not shut down, they would contribute to the fire problem, possibly allowing ignition or re-ignition. Since portable fire extinguishers do not shut off these heat sources, they should be used only after the system has activated.

50.4.4.2* A placard shall be conspicuously placed near each Class K extinguisher that states that the fire protection system shall be activated prior to using the fire extinguisher. [**96:**10.2.2]

A.50.4.4.2 NFPA 10, Annex A, provides recommendations for placards. [**96:**A.10.2.2]

In an effort to coordinate with NFPA 17A, *Standard for Wet Chemical Extinguishing Systems*, "Class K" was added to this requirement in the 2017 edition of NFPA 96 to clearly identify which

Exhibit 50.2

Required placard located directly above the fire extinguisher.

extinguishers need a placard. Exhibit 50.2 shows an example of a placard located directly above an extinguisher.

50.4.4.2.1 The language and wording for the placard shall be approved by the AHJ. [**96:**10.2.2.1]

Exhibit 50.3(a) and Exhibit 50.3(b) show the recommended wording for the Class K placard. This is the language suggested in NFPA 10, *Standard for Portable Fire Extinguishers*. The recommended size for the placard is 11 in. × 7 ⅝ in. (279 mm × 194 mm).

50.4.4.3* Automatic fire-extinguishing systems shall comply with ANSI/UL 300, *Standard for Fire Testing of Fire Extinguishing Systems for Protection of Restaurant Cooking Areas*, or other equivalent standards and shall be installed in accordance with the requirements of the listing. [**96:**10.2.3]

A.50.4.4.3 ANSI/UL 300 primarily addresses the method of fire testing for self-contained chemical extinguishing systems commonly referred to as pre-engineered systems. ANSI/UL 300 has been identified as a baseline for testing fire-extinguishing systems intended for the protection of commercial cooking–related hazards. Additional equivalent testing standards can and have been written for other types of fire-extinguishing systems not considered pre-engineered that demonstrate equivalent fire testing severity to the ANSI/UL 300 test standard. Current examples include, but are not limited to, ANSI/UL 199, UL Subject 199B, UL Subject 199E, and ANSI/UL 710B. [**96:**A.10.2.3]

Dry and wet chemical fire-extinguishing systems provide an agent that develops a blanket of soapy foam in reaction to the grease (a process called saponification) to keep the combustible surface separated from the oxygen. The change in the type of cooking media from animal fats to vegetable oils and the advent of more energy-efficient cooking equipment have had a dramatic effect on the ability of dry chemical extinguishing

Exhibit 50.3(a)

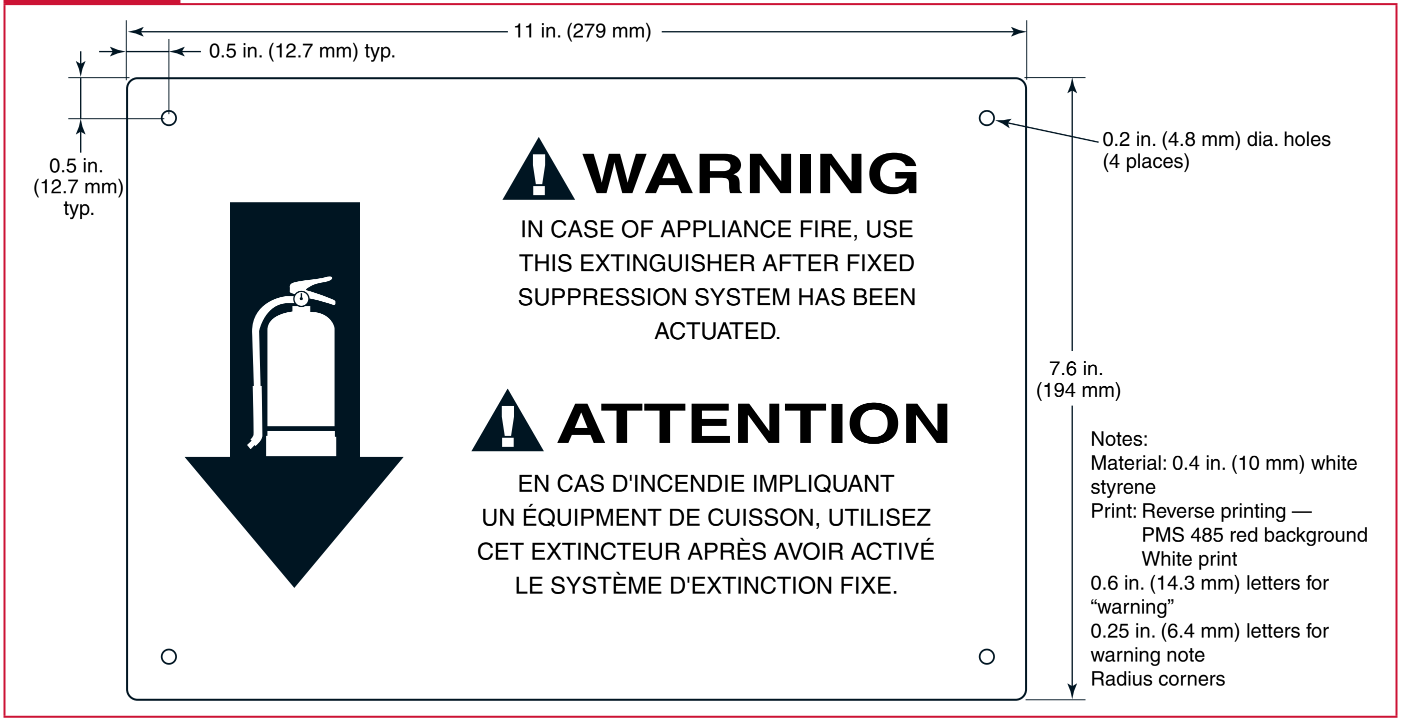
Exhibit 50.3(b)



Typical Class K placard in English and French. [Source: NFPA 10, 2016 edition, Figure A.5.5.5.3(b).]

agents to develop and maintain a layer of extinguishing agent over the cooking oil. This change in fire hazard contributed to the development of ANSI/UL 300, *Standard for Fire Testing of Fire Extinguishing Systems for Protection of Commercial Cooking Equipment,* which contains provisions that only wet chemical extinguishing systems have been able to meet.

ANSI/UL 300 is a fire test protocol for the listing of pre-engineered extinguishing systems. In addition to establishing fire test methods, ANSI/UL 300 includes fire tests for evaluating the capability of pre-engineered systems for the protection of cooking appliances, as well as the ability to protect hoods, plenums, and ducts. The test standard takes into consideration all the special characteristics of pre-engineered systems, including the limited supply of extinguishing agent. Since there is a limited quantity of agent in pre-engineered systems that is discharged over a short period of time, these systems are designed to quickly extinguish the test fires. The severity of the test fires is intended to far exceed anything that is likely to be encountered in the field. An example of one such system is provided in Exhibit 50.4.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, is commonly accepted as an equivalent standard to ANSI/UL 300. Automatic sprinkler systems installed in accordance with NFPA 13 for the protection of commercial cooking appliances are designed to discharge large quantities of water over long periods of time, thereby controlling the fire by cooling it and wetting the surrounding combustible materials. Additionally, NFPA 13 requires that sprinklers or automatic spray nozzles be specifically listed for the protection of fryers.

Other systems, referred to as engineered systems, must be custom engineered for each application. These systems have been designed primarily for other industrial and commercial food preparation applications involving materials with similar hazards, such as potato chip manufacturing and bulk bakery ovens, and have been applied to a limited degree to some restaurant cooking operations with varied success and acceptance. They can be used successfully in restaurant applications if their design criteria and performance limits are clearly understood and applied. The applicable NFPA extinguishing system standard for each system should be read in detail before it is applied. Some of the more common concerns about system usage are addressed in subsequent commentary sections.

Exhibit 50.4

Hood suppression system. (Courtesy of Tyco Fire Protection Products)

50.4.4.3.1* In existing dry or wet chemical systems not in compliance with ANSI/UL 300, the fire-extinguishing system shall be made to comply with 50.4.4.3 when any of the following occurs:

(1) The cooking medium is changed from animal oils and fats to vegetable oils.
(2) The positioning of the cooking equipment is changed.
(3) Cooking equipment is replaced.
(4) The equipment is no longer supported by the manufacturer.

[**96:**10.2.3.1]

The AHJ needs to evaluate the impact a change has on the overall operation. Insignificant changes in the position of some equipment and replacement of equipment with equipment of identical characteristics do not necessarily cause a code-compliant arrangement to become concurrently nonconforming.

One common question is: Are existing, unmodified extinguishing systems, installed prior to the development of ANSI/UL 300, required to be replaced with an extinguishing system that is compliant with ANSI/UL 300?

There have been safety concerns in the field that there was a potential for the language of 50.4.4.3.1 in previous editions to be misunderstood and misapplied. Past text implied that previously listed dry chemical systems could be used only with animal oils and fats, but it was not clearly stated in the requirement. Paragraph 50.4.4.3.1 was revised to provide a clear requirement that can be enforced without question. The new text makes it clear that where the cooking media is vegetable oil the system must comply with ANSI/UL 300.

Commercial cooking operations historically have been protected with pre-engineered extinguishing systems that use an extinguishing agent that chemically reacts with cooking oil to create a thick blanket of foam to suffocate the fire and prevent the escape of combustible vapors, thereby preventing reignition (saponification). The earlier versions of ANSI/UL 300 for listing pre-engineered systems were not rigorous enough to reflect typical modern day appliances and the cooking oils used in them. The fire test standard was updated to require using actual appliances with vegetable oil. Dry chemical systems that passed the old test are not able to pass the new test protocol. Only wet chemical systems are able to pass the new fire tests and can be listed for this application.

Unfortunately, only part of the problem was solved. Although dry chemical systems can no longer be listed for the protection of cooking appliances and associated hood and duct systems, the listing standard did not impact existing installations. Similar to other listing standards, it affects only the listing of products.

Dry chemical fire-extinguishing systems are now deemed to be inadequate for the protection of cooking appliances as well as the ability to protect hoods, plenums, and ducts; therefore, these systems need to be removed and replaced with appropriate systems. Only systems that meet the currently accepted level of safety established by ANSI/UL 300 or an equivalent standard are permitted to remain in place.

As written today, all automatic fire-extinguishing systems are required to comply with ANSI/UL 300 or other equivalent standards and to be installed in accordance with the requirements of the listing. Existing systems must be brought up to compliance with ANSI/UL 300 effective as of January 1, 2014.

A.50.4.4.3.1 A change from rendered animal fat to cooking oil likely will increase auto-ignition temperatures, and a change to insulated energy-efficient cooking equipment that does not allow ease of cooling likely will result in difficulties sustaining extinguishment with systems not complying with UL 300 or equivalent standards. [**96:**A.10.2.3.1]

50.4.4.3.2 All existing fire-extinguishing systems shall meet the requirements of 50.4.4.3. [**96:**10.2.3.2]

Since the effective date of January 1, 2014, specified in the 2014 edition of ANSI/UL 300, has passed, there is no need to identify a date. As of January 1, 2014, all systems (existing and new) are required to comply with ANSI/UL 300 or an equivalent standard.

50.4.4.4 Grease removal devices, hood exhaust plenums, exhaust ducts, and cooking equipment that are not addressed in ANSI/UL 300 or other equivalent test standards shall be protected with an automatic fire-extinguishing system(s) in accordance with the applicable NFPA standard(s), all local building and fire codes, and the fire extinguishing system's manufacturer's recommendations and shall be approved by the AHJ. [**96:**10.2.4]

ANSI/UL 300 contains testing criteria for a wide variety of cooking equipment and media found in restaurants. However, it does not cover all cooking equipment. Therefore, the basic requirement is that a fire-extinguishing system that has been tested to ANSI/UL 300 be used to protect cooking equipment and its associated cooking media. If the cooking equipment and its cooking media in question (such as non-restaurant-type equipment) are not addressed in ANSI/UL 300, other types of fire-extinguishing systems might be considered.

50.4.4.5 Automatic fire-extinguishing equipment provided as part of listed recirculating systems shall comply with ANSI/UL 710B, *Outline of Investigation for Recirculating Exhaust System*. [**96:**10.2.5]

Δ **50.4.4.6** Automatic fire-extinguishing systems shall be installed in accordance with the terms of their listing, the manufacturer's instructions, and the following standards where applicable:

(1) NFPA 12

Carbon dioxide extinguishing systems, as covered by NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*, require a concentration of carbon dioxide on top of the cooking oil in order to successfully protect against fire reflash. Achieving this concentration usually requires that all exhaust fans be shut off (even at adjacent hoods) and that the air-conditioning and ventilation also be shut off. Even under these conditions, a concentration adequate to prevent reflash is difficult to maintain. These systems are seldom used in typical commercial cooking operations.

(2) NFPA 13

Water systems are still fairly common in certain restaurant cooking operations, but many of these systems are spray systems rather than sprinkler systems covered by NFPA 13, *Standard for the Installation of Sprinkler Systems*. Spray systems are used mostly for hood protection, where their primary application is for wash-down of the hood or for grease extraction. However, spray systems are beginning to be used with standard sprinklers for duct and appliance protection. Because spray systems are small systems, they are usually supplied by a kitchen water line rather than a true sprinkler line.

NFPA 13 requires that sprinkler systems provide a sprinkler every 10 ft (3 m) for exhaust duct protection and includes provisions for the duct system as it changes directions. Installation is typically more complex than for conventional commercial cooking fire protection equipment. Also, with sprinklers, possible freezing conditions have to be addressed where such weather can occur.

(3) NFPA 17

NFPA 17, *Standard for Dry Chemical Extinguishing Systems*, addresses both pre-engineered systems and engineered systems. While no dry chemical systems are currently listed to ANSI/UL 300, NFPA 17 is included on this list to permit the installation of an engineered dry chemical system or the possibility of a dry chemical pre-engineered system listed to ANSI/UL 300. Currently, no pre-engineered dry chemical systems are listed to ANSI/UL 300-2014. However, engineered systems have been applied in some customized cooking product lines and are more often applied in large industrial cooking operations. Paragraph 50.4.4.3.1 prohibits systems that are not listed to ANSI/UL 300-2005 to remain in place.

(4) NFPA 17A

NFPA 17A poses strict requirements regarding the pre-engineered wet chemical systems that are applied in restaurant operations. Both dry and wet chemical systems have had success where they have been applied, since they both provide the saponifying effect on top of the shortening that separates the chemical from the air. However, a wet chemical also has an extra feature that is significant. It has the cooling (heat absorption) effect that can add to extinguishing capability and reflash prevention capability.

(5) NFPA 750
[**96:**10.2.6]

NFPA 750, *Standard on Water Mist Fire Protection Systems*, provides requirements to standardize the design, installation, maintenance, and testing requirements for a water-based suppression system using spray (mist) to absorb heat, displace oxygen, or block radiant heat to control, suppress, or extinguish fires as required by the application.

50.4.4.7 Modifications to Existing Hood Systems.

The requirements in 50.4.4.7 apply directly to systems that are already in use. The provisions located here ensure that changes to the cooking appliances or cooking media or modifications on the hood or duct system do not reduce the level of safety from the point when the system was first designed.

50.4.4.7.1 Any abandoned pipe or conduit from a previous installation shall be removed from within the hood, plenum, and exhaust duct. [**96:**10.2.7.1]

Abandoned pipe or conduit creates surfaces for the accumulation of grease, which increases the fire load.

50.4.4.7.2 Penetrations and holes resulting from the removal of conduit or piping shall be sealed with listed or equivalent liquidtight sealing devices. [**96:**10.2.7.2]

The term *liquidtight* is defined as being constructed and performing in such a manner as to not permit the passage of any liquid through at any temperature. An example of a listed patch seal for patching unwanted holes without welding is shown in Exhibit 50.5.

Exhibit 50.5

Example of listed penetration device. (Courtesy of Brooks Equipment Company, Inc.)

50.4.4.7.3 The addition of obstructions to spray patterns from the cooking appliance nozzle(s) such as baffle plates, shelves, or any modification shall not be permitted. [**96:**10.2.7.3]

The distribution pattern for appliance nozzles is tested and listed only under specific conditions and does not include testing with objects that will obstruct the application of the extinguishing agent onto the cooking appliance.

50.4.4.7.4 Changes or modifications to the hazard after installation of the fire-extinguishing systems shall result in re-evaluation of the system design by a properly trained, qualified, and certified person(s). [**96:**10.2.7.4]

50.4.4.8 Hoods with Water Wash.

This heading was revised in the 2017 edition of NFPA 96 to include terminology that clarifies the difference between a basic water-wash system and one that is listed as a fire-extinguishing system. A *water-wash fire-extinguishing system* is a water-wash system that is listed as a fire-extinguishing system. These types of systems provide water spray for the exhaust plenum in addition to the hood's automatic fire suppression system. A *water-wash system* provides a pressurized spray of hot water and detergent to clean the hood in a timed cycle. Some water-wash systems have a fire mode option that provides water spray for the exhaust plenum when the system is in fire mode that is in addition to the hood's automatic fire suppression system.

Δ **50.4.4.8.1** Areas requiring protection in accordance with 50.4.3.1 shall be permitted to be protected by a water-wash system that is listed as a fire-extinguishing system in compliance with ANSI/UL 300 or other equivalent standards and installed in accordance with the requirements of its listing. [**96:**10.2.8.1]

50.4.4.8.2 Each such area not provided with a listed water-wash fire-extinguishing system shall be provided with a fire-extinguishing system listed for the purpose. [**96:**10.2.8.2]

50.4.4.8.3 The water supply for water-wash fire-extinguishing systems shall be permitted to be supplied from the domestic water supply when the minimum water pressure and flow are provided in accordance with the terms of the listing. [**96:**10.2.8.3]

50.4.4.8.4 The water supply for water-wash fire-extinguishing systems shall be controlled by a listed indicating valve. [**96:**10.2.8.4]

50.4.4.8.5 Where a separate fire-extinguishing system is used for protection of cooking equipment only, a water-wash fire-extinguishing system listed for protection of the grease removal device(s), hood exhaust plenum(s), exhaust duct(s), or combination thereof shall be provided with instructions and appropriate means for electrical interface for simultaneous activation. [**96:**10.2.8.5]

50.4.4.8.6 A water-wash system approved to be used for protection of the grease removal device(s), hood exhaust plenum(s), exhaust duct(s), or combination thereof shall include instructions and appropriate electrical interface for simultaneous activation of the water-wash system from an automatic fire-extinguishing system, where the automatic fire-extinguishing system is used for cooking equipment protection only. [**96:**10.2.8.6]

50.4.4.8.7 Where the automatic fire extinguishing system in accordance with NFPA 17A provides protection for the hood and duct in a fixed baffle hood containing a water-wash system, the water-wash system shall be made inoperable or delayed for a minimum of 60 seconds upon operation of the automatic fire-extinguishing system. [**96:**10.2.8.7]

The delay of at least 60 seconds is necessary to allow the extinguishing agent to chemically react with cooking oil to create a thick blanket of foam to suffocate the fire and prevent the escape of combustible vapors, thereby preventing reignition.

Δ **50.4.4.8.8** Grease removal devices, hood exhaust plenums, and exhaust ducts on hoods with water wash shall be permitted to be protected by a sprinkler system with an individual control valve if the design of the hood prevents the water from reaching the cooking appliances. [**96:**10.2.8.8]

Paragraph 50.4.4.8.8 was added to the *Code* as a means of providing coverage for many water-wash systems that currently lack protection for these areas. The text provides a solution to the challenge of existing fixed baffle hoods with water wash; previously, the omission of this coverage was allowed.

50.4.4.9 Water-Based Fire-Extinguishing System.

50.4.4.9.1 The water required for listed automatic fire-extinguishing systems shall be permitted to be supplied from the domestic water supply where the minimum water pressure and flow are provided in accordance with the terms of the listing. The water supply shall be controlled by a supervised water supply control valve. [**96:**10.2.9.1]

50.4.4.9.2 Where the water supply is from a dedicated fire protection water supply in a building with one or more fire sprinkler systems, separate indicating control valves and drains shall be provided and arranged so that the hood system and sprinkler systems can be controlled individually. [**96:**10.2.9.2]

Δ **50.4.4.10 Water Valve Supervision.** Valves controlling the water supply to listed water-wash fire-extinguishing systems, automatic fire-extinguishing systems, or both shall be listed indicating type of valve and shall be supervised open by one of the following methods:

(1) Central station, proprietary, or remote station alarm service
(2) Local alarm service that will cause the sounding of an audible signal at a constantly attended point
(3) Locking valves open
(4)* Sealing of valves and approved weekly recorded inspection

[**96:**10.2.10]

A.50.4.4.10(4) An approved weekly recorded inspection could consist of a log of entries that would display the date and time of each inspection and the initials of the person(s) conducting the visual inspection. Attaching the log to a clipboard and mounting it near the valve in question serves as a convenient reminder of the need to conduct the inspection. [**96:**A.10.2.10(4)]

50.4.5 Simultaneous Operation.

50.4.5.1 Fixed pipe extinguishing systems in a single hazard area *(see 3.3.44 of NFPA 96 for the definition of single hazard area)* shall be arranged for simultaneous automatic operation upon actuation of any one of the systems. [**96:**10.3.1]

The term *single hazard area* is defined in NFPA 96 as "where two or more hazards can be simultaneously involved in fire by reason of their proximity, as determined by the authority having jurisdiction." In general, a single hazard area is considered to be two or more adjacent hazards so close together that one could directly ignite the other; or two or more separate hazards connected by common ductwork through which a fire could pass to ignite the other hazard(s).

50.4.5.1.1 Hoods installed end to end, back to back, or both, or sharing a common ductwork, not exceeding 22.9 m (75 ft) in distance from the farthest hood, and having a grease-producing appliance(s) located under one or more of the hoods shall be considered a single hazard area requiring simultaneous automatic fire protection in all hoods and ducts. [**96:**10.3.1.1]

While the definition of *single hazard area* identifies it as an area determined by the AHJ, this section identifies a specific type of arrangement that must be protected as a single hazard area. Paragraph 50.4.5.1.1.1 identifies arrangement(s) that do not need to be treated as such.

N **50.4.5.1.1.1** In hoods that are installed end to end, back to back, or both, and that share a common ductwork, the ductwork beyond 22.9 m (75 ft) from the farthest hood shall be protected by an independent fire-extinguishing system with its own detection system or by a fire-extinguishing system that activates simultaneously with the fire-extinguishing system(s) protecting the hoods. [**96:**10.3.1.1.1]

Δ **50.4.5.1.2** Hoods installed end to end, back to back, or both that do not share a common exhaust duct and are separated by a wall(s) or other means to ensure that grease-laden vapors exhausted under one hood cannot propagate to the other hoods, the hoods' fire-extinguishing system(s) shall be independent and shall not be required to simultaneously discharge. [**96:**10.3.1.2]

N **50.4.5.1.3** Fume incinerators, thermal recovery units, air pollution control devices, or other devices installed in the exhaust duct shall not be required to comply with 50.4.5.1.1. [**96:**10.3.1.3]

50.4.5.2 Simultaneous operation shall not be required where the one fixed pipe extinguishing system is an automatic sprinkler system. [**96:**10.3.2]

Each of the sprinklers typically will have its own fusible link that will activate when the temperature of that link reaches a certain point. To require simultaneous operation would require complex arrangements, and that is not the intent of NFPA 96.

50.4.5.2.1 Where an automatic sprinkler system is used in conjunction with a water-based fire-extinguishing system served by the same water supply, hydraulic calculations shall consider both systems operating simultaneously. [**96:**10.3.2.1]

The introduction of water-based fire-extinguishing systems within commercial cooking hoods, potentially using the same water supply as the building's fire sprinkler system, requires consideration of simultaneous operation.

50.4.5.3 Simultaneous operation shall be required where a dry or wet chemical system is used to protect common exhaust ductwork by one of the methods specified in NFPA 17 or NFPA 17A. [**96:**10.3.3]

Simultaneous operation provides for common actuation of all fire suppression systems protecting the hazards in the single hazard area. The goal of this requirement is to cover all the components of the cooking operation to suppress a fire.

Arguments have been made against the simultaneous operation approach, especially with respect to chemical systems, which provide a limited supply of extinguishing agent. Some believe it is safer to discharge the chemical only in the areas where the fire is burning. If the fire then spreads to other areas, some remaining chemical is still available. When chemical is prematurely discharged, dry chemical tends to be carried out of the system by fan action, while wet chemical tends to drain out of the system; therefore, if a fire subsequently spreads, no agent remains to extinguish the spreading fire.

The concern regarding premature discharge of extinguishing agent led to the sequential or separate component fire suppression approach as an alternative to simultaneous discharge. This approach is especially effective and practical in the case of a manifold exhaust system in a large restaurant or when manifolding multiple types of restaurant exhaust systems in a food court of a shopping mall. In either case, simultaneous actuation of all systems is messy and expensive, especially in the case of a food court, where a real or an accidental discharge in one restaurant can result in multiple lawsuits from the affected restaurants due to premature actuation of adjacent fire protection systems.

NFPA 17 contains requirements for fixed pipe extinguishing systems using dry chemical agents for protection of restaurant hood, duct, and cooking appliance systems. Additionally, NFPA 17A contains requirements for fixed pipe extinguishing systems using wet chemical agents for protection of cooking equipment.

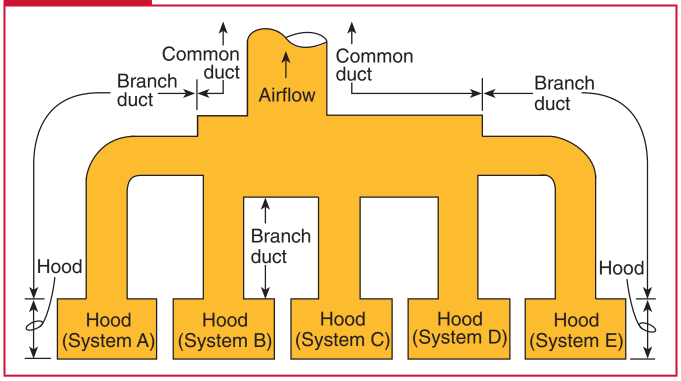
Alternative designs to simultaneous discharge are found in the annexes of NFPA 17 and NFPA 17A. These alternative systems segment the total manifold exhaust in different ways, all of which provide some backup protection in the common duct areas that permits some of the hoods or restaurants to continue operating while shutting down those that have experienced fire or those without a backup system in their common duct. These systems are a necessity for common design solutions for food courts with manifold exhaust systems and can be economical in large restaurants with multiple hoods on manifold exhaust systems. Exhibit 50.6 through Exhibit 50.9 illustrate various system configurations.

Example 1

A fire is detected by System A; its hood and branch duct are operated. Simultaneously, Systems B, C, D, and E are also actuated. All fuel or power to all protected appliances served by the common exhaust duct is shut off.

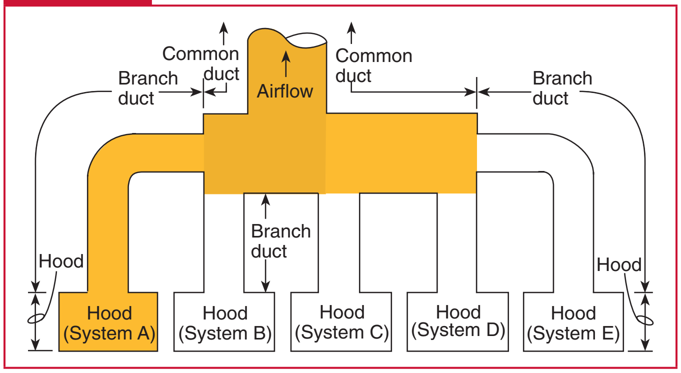
Upon operation of the common exhaust duct systems, the fuel or power to all protected appliances served by the common exhaust duct is shut off. The cooking appliance, hood, and branch duct systems provide protection in accordance with NFPA 17 and NFPA 17A. (See Exhibit 50.6.)

Exhibit 50.6



Simultaneous operation of all systems.

Exhibit 50.7



Simultaneous operation of a single cooking appliance, hood, or branch duct system and the system protecting the common duct.

Example 2

System 1, protecting the entire common exhaust duct, is separate from Systems A, B, C, D, and E. A fire is detected in System A. System A and System 1 operate simultaneously. Shutdown of all appliances protected by Systems A, B, C, D, and E is in accordance with NFPA 17. (See Exhibit 50.7.)

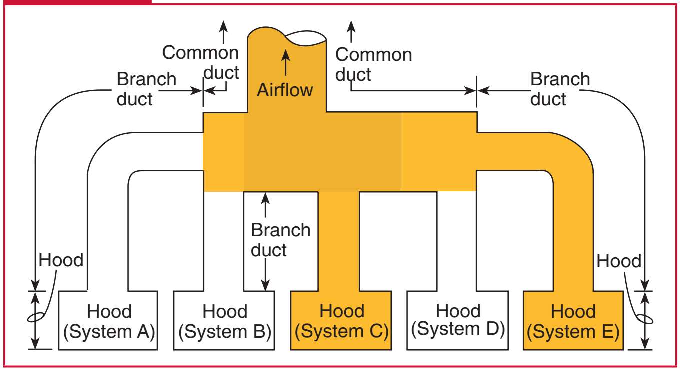
Example 3

System E also provides protection for the entire common exhaust duct. A fire is detected in System C. System C and System E operate simultaneously. Shutdown of all appliances protected by Systems A, B, C, D, and E is in accordance with NFPA 17. (See Exhibit 50.8.)

Example 4

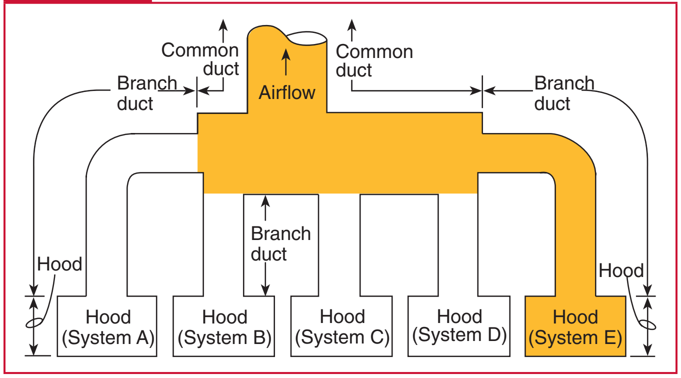
System E also provides protection for the entire common exhaust duct. A fire detected in System E will result in the actuation of System E only. Shutdown of all appliances protected by Systems A, B, C, D, and E is in accordance with NFPA 17. (See Exhibit 50.9.)

Exhibit 50.8



Simultaneous operation of two systems in which one also provides common duct protection.

Exhibit 50.9



Independent operation of a system that protects a hood and the common duct.

50.4.6 Fuel and Electric Power Shutoff.

50.4.6.1 Upon activation of any fire-extinguishing system for a cooking operation, all sources of fuel and electric power that produce heat to all equipment requiring protection by that system shall automatically shut off. [**96:**10.4.1]

If heat-producing appliances are not shut down, they will likely contribute to the fire, possibly allowing re-ignition.

When a fire-extinguishing system discharges, any possible source of re-ignition should be discontinued. This is typically accomplished through the use of a solenoid such as the one shown in Exhibit 50.10. This shutdown includes only heat-producing appliances that require protection (an appliance that requires protection typically has a nozzle directed at it). Therefore, this provision requires that only fuel or electrical power to appliances requiring protection be automatically shut off. Those appliances that do not require protection and are not gas appliances under the same hood as protected appliances are not to be shut off.

Questions have arisen regarding liquid extinguishing agents, such as wet chemical, flowing into electrical outlets and causing a shock hazard. As with sprinkler systems, no scientific evidence or experimental data have ever substantiated this as a valid safety concern.

Exhibit 50.10

Solenoid for providing fuel shutoff.

50.4.6.2 Steam supplied from an external source shall not be required to automatically shut off. [**96:**10.4.2]

Steam-heated appliances typically are not a fire protection concern since they do not have the capability of allowing the appliances to overheat and spontaneously ignite the cooking oil. Gas-fired and electrically heated appliances are the concern.

50.4.6.3 Any gas appliance not requiring protection but located under ventilating equipment where protected appliances are located shall be automatically shut off upon activation of the extinguishing system. [**96:**10.4.3]

50.4.6.4 Shutoff devices shall require manual reset. [**96:**10.4.4]

In a cooking fire, the two sources of heat are the burning grease and the normal source of heat used for cooking, which can be provided by any number of fuels, including electricity. This normal source of heat can pose a significant challenge to the effectiveness of the extinguishing agent, because effective extinguishment depends on lowering the fuel temperature to below its autoignition temperature. If the normal heat source continues to operate and heat the grease, such cooling might never occur. It is important to shut off all sources of fuel to the cooking equipment when the fire-extinguishing system has operated to allow the proper cooling to occur.

For gas appliances, a shutoff valve is typically directly connected to the operating controls for the fire-extinguishing system. Often cooking equipment, such as an oven, might be located under a hood that does not require a fire-extinguishing system. The gas supply to these appliances must also be shut down, because, if a fire occurs in the hood, heat produced by these appliances can inhibit the effectiveness of the fire-extinguishing system.

Exhibit 50.11

Manual reset for fuel and electric power.

Exhibit 50.12

Example of a properly located manual pull station.

A fire-extinguishing system has an interlock that automatically shuts off all sources of fuel and electrical power that produce heat to all equipment requiring protection. A manual reset, such as the one shown in Exhibit 50.11, allows time to analyze the cause of the fire before the shutoff is reset. If an automatic reset were permitted, the problem causing the fire might not be fixed before the reset operates.

Electrical power used as a source of heat for appliances must also be shut down. This includes outlets that are located under the hood that could be a potential source of heat to cooking appliances, regardless of whether they are currently connected to appliances. Power to the hood lights is not required to shut off.

N **50.4.6.5** Solid fuel cooking operations shall not be required to be shut down. [**96:**10.4.5]

50.4.7 Manual Activation.

To improve correlation between NFPA 17A and NFPA 96, the requirements in this subsection were revised for the 2017 edition of NFPA 96 and are applicable to all types of extinguishing systems.

50.4.7.1 All systems shall have both automatic and manual methods of actuation. [**96:**10.5.1]

50.4.7.1.1 At least one manual actuation device shall be located in means of egress or at a location acceptable to the AHJ. [**96:**10.5.1.1]

Manual pull stations should be strategically located, and employees should be trained how to use them. Exhibit 50.12 shows a manual pull station located next to a door in a path of egress. Access to the manual pull station needs to be maintained during the day-to-day operations of the system. While the pull stations can be designed for an appropriate location, placing movable tables or stacking boxes in front of a pull station defeats the purpose of 50.4.7.1.1, which is to allow for employees to easily activate the extinguishing system as they exit the area.

50.4.7.1.2 The manual actuation device shall clearly identify the hazard protected. [**96:**10.5.1.2]

50.4.7.2 An automatic sprinkler system shall not require a method of manual actuation. [**96:**10.5.2]

• Δ **50.4.7.3** Instruction regarding the proper use of portable fire extinguishers and the manual activation of fire-extinguishing equipment shall be documented and shall be provided by the management to new employees on hiring and to all employees annually. [**96:**10.5.3]

Experience has demonstrated that many employees of commercial cooking operations have not received initial instruction in the proper use of portable fire extinguishers and activation of fire-extinguishing equipment. Of those who have, many forget the lessons from their initial training, resulting in inappropriate responses to fire. The new language in 50.4.7.3 requiring training for new employees upon being hired and for all employees annually is consistent with the U.S. Department of Labor Occupational Safety and Health Administration (OSHA) requirements. Employees are required to be trained to manually discharge the fire-extinguishing system on noticing a fire in or around a cooking appliance. Class K extinguishers are the only extinguishers that should be used for cooking oil fires in appliances. Class K extinguishers should be used only after the system has been discharged because the system has an interlock to automatically shut down the heat source to the appliance.

Employees should be trained to use various types of portable fire extinguishers as a first line of defense for fires other than Class K fires. The importance of personal safety should be stressed, and persons should use extinguishers only if the fire is small and only if the person using the extinguisher understands how to use it and is comfortable with the fire situation.

50.4.8 System Annunciation.

50.4.8.1 Upon activation of an automatic fire-extinguishing system, an audible alarm or visual indicator shall be provided to show that the system has activated. [**96:**10.6.1]

Exhibit 50.13

Two examples of visual indicators.

The fire-extinguishing system must be equipped to indicate, visibly or audibly, that it has operated. If no fire alarm system is in the building, the extinguishing system needs only to provide a local indicator. This local indicator can be in the form of a light or even a sign-type indicator identifying that the system has operated and needs to be restored. Exhibit 50.13 illustrates examples of visual indicators that show when a system has activated.

50.4.8.2 Where a fire alarm signaling system is serving the occupancy where the extinguishing system is located, the activation of the automatic fire-extinguishing system shall activate the fire alarm signaling system. [**96:**10.6.2]

If the building is equipped with a fire alarm system, operation of the commercial cooking extinguishing system is required to cause an alarm signal in the protected building. Paragraph 50.4.8.2 does not mean that all buildings that have commercial cooking extinguishing systems must be provided with a fire alarm system.

50.4.9 Special Design and Application.

50.4.9.1 Hoods containing automatic fire-extinguishing systems are protected areas; therefore, these hoods shall not be considered obstructions to overhead sprinkler systems and shall not require additional sprinkler coverage underneath. [**96:**10.7.1]

Unlike other shadow areas that are shielded from the spray pattern of the automatic sprinkler system discharge and have no extinguishing agent reaching the shadow area, the area under the hood is protected with extinguishing agent from the discharge devices of the fire protection system in the hood. Therefore, commercial cooking hoods that have total fire protection installed are not considered obstructions to ceiling-installed sprinklers.

50.4.9.2 A single detection device, listed with the extinguishing system, shall be permitted for more than one appliance where installed in accordance with the terms of the listing. [**96:**10.7.2]

50.4.10 Review and Certification.

50.4.10.1 Where required, complete drawings of the system installation, including the hood(s), exhaust duct(s), and appliances, along with the interface of the fire-extinguishing system detectors, piping, nozzles, fuel and electric power shutoff devices, agent storage container(s), and manual actuation device(s), shall be submitted to the AHJ. [**96:**10.8.1]

In order to review plans of cooking operations and equipment for compliance, a printed guideline or checklist could promote consistency and completeness. Exhibit 50.14 is an example of such a guideline.

50.4.10.2* Installation Requirements.

A.50.4.10.2 Although training and qualification might be available elsewhere, the manufacturer of the equipment being installed should be considered an appropriate source of training and qualification. [**96:**A.10.9.2]

50.4.10.2.1 Installation of systems shall be performed only by persons properly trained and qualified to install the specific system being provided. [**96:**10.8.2.1]

A pre-engineered kitchen fire suppression system installation and maintenance technician typically completes a classroom or online course and is required to pass an examination offered by a pre-engineered system manufacturer, an agent of a pre-engineered system manufacturer, or an organization that is approved by the AHJ.

50.4.10.2.2 The installer shall provide certification to the AHJ that the installation is in agreement with the terms of the listing and the manufacturer's instructions and/or approved design. [**96:**10.8.2.2]

50.4.11 Portable Fire Extinguishers.

50.4.11.1* Portable fire extinguishers shall be selected and installed in kitchen cooking areas in accordance with Section 13.6 and shall be specifically listed for such use. [**96:**10.9.1]

Exhibit 50.14

OFFICE OF THE FIRE MARSHAL

(City, State, Zip Code)

In order to successfully review and approve a commercial cooking equipment submission, all the components required in the *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations* (NFPA 96) need to be shown on the drawing or in the plans. Mentioned below are some of the more common omissions that are resulting in plans not being approved:

The drawings/plans are to indicate the MSG gauge of the ductwork and the hood and whether steel or stainless.

The drawings/plans are to indicate that all welds on the exhaust duct are liquid tight and external to the duct.

In the case of listed hoods or duct systems, cut sheets of the listed component(s) need to be submitted in order to verify that the component is listed and that restrictions and conditions of the listing are not being violated.

Only filters listed by Underwriters Laboratories for use in cooking ventilation system are permitted in the hood.

For horizontal runs of exhaust duct, the drawings/plans are to indicate that at least one 20 in. x 20 in. (508 mm x 508 mm) opening is provided for personnel entry. Where this size opening is not possible, openings shall be provided at 12-foot (3.6 m) intervals.

If the supply air plenum is integral with the exhaust ventilation system, the drawings/plans are to indicate that fire actuated dampers are provided where the supply air duct penetrates the shell of the assembly.

The drawings/plans are to indicate the fan rating in CFM and the dimensions (width and depth or cross-sectional area) of the duct system in order to verify that a velocity of 500 ft/min (150 m/min) is being produced.

The drawings/plans are to indicate that the make-up (supply) air ventilation rate does not exceed the exhaust ventilation rate.

The drawings/plans are to show that a 10-foot (3.05 m) clearance exists between the discharge of an upblast fan and property lines, adjacent buildings, and all other air intakes, including between the discharge of the upblast fan and return air intake.

A distance of at least 16 inches (406 mm) is required between deep fat fryers and all other fired appliances. In lieu of this, a noncombustible baffle of at least 8 inches (203 mm) in height can be accepted provided it is indicated on the drawings/plans.

Deep fat fryers are to be equipped with a separate high limit control in addition to the operating control. It is to shut off fuel or energy when the fat temperature at 1 inch (25 mm) below the surface reaches 475°F (246°C).

On the resubmittal, make sure that all the components required in the *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations* (NFPA 96) are shown on the drawing or in the plans.

Plan review guidelines for cooking operations and equipment.

Most fires start small and can be extinguished with portable fire extinguishers. Notifying the fire department as soon as a fire is discovered is essential. This notification should not be delayed by awaiting results of using portable fire extinguishers.

A.50.4.11.1 The system used to rate extinguishers for Class B fires (flammable liquids in depth) does not take into consideration the special nature of heated grease fires. Cooking-grease fires are a special hazard requiring agents that saponify (make a soap foam layer to seal the top surface of the grease) for this application. [**96:**A.10.10.1]

Many restaurant fires have failed to be extinguished because an inappropriate portable fire extinguisher was used. Cooking oil fires that occur in deep vessels, such as in deep-fat fryers, require a fire-extinguishing agent that reacts with the cooking oil and forms a soapy foam layer (a process called saponification). This layer should keep the surface of the hot oil separated from the air until the oil is cooled to below its autoignition temperature, usually around 650°F (343°C).

If the fire-extinguishing agent does not support saponification, the fire can reignite when the agent discharge is stopped. No multipurpose dry chemical (known as type A:B:C), halon, or carbon dioxide fire-extinguishing agents are capable of saponification. Only carbonate-based agents saponify with cooking oil. Additionally, the high temperature of cooking oil can slowly break down the soapy foam layer before the oil drops below its autoignition temperature, and the fire can reignite. A properly trained individual should stand by with the proper portable fire extinguisher until the fire department arrives in case an extinguished cooking oil fire reignites.

While, in the past, some portable fire extinguishers have used bicarbonate-based dry chemical, wet chemical fire extinguishers, designated by a K rating, are available and are listed for use on actual fryer-type cooking oils.

50.4.11.2 Class K fire extinguishers shall be provided for cooking appliance hazards that involve combustible cooking media (vegetable oils and animal oils and fats). [**96:**10.9.2]

In the kitchen area, the essential hazard involves combustible cooking oils, and a Class K fire extinguisher is a match for the hazard. Class K combustible cooking media fires typically involve kitchen appliances containing quantities of cooking greases or oils that present special extinguishment and reflash concerns. The development of high-efficiency cooking equipment with high-energy input rates and the widespread use of vegetable oils with high autoignition temperatures have highlighted the need for Class K fire extinguishers.

The wet chemical extinguisher is the only extinguisher to qualify to the Class K listing requirements. In addition to offering rapid fire extinguishment, a thick foam blanket is formed to prevent reignition while cooling both the appliance and the hot cooking oil.

Fire extinguishers classified for use on Class K hazards do not have a number preceding the classification letter. According to NFPA 10, the maximum travel distance to a Class K extinguisher is not permitted to exceed 30 ft (9.1 m) from the hazard to the extinguisher.

50.4.11.3 Portable fire extinguishers shall be provided for other hazards in kitchen areas and shall be selected and installed in accordance with Section 13.6. [**96:**10.9.3]

NFPA 10 uses the following classifications for fires in determining appropriate extinguishers:

- Class A: Ordinary
- Class B: Flammable liquids
- Class C: Energized electrical equipment
- Class D: Combustible metals
- Class K: Cooking appliances that involve combustible cooking media

All buildings have Class A fire hazards. Where ordinary combustibles are present, there could be the need for fire extinguishers suitable for use on Class B and Class C fires (e.g., in the dining areas of a restaurant, the principal combustibles present are wood, paper, and fabrics, which are Class A materials).

According to NFPA 10, all solid fuel cooking appliances (whether or not under a hood) with fire boxes of 5 ft^3 (0.14 m^3) volume or less are required to have at least a listed 2-A rated water-type fire extinguisher or a 1.6 gal (6 L) wet chemical fire extinguisher that is listed for Class K fires.

N **50.4.11.4** Carbon dioxide–type extinguishers shall not be permitted. [**96:**10.9.4]

50.4.11.5 Portable fire extinguishers shall be maintained in accordance with Section 13.6. [**96:**10.9.5]

50.5 Procedures for the Use, Inspection, Testing, and Maintenance of Equipment

50.5.1 Operating Procedures.

50.5.1.1 Exhaust systems shall be operated whenever cooking equipment is turned on. [**96:**11.1.1]

When the cooking equipment is turned on, heat is being produced at all times. Even when no food is being cooked, residual grease is being heated and vaporized. Additionally, both the exhaust system and the extinguishing system are designed to function most effectively when excessive temperatures are exhausted and not lingering across the cooking surfaces and under the hood. An interlock is required in 8.2.3.3 of NFPA 96 so that the exhaust fan is activated when any appliance under the hood is turned on. This requirement can be accomplished with the installation of a separate heat detector that turns the fan on when a preset temperature is reached.

50.5.1.2 Filter-equipped exhaust systems shall not be operated with filters removed. [**96:**11.1.2]

In the normal mode, filter-equipped exhaust systems are designed to run when filters are in place. Filter spacers are often used to fill voids when standard size filters are used. These are solid blocks that fill in any gaps left after standard size filters are put in place at a point where they do not cover the entire hood but do not leave enough room for another filter. The spacers should be used only where the space being filled is not critical to airflow, typically on the very ends. Detection devices for the extinguishing system should not be installed directly above a spacer due to limited airflow that will pass through the solid filter.

Where any of the required filters are missing, exhaust volumes will be captured from a path of lesser resistance (where the filter is missing), resulting in unfiltered smoke and vapors being introduced into the exhaust system; thus, uncaptured grease and deposits accumulate on the plenum and duct surfaces.

During maintenance, a missing filter serves as a visual indicator that service is being conducted. Operating the exhaust system during maintenance could pose a hazard to service personnel and cause damage to mechanical parts of the equipment.

50.5.1.3 Openings provided for replacing air exhausted through ventilating equipment shall not be restricted by covers, dampers, or any other means that would reduce the operating efficiency of the exhaust system. [**96:**11.1.3]

Openings are commonly provided to afford sufficient airflow for the exhaust system to work properly to remove grease-laden vapors from the cooking area. Because covering the openings restricts airflow, covers, dampers, or other means are prohibited from being installed while the exhaust system is in operation.

50.5.1.4* Instructions shall be provided to new employees on hiring and to all employees semiannually on the use of portable fire extinguishers and the manual actuation of the fire-extinguishing system. [**96:**11.1.4]

N **A.50.5.1.4** It is important that all kitchen employees be instructed that the fire-extinguishing system is the primary protection and how to respond appropriately to a fire. If the fire cannot be extinguished by shutting off the fuel source to a pan of burning grease and covering the pan, then employees should perform the following:

(1) Operate the manual actuation device for the fire-extinguishing system to suppress the fire and automatically shut off fuel to the appliances.
(2) Call the fire department and report the fire.
(3) Evacuate personnel and guests, as needed.
(4) Stand by with a Class K fire extinguisher to be used if the fire is not fully extinguished by the fire-extinguishing system.

[**96:**A.11.1.4]

N **50.5.1.4.1** Responsibility for compliance with 11.1.4 shall be that of management of the commercial cooking operation. [**96:**11.1.4.1]

N **50.5.1.4.2** Records of compliance with 11.1.4 shall be maintained and shall be available to the authority having jurisdiction. [**96:**11.1.4.2]

N **50.5.1.4.3** Instructions for manually operating the fire-extinguishing system shall be posted conspicuously in the kitchen and shall be reviewed with employees by the management. [**96:**11.1.4.3]

The most common means for compliance with this requirement is to post a placard near each manual activation device for the fire-extinguishing system. The signage should be in a language commonly used by employees. Alternatively, pictographs (picture symbols) or a combination of pictographs and words can be used.

50.5.1.5 Listed exhaust hoods shall be operated in accordance with the terms of their listings and the manufacturer's instructions. [**96:**11.1.5]

50.5.1.6 Cooking equipment shall not be operated while its fire-extinguishing system or exhaust system is nonoperational or impaired. [**96:**11.1.6]

By its very nature, commercial cooking has been recognized as a hazard that requires appropriate protection. If the fire protection system is nonoperational, the hazard must be eliminated by discontinuing the cooking operation. Similarly, if cooking equipment were allowed to operate without the exhaust system operating, grease-laden vapors would not be removed and excessive heat would accumulate in the cooking area.

50.5.1.6.1 Where the fire-extinguishing system or exhaust system is nonoperational or impaired, the systems shall be tagged as noncompliant, and the system owner or owner's representative shall be notified in writing of the impairment, and where required, the AHJ shall be notified. [**96:**11.1.6.1]

In addition to providing written notification, it is important that the owner is made aware as soon as possible that the protective systems are not operative. Not all AHJs require notification, as they might have other procedures in place to address the inoperative equipment.

50.5.1.7 Secondary filtration and pollution control equipment shall be operated in accordance with the terms of its listing and the manufacturer's recommendations. [**96:**11.1.7]

The manufacturer's published operating guidelines regarding reducing the hazard through proper operation should be closely followed. The turnover of personnel in the food service industry makes it necessary for this information to be available for training of new personnel so as to continue the safe practices of equipment operation.

50.5.1.8 Inspection and maintenance of "other equipment" allowed in 9.3.1 of NFPA 96 shall be conducted by properly trained and qualified persons at a frequency determined by the manufacturer's instructions or equipment listing. [**96:**11.1.8]

The AHJ determines who is and who is not "properly trained and qualified."

50.5.2 Inspection, Testing, and Maintenance of Fire-Extinguishing Systems.

50.5.2.1* Maintenance of the fire-extinguishing systems and listed exhaust hoods containing a constant or fire-activated water system that is listed to extinguish a fire in the grease removal devices, hood exhaust plenums, and exhaust ducts shall be made by properly trained, qualified, and certified person(s) acceptable to the AHJ at least every 6 months. [**96:**11.2.1]

Most automatic fire-extinguishing systems installed for the protection of commercial cooking operations are wet chemical extinguishing systems listed to ANSI/UL 300. Certification of maintenance technicians for wet chemical fire-extinguishing systems is addressed in 7.3.1 and 7.3.1.1 of NFPA 17A. Service technicians performing maintenance on wet chemical extinguishing systems are required to be trained and to pass a written or online test that is acceptable to the AHJ and to possess a certification document confirming an acceptable score on the test. The certification document must be issued by a system manufacturer, an agent of a system manufacturer, or a testing organization that is acceptable to the AHJ.

It is important that the 6-month and annual inspections are performed on schedule. These inspections not only provide for the replacement of necessary components on schedule, they test the actual performance of the components to ensure they are all operating normally and are not compromised by grease buildup or by other mechanical seizures that would prevent the system from performing as designed. Without these inspections being properly performed, the system can easily slip into a condition of decay that eventually seizes up a cable or an operator or results in a grease buildup that thickly coats and insulates a detector link, so that the system is unable to respond when it is needed.

A.50.5.2.1 It is recommended that such training and qualification be performed by the manufacturer of the equipment being inspected and serviced. The various electrical, mechanical, and filtration components of the systems should be inspected and tested

Case Study

On Wednesday, August 29, 2007, a fire tore through a Cantonese restaurant in West Roxbury, Massachusetts, resulting in the deaths of two city fire fighters and injuries to several other fire fighters. A total of four employees were working in the restaurant on the night of the fire. One of the employees discovered the fire, evacuated coworkers, and called 911. Minutes after the fire was discovered, the restaurant erupted into a ball of flames, fully engulfing it and other properties nearby.

The fire appeared to have been caused by an accumulation of grease and fumes from the kitchen that ignited after smoldering in the restaurant's ceiling. When the fire fighters entered the building, they were responding to a standard kitchen fire, but it quickly took a turn for the worse. It was later discovered that the fire had been smoldering in the ceiling throughout the evening as patrons ate in the dining room below.

The kitchen was located in the right rear of the restaurant. Cooking equipment was fueled by natural gas and included five woks, two deep fryers, and an upright oven/broiler. (The deep fryers were located directly next to the oven/broiler, without the required clearance between them.) Kitchen exhaust hoods were located above the cooking equipment and ran along a partition wall ending at the building's cellar stairs. A tag from a local company was recovered during the fire investigation, which indicated that the hoods and ducts had been cleaned three months earlier.

A probable contributor to the deaths of the two fire fighters was the collapse of the roof, which occurred when a heating, ventilation, and air-conditioning (HVAC) unit fell through the roof and crashed down into the burning restaurant below. The HVAC system was an old-type roof model providing both heat and air-conditioning to the restaurant, powered by natural gas and electrically cooled. The unit, which had a 3 ton (2.7 metric ton) capacity and weighed approximately 400 lb (181 kg), was on the roof approximately 40 ft (12.2 m) from the front exterior wall of the restaurant

The cooking equipment was protected by a fire suppression system. The fire suppression system in the kitchen hoods did not operate until well after the fire started. It was documented that a few of the heads did not activate as designed because the caps were grease-bound.

The hood, kitchen exhaust duct, and roof curbing were of nonconforming construction and were contaminated by grease that had been building up unnoticed due to lack of maintenance cleaning, allowing the grease to escape to adjoining combustible areas, which allowed fire and the products of combustion to escape from the containment area. As reported by the local fire department, due to the substandard materials being used, the duct above the hood degraded, and a section of the duct became open. Flame and products of combustion, including heat, carbon monoxide, and other fire gases, escaped from the duct. Combustible building materials had become coated with grease. The fire in the ductwork above the hood escaped from containment and ignited combustible wall materials. The flame quickly spread vertically to the ceiling and the roof. The fire, smoke, and toxic gases expanded and also traveled horizontally, filling both the top and bottom ceiling voids in the dining room, as well as the ceiling void in the kitchen, allowing the fire to go undetected for an unknown length of time. By the time the fire did fall from the ceiling into the kitchen below, it was too late; it had grown to an unmanageable and tragic inferno.

Source: Boston Fire Department, *Board of Inquiry report on fatal fire of August 29th, 2007*

as required to ensure that they continue to function according to original design. [**96:**A.11.2.1]

50.5.2.2* All actuation and control components, including remote manual pull stations, mechanical or electrical devices, detectors, and actuators, shall be tested for proper operation during the inspection in accordance with the manufacturer's procedures. [**96:**11.2.2]

A.50.5.2.2 It is not intended that actual discharge of agent occur to test all components, but where pressure from the discharging agent or from compressed gas actuators is needed to activate control components, an alternate means for testing those components should be provided and used. [**96:**A.11.2.2]

All mechanical and electrical components need to be physically tested periodically to ensure that they remain operational. Generally, all such components will be tested during the semiannual inspection, although the last component that physically releases the extinguishing agent need not be tested, except during the inspection of the agent and tank as required by the applicable equipment standard. Where control components, such as gas or electric fuel shutoff devices, depend on release of the extinguishing agent or compressed gas for pressurizing a switch or similar component, alternative means for testing those components must be provided and followed.

The gas or electric shutoff is often critical for successful fire extinguishment and should be tested periodically.

50.5.2.3 The specific inspection and maintenance requirements of the extinguishing system standards as well as the applicable installation and maintenance manuals for the listed system and service bulletins shall be followed. [**96:**11.2.3]

Δ **50.5.2.4*** Fusible links of the metal alloy type and automatic sprinklers of the metal alloy type shall be replaced at least semiannually. [**96:**11.2.4]

A.50.5.2.4 The date of manufacture marked on fusible metal alloy sensing elements does not limit when they can be used. These devices have unlimited shelf life. The intent of 50.5.2.4 is to require semiannual replacement of fusible metal alloy sensing elements that have been installed in environments that subject them to

Exhibit 50.15

Fusible link requiring replacement.

contaminant loading, such as grease in restaurant hoods and ducts, that could adversely affect their proper operation. [**96:**A.11.2.4]

Fusible links, such as the one shown in Exhibit 50.15, act as the automatic activation component for most fire-extinguishing systems in hoods. The effectiveness of the extinguishing system is dependent on the fusible link activating the system in a timely manner before the fire becomes too large. The buildup of grease on the fusible link has the potential to affect its thermal characteristics and, therefore, possibly diminish the effectiveness of the extinguishing system. That is why the links are required to be replaced on a semiannual basis. (The year of manufacture indicated on the fusible link is not necessarily the date the link was installed. Links should be replaced every 6 months, regardless of the date that appears on the fusible link.)

50.5.2.5 The year of manufacture and the date of installation of the fusible links shall be marked on the system inspection tag. [**96:**11.2.5]

It should be noted that the year of manufacture indicated on the fusible link is not necessarily the date the link was installed. Link replacement should be every 6 months, regardless of the date that appears on the fusible link.

50.5.2.5.1 The tag shall be signed or initialed by the installer. [**96:**11.2.5.1]

50.5.2.5.2 The fusible links shall be destroyed when removed. [**96:**11.2.5.2]

Destroying links is a safety measure that prevents the removed links from ever being installed again in a fire-extinguishing system.

50.5.2.6 Detection devices that are bulb-type automatic sprinklers and fusible links other than the metal alloy type shall be examined and cleaned or replaced annually. [**96:**11.2.6]

Cleaning bulb-type automatic sprinklers and fusible links is essential for them to operate as designed. When they cannot be thoroughly cleaned, they must be replaced. It is also acceptable to replace them every 12 months if cleaning is undesirable or cost prohibitive, as allowed in 50.5.2.7.

50.5.2.7 Fixed temperature-sensing elements other than the fusible metal alloy type shall be permitted to remain continuously in service, provided they are inspected and cleaned or replaced if necessary in accordance with the manufacturer's instructions, every 12 months or more frequently to ensure proper operation of the system. [**96:**11.2.7]

50.5.2.8 Where required, certificates of inspection and maintenance shall be forwarded to the AHJ. [**96:**11.2.8]

N **50.5.2.8.1** Records, including certificates of inspection and maintenance, shall be permitted to be forwarded to or shared with the authority having jurisdiction either by hard copy or electronically. [**96:**11.2.8.1]

Recognizing that fire-extinguishing equipment might not operate as designed if not periodically inspected and maintained, some AHJs might require documentation of the inspections. Other AHJs might have different policies in place to address inspection and maintenance of equipment.

Permission to store and access inspection and maintenance documentation electronically is provided in NFPA 10; NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*; *NFPA 72®, National Fire Alarm and Signaling Code®*; NFPA 80, *Standard for Fire Doors and Other Opening Protectives*; and NFPA 731, *Standard for the Installation of Electronic Premises Security Systems.* This new requirement for the 2017 edition brings NFPA 96 in line with other documents, while still allowing for documentation in hard copy format.

50.5.3 Inspection of Fire Dampers.

Fire dampers can be vital to the overall performance of the fire-extinguishing system and the integrity of the ventilation system under fire conditions. These devices are typically activated by fusible links that must be inspected and replaced at regular intervals to allow for proper operation when needed.

50.5.3.1 Actuation components for fire dampers shall be inspected for proper operation in accordance with the manufacturer's listed procedures. [**96:**11.3.1]

50.5.3.2 Replacement of Fusible Links.

50.5.3.2.1 Fusible links on fire damper assemblies shall be replaced at least semiannually or more frequently as necessary. [**96:**11.3.2.1]

50.5.3.2.2 Replacement shall be made by a certified person acceptable to the AHJ. [**96:**11.3.2.2]

50.5.3.3* Documentation Tag.

A.50.5.3.3 See A.50.5.2.4. [**96:**A.11.3.3]

50.5.3.3.1 The year of manufacture and the date of installation of the fusible links shall be documented. [**96:**11.3.3.1]

Δ ***TABLE 50.5.4*** *Schedule of Inspection for Grease Buildup*

Type or Volume of Cooking	Inspection Frequency
Systems serving solid fuel cooking operations	Monthly
*Systems serving high-volume cooking operations	Quarterly
Systems serving moderate-volume cooking operations	Semiannually
†Systems serving low-volume cooking operations	Annually

*High-volume cooking operations include 24-hour cooking, charbroiling, and wok cooking.

†Low-volume cooking operations include churches, day camps, seasonal businesses, and senior centers.

[**96:** Table 11.4]

50.5.3.3.2 The tag shall be signed or initialed by the installer. [**96:**11.3.3.2]

Δ **50.5.4* Inspection for Grease Buildup.** The entire exhaust system shall be inspected for grease buildup by a properly trained, qualified, and certified person(s) acceptable to the AHJ and in accordance with Table 50.5.4. [**96:**11.4]

A.50.5.4 The primary focus of an inspection for cleanliness is to establish whether the volume of grease buildup within the exhaust system warrants cleaning and to determine whether adequate access is available throughout the exhaust system to remove the grease buildup. [**96:**A.11.4]

Excessive grease buildup increases the fire hazard and has been documented as the cause of many fires involving commercial cooking equipment. Cleaning of the exhaust hoods should be based on the amount of grease buildup observed during inspections. The intervals between inspections and cleanings can vary, depending on the types and volumes of cooking that take place, the condition of the equipment, and the efficiency of the hood filtration system. A reduced frequency of inspection might be justified for systems that are used on a part-time or seasonal basis only. Inspections for grease buildup should be conducted only by a person with adequate training, certifications, and qualifications acceptable to the AHJ.

50.5.5 Inspection, Testing, and Maintenance of Listed Hoods Containing Mechanical, Water Spray, or Ultraviolet Devices. Listed hoods containing mechanical or fire-actuated dampers, internal washing components, or other mechanically operated devices shall be inspected and tested by properly trained, qualified, and certified persons every 6 months or at frequencies recommended by the manufacturer in accordance with their listings. [**96:**11.5]

50.5.6 Cleaning of Exhaust Systems.

50.5.6.1* If upon inspection, the exhaust system is found to be contaminated with deposits from grease-laden vapors, the contaminated portions of the exhaust system shall be cleaned by a properly trained qualified, and certified person(s) acceptable to the AHJ. [**96:**11.6.1]

If an exhaust system is found to be contaminated with deposits from grease-laden vapors during an inspection, the contaminated portions of the system must be cleaned by a trained, qualified, and certified person(s) who is acceptable to the AHJ. By definition, a qualified person is a competent and capable person who has met the requirements and training for a given field acceptable to the AHJ. A certified person possesses a certification, which is a formally stated recognition and approval of an acceptable level of competency, acceptable to the AHJ. Certification can be provided by the manufacturer of the listed equipment being serviced or by an independent third party. A trained person is someone who has become proficient in performing a skill reliably and safely through instruction and practice/field experience acceptable to the AHJ. Formal or technical training can be administered by the employer or by a recognized training program.

A.50.5.6.1 ANSI/IKECA Standard C-10 provides guidance for cleaning the exhaust system.

A good operating practice is for cleaning personnel of commercial kitchen exhaust systems to have personal protective equipment (PPE) and height access equipment. The following items should be considered as a minimum:

(1) Eye protection
(2) Hand protection
(3) Head protection
(4) Foot protection
(5) Respiratory protection
(6) Fall protection
(7) Ladders
(8) Lock-out/tag-out kit

[**96:**A.11.6.1]

Preparation. The fan should be turned off, locked out, and tagged out. Open flames should be extinguished, and switches/breakers serving the appliance and cooking area outlets should be locked out. If the switches/breakers are not capable of being locked out and tagged out, any solid-fuel cooking appliances should be extinguished and the solid fuel removed. [**96:**A.11.6.1]

Removal or Covering of Equipment. Food products, cookware, and cooking support equipment that can be removed should be removed from the cleaning area. Equipment that cannot be removed should be covered. [**96:**A.11.6.1]

Cleaning Methods. The following methods for cleaning surfaces covered with grease and contaminants been proved to be effective:

(1) Manual cleaning by scraping, grinding, or scrubbing
(2) Chemical cleaning with agents and water
(3) Pressure washing with pressurized water or pressurized water and agents
(4) Steam cleaning with pressurized steam

[**96:**A.11.6.1]

Waste Water and Solid Waste. Water and agents used in the cleaning process and solid waste should be collected for disposal. [**96:**A.11.6.1]

N **50.5.6.1.1** A measurement system of deposition shall be established to trigger a need to clean when the exhaust system is inspected at the frequencies in Table 50.5.4. [**96:**11.6.1.1]

N **50.5.6.1.1.1** Hoods, grease removal devices, fans, ducts, and other appurtenances shall be cleaned to remove combustible contaminants to a minimum of 50 μm (0.002 in.). [**96:**11.6.1.1.1]

N **50.5.6.1.1.2** A grease depth gauge comb, as shown in Figure 50.5.6.1.1.2, shall be placed upon the surface to measure grease depth. [**96:**11.6.1.1.2]

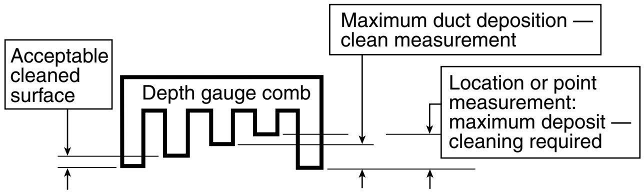


FIGURE 50.5.6.1.1.2 *Depth Gauge Comb.*

N **50.5.6.1.1.3** Where a measured depth of 2000 μm (0.078 in.) is observed, the surfaces shall be cleaned in accordance with 50.5.6.1. [**96:**11.6.1.1.3]

N **50.5.6.1.1.4** Where a measured depth of 3175 μm (0.125 in.) is observed in a fan housing, the surfaces shall be cleaned in accordance with 50.5.6.1. [**96:**11.6.1.1.4]

50.5.6.2 Hoods, grease removal devices, fans, ducts, and other appurtenances shall be cleaned to remove combustible contaminants prior to surfaces becoming heavily contaminated with grease or oily sludge. [**96:**11.6.2]

50.5.6.3 At the start of the cleaning process, electrical switches that could be activated accidentally shall be locked out. [**96:**11.6.3]

Switches that might start an exhaust fan, a heating element, an electrostatic precipitator, or a spray or wash system must be locked out (locked in the "off" position) to ensure safety during the cleaning process. These switches could be hazardous to those who are cleaning the exhaust system if not locked out. The agency responsible for the lockout is responsible for turning the switches back on at the end of the cleaning process, so the systems they control can resume their intended services.

50.5.6.4 Components of the fire suppression system shall not be rendered inoperable during the cleaning process. [**96:**11.6.4]

50.5.6.5 Fire-extinguishing systems shall be permitted to be rendered inoperable during the cleaning process where serviced by properly trained and qualified persons. [**96:**11.6.5]

Interfering with the normal operation of a fire suppression system can create a serious hazard. An untrained person who attempts to disarm the suppression system during cleaning of the exhaust system could discharge the suppression system accidentally. A person who successfully disarms the system but forgets to rearm it or rearms it incorrectly creates a serious problem if a subsequent fire in the exhaust system occurs. If the suppression system is allowed to be disarmed only by a qualified person, the responsibility for rearming the system remains with the qualified person.

50.5.6.6 Flammable solvents or other flammable cleaning aids shall not be used. [**96:**11.6.6]

These chemicals are not permitted because the fumes from flammable solvents or other flammable cleaning aids are heavier than air and invisible and can travel to an ignition source and cause a fire.

50.5.6.7 Cleaning chemicals shall not be applied on fusible links or other detection devices of the automatic extinguishing system. [**96:**11.6.7]

Some cleaning materials can cause corrosion of the detector links and the cables. Such corrosion could adversely affect the system, causing premature or delayed activation.

50.5.6.8 After the exhaust system is cleaned, it shall not be coated with powder or other substance. [**96:**11.6.8]

Some cleaning vendors find that applying special agents to the exhaust system interior prior to cleaning can assist in the cleaning. However, coating the inside of the duct with powder or other substance after the system is cleaned can cause grease buildup. The safest approach is to leave the metal duct surfaces as clean as possible.

50.5.6.9 When cleaning procedures are completed, all access panels (doors) and cover plates shall be restored to their normal operational condition. [**96:**11.6.9]

Access panels (doors) and cover plates must be replaced with the original hardware (gasketing and fasteners). An improperly placed access panel could allow grease to leak out of the duct and into concealed areas during the cooking operation. A subsequent duct fire could ignite this renegade grease. In addition, where there is a fire-rated chase, there are also panels or cover plates in the chase to allow access to the panels in the duct itself. If the fire chase panel is not replaced, the fire rating of the chase is voided. It is possible that, without the chase protection, some combustible materials in the vicinity of the chase could be subjected to radiated heat from a fire inside the duct. The total restoration of all duct and chase panels with a proper gasketing seal is critical.

50.5.6.10 When an access panel is removed, a service company label or tag preprinted with the name of the company and giving the date of inspection or cleaning shall be affixed near the affected access panels. [**96:**11.6.10]

50.5.6.11 Dampers and diffusers shall be positioned for proper airflow. [**96:**11.6.11]

Diffusers are not normally found in the exhaust system, but they can be found in the supply air system that is provided in some operations. Fire dampers (not balancing dampers) can be found in some exhaust and supply systems. Typically, these dampers do not have to be moved during the cleaning process of the exhaust system, but if moving is necessary, they must be returned to their original positions. This step ensures that the original airflows are maintained. If dampers are not returned to their original positions, it is possible that the hood will fail to capture all the effluent from the cooking process.

50.5.6.12 When cleaning procedures are completed, all electrical switches and system components shall be returned to an operable state. [**96:**11.6.12]

50.5.6.13 When an exhaust system is inspected or cleaned, a certificate showing the name of the servicing company, the name of the person performing the work, and the date of inspection or cleaning shall be maintained on the premises. [**96:**11.6.13]

Exhibit 50.16 is an example of such a certificate affixed to the exterior of the hood, showing all the required information.

Exhibit 50.16

Certificate on the exterior of a hood.

50.5.6.14 After cleaning or inspection is completed, the exhaust cleaning company and the person performing the work at the location shall provide the owner of the system with a written report that also specifies areas that were inaccessible or not cleaned. [**96:**11.6.14]

An area that is not cleaned should be noted so that it can, if necessary, be identified as a continuing hazard that needs to be corrected. Usually, an area is not cleaned because it is not easily accessible. In some instances, an area is not cleaned because multiple restaurants are feeding into a common duct, and no agreement designates who is responsible for maintaining the common duct. In rare instances, an area might not be cleaned because the operator does not want to spend the money necessary for the cleaning. In all cases, the cleaning agency must identify and keep records of the areas not cleaned and explain why they have not been cleaned. This information will be taken into consideration by the local AHJ when the cleaning records are reviewed.

50.5.6.15 Where required, certificates of inspection and cleaning and reports of areas not cleaned shall be submitted to the AHJ. [**96:**11.6.15]

N **50.5.6.16** Metal containers used to collect grease drippings shall be inspected or emptied at least weekly. [**96:**11.6.16]

New for the 2017 edition of NFPA 96, 50.5.6.16 addresses the subject of metal grease drip collectors within hoods that can become involved in a fire before the fire-extinguishing system operates. Typically, no agent is discharged into these devices, and a fire on an appliance and within the hood that is successfully extinguished can subsequently spread from a fire that is fueled from the grease collector into the exhaust system.

50.5.7 Cooking Equipment Maintenance.

50.5.7.1 Inspection and servicing of the cooking equipment shall be made at least annually by properly trained and qualified persons. [**96:**11.7.1]

50.5.7.2 Cooking equipment that collects grease below the surface, behind the equipment, or in cooking equipment flue gas exhaust, such as griddles or charbroilers, shall be inspected and, if found with grease accumulation, cleaned by a properly trained, qualified, and certified person acceptable to the AHJ. [**96:**11.7.2]

In most cases, maintenance and cleaning can be effectively conducted without moving the cooking appliances. For cooking appliances that are moved, 50.6.1.2.3.1 requires that an approved method be provided to ensure that the appliances are returned to their approved designated locations. In some cases where the cooking appliance must be moved, it might be possible to do so without disconnecting any of the fire-extinguishing system nozzles.

50.6 Minimum Safety Requirements for Cooking Equipment

50.6.1 Cooking Equipment.

Δ **50.6.1.1*** Cooking equipment shall be approved based on one of the following criteria:

(1) Listings by a testing laboratory
(2) Test data acceptable to the AHJ

[**96:**12.1.1]

The allowance for listed appliances is predicated on the assumption that the appliances will be used in the manner and for the use outlined in the listing. Where not listed, 50.6.1.1(2) will normally be accomplished with the manufacturer's cut sheets for the appliance, or the manufacturer might use a testing lab with which they have contracted (for quality assurance purposes). Although it might not be a traditional testing lab, if it produces data, it might be acceptable to an AHJ.

A.50.6.1.1 Cooking appliances that are designed for permanent installation, including, but not limited to, ranges, ovens, stoves, broilers, grills, fryers, griddles, and barbecues, should be installed in accordance with the manufacturer's installation instructions.

(1) Commercial electric cooking appliances should be listed and labeled in accordance with ANSI/UL 197.
(2) Microwave cooking appliances should be listed and labeled in accordance with ANSI/UL 923.
(3) Oil-burning stoves should be listed and labeled in accordance with ANSI/UL 896.
(4) Wood-fired cooking appliances should be listed and labeled in accordance with ANSI/UL 737, UL Subject 2162, or UL Subject 2728, depending on exact appliance type.
(5) Gas-fired cooking appliances should be listed and labeled in accordance with ANSI Z83.11.
(6) Gas-wood-fired cooking appliances should be listed and labeled in accordance with ANSI Z83.11, ANSI/UL 737, and/or UL Subject 2162, depending on exact appliance type.

[**96:** A.12.1.1]

50.6.1.2 Installation.

50.6.1.2.1* All listed appliances shall be installed in accordance with the terms of their listings and the manufacturer's instructions. [**96:**12.1.2.1]

A.50.6.1.2.1 Gas-fueled appliances should be installed to the requirements of NFPA 54 or NFPA 58. [**96:**A.12.1.2.1]

50.6.1.2.1.1 Solid fuel used for flavoring within a gas-operated appliance shall be in a solid fuel holder (smoker box) that is listed with the equipment. [**96:**12.1.2.1.1]

50.6.1.2.2* Cooking appliances requiring protection shall not be moved, modified, or rearranged without prior re-evaluation of the fire-extinguishing system by the system installer or servicing agent, unless otherwise allowed by the design of the fire-extinguishing system. [**96:**12.1.2.2]

A.50.6.1.2.2 The effectiveness of an automatic extinguishing system is affected by the placement of the nozzles. For this reason, it is essential that cooking appliances be situated in the area in which they were when the extinguishing equipment was designed and installed. If an appliance is moved from under the equipment for cleaning or any other reason, it should be returned to its original position prior to initiation of a cooking operation. [**96:**A.12.1.2.2]

When appliances are on wheels or casters for ease of cleaning, it is important that the appliance be placed in its design position to ensure that the fire-extinguishing system will be effective. An approved method should ensure that the appliance is returned to its appropriate position before cooking takes place. Channels, markings, or other approved methods assist in ensuring proper placement. [**96:**A.12.1.2.2]

50.6.1.2.2.1 A solid fuel holder shall not be added to an existing appliance until the fire-extinguishing system has been evaluated by the fire-extinguishing system service provider. [**96:**12.1.2.2.1]

Solid fuel used for flavoring can be used only in solid fuel holders within gas-operated appliances where the solid fuel holder is listed with the appliance. Where solid fuel holders are added to existing appliances, the existing fire-extinguishing system should be evaluated to determine if an upgrade is needed.

50.6.1.2.3 The fire-extinguishing system shall not require re-evaluation where the cooking appliances are moved for the purposes of maintenance and cleaning, provided the appliances are returned to approved design location prior to cooking operations, and any disconnected fire-extinguishing system nozzles attached to the appliances are reconnected in accordance with the manufacturer's listed design manual. [**96:**12.1.2.3]

In most cases, maintenance and cleaning can be effectively conducted without moving the cooking appliances. In some cases, where the cooking appliance does need to be moved, doing so without disconnecting any of the fire-extinguishing system nozzles might be possible.

50.6.1.2.3.1 An approved method shall be provided that will ensure that the appliance is returned to an approved design location. [**96:**12.1.2.3.1]

50.6.1.2.4 All deep-fat fryers shall be installed with at least a 16 in. (406 mm) space between the fryer and surface flames from adjacent cooking equipment. [**96:**12.1.2.4]

It is important to note that a deep-fat fryer located within 16 in. (406 mm) of another cooking appliance is not necessarily in violation of the requirement of 50.6.1.2.4. The requirement specifically addresses the distance between a deep-fat fryer and the surface flames of adjacent cooking appliances. Additionally, an electric cooking appliance typically does not have a flame.

Exhibit 50.17 shows a situation in which the fryer is located within 16 in. (406 mm) of the other cooking equipment. However, because the other cooking equipment is electric and does not produce a flame, this separation requirement does not apply.

50.6.1.2.5 Where a steel or tempered glass baffle plate is installed at a minimum 8 in. (203 mm) in height between the fryer and surface flames of the adjacent appliance, the requirement for a 16 in. (406 mm) space shall not apply. [**96:**12.1.2.5]

An 8 in. (203 mm) vertical barrier in effect creates 16 in. (406 mm) of travel [8 in. (203 mm) up, 8 in. (203 mm) down] between the deep-fat fryer and the flames of the adjacent appliance. Exhibit 50.18 shows a baffle plate that meets the separation requirement of 50.6.1.2.5.

Exhibit 50.17

Example of a situation in which separation is not required.

Exhibit 50.18

Example of a baffle plate providing separation between a fryer and an adjacent appliance that produces surface flames.

50.6.1.2.5.1 If the fryer and the surface flames are at different horizontal planes, the minimum height of 8 in. (203 mm) shall be measured from the higher of the two. [**96:**12.1.2.5.1]

If the vertical barrier were to be placed 8 in. (203 mm) above the lower of the two appliances, a situation in which a path of less than 16 in. (406 mm) between the deep-fat fryer and the flames of the adjacent appliance could exist. Therefore, where a vertical barrier method is utilized, it should be arranged to be at least 8 in. (203 mm) above the higher of the two appliances.

50.6.2 Operating Controls. Deep-fat fryers shall be equipped with a separate high-limit control in addition to the adjustable operating control (thermostat) to shut off fuel or energy when the fat temperature reaches 475°F (246°C) at 1 in. (25.4 mm) below the surface. [**96:**12.2]

A separate high-limit control has been required on all gas and electric fryers for many years. The requirement of 50.6.2 states that the separate high-limit control must operate a gas valve or electrical contactor that is separate from that operated by the normal operating thermostat. This arrangement ensures that, if the thermostat or its valve or contactor fails, the high-limit control will close the second valve or open the second contactor to shut off the fuel. Although it would be beneficial, this high-limit control is not required to have a manual reset.

50.6.3 Commercial Kitchen Cooking Oil Storage Tank Systems. Commercial kitchen cooking oil storage tank systems shall comply with 66.19.7.

Cooking oil storage tank systems fall under the jurisdiction of NFPA 30, *Flammable and Combustible Liquids Code*. Additional commentary regarding these types of systems can be found after 66.19.7.

N 50.7 Mobile and Temporary Cooking Operations

Recent incidents involving mobile and temporary cooking operations have created an awareness of the lack of minimum fire safety requirements for the growing number of these operations in jurisdictions throughout the world:

New York, NY

On April 11, 2011, a food truck collided with another vehicle on a highway in NYC. The accident caused the truck to burst into flames, and one of the propane tanks exploded. It was later found that the driver was carrying twice the maximum limit of propane (limit of 2 tanks, driver had 4) when he crashed into another car. The accident caused injuries to two workers aboard the food truck.

Toronto, Ontario

On August 24, 2012, at around 4 a.m., an explosion destroyed a food truck at the Canadian National Exhibition grounds. The explosion caused debris to be scattered throughout the parking lot where it was located. Fortunately, the explosion happened at a time of day when no one was in the area, and no injuries occurred. It is expected that the cause of the explosion, which was felt by police officers over a mile away, was a propane leak.

Philadelphia, PA

On July 1, 2014, an explosion involving a food truck resulted in 13 injuries, including the deaths of the mother and daughter operating the food truck. The truck was equipped with two 100-pound propane tanks. Investigators believe the cause of the problem was a rupture of the entire tank. The age of the tank could have contributed to this failure. The tragedy captured the world's attention, because the explosion was captured on video by a nearby surveillance camera, revealing how dangerous propane systems can be if not properly inspected and maintained.

Denver, CO

Two food trucks were damaged by a small propane explosion on September 12, 2014. An employee was switching out a propane tank when a leak that occurred during the refilling was ignited and caused a small explosion. One employee suffered facial burns, but no other injuries were reported.

Indianapolis, IN

On June 20, 2015, four people were injured when a fire destroyed a food truck in a parking lot. Two of those injured were employees of the food truck, who sustained serious burns. An investigation determined that the fire occurred when employees were trying to refuel the generator. Fumes from the gas hit a nearby open flame from a propane grill that was being used while the generator was being refueled.

Washington D.C

On November 16, 2016, a fire occurred on a food truck located on the George Washington University campus. Three employees were taken to the hospital with burns. The fire caused severe damage inside the food truck, which turned out to be a converted school bus. It was later determined that the cause of the fire was an employee refueling a gas generator while the truck engine was on and while food was being served. The fire started outside the truck and spread to the inside.

Portland, OR

On October 19, 2017, a fire and explosion occurred at a food cart pod in downtown Portland. As a result of the fire, two carts were destroyed and many cars in the parking lot nearby were damaged. A food cart employee was refueling a hot generator that was being used for power. Some of the fuel spilled and fumes were blown into an ignition source. Two additional propane tanks exploded in the fire. No injuries were reported.

It is important to note that there have been several other incidents involving food truck fires and explosions that have not been reported as such because these incidents are coded either as "Restaurant Fires" or "Vehicle Fires" in the National Fire Incident Reporting System (NFIRS).

It was the incident in Philadelphia that caused the International Fire Marshals Association (IFMA) to assemble a task group to develop minimum fire safety requirements for inclusion in NFPA 1 and NFPA 96. Section 50.7 is new to the 2017 edition of this *Code* and is based on the revisions recommended by IFMA as well as other contributions from the Fire Code Technical Committee made throughout the revision cycle.

Exhibit 50.19

Food truck. (Thinkstock)

To support the provisions of Section 50.7, a definition of *mobile or temporary cooking* was added to Chapter 3. It is defined in 3.3.187 as "any cooking apparatus or equipment operated on a one-time basis, interim basis, or for less than 90 days in the same location, other than at a fixed location, building, or structure that has been inspected and permitted under another section of this *Code*, regulation, or statute." Mobile or temporary cooking can include self-propelled trucks and vehicles; trailered units; push carts; equipment located under cover of awnings, canopies, or pop-up tents; or other structures for which a building permit has not been issued. The provisions of Section 50.7 are applicable not only to food trucks (mobile cooking operations) but also to stationary cooking operations that are temporary. Exhibit 50.19 shows an example of a food truck.

The information shown in Exhibit 50.20 is provided to help advance the safety of mobile and temporary cooking operations and is not intended to be a comprehensive list of requirements. Exhibit 50.20 and its accompanying text are included here as a useful starting point and quick reference tool when applying the provisions for mobile cooking requirements to food trucks. This information should not replace a full fire safety analysis. Users should check with their local jurisdiction for specific requirements. For more information, go to nfpa.org/foodtrucksafety.

N **50.7.1 General.**

N **50.7.1.1** Mobile and temporary cooking operations shall comply with 50.7.1 and the applicable section for the type of cooking performed.

N **50.7.1.2** Where required by the AHJ, permits shall be required for the location, design, construction, and operation of mobile and temporary cooking operations.

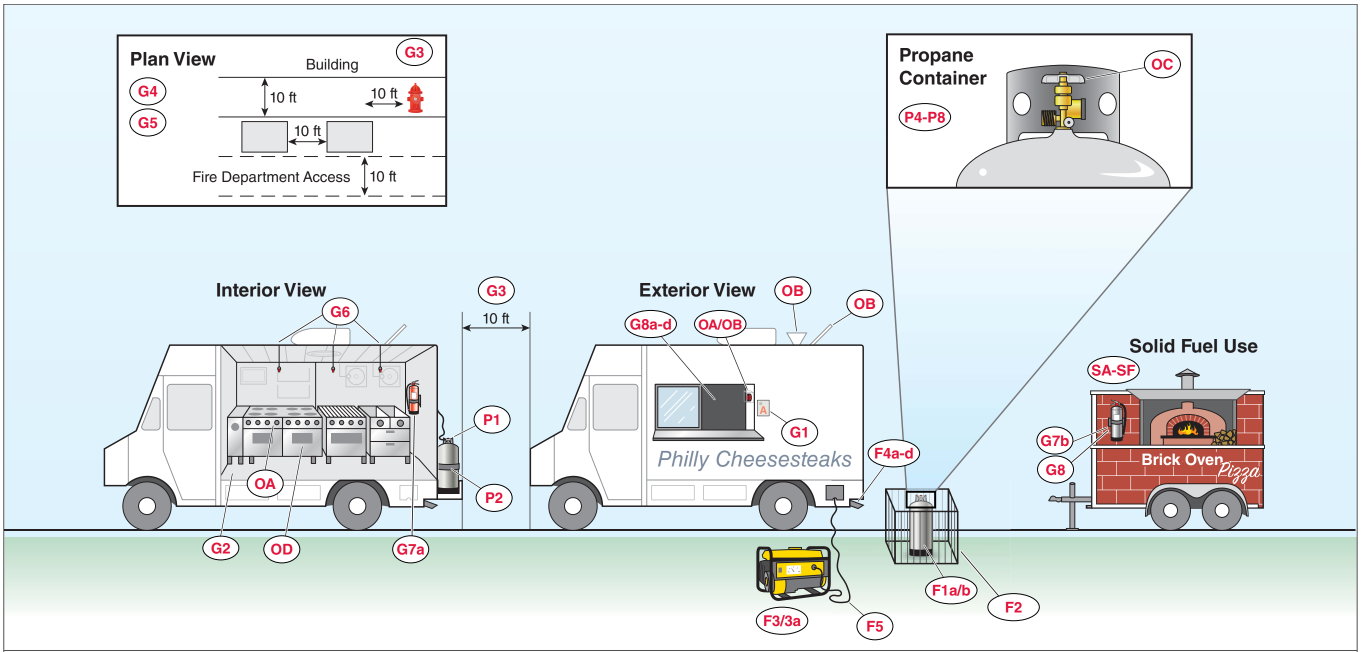
See 1.12.8 and Table 1.12.8(a) for permit requirements. Permits are required to conduct mobile cooking operations.

N **50.7.1.3** Wheel chocks shall be used to prevent mobile and temporary cooking units from moving.

N **50.7.1.4 Portable Fire Extinguishers.**

N **50.7.1.4.1** Portable fire extinguishers shall be provided per NFPA 96 for cooking operations.

Exhibit 50.20



NFPA code references are provided at the end of each item. The red keys correspond to the NFPA food truck safety diagram. For more detailed information, see Annex B in NFPA 96.

General Safety Checklist

- ❑ Obtain license or permits from the local authorities. [**1:**1.12.8(a)] **G1**
- ❑ Ensure there is no public seating within the mobile food truck. **G2**
- ❑ Check that there is a clearance of at least 10 ft away from buildings, structures, vehicles, and any combustible materials. [**96:**7.8.2; **96:**7.8.3 for carnivals only] **G3**
- ❑ Verify fire department vehicular access is provided for fire lanes and access roads. [**1:**18.2.4] **G4**
- ❑ Ensure clearance is provided for the fire department to access fire hydrants and access fire department connections. [**1:**13.1.3; **1:**13.1.4; **1:**13.1.5] **G5**
- ❑ Check that appliances using combustible media are protected by an approved fire extinguishing system. [**96:**10.1.2] **G6**
- ❑ Verify portable fire extinguishers have been selected and installed in kitchen cooking areas in accordance with NFPA 10. [**96:**10.9.3] **G7a**
- ❑ Where solid fuel cooking appliance produce grease-laden vapors, make sure the appliances are protected by listed fire-extinguishing equipment. [**96:**14.7.1] **G7b**
- ❑ Ensure that workers are trained in the following: [**96:**B.15.1]: **G8**
  - ❑ Proper use of portable fire extinguishers and extinguishing systems [**10:**1.2] **G8a**
  - ❑ Proper method of shutting off fuel sources [**96:**10.4.1] **G8b**
  - ❑ Proper procedure for notifying the local fire department [**1:**10.14.9 for carnivals only] **G8c**
  - ❑ Proper procedure for how to perform simple leak test on gas connections [**58:**6.16, **58:**6.17] **G8d**

Fuel & Power Sources Checklist

- ❑ Verify that fuel tanks are filled to the capacity needed for uninterrupted operation during normal operating hours. [**1:**10.14.10.1 for carnivals only] **F1a**
- ❑ Ensure that refueling is conducted only during non-operating hours. [**96:**B.18.3] **F1b**
- ❑ Check that any engine-driven source of power is separated from the public by barriers, such as physical guards, fencing, or enclosures. [**96:**B.16.2.2] **F2**
- ❑ Ensure that any engine-driven source of power is shut down prior to refueling from a portable container. [**1:**11.7.2.1.2] **F3**
- ❑ Check that surfaces of engine-driven source of power are cool to the touch prior to refueling from a portable container. **F3a**
- ❑ Make sure that exhaust from engine-driven source of power complies with the following: **F4**
  - ❑ At least 10 ft in all directions from openings and air intakes [**96:**B.13] **F4a**
  - ❑ At least 10 ft from every means of egress [**96:**B.13] **F4b**
  - ❑ Directed away from all buildings [**1:**11.7.2.2] **F4c**
  - ❑ Directed away from all other cooking vehicles and operations [**1:**11.7.2.2] **F4d**
- ❑ Ensure that all electrical appliances, fixtures, equipment, and wiring complies with the NFPA 70®. [**96:**B.18] **F5**

NOTE: This information is provided to help advance safety of mobile and temporary cooking operations. It is not intended to be a comprehensive list of requirements for mobile and temporary cooking operations. Check with the local jurisdiction for specific requirements. This safety sheet does not represent the official position of the NFPA or its Technical Committees. The NFPA disclaims liability for any personal injury, property, or other damages of any nature whatsoever resulting from the use of this information. For more information, go to nfpa.org/foodtrucksafety.

Propane System Integrity Checklist

- ❑ Check that the main shutoff valve on all gas containers is readily accessible. [**58:**6.26.4.1(3)] **P1**
- ❑ Ensure that portable gas containers are in the upright position and secured to prevent tipping over. [**58:**6.26.3.4] **P2**
- ❑ Inspect gas systems prior to each use. [**96:**B.19.2.3] **P3**
- ❑ Perform leak testing on all new gas connections of the gas system. [**58:**6.16; **58:**6.17] **P4**
- ❑ Perform leak testing on all gas connections affected by replacement of an exchangeable container. [**58:**6.16; **58:**6.17] **P5**
- ❑ Document leak testing and make documentation available for review by the authorized official. [**58:**6.26.5.1(M)] **P6**
- ❑ Ensure that on gas system piping, a flexible connector is installed between the regulator outlet and the fixed piping system. [**58:**6.26.5.1(B)] **P7**
- ❑ Where a gas detection system is installed, ensure that it has been tested in accordance with the manufacturer's instructions. [**96:**B.19.2.1] **P8**

Operational Safety Checklist

- ❑ Do not leave cooking equipment unattended while it is still hot. (This is the leading cause of home structure fires and home fire injuries.) **OA**
- ❑ Operate cooking equipment only when all windows, service hatches, and ventilation sources are fully opened. [**96:**14.2.2; **96:**14.2.3] **OB**
- ❑ Close gas supply piping valves and gas container valves when equipment is not in use. [**58:**6.26.8.3] **OC**
- ❑ Keep cooking equipment, including the cooking ventilation system, clean by regularly removing grease. [**96:**11.4] **OD**

Solid Fuel Safety Checklist (Where Wood, Charcoal, or Other Solid Fuel Is Used)

- ❑ Fuel is not stored above any heat-producing appliance or vent. [**96:**14.9.2.2] **SA**
- ❑ Fuel is not stored closer than 3 ft to any cooking appliance. [**96:**14.9.2.2] **SB**
- ❑ Fuel is not stored near any combustible flammable liquids, ignition sources, chemicals, and food supplies and packaged goods. [**96:**14.9.2.7] **SC**
- ❑ Fuel is not stored in the path of the ash removal or near removed ashes. [**96:**14.9.2.4] **SD**
- ❑ Ash, cinders, and other fire debris should be removed from the firebox at regular intervals and at least once a day. [**96:**14.9.3.6.1] **SE**
- ❑ Removed ashes, cinders, and other removed fire debris should be placed in a closed, metal container located at least 3 ft from any cooking appliance. [**96:**14.9.3.8] **SF**

NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*, 2017 Edition
NFPA 96: Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations Handbook, 2017 Edition

Food truck safety requirements.

N **50.7.1.4.2** A minimum of one 2A:10BC portable fire extinguisher shall be provided when a generator or other fuel fired appliance is used.

N **50.7.1.4.3** When wood or charcoal is used, a minimum of one 2A portable fire extinguisher or an approved hose line shall be provided.

N **50.7.1.5 Separation.** Mobile or temporary cooking operations shall be separated from buildings or structures, combustible materials, vehicles, and other cooking operations by a minimum of 10 ft (3 m).

This paragraph requires food trucks and other mobile or temporary cooking operations to be separated not only from buildings or structures but also from other vehicles by a minimum of 10 ft (3 m). Events such as food truck "rodeos" or festivals often have 20 or more food trucks present. The AHJ would need to verify the arrangement of the food trucks to ensure that the 10 ft (3 m) separation is provided at all times. The separation reduces the likelihood that a fire event in one truck will impact other surrounding trucks. Where a fire does occur, the separation can slow the spread of the fire to adjacent trucks or cooking operations. Exhibit 50.21 shows food trucks that do not meet the 10 ft (3 m) separation requirement.

Exhibit 50.21

Food trucks without the minimum 10 ft (3 m) separation. (Thinkstock)

N **50.7.1.6 Tents.**

N **50.7.1.6.1** Mobile or temporary cooking shall not take place within tents occupied by the public.

N **50.7.1.6.2** Tents shall comply with Chapter 25.

N **50.7.1.6.3** Seating for the public shall not be located within any mobile or temporary cooking vehicle.

NFPA staff have been asked about food truck–type buses that have both cooking operations and seating in the same vehicle. These vehicles often are double decker buses with cooking on the first level and seating on the second level or a similar arrangement. However, such vehicles would not be in compliance with the provisions of 50.7.1.6.3, which does not permit a seating area within the vehicle (bus).

N **50.7.1.7 Fire Department Access.** Mobile or temporary cooking operations shall not block fire department access roads, fire lanes, fire hydrants, or other fire protection devices and equipment.

N **50.7.1.8 Communications.**

N **50.7.1.8.1** An approved method of communication to emergency personnel shall be accessible to all employees.

N **50.7.1.8.2** The address of the current operational location shall be posted and accessible to all employees.

Food trucks do not have a permanent address. Because they are mobile cooking operations, they are often moving around to a different location, perhaps multiple locations, each day. The provision of 50.7.1.8.2 ensures that a mobile food truck's current location is posted and available should an employee need to report the location to emergency personnel. Posting the location allows staff to identify quickly the truck's exact location so that the dispatch or response of the fire department is not delayed in the event of an emergency.

N **50.7.1.9 Training.**

N **50.7.1.9.1*** Prior to performing mobile or temporary cooking operations, workers shall be trained in emergency response procedures, including the following:

(1) Proper use of portable fire extinguishers and extinguishing systems
(2) Proper method of shutting off fuel sources
(3) Proper procedure for notifying the local fire department
(4) Proper refueling
(5) How to perform leak detection
(6) Fuel properties

N **A.50.7.1.9.1** An approved method of leak detection would include pressurizing the LP-Gas system with LP-Gas and utilizing a gas meter to detect the presence of LP-Gas around the tank, piping, and appliances.

Many of the incidents described in the commentary following Section 50.7 were related to refueling, fuel sources and ignition sources (fuel leaks), and improper use of equipment. The items listed in 50.7.1.9.1(1) through (6) ensure that workers are trained and understand the proper use and handling of equipment and fire protection systems. Proper training should alleviate some of the mistakes and accidents that have already been cited as causing serious injuries or fatalities.

N **50.7.1.9.2** Refresher training shall be provided every year.

N **50.7.1.9.3** Initial and refresher training shall be documented and made available to the AHJ on request.

N **50.7.1.10 Internal Combustion Power Sources.**

N **50.7.1.10.1** Electric generator and internal combustion power sources used for mobile or temporary cooking shall comply with 11.7.2.

N **50.7.1.10.2** Portable generators shall be positioned so that the exhaust is at least 5 ft (1.5 m) in any direction away from any openings, air intakes, means of egress, or from any building, structure, or vehicle.

N **50.7.1.10.3** Electrical appliances, fixtures, equipment, or wiring other than low-voltage and automotive vehicle circuits or extensions thereof, installed within or on vehicles, shall comply with *NFPA 70*.

N **50.7.1.11 Charcoal and Wood Burning.**

N **50.7.1.11.1** Mobile or temporary cooking operations that use wood or charcoal shall comply with Section 14.9 of NFPA 96.

Section 14.9 of NFPA 96 addresses the minimum safety requirements for fuel storage, handling, and ash removal for solid fuel cooking.

N **50.7.1.11.2** An approved carbon monoxide detector shall be installed where mobile cooking operations are performed in an enclosed area.

N **50.7.1.12** Flammable liquids shall not be stored inside mobile cooking vehicles or in temporary cooking areas unless stored in accordance with NFPA 30.

N **50.7.2 Mobile Cooking.**

N **50.7.2.1 General.** Mobile cooking operations and equipment shall comply with 50.7.1, 50.7.2, and NFPA 96.

N **50.7.2.2 LP-Gas Systems.**

N **50.7.2.2.1** Cylinders shall be secured in an upright position to prevent tipping over.

Cylinders that are not secure, especially during transit, are at risk for tipping over.

N **50.7.2.2.2** Gas systems on mobile cooking vehicles shall comply with NFPA 58 and this section.

N **50.7.2.2.3** Where a shutoff valve is provided, it shall be readily accessible and identified with a sign permanently affixed to the vehicle in reflective decal material with letters a minimum of 2 in. (50 mm) high.

N **50.7.2.3* Leak Detection.**

N **A.50.7.2.3** The certification documentation might consist of the following:

(1) The name of the certification company
(2) The license number, certificate of fitness number or other applicable identifying number that demonstrates the certification company is approved to install, inspect, and maintain LP-Gas systems
(3) The corporate name of the mobile food service business
(4) The identifying name on the side of the mobile food vehicle
(5) Date of inspection
(6) Vehicle tag number and VIN 7
(7) A signed statement by the agent for the certification company that reads: The LP-Gas system has been inspected for compliance with the current edition of NFPA 58 and found to be in compliance with the provisions of the code. In addition, leak detection has been conducted on the LP-Gas system piping and the piping has been found to maintain integrity.

N **50.7.2.3.1** Gas systems shall be inspected prior to each use by a worker trained in accordance with 50.7.1.8.

N **50.7.2.3.2** Leak detection testing shall be documented and made available to the AHJ on request in accordance with 50.7.2.3.4.

N **50.7.2.3.3** Where a gas detection system has been installed, it shall be tested every month.

N **50.7.2.3.4*** LP-Gas systems on mobile food service vehicles shall be certified for compliance with NFPA 58 by an approved company with expertise in the installation, inspection, and maintenance of LP-Gas systems.

N **A.50.7.2.3.4** The certification documentation might consist of the following:

(1) The name of the certification company
(2) The license number, certificate of fitness number or other applicable identifying number that demonstrates the certification company is approved to install, inspect, and maintain LP-Gas systems
(3) The corporate name of the mobile food service business
(4) The identifying name on the side of the mobile food vehicle
(5) Date of inspection
(6) Vehicle tag number and VIN
(7) A signed statement by the agent for the certification company that reads: The LP-Gas system has been inspected for compliance with the current edition of NFPA 58 and found to be in compliance with the provisions of the code. In addition, leak detection has been conducted on the LP-Gas system piping and the piping has been found to maintain integrity.

N **50.7.2.3.4.1** The certification shall be good for one year.

N **50.7.2.3.4.2** Recertification shall occur every time an appliance is replaced or added and if a piping connection is modified in anyway.

N **50.7.2.3.4.2.1** A change in cylinder shall not be considered a piping connection modification.

N **50.7.2.3.4.3** Mobile food service vehicles equipped with an LP-Gas system, but without a current approved LP-Gas certification, shall not be permitted to be operated for mobile food service.

N **50.7.2.4 LP-Gas Systems on Vehicles (Other than Engine Fuel Systems).**

Paragraph 50.7.2.4 and its subparagraphs cover all LP-Gas systems mounted on vehicles, other than engine fuel systems, with the following exceptions:

- Manufactured housing (mobile homes)
- Recreational vehicles (RVs) (The provisions of NFPA 58, *Liquefied Petroleum Gas Code*, are used extensively for standards on LP-Gas systems in NFPA 1192, *Standard on Recreational Vehicles*.)
- Cargo tank vehicles (covered in Chapter 9 of NFPA 58)
- Engine fuel systems (covered in Chapter 11 of NFPA 58)

N **50.7.2.4.1* Application.** Section 50.7.2.4 shall apply to the following:

(1) Nonengine fuel systems on all vehicles
(2) Installations served by exchangeable (removable) cylinder systems and by permanently mounted containers.

[**58:**6.26.1]

N **A.50.7.2.4.1** Typical nonengine fuel systems include those on commercial, industrial, construction, and public service vehicles such as trucks, semitrailers, trailers, portable tar kettles, road surface heating equipment, mobile laboratories, clinics, and mobile cooking units (such as catering and canteen vehicles). [**58:**A.6.26.1]

A variety of LP-Gas systems are installed on vehicles where the gas is not used as a vehicle engine fuel. Examples include the following:

- Vehicles (usually trailers) with mounted tar kettles used in the construction industry for heating tar for roofing
- Food-warming delivery vehicles, such as pretzel or hot dog carts and larger hot dog or lunch wagons
- Service vehicles that need a source of heated water, such as those used by carpet cleaning services
- Food trucks that use the propane to prepare food

N **50.7.2.4.2 Nonapplication.** Section 50.7.2.4 shall not apply to the following:

(1) Systems installed on mobile homes
(2) Systems installed on recreational vehicles
(3) Cargo tank vehicles, including trailers and semitrailers, and similar units used to transport LP-Gas as cargo, which are covered by Chapter 9 of NFPA 58.
(4) LP-Gas engine fuel systems on the vehicles, which are covered by Chapter 11 of NFPA 58.

[**58:**6.26.2]

N **50.7.2.4.3 Container Installation Requirements.**

N **50.7.2.4.3.1** Containers shall comply with 50.7.2.4.3.1.1 through 50.7.2.4.3.1.5.

N **50.7.2.4.3.1.1** ASME mobile containers shall be in accordance with one of the following:

(1) A MAWP of 312 psig (2.2 MPag) or higher where installed in enclosed spaces of vehicles
(2) A MAWP of 312 psig (2.2 MPag) or higher where installed on passenger vehicles
(3) A MAWP of 250 psig (1.7 MPag) or higher for containers where installed on the exterior of nonpassenger vehicles

N **50.7.2.4.3.1.2** LP-Gas fuel containers used on passenger-carrying vehicles shall not exceed 200 gal (0.8 m^3) aggregate water capacity.

N **50.7.2.4.3.1.3** The capacity of individual LP-Gas containers on highway nonpassenger vehicles shall 1000 gal (3.8 m^3) or in accordance with U.S. Department of Transportation regulations.

N **50.7.2.4.3.1.4** The capacity of cargo tank motor vehicles shall not be limited by NFPA 58.

N **50.7.2.4.3.1.5** Containers designed for stationary service only and not in compliance with the container appurtenance protection requirements of 5.2.6 of NFPA 58 shall not be used. [**58:**6.26.3]

N **50.7.2.4.3.2** ASME containers and cylinders used for the purposes covered by 50.7.2.4 shall not be installed, transported, or stored (even temporarily) inside any vehicle covered by 50.7.2.4, except for ASME containers installed in accordance with 50.7.2.4.3.4.9, Chapter 9, or DOT regulations. [**58:**6.26.3.2]

N **50.7.2.4.3.3** The LP-Gas supply system, including the containers, shall be installed either on the outside of the vehicle or in a recess or cabinet vaportight to the inside of the vehicle but accessible from and vented to the outside, with the vents located near the top and bottom of the enclosure and 3 ft (1 m) horizontally away from any opening into the vehicle below the level of the vents. [**58:**6.26.3.3]

N **50.7.2.4.3.4** Containers shall be mounted securely on the vehicle or within the enclosing recess or cabinet. [**58:**6.26.3.4]

N **50.7.2.4.3.4.1** Containers shall be installed with road clearance in accordance with 11.8.3 of NFPA 58. [**58:**6.26.3.4(A)]

N **50.7.2.4.3.4.2** Fuel containers shall be mounted to prevent jarring loose and slipping or rotating, and the fastenings shall be designed and constructed to withstand, without permanent visible deformation, static loading in any direction equal to four times the weight of the container filled with fuel. [**58:**6.26.3.4(B)]

N **50.7.2.4.3.4.3** Where containers are mounted within a vehicle housing, the securing of the housing to the vehicle shall comply with this provision. Any removable portions of the housing or cabinet shall be secured while in transit. [**58:**6.26.3.4(C)]

N **50.7.2.4.3.4.4** Field welding on containers shall be limited to attachments to nonpressure parts such as saddle plates, wear plates, or brackets applied by the container manufacturer. [**58:**6.26.3.4(D)]

N **50.7.2.4.3.4.5** All container valves, appurtenances, and connections shall be protected to prevent damage from accidental contact with stationary objects; from loose objects, stones, mud, or ice thrown up from the ground or floor; and from damage due to overturn or similar vehicular accident. [**58:**6.26.3.4(E)]

As with vehicle propulsion engine fuel containers, exterior containers and appurtenances must be protected against material thrown up from the road, as set forth in 50.7.2.4.3.4.5. Slush and other hazards thrown up from the road must not block the regulator vent, and splashguards or the practice of locating the regulator in a compartment can protect from these hazards. A blocked vent can lead to higher than normal pressures in the utilization system and can lead to pilot failure and improper appliance operation. Appurtenances on a container, particularly those mounted below the vehicle, should be installed so that they are accessible for maintenance and readily accessible if needed for normal operations such as operation of the fixed maximum liquid level gauge during filling.

N **50.7.2.4.3.4.6** Permanently mounted ASME containers shall be located on the vehicle to provide the protection specified in 50.7.2.4.3.4.5. [**58:**6.26.3.4(F)]

N **50.7.2.4.3.4.7** Cylinders shall have permanent protection for cylinder valves and connections. [**58:**6.26.3.4(G)]

N **50.7.2.4.3.4.8** Where cylinders are located on the outside of a vehicle, weather protection shall be provided. [**58:**6.26.3.4(H)]

N **50.7.2.4.3.4.9** Containers mounted on the interior of passenger-carrying vehicles shall be installed in compliance with Section 11.9 of NFPA 58. Pressure relief valve installations for such containers shall comply with 11.8.5 of NFPA 58. [**58:**6.26.3.4(I)]

The container mounting arrangement must be strong enough to remain intact and to protect the container and its appurtenances and connections from damage caused by collisions, road debris, and weather. These provisions do not apply to engine fuel containers, as stated by the reference to Chapter 11 of NFPA 58.

N **50.7.2.4.4 Installation of Container Appurtenances.**

N **50.7.2.4.4.1** Container appurtenances shall be installed in accordance with the following:

(1) Pressure relief valve installation on ASME containers installed in the interior of vehicles complying with Section 11.9 of NFPA 58 shall comply with 11.8.5 of NFPA 58.
(2) Pressure relief valve installations on ASME containers installed on the outside of vehicles shall comply with 11.8.5 of NFPA 58 and 50.7.2.4.3.3.
(3) Main shutoff valves on containers for liquid and vapor shall be readily accessible.
(4) Cylinders shall be designed to be filled in either the vertical or horizontal position, or if they are the universal type, they are permitted to be filled in either position.
(5) All container inlets, outlets, or valves installed in container inlets or outlets, except pressure relief devices and gauging devices, shall be labeled to designate whether they communicate with the vapor or liquid space.
(6) Containers from which only vapor is to be withdrawn shall be installed and equipped with connections to minimize the possibility of the accidental withdrawal of liquid.

[**58:**6.26.4.1]

N **50.7.2.4.4.2** Regulators shall be installed in accordance with 6.10.2 of NFPA 58 and 50.7.2.4.4.2.1 through 50.7.2.4.4.2.5. [**58:**6.26.4.2]

N **50.7.2.4.4.2.1** Regulators shall be installed with the pressure relief vent opening pointing vertically downward to allow for drainage of moisture collected on the diaphragm of the regulator. [**58:**6.26.4.2(A)]

N **50.7.2.4.4.2.2** Regulators not installed in compartments shall be equipped with a durable cover designed to protect the regulator vent opening from sleet, snow, freezing rain, ice, mud, and wheel spray. [**58:**6.26.4.2(B)]

N **50.7.2.4.4.2.3** If vehicle-mounted regulators are installed at or below the floor level, they shall be installed in a compartment that provides protection against the weather and wheel spray. [**58:**6.26.4.2(C)]

N **50.7.2.4.4.2.4** Regulator compartments shall comply with the following:

(1) The compartment shall be of sufficient size to allow tool operation for connection to and replacement of the regulator(s).
(2) The compartment shall be vaportight to the interior of the vehicle.
(3) The compartment shall have a 1 in.^{2} (650 mm^2) minimum vent opening to the exterior located within 1 in. (25 mm) of the bottom of the compartment.
(4) The compartment shall not contain flame or spark-producing equipment.

[**58:**6.26.4.2(D)]

N **50.7.2.4.4.2.5** A regulator vent outlet shall be at least 2 in. (51 mm) above the compartment vent opening. [**58:**6.26.4.2(E)]

Two-stage pressure regulation must be used in all systems covered in Section 6.26 of NFPA 58. Multiple regulators provide several safety features. Regulators (and cylinders) used on vehicles are usually installed in a compartment for security and to comply with the requirement for protection of regulators from sleet, snow, freezing rain, and so forth. The enclosure cannot contain electrical devices that are a source of ignition and must be ventilated to allow any released propane to disperse. Louvers in the compartment or its door are typically used to provide this required ventilation. Louvers must communicate with the outdoors and not to the interior of the vehicle.

N **50.7.2.4.5 Piping.**

N **50.7.2.4.5.1** Piping shall be installed in accordance with 6.11.3 of NFPA 58 and 50.7.2.4.5.1.1 through 50.7.2.4.5.1.13. [**58:**6.26.5.1]

The main lines and branch connections must be kept outside the vehicle so that, if leakage occurs, gas will not accumulate in the vehicle. In order to avoid compounding problems in the event of collisions, overturns, and disconnection of vehicles, fuel lines cannot be connected between two vehicular units. These types of risks are regarded as greater than the corresponding risks in a system located completely on one vehicle.

N **50.7.2.4.5.1.1** Steel tubing shall have a minimum wall thickness of 0.049 in. (1.2 mm). [**58:**6.26.5.1(A)]

Steel tubing in vehicular installations has been specified as having a minimum 0.049 in. (1.2 mm) wall thickness to provide strength against vibration and also to provide an additional tolerance for corrosion.

N **50.7.2.4.5.1.2** A flexible connector shall be installed between the regulator outlet and the fixed piping system to protect against expansion, contraction, jarring, and vibration strains. [**58:**6.26.5.1(B)]

N **50.7.2.4.5.1.3** Flexibility shall be provided in the piping between a cylinder and the gas piping system or regulator. [**58:**6.26.5.1(C)]

N **50.7.2.4.5.1.4** Flexible connectors shall be installed in accordance with 6.11.6 of NFPA 58. [**58:**6.26.5.1(D)]

N **50.7.2.4.5.1.5** Flexible connectors longer than the length allowed in NFPA 58, or fuel lines that incorporate hose, shall be used only where approved. [**58:**6.26.5.1(E)]

N **50.7.2.4.5.1.6** The fixed piping system shall be designed, installed, supported, and secured to minimize the possibility of damage due to vibration, strains, or wear and to preclude any loosening while in transit. [**58:**6.26.5.1(F)]

N **50.7.2.4.5.1.7** Piping shall be installed in a protected location. [**58:**6.26.5.1(F)]

N **50.7.2.4.5.1.8** Where piping is installed outside the vehicle, it shall be installed as follows:

(1) Piping shall be under the vehicle and below any insulation or false bottom.
(2) Fastening or other protection shall be installed to prevent damage due to vibration or abrasion.
(3) At each point where piping passes through sheet metal or a structural member, a rubber grommet or equivalent protection shall be installed to prevent chafing.

[**58:**6.26.5.1(H)]

N **50.7.2.4.5.1.9** Gas piping shall be installed to enter the vehicle through the floor directly beneath or adjacent to the appliance served. [**58:**6.26.5.1(I)]

N **50.7.2.4.5.1.10** If a branch line is installed, the tee connection shall be located in the main gas line under the floor and outside the vehicle. [**58:**6.26.5.1(J)]

N **50.7.2.4.5.1.11** Exposed parts of the fixed piping system either shall be of corrosion-resistant material or shall be coated or protected to minimize exterior corrosion. [**58:**6.26.5.1(K)]

N **50.7.2.4.5.1.12** Hydrostatic relief valves shall be installed in isolated sections of liquid piping as provided in Section 6.15 of NFPA 58. [**58:**6.26.5.1(L)]

N **50.7.2.4.5.1.13** Piping systems, including hose, shall be pressure tested and proven free of leaks in accordance with Section 6.16 of NFPA 58. [**58:**6.26.5.1(M)]

N **50.7.2.4.5.2** There shall be no fuel connection between a tractor and trailer or other vehicle units. [**58:**6.26.5.2]

N **50.7.2.4.6 Equipment Installation.** Equipment shall be installed in accordance with Section 6.20 of NFPA 58, 50.7.2.4.6.1, and 50.7.2.4.6.2. [**58:**6.26.6]

N **50.7.2.4.6.1** Installation shall be made in accordance with the manufacturer's recommendations and, in the case of approved equipment, as provided in the approval. [**58:**6.26.6.1]

N **50.7.2.4.6.2** Equipment installed on vehicles shall be protected against vehicular damage as provided for container appurtenances and connections in 50.7.2.4.3.4.5. [**58:**6.26.6.2]

N **50.7.2.4.7 Appliance Installation on Vehicles.**

N **50.7.2.4.7.1** Subsection 50.7.2.4.7 shall apply to the installation of all appliances on vehicles. It shall not apply to engines. [**58:**6.26.7.1]

N **50.7.2.4.7.2** All appliances covered by 50.7.2.4.7 installed on vehicles shall be approved. [**58:**6.26.7.2]

N **50.7.2.4.7.3** Where the device or appliance, such as a cargo heater or cooler, is designed to be in operation while the vehicle is in transit, means, such as an excess-flow valve, to stop the flow of gas in the event of a line break shall be installed. [**58:**6.26.7.3]

Appliances used in vehicles and the vibration that occurs while vehicles are in transit can result in fittings loosening or becoming disconnected. The requirement in 50.7.2.4.7.3 recognizes that possibility and requires a positive means of stopping the flow if fittings are disconnected. Excess-flow valves are given as an example of protection, but other types of protection can be used. Excess-flow valves will close only when the design flow is reached, and they might not operate in the event of a partial separation of a fitting. If the vehicle comes under U.S. Department of Transportation (DOT) regulations, reference should be made to the DOT requirements that may apply.

N **50.7.2.4.7.4** Gas-fired heating appliances shall be equipped with shutoffs in accordance with 5.23.7(A) of NFPA 58, except for portable heaters used with cylinders having a maximum water capacity of 2.7 lb (1.2 kg), portable torches, melting pots, and tar kettles. [**58:**6.26.7.4]

N **50.7.2.4.7.5** Gas-fired heating appliances, other than ranges and illuminating appliances installed on vehicles intended for human occupancy, shall be designed or installed to provide for a complete separation of the combustion system from the atmosphere inside the vehicle. [**58:**6.26.7.5]

The concept of isolating the combustion system of appliances, except ranges in vehicle interiors where passengers might be, is consistent with all other vehicle standards on this subject, including the standards for RVs. No portable or conventional room heaters should be used inside such vehicles. Isolation can be accomplished through the use of direct vent–type heaters and water heaters or through separation by installing the appliance in a compartment with provisions for outside air. The range is an attended appliance and need not be isolated, but it should never be used for comfort heating.

Although extensive requirements for the installation of appliances fueled by LP-Gas are included in NFPA 54, *National Fuel Gas Code*, that code is limited to appliances that are connected to a fixed building piping system. The appliances covered under NFPA 58 are those not normally connected to a fixed building system.

N **50.7.2.4.7.6*** Where unvented-type heaters that are designed to protect cargo are used on vehicles not intended for human occupancy, provisions shall be made to provide air from the outside for combustion and dispose of the products of combustion to the outside. [**58:**6.26.7.6]

N **A.50.7.2.4.7.6** Requirements for the design of containers are located in Section 5.2 [of NFPA 58]. Requirements for container appurtenances are located in Section 5.3 [of NFPA 58]. [**58:**A.6.26.7.6]

N **50.7.2.4.7.7** Appliances installed in the cargo space of a vehicle shall be readily accessible whether the vehicle is loaded or empty. [**58:**6.26.7.7]

N **50.7.2.4.7.8** Appliances shall be constructed or otherwise protected to minimize possible damage or impaired operation due to cargo shifting or handling. [**58:**6.26.7.8]

N **50.7.2.4.7.9** Appliances shall be located so that a fire at any appliance will not block egress of persons from the vehicle. [**58:**6.26.7.9]

N **50.7.2.4.7.10** A permanent caution plate shall be affixed to either the appliance or the vehicle outside of any enclosure, shall be adjacent to the container(s), and shall include the following instructions:

(1) Be sure all appliance valves are closed before opening container valve.
(2) Connections at the appliances, regulators, and containers shall be checked periodically for leaks with soapy water or its equivalent.
(3) Never use a match or flame to check for leaks.
(4) Container valves shall be closed when equipment is not in use.

[**58:**6.26.7.10]

N **50.7.2.4.7.11** Gas-fired heating appliances and water heaters shall be equipped with automatic devices designed to shut off the flow of gas to the main burner and the pilot in the event the pilot flame is extinguished. [**58:**6.26.7.11]

N **50.7.2.4.8 General Precautions.**

N **50.7.2.4.8.1** All fat fryers shall have a lid over the oil vat that can be secured to prevent the spillage of cooking oil during transit. This lid shall be secured at all times when the vehicle is in motion.

N **50.7.2.4.9 Parking, Servicing, and Repair.**

N **50.7.2.4.9.1** Where vehicles with LP-Gas fuel systems used for purposes other than propulsion are parked, serviced, or repaired inside buildings, the requirements of 50.7.2.4.9.2 through 50.7.2.4.9.4 shall apply. [**58:**6.26.8.1]

N **50.7.2.4.9.2** The fuel system shall be leak-free, and the container(s) shall not be filled beyond the limits specified in Chapter 7 of NFPA 58. [**58:**6.26.8.2]

N **50.7.2.4.9.3** The container shutoff valve shall be closed, except that the container shutoff valve shall not be required to be closed when fuel is required for test or repair. [**58:**6.26.8.3]

N **50.7.2.4.9.4** The vehicle shall not be parked near sources of heat, open flames, or similar sources of ignition, or near unventilated pits. [**58:**6.26.8.4]

N **50.7.2.4.9.5** Vehicles having containers with water capacities larger than 300 gal (1.1 m3) shall comply with the requirements of Section 9.7 of NFPA 58. [**58:**6.26.8.5]

N **50.7.2.4.10*** Containers shall be designed, fabricated, tested, and marked (or stamped) in accordance with the regulations of the U.S. Department of Transportation (DOT); Section VIII of the ASME code, "Rules for the Construction of Unfired Pressure Vessels"; or the API-ASME *Code for Unfired Pressure Vessels for Petroleum Liquids and Gases*, except for UG-125 through UG-136. [**58:**5.2.1.1]

The DOT has approved the use of composite cylinders only when fabricated under a DOT special permit. They have a 15-year service life and must be requalified every 5 years. These cylinders can be used for all applications not prohibited by NFPA 58, such as outdoor gas grills, industrial trucks, and other applications not located in buildings.

A.50.7.2.4.10 Prior to April 1, 1967, regulations of the U.S. Department of Transportation were promulgated by the Interstate Commerce Commission. In Canada, the regulations of the Canadian Transport Commission apply and are available from the Canadian Transport Commission, Union Station, Ottawa, Canada. [**58:**A.5.2.1.1]

Construction of containers to the API-ASME *Code for Unfired Pressure Vessels for Petroleum Liquids and Gases* has not been authorized after July 1, 1961. [**58:**A.5.2.1.1]

N **50.7.2.4.10.1** Used containers constructed to specifications of the Association of American Railroads shall not be installed. [**58:**5.2.1.1(A)]

N **50.7.2.4.10.2** Adherence to applicable ASME code case interpretations and addenda that have been adopted and published by ASME 180 calendar days prior to the effective date of NFPA 58 shall be considered as compliant with the ASME code. [**58:**5.2.1.1(B)]

N **50.7.2.4.10.3** Where containers fabricated to earlier editions of regulations, rules, or codes listed in 5.2.1.1 of NFPA 58, and of the Interstate Commerce Commission (ICC) *Rules for Construction of Unfired Pressure Vessels*, prior to April 1, 1967, are used, the requirements of Section 1.4 of NFPA 58 shall apply. [**58:**5.2.1.1(C)]

The intent and application of 50.7.2.4.10.3 is often misinterpreted with regard to containers that were built to the API-ASME *Code for Unfired Pressure Vessels for Petroleum Liquids and Gases* (specifications U-200 and U-201) and pre-1949 editions of the ASME *Boiler and Pressure Vessel Code* (specifications U-68 and U-69). Because these ASME containers have a very long service life when properly maintained, many remain in use and are sometimes relocated and reinstalled. However, not all containers built to these older editions of the ASME Code can remain in use or relocated and reinstalled, regardless of their condition. The reinstallation of containers built to older editions of the code must be reviewed by the AHJ to determine if any current requirements meet a threshold for retroactivity.

N **50.7.2.4.10.4** DOT 4E specification (aluminum) cylinders and composite cylinders involved in a fire shall be removed from service. [**58:**5.2.1.1(D)]

N **50.7.2.4.11** After installation or modification, piping systems (including hose) shall be proven free of leaks by performing a pressure test at not less than the normal operating pressure. [**58:**6.16.1.1]

N **50.7.2.4.12 General Location of Cylinders.**

N **50.7.2.4.12.1** Cylinders in storage shall be located to minimize exposure to excessive temperature rises, physical damage, or tampering. [**58:**8.2.1.1]

Because of the smaller size of the cylinders covered in Chapter 8 of NFPA 58, the temperature of their contents tends to fluctuate more directly with ambient air temperatures or solar radiation than does the temperature of larger containers. These cylinders should not relieve LP-Gas through their pressure relief devices until the temperature of their contents exceeds 130°F (54°C), at which point the cylinder may become liquid full. These high temperatures could be reached in some extremely hot climates or in poorly located, poorly constructed, or unventilated storage locations.

In addition to temperature control, physical damage protection may be needed in storage locations. Certain facilities have considerable vehicular traffic — for example, forklift trucks — and require these precautions. Finally, tampering is a valid consideration. Although small portable cylinders, such as those used with grills, will not flow gas even if the valve is opened by hand, it is still important to provide protection from tampering, which could affect the safety devices.

N **50.7.2.4.12.2** Cylinders in storage having individual water capacity greater than 2.7 lb (1.1 kg) [nominal 1 lb (0.45 kg) LP-Gas capacity] shall be positioned so that the pressure relief valve is in direct communication with the vapor space of the cylinder. [**58:**8.2.1.2]

The requirement that cylinders, other than very small cylinders, be stored so that the pressure relief valve is in the vapor space of the cylinder is an important safety concept that is repeated in several locations throughout NFPA 58. The requirement is important because the capacity of pressure relief valves is based on gas flow, not liquid flow. If the pressure in a cylinder were sufficiently high to cause the pressure relief valve to operate, and the pressure relief valve were in communication with the liquid space of the cylinder, the following might occur:

- It might take more time to reduce the pressure in the container, since liquid is more dense than gas and would therefore require a larger flow of liquid before resetting the valve.
- Liquid discharged from the cylinder will vaporize almost instantly, resulting in approximately 270 times as much vapor by volume as a gaseous release. If fire is the cause of the pressure relief valve operation, a liquid release will provide more fuel to the fire than a gaseous release.
- Liquid discharge will reduce the volume of liquid inside the container that would have contributed to the autorefrigeration reaction. Autorefrigeration occurs when the vapor pressure in the container decreases and causes the liquid to change phases. The liquid utilizes heat from the container as it changes phases, and the decrease in temperature of the container reduces the overall pressure in the container.

Cylinders less than 2.7 lb (1.1 kg) water capacity [about 1 lb (0.45 kg) of propane] are excluded from this requirement. Examples of such cylinders are those used for handheld soldering torches, portable stoves, camping equipment, refillable portable appliances such as cigarette lighters, and so forth. These small cylinders are normally stored in cardboard shipping containers, and the proper storage orientation should be indicated on the shipping container.

N **50.7.2.4.12.3** Cylinders stored in buildings in accordance with Section 8.3 of NFPA 58 shall not be located near exits, near stairways, or in areas normally used, or intended to be used, for the safe egress of occupants. [**58:**8.2.1.3]

N **50.7.2.4.12.4** If empty cylinders that have been in LP-Gas service are stored indoors, they shall be considered as full cylinders for the purposes of determining the maximum quantities of LP-Gas permitted by 8.3.1, 8.3.2.1, and 8.3.3.1 of NFPA 58. [**58:**8.2.1.4]

Once filled, an LP-Gas cylinder seldom becomes completely empty. At the very least, the cylinder will usually be full of vapor and may contain some liquid or a residue that could contain the flammable odorant. If empty cylinders were not counted as full cylinders, it would be impossible for an enforcing authority to determine whether the storage limits were being exceeded without weighing all the cylinders.

N **50.7.2.4.12.5** Cylinders shall not be stored on roofs. [**58:**8.2.1.5]

N **50.7.2.4.13 Protection of Valves on Cylinders in Storage.**

N **50.7.2.4.13.1** Cylinder valves shall be protected as required by 5.2.6.1 and 7.2.2.5 of NFPA 58. [**58:**8.2.2.1]

N **50.7.2.4.13.2** Screw-on-type caps or collars shall be in place on all cylinders stored, regardless of whether they are full, partially full, or empty, and cylinder outlet valves shall be closed. [**58:**8.2.2.2]

Protection for all cylinder valves is required by the DOT requirements for containers of hazardous materials. Smaller portable cylinders typically use a metal protective collar around the cylinder valve, while larger cylinders typically found in stationary service may have a screw-on cap or a dome cover.

N **50.7.2.4.13.3** Valve outlets on cylinders less than 108 lb (49 kg) water capacity [nominal 45 lb (20 kg) propane capacity] shall be plugged, capped, or sealed in accordance with 7.2.2.5 of NFPA 58. [**58:**8.2.2.3]

N **50.7.2.4.14 Transportation of Cylinders.**

N **50.7.2.4.14.1** Cylinders having an individual water capacity not exceeding 1000 lb (454 kg) [nominal 420 lb (191 kg) propane capacity], when filled with LP-Gas, shall be transported in accordance with the requirements of Section 9.3 of NFPA 58. [**58:**9.3.2.1]

The maximum size of an individual cylinder permitted under DOT regulations is 1000 lb (454 kg) water capacity [nominal 420 lb (191 kg) of propane]. Portable ASME containers, which generally serve the same purpose as DOT cylinders, may be encountered and are also limited to this size for transportation.

N **50.7.2.4.14.2** Cylinders shall be constructed as provided in Section 5.2 of NFPA 58 and equipped in accordance with Section 5.7 of NFPA 58 for transportation as cylinders. [**58:**9.3.2.2]

N **50.7.2.4.14.3** The quantity of LP-Gas in cylinders shall be in accordance with Chapter 7 of NFPA 58. [**58:**9.3.2.3]

N **50.7.2.4.14.4** Cylinder valves shall comply with the following:

(1) Valves of cylinders shall be protected in accordance with 5.2.6.1 of NFPA 58.
(2) Screw-on-type protecting caps or collars shall be secured in place.
(3) The provisions of 7.2.2.5 of NFPA 58 shall apply.
[**58:**9.3.2.4]

Refer to the commentary following 69.4.2.2.5 for the requirements referenced on cylinder valve plugs. The importance of providing protection for cylinder valves from damage cannot be overstated. A damaged or separated cylinder valve could result in an uncontrolled release of LP-Gas and perhaps even the propulsion of the cylinder itself.

N **50.7.2.4.14.5** The cargo space of the vehicle shall be isolated from the driver's compartment, the engine, and the engine's exhaust system. [**58:**9.3.2.5]

N **50.7.2.4.14.5.1** Open-bodied vehicles shall be considered to be in compliance with this provision. [**58:**9.3.2.5(A)]

N **50.7.2.4.14.5.2** Closed-bodied vehicles having separate cargo, driver, and engine compartments shall be considered to be in compliance with this provision. [**58:**9.3.2.5(B)]

N **50.7.2.4.14.5.3** Closed-bodied vehicles, such as passenger cars, vans, and station wagons, shall not be used for transporting more than 215 lb (98 kg) water capacity [nominal 90 lb (41 kg) propane capacity], but not more than 108 lb (49 kg) water capacity [nominal 45 lb (20 kg) propane capacity] per cylinder, unless the driver and engine compartments are separated from the cargo space by a vaportight partition that contains no means of access to the cargo space. [**58:**9.3.2.5(C)]

The transportation of privately owned cylinders in passenger automobiles is a safety concern that is addressed based on the vehicle type. The transportation of LP-Gas by private parties, where the transportation is not considered to be "in commerce" as defined by the DOT, is not regulated by the DOT, and therefore only the provisions of NFPA 58 apply. The provisions of Section 9.3 of NFPA 58 are applied in the following situations:

1. **Cylinder transported in an open-bodied vehicle (such as a pickup truck) or in a closed-bodied vehicle with a vaportight partition between the cargo space and the driver and engine compartments.** In both cases, up to 1000 lb (454 kg) of LP-Gas (total weight, including the weight of the LP-Gas and the cylinders) can be transported in the vehicle as stated in 50.7.2.4.14.1. Where the LP-Gas exceeds 1000 lb (454 kg), the requirements of 50.7.2.4.14.10 and the DOT would apply to the vehicle.
2. **Cylinder transported in a closed-body vehicle.** A maximum of 90 lb (41 kg) of propane can be transported in the passenger or cargo space of the vehicle. This requirement allows up to four typical grill cylinders [20 lb (9.1 kg) propane capacity each], up to three 30 lb (13.6 kg) cylinders, or up to two 40 lb (18 kg) cylinders to be transported.

Note that the 90 lb (41 kg) limit in closed-body vehicles effectively prohibits the transportation of a 100 lb (45 kg) LP-Gas cylinder in passenger cars, vans, sport utility vehicles, and station wagons. Also, see 50.7.2.4.14.9 for requirements on cylinder orientation during transport.

These rules apply to all transportation of cylinders, whether by propane company employees delivering cylinders to residences, by exchange cabinets, or by forklift operators or private citizens taking grill cylinders in for filling or exchange. These rules apply in much the same way as building codes apply to the modification a citizen makes to a house. In the case of building codes (and this varies with location), the citizen is responsible for obtaining a building permit, for having construction done to meet the applicable code(s), and for getting an inspection by a building code official during construction and/or after the work is complete.

NFPA 58's requirements are less well known to consumers than building codes are, which is why some jurisdictions consider it the responsibility of propane company employees to ensure that cylinders transported by customers are properly placed and secured in their vehicles before they leave the dispensing site.

N **50.7.2.4.14.6** Cylinders and their appurtenances shall be determined to be leak-free before being loaded into vehicles. [**58:**9.3.2.6]

N **50.7.2.4.14.7** Cylinders shall be loaded into vehicles with flat floors or equipped with racks for holding cylinders. [**58:**9.3.2.7]

N **50.7.2.4.14.8** Cylinders shall be fastened in position to minimize the possibility of movement, tipping, and physical damage. [**58:**9.3.2.8]

N **50.7.2.4.14.9** Cylinders being transported by vehicles shall be positioned in accordance with Table 50.7.2.4.14.9. [**58:**9.3.2.9]

***TABLE 50.7.2.4.14.9** Orientation of Cylinders on Vehicles*

Propane Capacity of Cylinder lb	kg	Open Vehicles	Enclosed Spaces of Vehicles
≤45	≤20	Any position	
>45	>20	Relief valve in communication with the vapor space	
≤4.2	≤1.9		Any position
>4.2	>1.9		Relief valve in communication with the vapor space

[**58:**Table 9.3.2.9]

Racks that hold cylinders in a horizontal position are commonly used for the delivery of industrial truck cylinders in open-body vehicles. The safety experience with this type of transportation has been good and is the reason that LP-Gas cylinders with a maximum propane capacity of 45 lb (20 kg) can be transported with the relief valve in contact with the liquid space of the container. That size is the maximum portable cylinder generally used in industrial trucks. Larger containers must be transported in a position such that the pressure relief valve is in communication with the vapor space of the container.

In closed-body vehicles, the requirements are much more stringent. Only cylinders less than or equal to 4.2 lb (1.9 kg) propane capacity can be transported in any position, thereby resulting in the relief valve being in communication with liquid. As a result of this provision, nominal 20 lb (9.1 kg) cylinders (gas grill cylinders) cannot be transported on their sides inside a vehicle.

N **50.7.2.4.14.10** Vehicles transporting cylinders where the total weight is more than 1000 lb (454 kg), including the weight of the LP-Gas and the cylinders, shall be placarded as required by DOT regulations or state law. [**58:**9.3.2.10]

Placard is a term used in the DOT regulations. Placards are used to warn others of hazardous materials present on the vehicle, placed on the outside of the vehicle or its cargo tank to identify the hazard class of the cargo. For LP-Gas, "1075" is the identification number, the "2" in the lower part is the hazard class ("gas," in this case), and the hazard class division is "flammable," as shown by the flame. A placard must convey this information to emergency responders. A typical flammable gas placard such as the one described above is shown in Exhibit 50.22. DOT rules require the placard to be identical to the one shown, with a red background color.

Exhibit 50.22

Placard for propane truck. (Courtesy of U.S. Department of Transportation)

N **50.7.3 Temporary Cooking.**

N **50.7.3.1** Temporary cooking operations and equipment shall comply with NFPA 96, Section 50.7.1 and Section 50.7.3.

N **50.7.3.2** Temporary cooking equipment and installations shall comply with NFPA 58.

N **50.7.3.3** Deep fat fryers, fry-o-lators, or other appliances having combustible liquids heated by LP Gas, solid fuels, or electricity shall be protected by an approved hood fire suppression system or other approved means of extinguishment in the event of fire.

Industrial Ovens and Furnaces

Explosions and fires in fuel-fired and electric heat utilization equipment constitute a potential loss to life, property, and production. Other regulations and conditions should be reviewed for the design and operation of furnaces not covered by this chapter or by NFPA 86, *Standard for Ovens and Furnaces*. Subjects covered in other regulations include, but are not limited to, toxic vapors; hazardous materials; noise levels; heat stress; and local, state, and federal regulations, such as those by the U.S. Environmental Protection Agency (EPA) and the Occupational Safety and Health Administration (OSHA).

51.1 General

Δ **51.1.1 Application.** Industrial ovens and furnaces shall comply with this chapter and the applicable provisions of NFPA 86.

The effective date for the edition of NFPA 86 referenced in this *Code* is May 19, 2014. However, the provisions of NFPA 86 might not be enforceable retroactively to its effective date if the standard has not been adopted by a separate action in the jurisdiction. The date that NFPA 1, *Fire Code*, was adopted in the jurisdiction establishes the effective date for enforcement of not only NFPA 1 but also other codes and standards incorporated into this *Code*.

Ovens and furnaces are used in many industrial processes to dry, cure, or alter the physical characteristics of materials. Common examples would be a bakery or a kiln. The fire and explosion hazards presented by ovens and furnaces are related to their operation at elevated temperatures in conjunction with their use of flammable and combustible fuels, flammable and combustible materials in process, and flammable special processing atmospheres. Examples of industrial processes that use ovens and furnaces include the following:

1. Melting metals
2. Drying cloth
3. Baking painted metal parts
4. Curing rubber conveyor belts
5. Annealing steel under a hydrogen atmosphere
6. Treating metal parts in molten salts
7. Heating materials under vacuum

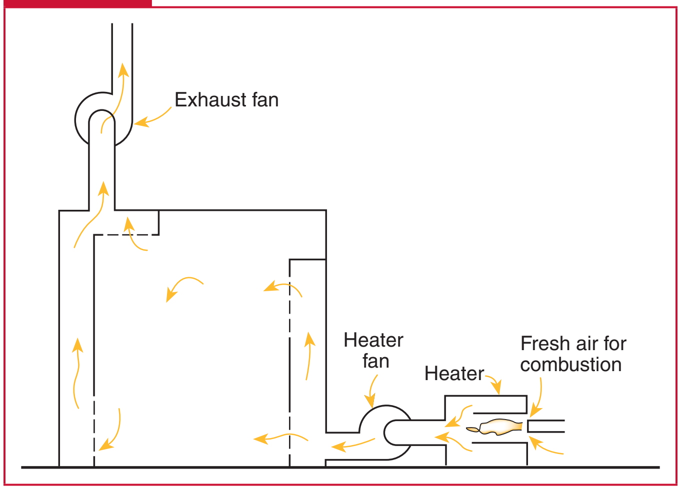
In industry, the terms *oven* and *furnace* are used interchangeably. Ovens and furnaces can be batch or continuous units. In a batch furnace, materials are loaded, the furnace is operated, the furnace is shut down, then the materials are unloaded. In a continuous furnace, materials enter one end of the furnace, are processed as they move through the furnace, then exit the furnace at the other end. In a continuous furnace, the furnace is continuously operated as new materials are constantly introduced.

Exhibit 51.1, Exhibit 51.2, and Exhibit 51.3 illustrate three examples of batch units. Exhibit 51.4 shows an example of a continuous unit.

All ovens and furnaces share similar hazards associated with their heating systems. In addition to these hazards, ovens and furnaces are classified as Class A, Class B, Class C, or Class D to address additional process hazards. Descriptions of those classifications follow.

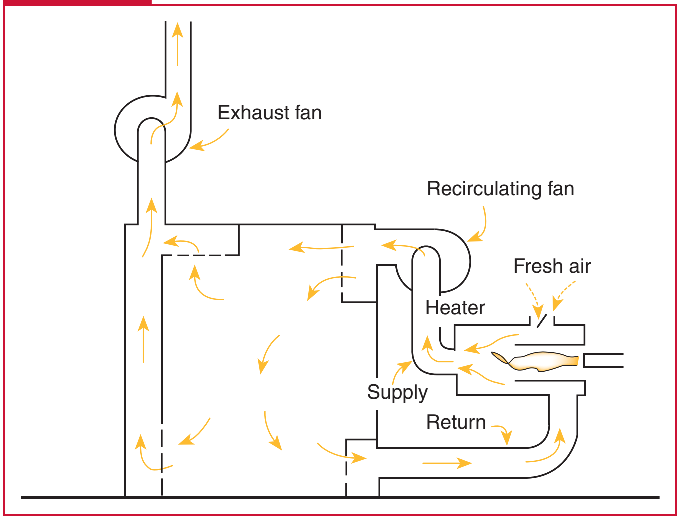
Class A. Class A ovens or furnaces have heat utilization equipment where there is a potential explosion or fire hazard that could be accompanied by the presence of flammable volatiles or combustible materials processed or heated in the furnace.

Exhibit 51.1



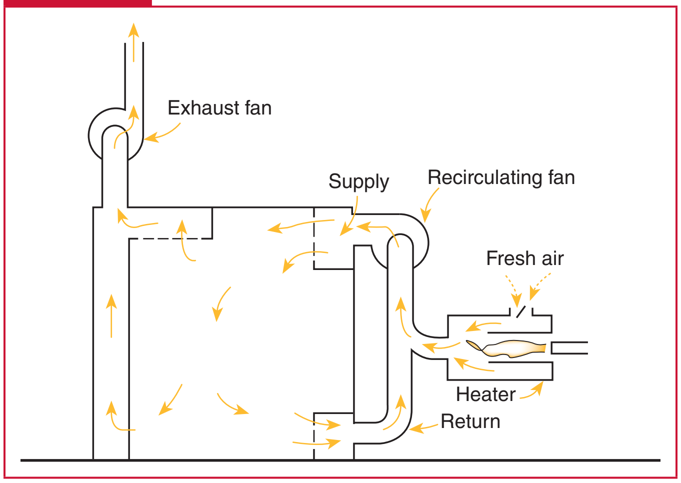
Direct-fired, external, nonrecirculating heater.

Exhibit 51.2



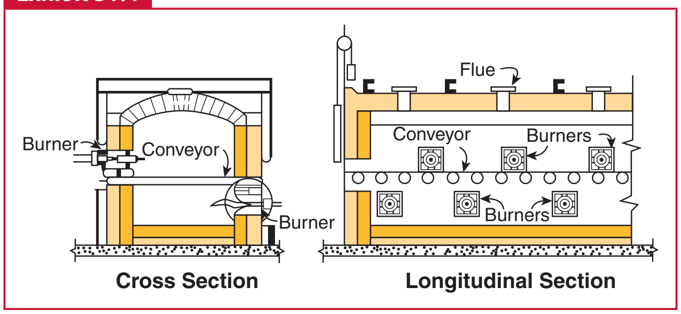
Direct-fired, external, recirculating-through heater.

Exhibit 51.3



Direct-fired, external, recirculating-not-through heater.

Exhibit 51.4



Direct-fired continuous furnace with multiple internal burners.

Flammable volatiles or combustible materials can include, but are not limited to, any of the following:

1. Paints, powders, inks, and adhesives from finishing processes, such as dipping, coating, or spraying, and impregnated materials
2. Substrate material
3. Wood, paper, and plastic pallets, spacers, or packaging materials
4. Polymerization or other molecular rearrangements

In addition, potentially flammable materials, such as quench oil, waterborne finishes, cooling oil, or cooking fats, that present a hazard should be ventilated according to Class A standards.

Class B. Class B ovens or furnaces have heat utilization equipment where there are no flammable volatiles or combustible materials being heated. It is important to note that the loads processed in Class B furnaces typically do not contain any flammable volatiles or combustible materials. However, when small amounts of flammable volatiles or combustible materials are present, it can be appropriate not to add safety ventilation, as would be required for a Class A furnace, when doing so would be detrimental to the process and would not increase the level of safety.

Class C. Class C ovens or furnaces have a potential hazard due to a flammable or other special atmosphere being used for the treatment of material in process. This type of furnace uses any type of heating system and includes a special atmosphere supply system(s). Included in this classification are integral quench furnaces and molten bath furnaces.

Class D. Class D ovens or furnaces, referred to as *vacuum furnaces,* have a pressure vessel that operates under vacuum for all or part of the process cycle. Such furnaces can process any product or material. These furnaces can use special atmospheres introduced when the furnace is above or below atmospheric pressure. During inert quenching, Class D furnaces operate at pressures from below atmospheric to over gauge pressure of 100 psi (690 kPa).

NFPA 86 provides information on the protection of Class A, Class B, Class C, and Class D ovens and furnaces against the hazards of fire and explosion. It is a compilation of guidelines, rules, and methods applicable to the safe operation of this type of equipment. Specifically, requirements on furnace location, arrangement, installation, control, and use are detailed in NFPA 86.

NFPA 86 requires that personnel who operate, maintain, or supervise the furnace be thoroughly instructed and trained in their respective job functions under the direction of a qualified person(s). When training, they must demonstrate an understanding of the equipment, its operation, and the practice of safe operating procedures in their respective job functions. A typical training program could include the following items:

1. Review of operating and maintenance information
2. Periodic formal instruction
3. Use of simulators

4. Field training
5. Other procedures
6. Comprehension testing

The following topics may be included as part of the training when it is being developed:

1. Process and equipment inspection testing
2. Combustion of fuel-air mixtures
3. Explosion hazards, including improper purge timing and purge flow and safety ventilation
4. Sources of ignition, including autoignition (e.g., by incandescent surfaces)
5. Functions of controls, safety devices, and maintenance of proper set points
6. Handling of special atmospheres
7. Handling of low-oxygen atmospheres
8. Handling and processing of hazardous materials
9. Confined space entry procedures
10. Operating instructions
11. Lockout/tagout procedures
12. Hazardous conditions resulting from interaction with surrounding processes
13. Fire protection systems
14. Molten material
15. Quench systems

In addition, personnel are required to receive regularly scheduled refresher training and must demonstrate understanding of the equipment, its operation, and the practice of safe operating procedures in their respective job functions.

Personnel must have access to written operating instructions at all times. Instructions include normal startup, normal shutdown, and emergency shutdown. Where necessary, separate instructions should be provided for cold startup and for warm startup. A warm startup might occur after a weekend when a furnace is not in use; rather than shutting down and allowing the furnace to cool off, the furnace can be brought back to an idling temperature.

Operator error has been identified as a significant cause or contributing factor in upsets and explosions involving heat utilization equipment. These unwanted events usually result from operators taking actions that deviate from written operating instructions. Operators must be thoroughly instructed and trained in the written operating instructions. When abnormal or unusual conditions are detected, written emergency shutdown procedures should be implemented. Deviation from normal or emergency written operating instructions should not be permitted at the operator level.

The cold startup of heat utilization equipment should occur under the supervision of a trained operator. When heat utilization equipment experiences an automatic safety shutdown or a manual emergency shutdown by the operator, restart of the equipment is not permitted without maintenance personnel first identifying and correcting the cause of the off-normal shutdown.

Heat utilization equipment is equipped with numerous control and safety devices intended to maintain the equipment within safe operating boundaries or cause a safety shutdown. If these controls and safety devices are to be reliable, they must be periodically inspected and tested. Maintenance must then be provided as needed.

NFPA 86 places the responsibility for establishing an inspection, testing, and maintenance program, as well as the frequency and extent of the inspection and corrective action to be taken, with the equipment user. The program should identify the features to be inspected, tested, and maintained. Frequencies for each action are based on specific installation needs.

Leak testing of fuel gas safety shutoff valves is an essential program that users often overlook. A leak test program offers a control over one of the primary causes of explosions in heat utilization equipment, that is, fuel leakage into idle equipment. NFPA 86 requires an annual leak test of each fuel gas safety shutoff valve. Written leak test procedures describing how the test is to be conducted should be provided. The typical leak test is the bubble test. In this test, one end of a flexible hose is connected to an outlet located between the safety shutoff valve to be tested and a downstream blocking valve. The other end of the flexible hose is submerged into a water bath for several minutes. The number of fuel gas bubbles per minute is measured.

The written procedure should define a pass/fail leak standard in terms of bubbles per minute. No valve is perfect; therefore, a minimum acceptable leakage rate is established. Because the head of water above the end of the hose could create sufficient pressure to hold back any leaking gas, the test operator should avoid submerging the hose too deeply into the water bath during the test.

A test procedure is to be established for verifying the performance of each safety control. Off-normal conditions should be corrected promptly. Where the control has a design set point, the following actions should be taken:

1. ***Inspect.*** Verify that the device is at the correct setting.
2. ***Test.*** Verify that the device operates at the correct set point.
3. ***Maintain.*** Recalibrate or replace the device if the displayed setting deviates from the actual setting beyond an acceptable limit.

The inspection of safety devices should include an evaluation of their physical condition. Missing cover plates should be promptly replaced. Corroded devices or devices with obvious physical damage should be repaired or replaced. Tampering with devices must not be allowed. Evidence of tampering could include wire jumpers inserted across contacts, foreign material inserted between contacts, and adjustment of devices to improper settings. Where adjustable safety devices are found adjusted to extreme high or low settings, the device is not at its proper setting.

For Class A ovens that pose a solvent hazard — for example, ovens that remove a flammable solvent from painted metal parts — a safety design form is used that describes the solvent hazard the oven is designed to handle. The form should identify the solvent that the furnace is designed for and the solvent introduction rates. Inspections should verify that no unauthorized solvents are being used and that design solvent input rates are not being violated. Deviations should receive prompt attention.

Class A ovens and their associated ductwork might be equipped with fixed fire protection systems, such as automatic sprinklers or carbon dioxide systems. Where installed, fire protection systems must be inspected, tested, and maintained in accordance with the appropriate NFPA standard for the type of system involved. See Chapter 13 for additional guidance.

Combustible materials, such as stock and other storage, should not be allowed close to heat utilization equipment. Suitable clearance should be maintained at all times. NFPA 86 specifies a minimum required separation distance of 2½ ft (0.76 m).

51.1.2 Permits.

51.1.2.1 Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the operation of an industrial oven or furnace [(see Table 1.12.8(a)]. Depending on the fuel used with the furnace, additional permits might be required for the storage and use of the particular fuel.

51.1.2.2 Applications for a permit shall be accompanied by plans for safe operation showing all essential details and calculations.

Compliance with this *Code* does not eliminate the need for an engineer or for competent engineering judgment. The intent of this *Code* is that a designer who is capable of applying more complete and rigorous analysis to special or unusual problems should be given latitude in the development of an oven or furnace design. In such cases, the designer is required to be responsible for demonstrating and documenting the safety and validity of the design.

NFPA 86 requires plans that show all essential details with respect to location, construction, ventilation, piping, and electrical safety equipment. A list of all combustion, control, and safety equipment that includes the name of the manufacturer and the type number is also required. Wiring diagrams and instructions for sequence of operations for all safety controls must also be provided. Ladder-type schematic diagrams are recommended.

As part of the approval process, the authority having jurisdiction (AHJ) should consider using the two-page application form entitled Furnace or Oven Manufacturer's Application for Acceptance, shown in Exhibit 51.5.

Furnace or oven manufacturer's application for acceptance.

51.2 Location

Special consideration shall be given to the location of equipment using flammable liquids or when using gas fuels with a vapor density greater than air.

Ovens and furnaces are usually associated with a production process. As such, they typically are found located within a production area separated only by some physical distance from other process equipment. The decision as to where to locate an oven or furnace should take into account the following factors:

1. Where possible, the oven or furnace should be located in a separate cutoff area.
2. Where a separate cutoff area is not feasible, there should be adequate separation from paint spray booths, dipping or coating operations, external quench tanks, and combustible storage.
3. Where furnaces use or process flammable gases or combustible liquids with a vapor density greater than air, low points where vapors might collect if accidentally released should be evaluated. Adequate ventilation should be provided, and ignition sources controlled to eliminate serious fire or explosion potentials.
4. Where molten materials are involved (e.g., molten metal, molten glass), the effects of a release or spill of the molten material should be considered. Containment systems should be provided to limit the spread of spills, and combustible building construction, exposed steel building columns, or exposed steel furnace supports protected from thermal damage.
5. Where furnaces have integral quench tanks that use combustible oils, spill containment and supplemental fixed fire protection (e.g., a carbon dioxide extinguishing system) should be provided for pits, oil filter stations, and the area immediately outside the furnace vestibule door and within any hood and associated exhaust ductwork over the furnace vestibule door.

Where ovens are equipped with explosion relief features, it is essential that those features be free and unobstructed, so that they are operable if an explosion occurs. Work waiting to be processed must not be placed in front of doors that are designed to open in the event of an explosion. Beams, columns, piping, ductwork, stock, or other obstructions must not impair the functioning of explosion relief panels in the oven's walls or roof.

Oven ductwork exposed to combustible dusts or condensed flammable or combustible liquids requires periodic internal inspections and periodic cleaning. Suitable access to ductwork is required. The inspector should review NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*, for additional requirements. Frequencies for duct inspection and cleaning must be determined on a case-by-case basis.

51.3 Safety Controls

Safety controls, as specified in NFPA 86, shall be sufficient in number and substantially constructed and arranged to maintain the required conditions of safety and prevent the development of fire and explosion hazards.

In general, the interior volume of any fuel-fired oven or furnace is purged with air before ignition of the burners. The objective of the purging is to remove accumulated fuel vapors or other flammable vapors that might have leaked into the equipment during the preceding idle period. For ovens and furnaces, four volume changes are needed to accomplish the purge.

A complete pre-ignition purge interval must occur before any attempt is made to ignite burners. Even when nuisance safety shutdowns occur, the restart must include another purge interval. Because the purge interval, especially repeated purge intervals, will encroach on valuable production time, operators or maintenance personnel might be tempted to reduce or eliminate the purge interval. Because tampering with the purge interval is a dangerous practice that has led to explosions, inspectors should be on the lookout for signs of such tampering.

For heat utilization equipment with a single burner, the purge interval can be regulated by the flame safeguard. With this arrangement, the purge interval is fixed and can be altered only by modifying the flame safeguard (i.e., replacing a plug-in purge time module). This arrangement greatly reduces the potential for purge interval tampering.

With more complex heat utilization equipment, such as multiple burner systems, a purge timer is typically provided that is physically external to the flame safeguard. Listed purge timers are adjustable devices (e.g., 0 minutes to 30 minutes), and the adjustable feature introduces the opportunity for tampering. Finding purge timers adjusted to zero is not uncommon. Such a situation is serious and should be addressed promptly.

Oven and furnace fans are referred to as combustion air, exhaust air, and recirculation air fans. All fans needed for safe operation must be functioning during the purge interval and during operation. The manufacturer of the heat utilization equipment should establish which fans are needed for purge and which are needed for operation.

The functional operation of fans are accomplished with devices such as the following:

1. ***Pressure switch.*** A pressure switch senses air pressure after a fan is actuated when the airflow from the fan is adequate.
2. ***Suction switch.*** A suction switch senses negative pressure before a fan is activated when airflow into the fan is adequate.
3. ***Differential pressure switch.*** A differential pressure switch senses the pressure on each side of a fan or other feature, such as an orifice plate. The differential pressure switch is activated when the airflow through the fan or other feature is adequate.
4. ***Airflow switch.*** An airflow switch has a paddle or sail that is inserted into the airstream. The switch is activated when the airflow past the paddle or sail is adequate.

Many pressure switches, suction switches, and differential pressure switches are adjustable devices. Equipment records should clearly indicate the appropriate setting for each device. If, during an inspection, a switch is found to have been adjusted to an extreme upscale or downscale setting, an investigation should be made. The switch might never have been adjusted at the time of installation, or the switch might simply have been adjusted to the extreme to resolve a nuisance trip problem.

The pipe, fittings, and devices that make up the fuel piping of a piece of heat utilization equipment are referred to as the fuel train. For main and pilot fuel gas trains, double safety shutoff valves are always needed.

Fuel gas pressure regulators, fuel gas pressure relief valves, and fuel gas pressure switches contain rubber diaphragms. Fuel gas pressure acts on the bottom side of the diaphragm. A spring or microswitch, along with atmospheric pressure, acts on the top side. To maintain atmospheric pressure on the top side, a vent is provided in the device housing. This vent needs to be managed so that an excessive amount of fuel gas is not released into the building if the rubber diaphragm breaks.

Typically, vents are piped to a safe outdoor location; however, some vents might be equipped with a listed vent limiter that limits the release of fuel gas to acceptable levels. General guidelines and principles on the use of vented devices incorporating vent limiters from A.6.2.6.4 of NFPA 86 include the following:

1. The listing requirements for vent limiters are covered in ANSI Z21.18/CSA 6.3, *Standard for Gas Appliance Pressure Regulators*, for regulators, and UL 353, *Standard for Limit Controls*, for pressure switches and limit controls. ANSI Z21.18/CSA 6.3 requires maximum allowable leakage rates of 2.5 ft^3/hr (0.071 m^3/hr) for natural gas and 1.0 ft^3/hr (0.028 m^3/hr) for LP-Gas at the device's maximum rated pressure. UL 353 allows 1.0 ft^3/hr (0.028 m^3/hr) for natural gas and 1.53 ft^3/hr (0.043 m^3/hr) for LP-Gas at the device's maximum rated pressure. Since a vent limiter may be rated less than the device itself and may be a field-installable device, a combination listed device–vent limiter should be used.
2. Where a vent limiter is used, there should be adequate airflow through the room or enclosure in which the equipment is installed. In reality, conditions may be less ideal, and care should be exercised for the following reasons:
   - **(a)** The relative density of the gas influences its ability to disperse in air. The higher the relative density, the more difficult it is for the gas to disperse (propane, for instance, will disperse more slowly than natural gas).
   - **(b)** Airflow patterns through a room or enclosure, especially in the vicinity of the gas leak, affect the ability of the air to dilute the gas. The greater the local air movement, the greater the ease with which the gas is able to disperse.
   - **(c)** The vent limiter may not prevent the formation of a localized flammable air–gas concentration for the reasons given in items (a) and (b).

NFPA 86 requires that vents be terminated to an approved location. The official NFPA definition for the term *approved* is "acceptable to the authority having jurisdiction." Therefore, the AHJ can determine the acceptable termination point for a vent. Paragraph A.6.2.6.3 in NFPA 86 offers guidance to the AHJ regarding suitable locations for terminating vents. NFPA 68, *Standard on Explosion Protection by Deflagration Venting*, should be reviewed for additional considerations regarding deflagration (explosion) venting. Paragraph A.6.2.6.3 in NFPA 86 reads as follows:

> Paragraph 6.2.6.3 [of NFPA 86] covers venting of flammable and oxidizing gases only. Gases that are asphyxiants, toxic, or corrosive are outside of the scope of this standard. In this regard, other standards should be consulted for appropriate venting. Flammable gases and oxidizers should be vented to a safe location to prevent fire or explosion hazards. When gases are vented, the vent pipe should be located in accordance with the following:
>
> (1) Gas should not impinge on equipment, support, building, windows, or materials because the gas could ignite and create a fire hazard.
> (2) Gas should not impinge on personnel at work in the area or in the vicinity of the exit of the vent pipe because the gas could ignite and create a fire hazard.
> (3) Gas should not be vented in the vicinity of air intakes, compressor inlets, or other devices that utilize ambient air.
>
> The vent exit should be designed in accordance with the following:
>
> (1) The pipe exit should not be subject to physical damage or foreign matter that could block the exit.
> (2) The vent pipe should be sized to minimize the pressure drop associated with length, fitting, and elbows at the maximum vent flow rate.
> (3) The vent piping should not have any shutoff valves in the line.
>
> If the gas is to be vented inside the building, the following additional guidance is offered:
>
> (1) If the gas is flammable and lighter than air, the flammable gases should be vented to a location where the gas is diluted below its lower flammable limit (LFL) before coming in contact with sources of ignition and the gas cannot re-enter the work area without extreme dilution.
> (2) If the gas is oxygen or air enriched with oxygen, the vent gas should be vented to a location where the gas will blend with atmospheric air to a point

between 19 percent and 23 percent oxygen before coming in contact with combustibles or personnel.

(3) See also Chapter 4 of NFPA 56, *Standard for Fire and Explosion Prevention During Cleaning and Purging of Flammable Gas Piping Systems*, which provides information about the development and implementation of written procedures for the discharge of flammable gases.

Heat utilization equipment that is equipped with only a single burner needs simple burner management. In particular, the equipment needs a supervised flame monitored by a flame detector and combustion safeguard. It is not unusual, however, for equipment to have numerous burners. Numerous burners require numerous flame safeguards and increased safety control complexity. Where a supervised flame is required for a burner, each pilot and main burner is required to be equipped with flame supervision in one of three ways: (1) main and pilot flames supervised with independent flame sensors; (2) main and interrupted pilot flames supervised with a single flame sensor; or (3) self-piloted burner supervised with a single flame sensor.

Currently, four types of flame-sensing devices are listed for proving the presence of flame at a burner, as shown in Commentary Table 51.1.

Although ultraviolet (UV) scanners are popular and very common flame-sensing devices, they can fail. In some failure modes, the UV scanner might report the presence of flame, regardless of whether flame is present. This concern is addressed by the following two means:

First, self-checking flame safeguards are available. These devices include a shutter assembly that tests the scanner by periodically closing the shutter while the scanner is in normal use. If the flame signal does not disappear when the shutter is closed, a safety shutdown occurs.

Second, most flame safeguards offer a "safe-start check" diagnostic. During each burner start sequence, the safe-start check diagnostic verifies that the UV scanner does not see flame. If the UV scanner is reporting flame, the start sequence is not allowed to proceed. A safe-start check is required to be performed during each burner startup sequence.

For ovens and furnaces, the use of a self-checking UV scanner where burners operate for more than 24 hours at a time is good practice; however, this feature is not required. In all cases, a safe-start check feature is required.

COMMENTARY TABLE 51.1 *Flame-Sensing Devices*

Type Scanner	*Application*	*Potential Problems*
Ultraviolet (UV)	Fuel gas or oil	Can read spark as flame scanner
Flame rod	Fuel gas only	Oil will cause carbon buildup
Infrared (IR)	Fuel gas or oil	Can read refractory glow scanner as flame
Photoelectric cell	Oil only	Fuel gas is invisible

NFPA 86 requires that safety devices be listed for their intended purpose; however, if a listed device is not available, an approved device must be used. As discussed previously, NFPA defines the term *approved* as "acceptable to the authority having jurisdiction." Therefore, instances might occur where the AHJ is asked to determine if a nonlisted safety device is acceptable when a listed device is not available.

As an example, no fuel gas safety shutoff valves over the size of 8 in. (200 mm) are listed. For valves 10 in. (250 mm) and larger, a nonlisted valve must be selected. The AHJ might be asked to approve the selected valve. In the course of making the decision, the AHJ might apply the following thought process:

Step 1. A listed valve of the needed size is not commercially available.

Step 2. The proposed valve is made by a manufacturer that also produces smaller valves that are listed as fuel gas safety shutoff valves.

Step 3. The larger nonlisted valve is built to the same standards as the smaller listed valves. According to the manufacturer, it is rated for the proposed operating pressure, and it is rated for the proposed fuel gas.

Step 4. The larger valve is approved.

Where an oven handles a combustible product, a fixed fire-extinguishing system is needed within the oven to protect the unit. Chapter 9 of NFPA 86 addresses fire protection in general.

Where a sprinkler system is selected for the protection of ovens, furnaces, or related equipment, the use of closed-head sprinkler systems is prohibited, and only deluge sprinkler systems can be used where both the temperatures in the equipment can exceed 625°F (329°C) and flash conditions can occur. If the oven operating temperature is above the boiling point of water [212°F (100°C)], a dry pipe system is needed. If a wet pipe system were used, the water would attempt to boil within the pipes. This attempt to boil would be countered by the confining strength of the sprinkler system pipe and fittings. Excessive pressures would eventually lead to a failure at some point in the system.

Rubber-gasketed sprinkler fittings might not be appropriate. Such fittings must not be used at temperatures beyond their listing. Their maximum operating temperature is typically 150°F (66°C), unless specifically listed otherwise.

Some AHJs require dry pipe systems to be made of galvanized pipe. The use of galvanized pipe, however, should be avoided in sprinkler or water spray systems in ovens, furnaces, or related equipment. Experience has shown that the galvanizing can flake off when exposed to oven temperatures. This flaking within the pipes could lead to obstructions or plugging.

Class C furnaces and some Class D furnaces use special processing atmospheres to protect the work in process from oxidation and to cause desired metallurgical changes to the surface of the work in process. Because products of combustion are usually detrimental to such furnaces, these furnaces are usually indirect fired, that is, the products of combustion do not come into contact with the work in process.

Special atmospheres include those listed in Commentary Table 51.2. These special atmospheres can be used alone or in different combinations. Concern develops where flammable atmospheres are used.

Hydrogen, nitrogen, and argon are atmosphere gases that normally are supplied to the furnace from storage tanks, although hydrogen and nitrogen generators are available for use at industrial facilities with large atmosphere gas demands. For requirements on the storage of hydrogen, the AHJ should consult Chapter 10 or Chapter 11 of NFPA 55, *Compressed Gases and Cryogenic Fluids Code*. Also, see Chapter 63 of this *Code*.

Dissociated ammonia, exothermic gas, and endothermic gas are atmosphere gases that are produced in heated generators. An ammonia dissociator heats ammonia (NH_3) to crack or dissociate its molecules into its constituent parts (25 percent nitrogen and 75 percent hydrogen). An exothermic gas generator partially burns natural gas with air in a controlled ratio to form the desired atmosphere. An endothermic gas generator requires heat to complete the reaction of the gas and air generating the desired atmosphere. Requirements on the protection of these atmosphere generators can be found in Chapter 13 of NFPA 86.

Methanol and anhydrous ammonia are liquids that will vaporize and dissociate to form the desired atmosphere when they are injected into a hot furnace.

Flammable special processing atmosphere gases are introduced to and removed from furnaces in either the burn-in/burn-out method or the purge-in/purge-out method. With the burn-in/burn-out method, the furnace must be above 1400°F (760°C), so that all flammables will be reliably ignited and consumed as they are introduced. A burning flame front gradually moves from the atmosphere inlet to the open furnace ends (in a continuous furnace) or to the effluent vent stack (in a batch furnace). Proven pilots provide reliable means for maintaining combustion of the flammable atmosphere gas as it exits the furnace. A positive flow of atmosphere gas is needed to continually replenish the gas consumed at the exits or the stacks.

COMMENTARY TABLE 51.2 *Special Atmospheres*

Stored Atmospheres	Generated Atmospheres	Liquids for Atmospheres
Hydrogen	Dissociated ammonia	Methanol
Nitrogen*	Exothermic gas	Anhydrous ammonia
Argon*	Endothermic gas	—

*Nonflammable gas.

With the purge-in/purge-out method, nitrogen is used to purge the furnace before the flammable atmosphere is introduced. With the purge-in method, the nitrogen purge must provide five oven volume changes. Once this step is accomplished, atmosphere sampling is conducted. When two consecutive manual samples confirm that less than 1 percent oxygen is in the furnace atmosphere, the flammable atmosphere gas can be introduced. During furnace commissioning, the time needed to reach less than 1 percent oxygen can be measured. Thereafter, a purge timer can be used in conjunction with a nitrogen pressure switch to confirm the purge-in without manually sampling the atmosphere.

Regardless of which introduction and removal method is used, the operator must follow written instructions for normal atmosphere introduction, normal atmosphere removal, and emergency action. The emergency action typically involves the initiation of a nitrogen purge of the furnace.

When a special processing atmosphere furnace is operating under a flammable atmosphere, only the addition of air or oxygen is needed to cause an explosion. Keeping the furnace under positive pressure controls air infiltration. Some conditions that can lead to air infiltration follow.

Furnace safety shutdown. When a safety shutdown occurs, the sudden interruption of heat causes the furnace temperature to drop. This temperature drop causes the furnace atmosphere to contract or shrink. Because the special atmosphere flow might not be able to maintain positive furnace pressure under this condition, an emergency nitrogen purge should be initiated when safety shutdown of the furnace heat source occurs.

Cold work load. The introduction of a cold work load into a furnace causes the atmosphere to cool and shrink, which is normally accommodated by furnace design.

Liquids injection. Where liquids are injected into a furnace to produce the desired atmosphere, any condition that causes the furnace temperature to fall below that needed to vaporize the liquid quickly causes a loss of internal furnace pressure. Minimum operating temperatures for liquid-injected special atmospheres must be maintained at all times.

Energy Storage Systems

52

Chapter 52 addresses the specific use of energy storage systems and the inherent hazard these systems and operations present. In the past, this chapter applied only to batteries using lead-acid technology. Due to changes over the past few editions of the *Code*, other types of energy storage technology have been introduced. The basis for the chapter title and the scope changes is to include additional energy storage technologies. The types of energy storage systems now include lead-acid, nickel-cadmium, valve-regulated lead–acid (VRLA), lithium-ion of various chemistries, sodium, flow, and other new technologies and capacitors.

The use of energy storage systems to provide uninterruptible power has steadily increased over the years. This increase originally occurred within the telecommunications industry using lead-acid energy storage systems, which has decentralized into additional, smaller telephone switching operations and call sites. Computer-dependent companies and operations have also increased their use of energy storage systems to provide backup power in the event of an emergency. The need for uninterruptible power provided by energy storage systems will continue to increase as new industries and processes demand additional reliability and increased power from energy storage systems. As telecommunications and computer use continue to grow worldwide, faster, more efficient, long-lasting power sources are needed to meet the increased demand. Many communities worldwide are increasing their use of alternative energy sources, such as wind and solar power, and the need to store the extra energy for their own use and to provide personal and public energy flowing into the grid also has increased tremendously. That need will continue to increase as alternative power sources grow in profitability, popularity, and efficiency.

A number of safety concerns must be considered in the response to emergencies involving energy storage systems. The most expected risk is electric shock, fire, or explosion due to a short in the electrical connection system or a malfunction of the thermal chemical electrical process. Fire involving energy storage systems can create numerous hazards, including dense acidic smoke, flammable gas, heavy flame generation, toxic gas, and potential explosion.

N 52.1 General

Chapter 52 is divided into three sections: Section 52.1 covers general issues regarding energy storage systems; Section 52.2 applies to larger lead-acid stationary battery systems; and Section 52.3 applies to all other energy storage systems. The intent was to keep the current lead-acid systems unaffected by *Code* changes and to address the newest technologies. This chapter does not apply to small batteries found in connection with backup power for small one-cell systems. A larger system poses an increased risk to responding personnel due to the amount of corrosive liquid found in some systems and due to the potential for escaping gas to produce fire or explosion when subjected to a source of ignition, such as a *dead short* or a *thermal runaway*, which are defined as follows:

1. *Dead short* refers to a system failure that produces a line-to-ground current where the system is not provided with protection of equipment from damaging line-to-ground fault currents.
2. *Thermal runaway* refers to the reaction of certain battery types, such as VRLA or nickel-cadmium batteries, that can experience thermal failure when overcharged or damaged by physical mechanical means.

Section 52.2 provides requirements for flooded lead-acid, nickel-cadmium, and VRLA battery systems containing electrolyte solution in excess of 100 gal (378.5 L) in buildings provided with a sprinkler system and in excess of 50 gal (189.3 L) in unsprinklered buildings. Doubling the amount of electrolyte for buildings provided with automatic sprinkler protection is consistent with other hazardous materials amounts where special protection features are provided. The sprinkler protection is provided to address the potential for fire directly involved with the battery system and to prevent an unrelated fire from spreading to the system. See NFPA's *Fire Protection Guide to Hazardous Materials* for more information on battery electrolytes.

Section 52.3 provides requirements for additional energy storage types like lithium-ion, sodium, and flow batteries that do not contain energy capacities in excess of 20 KWh (18.0 Mega joules) in buildings, whether provided with a sprinkler system or not. Additionally capacitors are being introduced as an energy storage system that does not contain energy capacities in excess of 70 KWh (25.2 Mega joules).

Where energy storage exceeds these amounts and where approved by the AHJ, areas containing stationary storage battery systems that exceed the amounts in Table 52.3.2.2.1 shall be permitted to be treated as an ordinary-hazard and not a high-hazard classification based on a hazardous mitigation analysis in accordance with 52.3.2.4 and large-scale fire and fault condition testing conducted or witnessed and reported by an approved testing laboratory.

With the addition of today's energy storage systems, it is imperative that battery management systems be used to protect the integrity of the system and prevent system failures that can result in loss of power, shock, and fire. Energy storage systems are being addressed in a new standard, NFPA 855, *Standard for the Installation of Energy Storage Systems*, currently being developed and going through the NFPA standards development process. More information about NFPA 855 can be found at http://www.nfpa.org/855.

Exhibit 52.1 shows an example of a stationary storage battery system.

N **52.1.1** Energy storage systems shall comply with Chapter 52.

N **52.1.2 Permits.**

N **52.1.2.1** Permits, where required, shall comply with Section 1.12.

N **52.1.2.2** Prior to installation, plans shall be submitted and approved by the AHJ.

Exhibit 52.1

Stationary storage battery system. (Courtesy of Applied Power Services, LLC)

N 52.2* Lead-Acid and Nickel-Cadmium Batteries

A.52.2 The requirements in Section 52.2 supersede all the hazardous material designations, permits, and requirements in Chapter 60.

Permit requirements are listed in Section 1.12.

Δ **52.2.1 General.** Stationary storage battery systems having an electrolyte capacity of more than 100 gal (378.5 L) in sprinklered buildings or 50 gal (189.3 L) in unsprinklered buildings for flooded lead-acid, nickel-cadmium, and valve-regulated lead–acid (VRLA) batteries used for facility standby power, emergency power, or uninterrupted power supplies shall be in accordance with Section 52.2 and Table 52.2.1.

•

Table 52.2.1 is a quick guide to what safety provisions are required for these types of systems. The authority having jurisdiction (AHJ) needs to pay particular attention to the requirements and ensure that they are included in the permitting and approval process.

Δ ***TABLE 52.2.1*** *Battery Requirements*

	Nonrecombinant Batteries		Recombinant Batteries
Requirement	**Flooded Lead-Acid**	**Flooded Nickel-Cadmium (Ni-Cd)**	**Valve-Regulated Lead–Acid (VRLA)**
Safety caps	Venting caps	Venting caps	Self-resealing flame-arresting caps
Thermal runaway management	Not required	Not required	Required
Spill control	Required	Required	Not required
Neutralization	Required	Required	Required
Ventilation	Required	Required	Required
Signage	Required	Required	Required
Seismic control	Required	Required	Required
Fire detection	Required	Required	Required

52.2.2 Safety Features.

Δ **52.2.2.1 Safety Venting.** Batteries shall be provided with safety venting caps per 52.2.2.1.1 and 52.2.2.1.2.

Δ **52.2.2.1.1 Nonrecombinant Batteries.** Vented lead-acid and nickel-cadmium shall be provided with safety venting caps.

Δ **52.2.2.1.2 Recombinant Batteries.** VRLA shall be equipped with self-resealing flame-arresting safety vents.

Δ **52.2.2.2 Thermal Runaway.** VRLA systems shall be provided with a listed device or other approved method to preclude, detect, and control thermal runaway.

Battery management systems are used to control the amount of charge and output of battery systems and are meant to shut down or control the battery before thermal runaway can occur. Battery management systems are computer motherboard-like devices that are co-located with the battery system. Depowering the battery management system can occur if the battery system is shut down. Residual heat in the batteries can lead to thermal runaway because the cooling system and battery management system is no longer operational to control the system. Caution should be exercised in deciding if shutting down the battery system is the right thing to do based on the observed operational problems of the system.

Select care must be taken in approving the location of energy storage systems. In the event of overheating or thermal runaway, there are often large amounts of smoke and possibly overpressurization of the enclosure. The amount of radiant heat from open flaming of the systems are considerable, and most often the cells cannot be reached with adequate water to cool them. The cells are so tightly wrapped that water keeps only the exterior of the cells cool while the interior of the cell continues to promote thermal energy. Abundant water supplies are usually required for lengthy periods of time to actually cool the cells. It is probably best to consider tactically active control rather than extinguishment if responding to this type of energy storage system.

52.2.2.3 Location and Occupancy Separation.

52.2.2.3.1 Battery systems shall be permitted in the same room as the equipment that they support.

52.2.2.3.2 Battery systems shall be housed in a noncombustible, locked cabinet or other enclosure to prevent access by unauthorized personnel unless located in a separate equipment room accessible only to authorized personnel.

Δ **52.2.2.3.3** In other than assembly, educational, detention, and correction facilities; health care, ambulatory health care, and day care centers; and residential board and care and residential occupancies, battery systems shall be located in a room separated from other portions of the building by a minimum of a 1-hour fire barrier.

Δ **52.2.2.3.4** In assembly, educational, detention and correction facilities; health care, ambulatory health care, and day care centers; and, residential board and care and residential occupancies, battery systems shall be located in a room separated from other portions of the building by a minimum of a 2-hour fire barrier.

52.2.2.4 Spill Control.

52.2.2.4.1 Rooms, buildings, or areas containing free-flowing liquid electrolyte in individual vessels having a capacity of more than 55 gal (208 L) or multiple vessels having an aggregate capacity exceeding 1000 gal (3785 L) shall be provided with spill control to prevent the flow of liquids to adjoining areas.

Paragraph 52.2.2.4.1 identifies the need to restrict any possibility of corrosive liquid that is released from spreading outside the immediate battery storage and use area. The term *free-flowing* is used to indicate that released electrolyte has the potential to flow unrestricted throughout the battery area. The *Code* also provides for different techniques for storing electrolyte within the battery, such as saturating pads and other materials with electrolyte or gel. In these non-free-flowing types of containers, cracks or breaks in the case might create slow drips or spills, but large amounts of free-flowing electrolyte will not be released and expose adjacent equipment or responding personnel.

Free-flowing electrolyte causes damage to metal objects adjacent to the battery system if a spill occurs and, if undetected, could cause structural damage to racks or supports of other batteries. Emergency responders should be aware that spilled electrolyte might be contained under or near the battery system.

Personnel responding to an incident might expect to find damaged battery systems and equipment in the storage area. Emergency responders should use appropriate personal protective equipment (PPE), given the potential for chemical burns upon contact with electrolyte and the fact that exposure to smoke and fumes can be toxic. NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response,* covers identification of hazardous areas to assist emergency responders in identifying the appropriate response and protection.

NFPA 472, *Standard for Competence of Responders to Hazardous Materials/Weapons of Mass Destruction Incidents,* should be reviewed for applicable requirements for personal protection of emergency responders, while NFPA 600, *Standard on Facility Fire Brigades,* should be reviewed for applicable requirements for personal protection of facility fire brigade members.

52.2.2.4.2* An approved method and materials for the control of a spill of electrolyte shall be provided that will be capable of controlling a spill from the single largest vessel.

A.52.2.2.4.2 Methods of achieving this protection can include, but are not limited to, the following:

(1) Liquidtight sloped or recessed floors in indoor locations or similar areas in outdoor locations
(2) Liquidtight floors in indoor locations or similar areas in outdoor locations provided with liquidtight raised or recessed sills or dikes
(3) Sumps and collection systems
(4) Spill containment systems such as that described in A.52.2.2.5.1

A range of methods for controlling spilled electrolyte liquid is outlined in A.52.3.4.2. These methods include, but are not limited to, fixed dike or sump systems designed to hold the spill of the largest container. The *Code* assumes that the largest spill in the majority of incidents would be from one container, and this amount is based on the largest single container. Additional spill protection might include the storage of absorbent pads or blankets within the containment area that are designed to hold the liquid in place. These control systems must be designed to contain the spill without human intervention and to operate automatically. The intent of 52.3.4.2 does not require someone to apply absorbent material to the spill. If the corrosive liquid spreads beyond the immediate storage area, intervention by emergency responders will be necessary.

Δ **52.2.2.4.3** VRLA batteries with immobilized electrolyte shall not require spill control.

Paragraph 52.2.2.4.3 requires that neutralizing material be available to handle an on-site spill from the battery system, including absorbent material, neutralizing chemicals, or a containment and removal system. Neutralizing the corrosive liquid hazard is an important consideration, and a response plan and neutralizing material must be available on-site. In addition, eyewash or safety showers are needed adjacent to battery storage areas where the potential exists for exposure of personnel to acid spill or spray.

52.2.2.5 Neutralization.

52.2.2.5.1* An approved method to neutralize spilled electrolyte shall be provided.

A.52.2.2.5.1 One method to determine compliance with the neutralization requirements of this subsection is found in Underwriters Laboratories Subject 2436, *Outline of Investigation for Spill Containment for Stationary Lead Acid Battery Systems*. Subject 2436 investigates the liquid tightness, level of electrolyte absorption, pH neutralization capability, and flame spread resistance of spill containment systems.

Δ **52.2.2.5.2** For VRLA batteries, the method shall be capable of neutralizing a spill from the largest battery to a pH between 7.0 and 9.0.

•

Lowering the pH of the corrosive liquid to between 7.0 and 9.0 should eliminate the potential for additional damage to equipment and hazard to personnel. Personnel responsible for responding to the spill must have adequate personal protection and proper quantities of neutralizing material available to handle the spill. The method of neutralization used to counteract the spill must be consistent with the nature and size of the spill.

52.2.2.6* Ventilation. For flooded lead-acid, flooded nickel-cadmium, and VRLA batteries, ventilation shall be provided for rooms and cabinets in accordance with the mechanical code and one of the following:

(1) The ventilation system shall be designed to limit the maximum concentration of hydrogen to 1.0 percent of the total volume of the room during the worst-case event of simultaneous "boost" charging of all the batteries, in accordance with nationally recognized standards.

(2) Continuous ventilation shall be provided at a rate of not less than 1 $ft^3/min/ft^2$ (5.1 $L/sec/m^2$) of floor area of the room or cabinet.

The direction provided within this *Code* is to identify the minimum requirements for protection from flammable gas buildup. A major concern with battery systems is the creation of flammable hydrogen gas during the charging period. To reduce this potential danger, a ventilation system must be designed to remove any concentration of hydrogen gas, which is lighter than air, from the area or the cabinet used to enclose the battery system. The installation and design of the battery area ventilation system must meet the mechanical code requirements adopted by the jurisdiction.

Paragraph 52.2.2.6 provides two ways to reduce the hazard: (1) limiting the percentage of hydrogen gas to 1.0 percent of the total volume of the room or (2) providing a storage cabinet to isolate the remaining space from reaching the explosive level.

The ventilation system must be reviewed by the AHJ to ensure that the design manages the peak period of greatest hydrogen gas production, with the understanding that all batteries are assumed to be charging at the same time under the rapid charge, or "boost," cycle. The ventilation system must also provide continuous ventilation for the room or cabinet based on the floor area. Hydrogen gas is lighter than air; therefore, ventilation must be provided to bring in fresh air at the floor level and exhaust the gas at the ceiling or roof level. The continuous ventilation rate of 1 ft^3/min of air for every square foot of floor area (5.1 L/sec of air for every square meter of floor area) has demonstrated a reduced risk of an explosion and that accumulations of hydrogen gas will not reach an explosive level. This approach is used in many different types of operations where flammable gases are produced or might be present. See NFPA 69, *Standard on Explosion Prevention Systems,* for more information about techniques for reducing concentrations of flammable gases.

A.52.2.2.6 Information on battery room ventilation can be found in IEEE 1635/ASHRAE 21, *Guide to Battery Room Ventilation and Thermal Management*.

•

52.2.2.7 Environment. The battery environment shall be controlled or analyzed to maintain temperature in a safe operating range for the specific battery technology used.

52.2.2.8 Signs.

The use of identification signs is important to inform responding personnel of potential hazards in areas where battery systems are stored or operated. Paragraphs 52.2.2.8.1 through 52.2.2.8.5 require that clear signage expressing the potential for exposure to corrosive liquids and flammable gases be posted at the doors or other access into battery storage buildings, rooms containing stationary storage battery systems, or other areas containing stationary storage battery systems. This hazard identification is important during times of power failures, earthquakes, or similar events, as well as during fire-related events.

52.2.2.8.1 Doors or accesses into the following shall be provided with approved signs:

(1) Battery storage buildings
(2) Rooms containing stationary storage battery systems
(3) Other areas containing stationary storage battery systems

52.2.2.8.2 For rooms that contain VRLA batteries, the signs required by 52.2.2.8.1 shall state the following:

This room contains:

(1) Stationary storage battery systems
(2) Energized electrical circuits

Δ **52.2.2.8.3** For rooms that contain flooded lead-acid or flooded Ni-Cd batteries, the signs required by 52.2.2.8.1 shall state the following:

This room contains:

(1) Stationary storage battery systems
(2) Energized electrical circuits
(3) Corrosive battery electrolyte

52.2.2.8.4 Battery cabinets shall be provided with exterior labels that identify the manufacturer and model number of the system and electrical rating (i.e., voltage and current) of the contained battery system.

52.2.2.8.5 Signs shall be provided within battery cabinets to indicate the relevant electrical, chemical, and fire hazard.

52.2.2.9 Seismic Protection. Battery systems shall be seismically braced in accordance with the building code.

Within known seismic areas, the battery system must be designed and protected from movement in accordance with the building code adopted by the jurisdiction. Braces for the racks and cases must be compatible with the proposed protection features and the storage space, including the spill control and detection systems.

52.2.2.10 Smoke Detection. An approved automatic smoke detection system shall be installed in rooms containing stationary battery storage systems in accordance with *NFPA 72*.

Area smoke detection provides early warning that a problem is occurring at or near the battery system. This type of detection is specific to smoke, because the smoke produced from a fire involving these systems is very hazardous and, if not detected early, might delay and increase the danger to evacuation and impact first responders. See *NFPA 72®, National Fire Alarm and Signaling Code®*, for more information on the design and installation of smoke detection systems.

N **52.2.2.10.1** The required automatic smoke detection system shall be supervised by an approved central, proprietary, or remote station service or a local alarm that will give an audible signal at a constantly attended location.

N **52.2.2.10.2** Normally unoccupied, stand-alone telecommunications structures with a gross floor area of less than 1,500 ft^2 (140 m^2) shall not be required to have the detection as indicated in 52.2.2.10.

N 52.3* Additional Battery Technologies

N **A.52.3** The requirements in Section 52.3 supersede all the hazardous material designations, permits, and requirements in Chapter 60.

N **52.3.1 General.** Energy storage systems having a capacity greater than the quantities listed in Table 52.3.1 shall be in accordance with Section 52.3 and where used as a legally required emergency or standby power system, shall also comply with 11.7.3.

TABLE 52.3.1 *Energy Storage System Threshold Quantities*

Type	Capacity[a]
Lithium batteries, all types	20 KWh (18.0 Mega joules)
Sodium batteries, all types	20 KWh (18.0 Mega joules)[c]
Flow batteries[b]	20 KWh (18.0 Mega joules)
Other battery technologies	10 KWh (10.8 Mega joules)
Capacitors	70 KWh (25.2 Mega joules)

Notes:

[a]For batteries and capacitors rated in Amp-Hours, KWh should equal rated voltage times amp-hour rating divided by 1000.

[b]Includes vanadium, zinc-bromine, polysulfide-bromide, and other flowing electrolyte-type technologies.

[c]Or 70 KWh (25.2 Mega joules) for sodium-ion technologies.

Due to the increase in types of energy storage systems, the protection features for venting the battery case must be designed to match the potential hazard. Some battery types do not require venting due to the solid nature of the storage material within lithium-ion and lithium metal polymer batteries. Section 52.3 details the same safety features as found in Table 52.2.1.

The battery type defined as VRLA is required to have self-resealing flame-arresting caps. This type of venting protection is designed to release pressure and provide a seal.

The concern regarding the use of flooded lead-acid and flooded nickel-cadmium batteries with any sealed vessel is their potential to rupture due to overpressurization in the case of vented lead-acid or nickel-cadmium batteries. With sealed batteries containing electrolyte, this possibility is very real. History has shown that battery cases bulge and crack due to outside heat sources or interior heat buildup. Charging can produce pressure within the battery. Overcharging without appropriate safety venting can cause overpressurization and battery case failure. Safety vent caps are designed to release pressure from within the sealed battery case above the liquid level into the room. When batteries are charging, safety vent caps must be kept in place to avoid release of electrolyte spray. Safety vent caps must be inspected to ensure their proper performance. If a major problem occurs within the case, or the case is exposed to an outside heat source, the safety vent caps are not designed to eliminate the potential for the case to fail.

N **52.3.2* Stationary Storage Battery Systems.**

Thermal runaway is a decomposition chemical reaction that is self-accelerating due to the heat that evolves from the chemical decomposing or degrading. The reaction continues until the chemical experiencing the phenomenon is used up.

Battery management systems designed to prevent or detect a thermal runaway of the battery must be listed or approved by the AHJ as part of the installation and permit process for the battery system. Thermal runaway can produce excessive amounts of heat and can cause damage to the battery, which could result in a fire or loss of the battery case.

Battery management systems are used to control the amount of charge and output of battery systems and are meant to shut down or control the battery before thermal runaway can occur. Battery management systems are computer motherboard–like devices that are co-located with the battery system. Depowering the battery management system can occur if the battery system is shut down. Residual heat in the batteries can lead to thermal runaway because the cooling system and battery management system is no longer operational to control the system. Caution should be exercised in deciding if shutting down the battery system is the right thing to do based on the observed operational problems of the system.

N **A.52.3.2** This section covers stationary battery systems that are typically used for facility standby power, emergency power, uninterrupted power supplies, or load shedding/load balancing applications.

Stationary storage battery systems that exceed the amounts specified in Table 52.3.1 pose potential hazards that are significant enough to require compliance with the requirements in Chapter 52. It is not the intent of Chapter 52 to regulate equipment with integral standby power systems below the amounts in Table 52.3.1, such as emergency lighting units, fire alarm control units, and other appliances and equipment.

N **52.3.2.1 Location and Occupancy Separation.** Stationary storage battery systems shall be located and constructed in accordance with this section.

N **52.3.2.1.1** Stationary storage battery systems shall be housed in a noncombustible, locked cabinet or other enclosure to prevent access by unauthorized personnel unless located in a separate equipment room accessible only to authorized personnel.

N **52.3.2.1.2 Location.**

N **52.3.2.1.2.1** Stationary storage battery systems shall not be located in areas where the floor is located more than 75 ft (22,860 mm) above the lowest level of fire department vehicle access, or where the floor level is more than 30 ft (9144 mm) below the finished floor of the lowest level of exit discharge, unless otherwise permitted by 52.3.2.1.2.

N **52.3.2.1.2.2** Installations on noncombustible rooftops of buildings exceeding 75 ft (22,860 mm) in height that do not obstruct fire department rooftop operations shall be permitted when approved by the AHJ.

N **52.3.2.1.3 Separation.** Rooms containing stationary storage battery systems shall be located in high-hazard occupancies, or shall be separated from other areas of the building as stated in 52.3.2.1.3.1 and 52.3.2.1.3.2. Stationary storage battery systems shall be allowed to be in the same room with the equipment they support.

N **52.3.2.1.3.1** In other than assembly, educational, detention, and correction facilities; health care, ambulatory health care, and day care centers; and residential board and care and residential occupancies, stationary storage battery systems shall be located in a room separated from other portions of the building by a minimum of a 1-hour fire barrier.

Paragraph 52.3.3.3 requires that rooms used for battery systems in the specified occupancies be separated from the remaining portion of the building with a 1-hour fire barrier. This rated separation reduces the potential of a fire within the battery system to reach the adjacent spaces. It also prevents a fire outside the space from reaching the battery system.

N **52.3.2.1.3.2** In assembly, educational, detention, and correction facilities; health care, ambulatory health care, and day care centers; and residential board and care and residential occupancies, stationary storage battery systems shall be located in a room separated from other portions of the building by a minimum of a 2-hour fire barrier.

Paragraph 52.3.3.4 requires separation from the remaining portion of the buildings with a 2-hour fire barrier for occupancies that have large numbers of persons who are unfamiliar with the hazards of battery systems or who might be delayed in evacuating the area used for battery systems. The increased fire separation helps provide the extra time occupants need to evacuate the occupancy or building prior to being exposed to a fire within the battery system room.

N **52.3.2.1.4 Outdoor Installations.** Stationary storage battery systems located outdoors shall comply with this paragraph, in addition to all applicable requirements of Section 52.3.

Select care must be taken in approving the location of energy storage systems. In the event of overheating or thermal runaway there are often large amounts of smoke and possibly overpressurization of the enclosure. The amount of radiant heat from open flaming of these systems are considerable, and most often the lithium cells cannot be reached with adequate water to cool them. These cells are so tightly wrapped that water keeps only the exterior of the cells cool while the interior of the cell continues to promote thermal energy. Abundant water supplies are usually required for lengthy periods of time to actually cool the cells. It is probably best to consider tactically active control rather than extinguishment if responding to this type of energy storage system.

N **52.3.2.1.4.1** Installations in outdoor enclosures or containers that are occupied for servicing, testing, maintenance, and other functions shall be treated as stationary storage battery system rooms.

N **52.3.2.1.4.2** Battery arrays in noncombustible containers shall not be required to be spaced 3 ft (914 mm) from the container walls.

N **52.3.2.1.4.3** Stationary storage battery systems located outdoors shall be separated by a minimum 5 ft (1524 mm) from the following:

(1) Lot lines
(2) Public ways
(3) Buildings
(4) Stored combustible materials
(5) Hazardous materials
(6) High-piled stock
(7) Other exposure hazards

N **52.3.2.1.4.4** The AHJ shall be permitted to authorize smaller separation distances if large-scale fire and fault condition testing conducted or witnessed and reported by an approved testing laboratory is provided showing that a fire involving the system will not adversely impact occupant egress from adjacent buildings, or adversely impact adjacent stored materials or structures.

As more manufacturers bring their systems to market, it will be necessary for them to have those systems listed and labeled. Where they are not, the AHJ has to depend on the systems being tested so the hazards can be understood and planned for. Most fire test data for these systems are not publicly available. However the AHJ can require the testing so the fire performance can be evaluated and appropriate requirements put in place to protect the public from hazards.

N **52.3.2.1.4.5 Means of Egress.**

N **52.3.2.1.4.5.1** Stationary storage battery systems located outdoors shall be separated from any means of egress as required by the AHJ to ensure safe egress under fire conditions, but in no case less than 10 ft (3048 mm).

N **52.3.2.1.4.5.2** The AHJ shall be permitted to authorize smaller separation distances if large-scale fire and fault condition testing conducted or witnessed and reported by an approved testing laboratory is provided showing that a fire involving the system will not adversely impact occupant egress.

N **52.3.2.1.4.6 Security of Areas.** Outdoor areas in which stationary storage battery systems are located shall be secured against unauthorized entry in an approved manner.

N **52.3.2.2 Maximum Allowable Quantities.**

N **52.3.2.2.1** Fire areas within buildings containing stationary storage battery systems exceeding the maximum allowable quantities in Table 52.3.2.2.1 shall comply with all applicable ordinary-hazard and high-hazard requirements as identified in 6.2.2 of NFPA *101* and the building code.

TABLE 52.3.2.2.1

Type	Maximum Allowable Quantities[a]	Hazard Classification
Lithium batteries, all types	600 KWh	High hazard[c]
Sodium batteries, all types	600 KWh	High hazard[c]
Flow batteries[b]	600 KWh	High hazard[c]
Other battery technologies	200 KWh	High hazard[c]

Notes:

[a]For batteries rated in amp-hours, KWh should equal rated voltage times amp-hour rating divided by 1000.

[b]Includes vanadium, zinc-bromine, polysulfide-bromide, and other flowing electrolyte-type technologies.

[c]Can be permitted to be ordinary hazard classification if approved by the AHJ based on (1) a hazard mitigation analysis conducted in accordance with 52.3.2.4 and (2) large-scale fire and fault condition testing conducted or witnessed and reported by an approved testing laboratory that shows that a fire involving the stationary storage battery system is contained within the room for a duration equal to the fire resistance rating of the room separation required in 52.3.2.1.3.1 or 52.3.2.1.3.2, as applicable.

N **52.3.2.2.2** Where approved by the AHJ, areas containing stationary storage battery systems that exceed the amounts in Table 52.3.2.2.1 shall be permitted to be treated as a ordinary-hazard and not a high-hazard classification based on a hazardous mitigation analysis in accordance with 52.3.2.4 and large-scale fire and fault condition testing conducted or witnessed and reported by an approved testing laboratory.

N **52.3.2.2.3** Where areas within buildings contain a combination of energy system technologies, the total aggregate quantities shall be determined based on the sum of percentages of each type divided by the maximum allowable quantity of each type. If the sum of the percentages exceeds 100 percent, the area shall be treated as a high-hazard classification in accordance with Table 52.3.2.2.1.

Where multiple independent battery storage systems are located in the same room or on the same floor, it is important to understand how they can interact in a fire situation. Knowing the amount of energy that responders may be exposed to and its impact on the room, the floor, or the facility in which they are housed is necessary to plan response procedures. Knowing if the location is ordinary or high hazard is important to the facility and to first responders.

N **52.3.2.3* Battery Arrays.**

N **A.52.3.2.3** A stationary battery array is an arrangement of individual stationary storage batteries in close proximity to each other, mounted on storage racks or in modules, battery cabinets, or other enclosures.

N **52.3.2.3.1** Battery arrays shall comply with 52.3.2.3.2 and 52.3.2.3.3 unless otherwise permitted by 52.3.2.3.4 or 52.3.2.3.5.

N **52.3.2.3.2** Storage batteries, prepackaged stationary storage battery systems, and pre-engineered stationary storage battery systems shall be segregated into arrays not exceeding 50 KWh (180 Mega joules) each.

N **52.3.2.3.3** Each array shall be spaced a minimum 3 ft (914 mm) from other arrays and from walls in the storage room or area. The storage arrangements shall comply with the egress provisions in NFPA *101*.

N **52.3.2.3.4** Listed pre-engineered stationary storage battery systems and prepackaged stationary storage battery systems shall not exceed 250 KWh (900 Mega joules) each.

N **52.3.2.3.5** The AHJ shall be permitted to approve listed pre-engineered and prepackaged battery arrays with larger capacities or smaller battery array spacing if large-scale fire and fault condition testing conducted or witnessed and reported by an approved testing laboratory is provided showing that a fire involving one array will not propagate to an adjacent array, and be contained within the room for a duration equal to the fire resistance rating of the room separation required by 52.3.2.1.3.

N **52.3.2.4 Hazard Mitigation Analysis.** A failure mode and effects analysis (FMEA) or other approved hazard mitigation analysis shall be provided to the AHJ when any of the following conditions are present:

(1) Battery technologies not specifically identified in Table 52.3.1 are provided.
(2) More than one stationary storage battery technology is provided in a room or indoor area where there is a potential for adverse interaction between technologies.
(3) When allowed as a basis for increasing maximum allowable quantities as specified in Table 52.3.2.2.1.

N **52.3.2.4.1** The analysis shall evaluate the consequences of the following failure modes, and others deemed necessary by the AHJ. Only single failure modes shall be considered for each mode:

(1) Thermal runaway condition in a single module or array
(2) Failure of a battery management system
(3) Failure of a required ventilation system
(4) Voltage surges on the primary electric supply
(5) Short circuits on the load side of the stationary battery storage system
(6) Failure of the smoke detection, fire suppression, or gas detection system

N **52.3.2.4.2** The AHJ shall be permitted to approve the hazardous mitigation analysis provided the consequences of the FMEA demonstrate the following:

(1) Fires or explosions will be contained within unoccupied stationary storage battery system rooms for the minimum duration of the fire resistance rated specified in 52.3.2.1.3.1 or 52.3.2.1.3.2, as applicable
(2) Fires and explosions in stationary storage battery system cabinets in occupied work centers allow occupants to safely evacuate
(3) Toxic and highly toxic gases released during charging, discharging, and normal operation shall not exceed the permissible exposure limit (PEL)
(4) Toxic and highly toxic gases released during fires and other fault conditions shall not reach concentrations in access of IDLH level in the building or adjacent means of egress routes during the time deemed necessary to evacuate from that area
(5) Flammable gases released from batteries during charging, discharging, and normal operation shall not exceed 25 percent of the lower flammable limit (LFL)

N **52.3.2.4.3** Construction, equipment, and systems that are required for the stationary storage battery system to comply with the hazardous mitigation analysis shall be installed, maintained, and tested in accordance with nationally recognized standards and specified design parameters.

N **52.3.2.5 Listings.** Storage batteries shall be listed in accordance with UL 1973, *Standard for Batteries for Use in Light Electric Rail (LER) Applications and Stationary Applications*. Prepackaged and pre-engineered stationary storage battery systems shall be listed in accordance with UL 9540, *Outline of Investigation for Energy Storage Systems and Equipment*.

N **52.3.2.5.1* Prepackaged and Pre-engineered Systems.** Prepackaged and pre-engineered stationary storage battery systems shall be installed in accordance with their listing and the manufacturer's instructions.

N **A.52.3.2.5.1** A prepackaged stationary storage battery system is designed and investigated as a single unit, assembled in a factory, and shipped to the site. A pre-engineered stationary storage battery system is designed and investigated as a single unit, but is shipped in modular form for assembly at the site.

N **52.3.2.5.2 Environment.** The storage battery environment shall be controlled to maintain temperatures and conditions within the battery manufacturer's specifications.

N **52.3.2.6 Installation.**

N **52.3.2.6.1 Battery Management System.** An approved battery management system shall be provided for battery technologies for monitoring and balancing cell voltages, currents, and temperatures within the manufacturer's specifications. The system shall transmit an alarm signal to an approved location if potentially hazardous temperatures or other conditions including short circuits, overvoltage (i.e., overcharge) or under voltage (i.e., over discharge) are detected.

A battery management system is the controlling function and hazard protection tool for any battery storage system. It regulates the amount of charge, the output, and the condition of the system. It is essentially the brains of the system. It should be recognized that removing the power for the battery management system during an emergency will remove its ability to control the system and shut it down in the event of an incident.

N **52.3.2.6.2 Battery Chargers.** Battery chargers shall be compatible with the battery manufacturer's electrical ratings and charging specifications. Battery chargers shall be listed in accordance with the UL 1564, *Standard for Industrial Battery Chargers*, or provided as part of a listed pre-engineered or prepackaged stationary storage battery system.

N **52.3.2.6.3 Vehicle Impact Protection.** Vehicle impact protection shall be provided where stationary storage battery systems are subject to impact by motor vehicles.

N **52.3.2.6.4 Combustible Storage.**

N **52.3.2.6.4.1** Combustible materials not related to the stationary storage battery system shall not be stored in battery rooms, cabinets, or enclosures.

N **52.3.2.6.4.2** Combustible materials in occupied work centers shall comply with Section 10.18 and shall not be stored within 3 ft (915 mm) of battery cabinets.

N **52.3.2.6.5 Signage.**

N **52.3.2.6.5.1** Approved signage shall be provided on doors or in approved locations near entrances to stationary battery storage system rooms.

N **52.3.2.6.5.2** New signage installations shall require the following items:

(1) Hazard identification markings in accordance with NFPA 704.
(2) "This room contains energized battery systems," or the equivalent.
(3) Identification of the type(s) of batteries present
(4) AUTHORIZED PERSONNEL ONLY
(5) Technology-specific markings, if required in 52.3.2.11

N **52.3.2.6.5.3** Where the battery storage system disconnecting means is not within sight of the main service disconnect, placards or directories shall be installed at the locations of the main service disconnect to indicate the location of all battery storage disconnecting means in accordance with *NFPA 70*.

It always should be assumed that there are multiple electronic feeds into any one system. It is important to have technical support from the system operator to fully know when a system is truly disconnected.

N **52.3.2.6.5.4** Existing stationary storage battery systems shall be permitted to include the signage required at the time it was installed.

N **52.3.2.6.5.5** Battery cabinets shall be provided with exterior labels that identify the manufacturer and model number of the system and electrical rating (i.e., voltage and current) of the contained battery system.

N **52.3.2.6.5.6** Signs shall be provided within battery cabinets to indicate the relevant electrical, chemical, and fire hazard.

N **52.3.2.6.5.7** Fire command centers in buildings containing stationary storage battery systems shall include signage or readily available documentation that describes the location of stationary storage battery systems, the types of batteries present, operating voltages, and location of electrical disconnects.

N **52.3.2.6.6 Seismic Protection.** Battery systems shall be seismically braced in accordance with the building code.

N **52.3.2.6.7 Safety Caps.** Vented batteries shall be provided with flame-arresting safety caps.

N **52.3.2.6.8* Mixed Battery Systems.** Different types of batteries shall not be installed in the same room or cabinet if there is a potential for unsafe interaction between them, as determined by the AHJ.

N **A.52.3.2.6.8** This section is intended to address unique situations where the installation of different types of batteries in the same room or cabinet could create a situation where there is unacceptable chemical, thermal, or other interaction between them, or where the surrounding environment is not within the battery manufacturers' specifications. The AHJ has the option to require a hazard mitigation analysis, conducted in accordance with 52.3.2.4, to identify hazards and potential solutions that will mitigate the hazards.

N **52.3.2.7 Suppression and Detection.**

N **52.3.2.7.1 Fire suppression.** Rooms containing stationary storage battery systems shall be protected by an automatic sprinkler system installed in accordance with Section 13.3.

N **52.3.2.7.1.1** Commodity classifications for specific technologies of storage batteries shall be in accordance with Chapter 5 of NFPA 13.

N **52.3.2.7.1.2** If the storage battery types are not specifically addressed in Chapter 5 of NFPA 13, the AHJ shall be permitted to approve the fire suppression system based on full-scale fire and fault condition testing conducted or witnessed and reported by an approved laboratory.

N **52.3.2.7.2 Smoke Detection.** An approved automatic smoke detection system shall be installed in rooms containing stationary battery storage systems in accordance with *NFPA 72* and the required automatic smoke detection system shall be supervised by an approved central, proprietary, or remote station service or a local alarm that will give an audible signal at a constantly attended location.

N **52.3.2.8* Ventilation.** Where required by 52.3.2.11, ventilation shall be provided for rooms and cabinets in accordance with the mechanical code and one of the following:

(1) The ventilation system shall be designed to limit the maximum concentration of flammable gas to 25 percent of the lower flammable limit (LFL) of the total volume of the room during the worst-case event of simultaneous "boost" charging of all the batteries, in accordance with nationally recognized standards.
(2) Mechanical ventilation shall be provided at a rate of not less than 1 $ft^3/min/ft^2$ (5.1 $L/sec/m^2$) of floor area of the room or cabinet. The ventilation can be either continuous, or activated by a gas detection system in accordance with 52.3.2.8.2.

N **A.52.3.2.8** Information on battery room ventilation can be found in IEEE 1635/ASHRAE 21, *Guide to Battery Room Ventilation and Thermal Management.*

N **52.3.2.8.1** Required mechanical ventilation systems for rooms and cabinets containing storage batteries shall be supervised by an approved central, proprietary, or remote station service or shall initiate an audible and visual signal at an approved constantly attended on-site location.

N **52.3.2.8.2** Where required by 52.3.2.8(2), rooms containing stationary storage battery systems shall be protected by an approved continuous gas detection system.

N **52.3.2.8.2.1** The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammable limit (LFL)

N **52.3.2.8.2.2** Activation of the gas detection system shall result in activation of the mechanical ventilation system, which shall remain on until the flammable gas detected is less than 25 percent of the LFL.

N **52.3.2.8.2.3** The gas detection system shall include a minimum two hours of standby power.

N **52.3.2.8.2.4** Failure of the gas detection system shall annunciate a trouble signal at an approved central, proprietary, or remote station service, or when approved at a constantly attended onsite location.

N **52.3.2.9* Spill Control and Neutralization.** Where required by 52.3.2.11, approved methods and materials shall be provided for the control and neutralization of spills of electrolyte or other hazardous materials in rooms containing stationary storage batteries as follows:

(1) For batteries with free-flowing electrolyte, the method and materials shall be capable of neutralizing a spill of the total capacity from the largest cell or block to a pH between 5.0 and 9.0.
(2) For batteries with immobilized electrolyte, the method and materials shall be capable of neutralizing a spill of 3.0 percent of the capacity of the largest cell or block in the room to a pH between 5.0 and 9.0.

N **A.52.3.2.9** Methods of achieving this protection can include, but are not limited to, the following:

(1) Liquidtight sloped or recessed floors in indoor locations or similar areas in outdoor locations
(2) Liquidtight floors in indoor locations or similar areas in outdoor locations provided with liquidtight raised or recessed sills or dikes
(3) Sumps and collection systems

N **52.3.2.10 Thermal Runaway.** Where required by 52.3.2.11, a listed device or other approved method shall be provided to preclude, detect, and control thermal runaway.

N **52.3.2.11 Battery-Specific Protection.** Stationary storage battery systems shall comply with 52.3.2 through 52.3.2.10 and this section, as applicable.

N **52.3.2.11.1 Lithium Batteries.** Stationary storage battery systems utilizing lithium batteries shall be provided with thermal runaway protection in accordance with 52.3.2.10.

N **52.3.2.11.2 Sodium Batteries.** Stationary storage battery systems utilizing sodium batteries shall comply with the following:

(1) Ventilation shall be provided in accordance with 52.3.2.8.
(2) Spill control and neutralization shall be in accordance with 52.3.2.9.
(3) Thermal runaway protection shall be provided for in accordance with 52.3.2.10.
(4) A hazard mitigation analysis shall be provided for systems that utilize sodium sulfur batteries, or other sulfur-type battery systems that operate above ambient temperatures.
(5) The signage required in 52.3.2.6.5 shall include, where applicable, "Water Reactive Hazard — Apply No Water."

N **52.3.2.11.3 Flow Batteries.** Stationary storage battery systems utilizing flow batteries shall comply with the following:

(1) Ventilation shall be provided in accordance with 52.3.2.8.
(2) Spill control and neutralization shall be in accordance with 52.3.2.9.

N **52.3.2.11.4 Other Battery Types.** Stationary storage battery systems utilizing battery technologies other than those described in 52.3.2.11.1 through 52.3.2.11.1 shall comply with the following:

(1) Ventilation shall be provided in accordance with 52.3.2.8 where flammable, toxic or highly toxic gases could be present during charging, discharging, and normal system use.
(2) Spill control and neutralization shall be in accordance with 52.3.2.9 where the batteries contain electrolytes that could be released from the batteries.
(3) Thermal runaway protection shall be provided in accordance with 52.3.2.10.
(4) The signage required in 52.3.2.6.5 shall also identify any potential hazards associated with the batteries.

N **52.3.2.12 Testing, Maintenance, and Repairs.**

N **52.3.2.12.1** Stationary storage batteries and associated equipment and systems shall be tested and maintained in accordance with the manufacturer's instructions.

N **52.3.2.12.2** Any storage batteries or system components used to replace existing units shall be compatible with the battery charger, battery management systems, other storage batteries, and other safety systems.

N **52.3.3 Capacitor Energy Storage Systems.**

N **52.3.3.1 Capacity.** Stationary capacitor energy storage systems having capacities greater than those described in Table 52.3.1 shall comply with 52.3.3.

Battery systems historically have been kept in a separate location that is typically considered an equipment area. Some AHJs have interpreted this action to mean that a separation is required between the battery system and the equipment served. Separation between the two areas is not the intent of 52.3.3.1 and

52.3.3.2; therefore, if the designer determines that the battery and the equipment are to be located in one space, no separation is needed.

N **52.3.3.2 Location and Occupancy Separation.** Stationary capacitor energy storage systems shall be located and constructed as required for stationary storage battery system in accordance with 52.3.2.1 through 52.3.2.1.4.3.

The security of a battery system is one of the safety features designed to limit battery system problems. Misuse or vandalism of a battery system or unintended damage can cause a system to fail or start a fire. Any contact of the system with metal objects, liquid spills, or physical impact could start a series of events that would override built-in safety features. Battery racks, trays, and cabinets must be made of substantial construction and protected to withstand corrosion from trace amounts of acid released during charging, particularly from open systems. Persons within the room or having access to the room or cabinet must be trained to understand the hazards associated with this type of equipment.

N **52.3.3.3 Maximum Allowable Quantities.** Fire areas within buildings containing capacitor energy storage systems exceeding 600 KWh (2160 mJ) shall comply with all applicable ordinary-hazard and high-hazard requirements as identified in 6.2.2 of NFPA *101* and the building code.

N **52.3.3.4 Capacitor Arrays.**

N **52.3.3.4.1** Capacitors, prepackaged stationary capacitor energy storage systems, and pre-engineered capacitor energy storage systems shall be segregated into arrays not exceeding 50 KWh (180 Mega joules) each.

N **52.3.3.4.2** Each array shall be spaced a minimum 3 ft (914 mm) from other arrays and from walls in the storage room or area. The storage arrangements shall comply with the egress provisions in NFPA *101*.

N **52.3.3.5 Listings.** Capacitors shall be listed in accordance with UL 1973, *Standard for Batteries for Use in Light Electric Rail (LER) Applications and Stationary Applications*. Prepackaged and pre-engineered capacitor energy systems shall be listed in accordance with UL 9540, *Outline of Investigation for Energy Storage Systems and Equipment*.

N **52.3.3.5.1* Prepackaged and Pre-engineered Systems.** Prepackaged and pre-engineered capacitor energy storage systems shall be installed in accordance with their listing and the manufacturer's instructions.

N **A.52.3.3.5.1** A prepackaged capacitor energy system is designed and investigated as a single unit, assembled in a factory, and shipped to the site. A pre-engineered capacitor energy system is designed and investigated as a single unit, but is shipped in modular form for assembly at the site.

N **52.3.3.5.2 Environment.** The environment surrounding the capacitors shall be controlled to maintain temperatures and conditions within the manufacturer's specifications.

N **52.3.3.6 Chargers.** Capacitor chargers shall be compatible with the capacitor manufacturer's electrical ratings and charging specifications, and shall be listed in accordance with the UL 1564, *Standard for Industrial Battery Chargers*, or provided as part of a listed pre-engineered or prepackaged capacitor energy storage system.

N **52.3.3.7 Vehicle Impact Protection.** Vehicle impact protection shall be provided where capacitor energy storage systems are subject to impact by motor vehicles.

N **52.3.3.8 Combustible Storage.**

N **52.3.3.8.1** Combustible materials not related to the capacitor energy storage system shall not be stored in capacitor rooms, cabinets, or enclosures.

N **52.3.3.8.2** Combustible materials in occupied work centers shall comply with Section 10.18 and shall not be stored within 3 ft (915 mm) of capacitor cabinets.

N **52.3.3.9 Signage.** Approved signage shall be provided on doors or in approved locations near entrances to capacitor energy storage systems, and shall include the following:

(1) Hazard identification markings in accordance with NFPA 704.
(2) "This room contains energized capacitor systems," or the equivalent
(3) Identification of the type(s) of capacitors present
(4) AUTHORIZED PERSONNEL ONLY

N **52.3.3.9.1** Where the capacitor energy storage system disconnecting means is not within sight of the main service disconnect, placards or directories shall be installed at the locations of the main service disconnect to indicate the location of all capacitor energy storage system disconnecting means in accordance with *NFPA 70*.

N **52.3.3.9.2** Capacitor cabinets shall be provided with exterior labels that identify the manufacturer and model number of the system and electrical rating (i.e., voltage and current) of the contained battery system.

N **52.3.3.9.3** Signs shall be provided within capacitor cabinets to indicate the relevant electrical, chemical, and fire hazard.

N **52.3.3.9.4** Fire command centers in buildings containing capacitor energy storage systems shall include signage or readily available documentation that describes the location of the systems, the types of capacitors present, operating voltages, and location of electrical disconnects.

N **52.3.3.10 Seismic Protection.** Capacitor energy storage systems shall be seismically braced in accordance with the building code.

N **52.3.3.11 Testing, Maintenance, and Repairs.**

N **52.3.3.11.1** Capacitor energy storage systems and associated equipment and systems shall be tested and maintained in accordance with the manufacturer's instructions.

N **52.3.3.11.2** Capacitors or system components used to replace existing units shall be compatible with the capacitor charger, other capacitors, and other safety systems.

53 Mechanical Refrigeration

Chapter 53 covers mechanical refrigeration systems, which are usually designed to provide a means for cooling specific locations or processes to temperatures below ambient. Although the types of mechanical refrigeration systems are many, all involve heat exchangers, differing only in size, mechanical and thermal design, and use of different fluids as refrigerants.

53.1* General

A.53.1 See the mechanical code for refrigerant group descriptions.

For the most part, the design of mechanical refrigeration systems is overseen by regulations listed in the mechanical code adopted by the jurisdiction. For mechanical refrigeration systems, the intent of this *Code* is to identify appropriate safety features for the system. Depending on the type of refrigerant gas used, different levels of safety are necessary. Traditional refrigerant gases, such as chlorofluorocarbons (CFCs), have been eliminated from all new systems because of scientific evidence that they have the capability of destroying the ozone layer surrounding the earth. CFCs have been replaced by CFC substitutes, natural refrigerants, which have a lower global warming potential (GWP). One type of natural refrigerant are hydrocarbons, such as propane, which are classified as A3 refrigerants. Most common CFC substitute refrigerant gases are relatively harmless. However, one longtime refrigerant gas still in use is ammonia.

The material safety data sheet (MSDS) on a refrigerant gas is a good way to become familiar with the properties of the refrigeration agent. To effectively use Chapter 53, the user should know whether the refrigerant gas is toxic, highly toxic, or flammable and whether it has other hazard characteristics or no characteristics. The user also should know whether the gas is lighter or heavier than air in order to implement the proper protection features.

A refrigerant can be a liquid, a gas, or a combination of both. In order to measure the amount of refrigerant, the refrigeration industry measures the refrigerant by its weight, referring to pounds (or kilograms) of refrigerant. Section 53.1 explains the conditions under which the refrigeration equipment and system must comply with the stated provisions, which are based on the type of refrigerant and the number of pounds (kilograms) of refrigerant in the system.

If the refrigeration equipment contains refrigerant gases that are classified as hazardous (toxic, highly toxic, or flammable — including ammonia, which deflagrates), the refrigeration system and its components might be required to meet additional protection levels, including stronger seismic restraint, as required by the building code adopted by the jurisdiction.

Safety group classification of refrigerants can be found in Exhibit 53.1. Exhibit 53.2 is a schematic of a refrigeration system, consisting of a circulating refrigerant, a condenser and receiver, a control device, an evaporator, and a compression device.

53.1.1 Applicability.

53.1.1.1* Refrigeration unit and system installations having a refrigerant circuit containing more than 220 lb (100 kg) of Group A1 or 30 lb (13.6 kg) of any other group refrigerant shall be in accordance with Chapter 53 and the mechanical code.

Refrigerant groups are found in the IAPMO *Uniform Mechanical Code*™. Most refrigerants made from CFCs are classified as Group A1. These refrigerants generally have a very low toxicity level, usually an immediately dangerous to life and health (IDLH) rating of 50,000 ppm, and are nonflammable, as listed in the *Uniform Mechanical Code*.

Other refrigerant gases have been developed that might be identified in other refrigerant classifications. An important practice is always to ask for the refrigerant name and an MSDS on the refrigerant. The American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) helps maintain the accuracy of Table 1102.3, Refrigerant Groups Properties and Allowable Quantities, found in the *Uniform Mechanical Code*. The table can be a valuable resource in helping to properly classify refrigerant gases.

Chapter 53 regulates refrigeration systems having a refrigerant circuit containing more than 220 lb (100 kg) of Group A1 or 30 lb (13.6 kg) of any other group refrigerant.

A.53.1.1.1 Refrigerant safety groups are established by ANSI/ASHRAE 34, *Designation and Safety Classification of Refrigerants*. Safety groups are based on the relative safety with respect to toxicity and flammability. The classification groups include a letter designation that indicates the toxicity (A is "lower toxicity" and B is "higher toxicity") and a number that indicates flammability (1 indicates no flame propagation in air when tested by prescribed methods at specified conditions, 2 is "lower flammability," and 3 is "higher flammability").

53.1.1.2 Temporary and portable installations shall be exempt from the requirements of this chapter when approved.

53.1.2 Permits and Plans.

53.1.2.1 Permits, where required, shall comply with Section 1.12.

A permit might be required for a variety of reasons, including for construction or installation of the refrigeration system once it has been proven to comply with the provisions of Chapter 53. The authority having jurisdiction (AHJ) should inspect the refrigeration system annually to ensure that compliance with Chapter 53 is maintained throughout the life of the refrigeration system. A permit also provides the advantage of spotting a potential hazard within a jurisdiction.

A useful reference for the permit application process is the Hazardous Materials Management Plan (HMMP) Instructions shown in Figure D.3.1 of this *Code*. The HMMP provides the name of the facility, the names of responsible individuals at the location, a chemical inventory statement (for amounts of refrigerant gases on site), and a sketch of the building that includes locations of emergency controls. This provision references the standard permit requirement found in Table 1.12.8(a).

53.1.2.2 Plans and specifications for devices and systems required by this chapter shall be submitted to the AHJ for review and approval prior to installation.

The AHJ usually does not require permits to maintain a refrigeration system. Where a system is being maintained, it is assumed that it is being run in a safe operating condition, just as it was at the time of installation. An exception to this rule is when a refrigerant is replaced with a different type of gas. (See 53.3.1.4.)

53.1.3 Reference Codes and Standards. Refrigeration systems shall be in accordance with ASHRAE 15 and the mechanical code. Refrigeration systems using ammonia as a refrigerant shall also comply with ANSI/IIAR 2, *Standard for Equipment, Design and Installation of Closed-Circuit Ammonia Mechanical Refrigerating Systems*.

Subsection 53.1.3 was updated for the 2015 edition of the *Code* to reference not only ANSI/ASHRAE 15, *Safety Standard for Refrigeration Systems,* but also ANSI/IIAR 2, *Standard for Equipment, Design and Installation of Closed-Circuit Ammonia Mechanical Refrigerating Systems,* for ammonia refrigerants, which is a common CFC replacement gas. For ammonia refrigeration systems, IIAR 2 is an ANSI-accredited document that supplements ASHRAE 15 and provides important additional safeguards regarding the equipment, design, and installation of closed-circuit ammonia mechanical refrigerating systems. ANSI/IIAR 2 is also referenced by other recognized mechanical codes.

53.2 Safety Features

53.2.1 Emergency Pressure Control System. Refrigeration systems containing more than 6.6 lb (3 kg) of flammable, toxic, or highly toxic refrigerant or ammonia shall be provided with an emergency pressure control system in accordance with 53.2.1.1 and 53.2.1.2.

Earlier editions of this *Code* required manually operated emergency control boxes for certain refrigeration systems. Subsection 53.2.1 now requires an automatic emergency pressure control system to be installed. The International Institute of Ammonia Refrigeration (IIAR) has developed a detailed design guide for emergency pressure control systems, which can be found in Appendix K of ANSI/IIAR 2.

Enhancements in refrigeration system control equipment associated with new technologies now make it possible to provide an automatic emergency control system to replace key functions of the traditional emergency control box. The proposed automatic controls provide a means of mitigating an overpressure condition prior to operation of emergency pressure relief vents and, most likely, prior to the arrival of emergency responders. The automatic valves also eliminate the need for emergency responders to decipher the condition of a system in an attempt to determine whether operation of manual crossover valves in an emergency control box would be of benefit in mitigating a system malfunction.

This requirement ensures that lower pressure zones will be capable of handling the additional pressure added by a crossover condition without overpressurizing or operating the emergency relief vents on the lower zone. Earlier editions of the *Code* did not address this concern on the assumption that someone operating a manual bypass valve in the emergency control box would be knowledgeable with regard to system limitations. Nevertheless, this *Code* has never required the low pressure side of the system to handle the high pressure side, and, therefore, some systems with emergency control boxes could present the potential for an emergency responder to overpressurize a system zone by fully opening a manual crossover valve too quickly. The resulting overpressure condition could cause a relief vent to operate or even cause a failure in the piping system.

Overall, the requirement for a fully redundant safety control system in lieu of a manual system has rarely, if ever, been utilized by the fire service. Such a requirement would resolve long-standing concerns regarding the potential for harm caused by an untrained person operating valves in an emergency control box. There is no condition under which removal of refrigerant from a refrigeration system by the fire service is considered advisable. In contrast, automatic transfer of excess pressure to another zone of the system in conjunction with stopping the pressure source (compressors) can safely mitigate an overpressure condition.

The unlikely event in which a fire causes an overpressure condition that allows system zones to automatically interconnect creates a much larger heat sink to limit pressure buildup while safely containing refrigerant. If the exposure fire continues to grow, emergency relief vents can protect the refrigeration system, and automatic-reseating valves can automatically limit the release of refrigerant to the amount necessary to maintain the system within design limits. In contrast, an emergency responder normally would not know how to properly cycle a manual valve in an emergency control box to limit the release of refrigerant to the minimum amount necessary for safety.

The 6.6 lb (3 kg) threshold parallels existing provisions found in other model codes.

53.2.1.1 High and Intermediate Pressure Zones. Each high and intermediate pressure zone in a refrigeration system shall be provided with a single automatic valve providing a crossover connection to a lower pressure zone. Automatic crossover valves shall comply with 53.2.1.1.1 through 53.2.1.1.4.

53.2.1.1.1 Overpressure Limit Set Point for Crossover Valves. Automatic crossover valves shall be provided to automatically relieve excess system pressure to a lower pressure zone if the pressure in a high or intermediate pressure zone rises to within 90 percent of the set point for emergency pressure relief devices.

Prior to the 2009 edition of the *Code*, this requirement used 15 psi (103.3 kPa) as the trigger for application of this paragraph. Beginning with the 2009 edition, however, this section instead uses the trigger of 90 percent of the set point differential between operation of the crossover valve and the emergency relief vent. The intent has not changed, and there continues to be a minimum to permit the overpressure condition to be mitigated prior to operation of the emergency relief vent. A larger pressure differential is preferred where possible, because emergency relief vents will often begin to open at a pressure below the indicated operating pressure. Larger differentials provide an increased factor of safety and can prevent unnecessary operation of a relief vent. This additional safety system is likely to lead to a dramatic reduction in fugitive discharges from refrigeration systems during both day-to-day operations and emergency conditions.

53.2.1.1.2 Manual Operation. Where required by the AHJ, automatic crossover valves shall be capable of manual operation.

Paragraph 53.2.1.1.2 permits the AHJ to require manual control capabilities for the crossover valve. Although this requirement is not regarded as necessary, it recognizes the option for manual controls. Some fire departments are reluctant to give up manual controls, which the AHJ can mandate if necessary.

53.2.1.1.3 System Design Pressure. Refrigeration system zones that are connected to a higher pressure zone by an automatic crossover valve shall be designed to safely contain the maximum pressure that can be achieved by interconnection of the two zones.

53.2.1.1.4 Automatic Emergency Stop. Operation of an automatic crossover valve shall cause all compressors on the affected system to immediately stop in accordance with the following:

(1) Dedicated pressure-sensing devices located immediately adjacent to crossover valves shall be permitted as a means for determining operation of a valve.
(2) To ensure that the automatic crossover valve system provides a redundant means of stopping compressors in an overpressure

condition, high pressure cutout sensors associated with compressors shall not be used as a basis for determining operation of a crossover valve.

The intent of this provision is for the automatic crossover system to have a fully redundant means of stopping compressors. Compressors are ordinarily provided with automatic high pressure cutout controls, but 53.2.1.1.4 requires that these controls not be used to satisfy the *Code* requirement. An additional set of controls is required to serve as a backup means of preventing a severe overpressure condition that could cause operation of an emergency relief vent.

53.2.1.2 Low Pressure Zone.

The lowest pressure zone of a system cannot be arranged to bleed pressure to another system zone, since crossing the lowest pressure zone to a higher pressure zone would most likely result in reverse flow. However, by providing a redundant emergency stop control, which would disengage the compressor, an overpressure condition should be automatically mitigated.

Overpressure on a low pressure zone would most likely result from a defrost line from the high pressure side that is stuck in the open position, and stopping the compressor will disengage the pressure source for the defrost system. Note that compressors will cut out only if an overpressure condition occurs. If the emergency condition involves a leak on the low pressure side, compressors will continue to operate, which is beneficial in pumping down the low pressure side for this type of event.

53.2.1.2.1 Overpressure Limit Set Point for Emergency Stop. The lowest pressure zone in a refrigeration system shall be provided with a dedicated means of determining a rise in system pressure to within 90 percent of the set point for emergency pressure relief devices.

53.2.1.2.2 Automatic Emergency Stop. Activation of the overpressure sensing device shall cause all compressors on the affected system to immediately stop.

53.2.2 Treatment, Flaring, and Diffusion Systems for Refrigerant Discharge.

53.2.2.1 Required Systems. Unless the AHJ determines, upon review of an engineering analysis prepared at the expense of the owner, that a significant fire, health, or environmental hazard would not result from an atmospheric release, refrigeration systems that are designed to discharge refrigerant vapor to the atmosphere shall be provided with an approved treatment, flaring, or diffusion system where required by 53.2.2.1.1 through 53.2.2.1.3.

Paragraph 53.2.2.1 requires a treatment system for the discharge of the refrigerant. In some cases, this paragraph allows for review of the protection needs and allows the AHJ to permit other types of protection based on the review. An example of the application of this provision might include a cold storage (refrigerated) warehouse that could be located so far from populations, including rural housing, that a release of refrigerant would not impact public health or the environment. The refrigeration system installer needs to show, by a calculation or dispersion model that, by the time it disperses over a populated area, the refrigerant gas will be diluted in air to the point that it is not a health hazard to the public. The AHJ should check with other jurisdictional authorities to see whether future planned development includes a densely populated area located within the calculated impact area of the dispersion model.

53.2.2.1.1 Toxic and Highly Toxic Refrigerants. Systems containing toxic or highly toxic refrigerants shall discharge vapor to the atmosphere only through an approved treatment system in accordance with Chapter 63 or flaring system in accordance with 53.2.2.2.

Currently, the only amounts of toxic or highly toxic refrigerant gas that would trigger the need for a treatment system are those specified in 53.1.1.1. The definitions of the terms *toxic material* and *highly toxic material,* also found in 3.3.180.14 and 3.3.180.7, respectively, and extracted from NFPA 400, *Hazardous Materials* Code, are as follows:

> **Toxic Material.** A material that produces a lethal dose or a lethal concentration within any of the following categories: (1) a chemical or substance that has a median lethal dose (LD_{50}) of more than 50 mg/kg but not more than 500 mg/kg of body weight when administered orally to albino rats weighing between 200 g and 300 g each; (2) a chemical or substance that has a median lethal dose (LD_{50}) of more than 200 mg/kg but not more than 1000 mg/kg of body weight when administered by continuous contact for 24 hours, or less if death occurs within 24 hours, with the bare skin of albino rabbits weighing between 2 kg and 3 kg each; (3) a chemical or substance that has a median lethal concentration (LC_{50}) in air of more than 200 parts per million but not more than 2000 parts per million by volume of gas or vapor, or more than 2 mg/L but not more than 20 mg/L, of mist, fume, or dust when administered by continuous inhalation for 1 hour, or less if death occurs within 1 hour, to albino rats weighing between 200 g and 300 g each. [**400,** 2016]

> **Highly Toxic Material.** A material that produces a lethal dose or lethal concentration that falls within any of following categories: (1) a chemical that has a median lethal dose (LD_{50}) of 50 mg/kg or less of body weight when administered orally to albino rats weighing between 200 g and 300 g each; (2) a chemical that has a median lethal dose (LD_{50}) of 200 mg/kg or less of body weight when administered by continuous contact for 24 hours, or less if death occurs within 24 hours, with the bare skin of albino rabbits weighing between 2 kg and 3 kg each or albino rats weighing 200 g to 300 g each; (3) a chemical that has a median lethal concentration (LC_{50}) in air of 200 parts per million by

volume or less of gas or vapor, or 2 mg/L or less of mist, fume, or dust, when administered by continuous inhalation for 1 hour, or less if death occurs within 1 hour, to albino rats weighing between 200 g and 300 g each. [**400,** 2016]

Discharges from any treatment system for toxic or highly toxic gases must not be closer than 75 ft (23 m) from any building opening (e.g., windows, doors, mechanical air intake) or property line.

53.2.2.1.2 Flammable Refrigerants. Systems containing flammable refrigerants shall discharge vapor to the atmosphere in accordance with the following:

(1) For refrigerants having a density equal to or greater than the density of air, discharge shall be through an approved treatment system in accordance with or flaring system in accordance with 53.2.2.2.
(2) For refrigerants having a density less than the density of air, discharge to the atmosphere shall be permitted, provided that the point of discharge is located outside of the structure at not less than 15 ft (4.6 m) above the adjoining grade level and not less than 20 ft (6.1 m) from any window, ventilation opening, or exit.

53.2.2.1.3 Ammonia Refrigerant. Systems containing ammonia refrigerant shall discharge vapor to the atmosphere through a treatment system in accordance with 53.2.2.1, through a flaring system in accordance with 53.2.2.2, through an approved ammonia diffusion system in accordance with 53.2.2.3, or by other approved means except as follows:

(1) Discharge through a treatment, flaring, or diffusion system shall not be required for ammonia–water absorption unit systems installed outdoors serving a dwelling unit, provided that the discharge is shielded and dispersed.
(2) Discharge through a treatment, flaring, or diffusion system shall not be required for ammonia–water absorption unit systems containing less than 22 lb (10 kg) of ammonia and for which the ammonia circuit is located entirely outdoors.

53.2.2.2 Design of Flaring Systems.

53.2.2.2.1 Flaring systems for incineration of flammable, toxic, or highly toxic refrigerants or ammonia shall be designed to incinerate the entire discharge.

53.2.2.2.2 The products of refrigerant incineration shall not pose health or environmental hazards.

The MSDS helps determine which products of combustion will be released into the atmosphere after the incineration process and whether the particles of combustion pose harm to populations downwind of a flaring system.

53.2.2.2.3 Incineration shall be automatic upon initiation of discharge, shall be designed to prevent blowback, and shall not expose structures or materials to threat of fire.

53.2.2.2.4 Standby fuel, such as LP-Gas, and standby power shall have the capacity to operate for one and one half the required time for complete incineration of refrigerant in the system.

See Chapters 60, 66, and 69 of this *Code* for proper amounts, storage, and separation of standby fuel system requirements.

53.2.2.3 Design of Ammonia Diffusion Systems.

53.2.2.3.1 Ammonia diffusion systems shall include a tank containing 1 gal of water for each pound of ammonia (4 L of water for each kg of ammonia) that will be released in 1 hour from the largest relief device connected to the discharge pipe.

53.2.2.3.2 The water used shall be prevented from freezing without the use of salt or chemicals by burial of the discharge pipe below frost depth or other approved means.

53.2.2.3.3 The discharge pipe from the pressure relief device shall distribute ammonia in the bottom of the tank, but no lower than 33 ft (10 m) below the maximum liquid level.

53.2.2.3.4 The tank shall contain the volume of water and ammonia, described in 53.2.2.3.1, without overflowing.

53.2.2.3.5 The tank shall be substantially constructed of not less than ⅛ in. (2.51 mm) (10 gauge) steel.

53.2.2.3.6 The horizontal dimensions of the tank shall be equal to or less than one half of the height.

53.2.2.3.7 The tank shall have a hinged cover or, if of the enclosed type, shall have a vent hole at the top.

53.2.2.3.8 Pipe connections shall be through the top of the tank.

53.2.3 Refrigeration Machinery Rooms. Where required by the mechanical code, refrigeration systems shall be provided with a refrigeration machinery room, which shall comply with 53.2.3.1 through 53.2.3.4.

Refrigeration machinery rooms are rooms that contain stop valves for all the refrigerant gas–entrained portions of the system, except some evaporators, cooling towers, and other piping allowed to be omitted by the mechanical code. The *Uniform Mechanical Code* states that the refrigeration mechanical room must be not less than 6 ft 8 in. (2 m) high, with an unobstructed space of not less the 36 in. (915 mm), to gain access.

53.2.3.1 Refrigerant Vapor Detection, Monitoring, Alarm, and Electrical Systems. Refrigeration machinery rooms shall have an approved refrigerant vapor detection, monitoring, and alarm system in accordance with 53.2.3.1.1 through 53.2.3.1.7 and the mechanical code.

53.2.3.1.1 Alarm Threshold. The refrigerant vapor detector shall activate approved visual and audible alarm signaling devices at one of the following refrigerant thresholds:

(1) At a value not greater than the corresponding TLV-TWA (or toxicity measure consistent therewith); not to exceed 25 percent of the lower flammable limit (LFL)
(2) For ammonia, at a concentration not exceeding 25 parts per million

Depending on the type of refrigerant, vapor detectors need to be placed either at floor level for refrigerants heavier than air or at the highest point of the ceiling for refrigerants lighter than air. The AHJ should witness the detector's ability to function and record the vapor concentration at which the detector is activated. Detectors must activate at a point not greater than 50 percent of the IDLH, at the gas's permissible exposure limit (PEL), measured in ppm, or at 25 percent of the lower flammability limit (LFL). When the system detects the refrigerant's PEL, it is not unusual to have a gas detection system cause a warning alarm and then activate an emergency alarm capable of "dumping" the system of refrigerant when a given gas reaches 50 percent of the IDLH or 25 percent of the LFL.

Information on flammability limits for flammable gases and vapors can be found in NFPA 69, *Standard on Explosion Prevention Systems,* and NFPA's *Fire Protection Guide to Hazardous Materials*.

53.2.3.1.2 Location of Signaling Devices. Audible and visual alarm signaling devices shall be located inside the refrigeration machinery room and outside the room at each entrance into the room.

53.2.3.1.3 Audibility. Audible alarm signaling devices shall provide a sound level of at least 15 dB above the operating ambient noise sound pressure level of the space in which they are installed and shall provide approved, distinctive audible and visual alarms.

The alarms identified in 53.2.3.1.3 are not permitted to be fire alarms. The system must activate a distinctive audible alarm system that differs from the sound and visual color of a fire alarm. The refrigerant gas detection devices need to be located either near floor level for refrigerant gases that are heavier than air or at the highest ceiling point for refrigerant gases lighter than air.

Refrigerant vapor detection alarm systems are usually not required if the system can be sufficiently exhausted by natural ventilation or if the system contains a refrigerant amount not regulated by Chapter 53.

53.2.3.1.4* Emergency Shutoff Interface. Where the quantity of a Group A2, B2, A3, or B3 refrigerant, other than ammonia, in an independent circuit would exceed 25 percent of the LFL if released to the surrounding room, either of the following shall apply:

(1) Electrical equipment shall comply with the requirements of *NFPA 70* for Class I, Division 2.
(2) The refrigerant vapor detection system required by 53.2.3.1 shall automatically de-energize all electrical power within the space at vapor concentrations at or above 25 percent of the LFL.

A.53.2.3.1.4 See A.53.1.1.1.

53.2.3.1.5 Power and Supervision. Refrigerant vapor detection and alarm systems shall be powered and supervised as required for fire alarm systems in accordance with *NFPA 72*.

53.2.3.1.6 Monitoring and Annunciation. Refrigerant vapor detection and alarm systems shall transmit a signal to an approved location.

53.2.3.1.7 Installation and Maintenance. Detection and alarm systems shall be installed and maintained in accordance with the equipment manufacturers' specifications. *(Also see 53.3.2.1.)*

53.2.3.2* Prohibited Sources of Ignition. Open flames or devices having an exposed surface temperature exceeding 800°F (427°C) shall be prohibited in refrigeration machinery rooms except as follows:

(1) Momentary temperature excursions such as electrical contacts in Group A1 and B1 systems shall be permitted.
(2) Open flames or devices having an exposed surface temperature exceeding 800°F (427°C) shall be permitted in refrigeration machinery rooms used exclusively for direct-fired absorption equipment.
(3) Existing nonconforming installations shall be permitted where approved by the AHJ, where the combustion system is interlocked with the refrigerant detection system to shut off at the permissible exposure limit (PEL).
(4) Direct-vented combustion equipment shall be permitted in accordance with the mechanical code.

A.53.2.3.2 See A.53.1.1.1.

53.2.3.3 Ventilation Systems.

53.2.3.3.1 Fans providing emergency purge ventilation for refrigerant escape from a refrigeration room shall have a clearly identified switch of the break-glass type providing on-only control immediately adjacent to, and outside of, each refrigerant machinery room means of egress.

53.2.3.3.2 An emergency purge control shall be provided with a manual reset only.

53.2.3.3.3 For systems using a refrigerant other than ammonia, purge fans shall also respond automatically to the refrigerant concentration detection system set to activate the ventilation system at the threshold levels set forth in 53.2.3.1.1. For systems using ammonia, purge fans shall also respond automatically to the refrigerant concentration detection system set to activate the ventilation system at an ammonia concentration not exceeding 150 parts per million.

New for the 2018 edition of the *Code*, 53.2.3.3.3 was updated to differentiate the detection threshold for activation of ventilation systems from refrigeration rooms for systems using a refrigerant other than ammonia and also for those using ammonia. This change correlates with the provisions of ANSI/IIAR-2, *Standard for the Safe Design of Closed-Circuit Ammonia Refrigeration Systems.*

53.2.3.3.4 Mechanical ventilation systems serving refrigeration rooms shall have switches to control the power to each fan.

53.2.3.3.5 The switches shall be key-operated or within a locked glass-covered or tamper-resistant enclosure at an approved location adjacent to and outside of the principal entrance to the refrigeration machinery room.

53.2.3.3.6 Keys necessary for operation of ventilation systems shall be located in a single approved location.

An example of "a single approved location" required by 53.2.3.3.6 is the access box for the building, as described in 18.2.2.1, which addresses access to structures or areas.

53.2.3.3.7 Switches controlling fans providing continuous ventilation shall be of the two-position, on/off type.

53.2.3.3.8 Switches controlling fans providing intermittent or emergency ventilation shall be of the three-position, automatic on/off type.

53.2.3.3.9 Switches shall be labeled identifying both the function and the specific fan being controlled.

53.2.3.3.10 Two colored and labeled indicator lamps responding to the differential pressure created by airflow shall be provided for each switch.

53.2.3.3.11 One lamp shall indicate flow, and the other shall indicate no flow.

53.2.3.3.12 Exhaust from mechanical ventilation systems in refrigeration rooms shall be discharged 20 ft (6.1 m) or more from a property line or openings into buildings.

53.2.3.3.13 Discharges capable of exceeding 25 percent of the LFL or 50 percent of the immediately dangerous to life and health (IDLH) value shall be equipped with approved treatment systems to reduce the discharge concentrations to these values or lower, except as provided in 53.2.3.3.13.1 and 53.2.3.3.13.2. *(Also see 53.2.2.1.)*

53.2.3.3.13.1 A treatment system shall not be required when an approved engineering analysis of plume dispersion demonstrates that the limiting value will not be exceeded at the property line.

53.2.3.3.13.2 A treatment system shall not be required for ventilation provided for an ammonia refrigeration system.

See NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*, for requirements on mechanical ventilation systems used to exhaust refrigerants. See NFPA 69 for requirements to keep exhaust discharges from introducing explosion hazards into buildings and surrounding areas.

53.2.3.4 Electrical.

53.2.3.4.1 The refrigeration machinery room shall not be required to be classified as a hazardous location for electrical equipment except as provided in the mechanical code or *NFPA 70*.

53.2.3.4.2 Refrigeration machinery rooms used exclusively for direct-fired absorption equipment shall be permitted not to be classified as a hazardous location for electrical equipment in accordance with *NFPA 70*.

53.2.3.4.3 Electrical equipment and electrical installations in refrigeration machinery rooms shall comply with Section 11.1.

53.2.3.4.4 Where treatment, detection, or alarm systems are required, such systems shall be connected to a secondary source of power to automatically supply electrical power in the event of loss of power from the primary source.

53.2.3.4.5 A clearly identified switch of the break-glass type or with an approved tamper-resistant cover shall provide off-only control of refrigerant compressors, refrigerant pumps, and normally closed, automatic refrigerant valves located in the machinery room. In addition, this equipment shall be automatically shut off whenever the refrigerant vapor concentration in the machinery room exceeds the vapor detector's upper detection limit or 25 percent of the LFL, whichever is lower.

53.2.3.4.5.1 In machinery rooms where only nonflammable refrigerants are used, only compressors shall be required to be stopped by vapor detection or the cut-off switch. *(Also see 53.2.3.1.4.)*

53.2.4 Signs and Labels.

Δ **53.2.4.1 General.** Refrigeration units or systems shall be provided with approved hazard identification signs in accordance with NFPA 704, emergency operational signs, charts, and labels in accordance with the mechanical code, and the following:

(1) Name and address of the manufacturer or installer
(2) Type and total number of pounds of refrigerant contained in the system
(3) Field test pressure applied

53.2.4.2 Systems with More Than 110 lb (50 kg) of Refrigerant. Systems containing more than 110 lb (50 kg) of refrigerant shall be provided with signs having letters not less than ½ in. (12.7 mm) high, designating the following:

(1) Main shutoff valves to each vessel
(2) Mainstream or electrical controls
(3) Remote control switch
(4) Pressure-limiting device

53.3 Operations, Maintenance, Testing, and Decommissioning

53.3.1 Operations and Maintenance.

53.3.1.1 General. Refrigeration systems shall be operated and maintained in a safe and operable condition, free from accumulations of oil, dirt, waste, excessive corrosion, other debris, or leaks, and in accordance with ASHRAE 15, *Safety Standard for Refrigeration Systems,* and the mechanical code. Ammonia refrigerator systems shall be operated and maintained in accordance with ANSI/IIAR 7, *Developing Operating Procedures for Closed-Circuit Ammonia Mechanical Refrigerating Systems*.

ANSI/IIAR 7, *Developing Operating Procedures for Closed-Circuit Ammonia Mechanical Refrigerating Systems,* defines the minimum requirements for developing operating procedures for closed-circuit ammonia mechanical refrigerating systems. The operating procedures were developed to be easy to understand; to be safe, effective, and reliable; and to meet applicable regulatory requirements. ANSI/IIAR 7 is intended for those who develop, define, and/or review operating procedures for ammonia refrigeration systems. The reference to ANSI/IIAR 7 in this paragraph provides important safety information on the maintenance, inspection, and operation of ammonia refrigeration systems not currently covered elsewhere in the *Code* and is suitable for adoption and enforcement.

53.3.1.2 Access to System. Refrigeration systems shall be maintained accessible to the fire department as required by the AHJ.

Fire department emergency access to refrigeration systems, including passageways and access to control panels, usually requires an accessway of not less than 36 in. (915 mm) in width.

53.3.1.3 Storage in Machinery Rooms.

53.3.1.3.1 Flammable and combustible materials shall not be stored in refrigeration machinery rooms except for incidental materials necessary for the safe and proper operation and maintenance of the system.

53.3.1.3.2 Storage of materials in a refrigeration machinery room, including reserve supplies of refrigerants or refrigerant oils, shall be in accordance with other applicable chapters of this *Code*.

53.3.1.4 Changing of Refrigerant Type. Refrigerant types shall not be changed without prior notification and approval of the AHJ.

When refrigerant types are to be changed, the AHJ should verify that the previous refrigerant is chemically compatible with the new refrigerant and that components of the system are compatible with the new refrigerant material. The AHJ needs to verify that new vapor detectors are included in the changeover and that they will provide the same level of detection and protection required by Chapter 53.

53.3.1.5 Records of Refrigerant Quantities. The person in charge of the premises on which a refrigeration unit or system subject to these regulations is installed or maintained shall keep a written record of refrigerant quantities brought onto and removed from the premises, which shall be made available to the AHJ upon request.

53.3.1.6 Permissible Refrigerant Discharges. Refrigerant shall be only permitted to be released to atmosphere in the following circumstances:

(1) Refrigeration systems operating at pressures below atmospheric and incorporating automatic purge cycles
(2) Incidental operation of automatic pressure relief valves resulting in minor release of the refrigerant charge
(3) Incidental minor releases associated with service operations after system pumpdown has been accomplished
(4) In an emergency

For information regarding acceptable conditions for discharge of refrigerant gases, see ASHRAE safety pamphlets, which can be obtained from the ASHRAE website at www.ASHRAE.org.

Δ **53.3.1.7 Notification of Fugitive Releases.** Where required by the fire department, the fire department shall be notified upon discharges of refrigerant that are not in accordance with 53.3.1.6(1), (2), or (3).

53.3.2 Testing of Equipment.

53.3.2.1 Acceptance Testing. The following emergency devices or systems shall be tested to demonstrate their safety and effectiveness upon completion of the installation or alteration:

(1) Treatment and flaring systems
(2) Ammonia diffusion systems
(3) Fans and associated equipment intended to operate emergency purge ventilation systems
(4) Refrigerant vapor detection and alarm systems

Acceptance testing can be accomplished with a test gas connected by tubing directly to the gas detector. The gas detector must then activate the devices identified in 53.3.2.1, as required, to verify function and operation. The AHJ must witness the testing. Written verification from the manufacturer or the installer of the emergency gas detection system should not be the only condition of acceptance.

53.3.2.2 Periodic Testing. The following emergency devices or systems shall be tested in accordance with the manufacturers' specifications at intervals not exceeding one year:

(1) Treatment and flaring systems
(2) Fans and associated equipment intended to operate emergency purge ventilation systems
(3) Refrigerant vapor detection and alarm systems

53.3.2.3 Records of Required Testing. A written record of required testing shall be maintained on the premises.

53.3.2.4 Testing Personnel Qualifications. Tests of emergency devices or systems required by Chapter 53 shall be conducted by persons trained in such testing.

N **53.3.3 Decommissioning of Ammonia Refrigeration Systems.** Decommissioning of closed-circuit ammonia refrigeration systems shall comply with ANSI/IIAR 8, *Decommissioning of Closed-Circuit Ammonia Mechanical Refrigerating Systems*.

Subsection 53.3.3 is new to the 2018 edition of the *Code*. ANSI/IIAR 8, *Decommissioning of Closed-Circuit Ammonia Refrigeration Systems*, specifies the minimum criteria for removing the ammonia charge in conjunction with the decommissioning of closed-circuit ammonia refrigeration systems.

Ozone Gas–Generating Equipment

54

54.1 Scope

54.1.1 Equipment having a maximum ozone-generating capacity of not less than ½ lb (0.23 kg) over a 24-hour period shall comply with Chapter 54 unless otherwise permitted by 54.1.2.

54.1.2 Chapter 54 shall not apply to ozone-generating equipment used in one- and two-family dwellings or lodging or rooming house occupancies.

Chapter 54 also deals with water treatment facilities. Section 54.1 allows for small ozone generators, which would be used for swimming pools or spas in residential occupancies. Ozone is not widely used as a disinfectant for water treatment.

For requirements and an explanation of the water treatment process, refer to NFPA 820, *Standard for Fire Protection in Wastewater Treatment and Collection Facilities.*

54.2 Location

54.2.1 General.

54.2.1.1 Ozone generators shall be located in approved cabinets or ozone generator rooms in accordance with Section 54.2 unless otherwise permitted by 54.2.1.2.

54.2.1.2 Ozone generators within approved pressure vessels located outside of buildings shall not be required to be located in a cabinet or ozone generator room.

For approval criteria of cabinets used for ozone generators, see NEMA 250, *Enclosures for Electrical Equipment,* which describes construction details and compatible materials.

54.2.2 Cabinets.

54.2.2.1 Ozone cabinets shall be constructed of approved materials compatible with ozone in accordance with nationally recognized standards.

54.2.2.2* Cabinets shall display an approved sign stating: OZONE GAS GENERATOR — HIGHLY TOXIC — OXIDIZER.

A.54.2.2.2 NEMA 250, *Enclosures for Electrical Equipment*, is intended for use as a guide in the design, fabrication, testing, and use of equipment regulated by Chapter 54.

54.2.2.3 Cabinets shall be braced for seismic activity in accordance with the building code.

54.2.2.4 Cabinets shall be mechanically ventilated in accordance with all of the following:

(1) Not less than six air changes per hour shall be provided.
(2) Exhausted air shall be directed to a treatment system designed to reduce the discharge concentration of the gas to one-half of the immediately dangerous to life and health (IDLH) value at the point of discharge to the atmosphere.
(3) The average velocity of ventilation at makeup air openings with cabinet doors closed shall not be less than 200 ft/min (1.02 m/s).

54.2.3 Ozone Generator Rooms. Ozone generator rooms shall comply with all of the following:

(1) Not less than six air changes per hour shall be provided.
(2) Exhausted air shall be directed to a treatment system designed to reduce the discharge concentration of the gas to one-half of the IDLH value at the point of discharge to the atmosphere, or the ozone generator room shall be equipped with a continuous gas detection system that will shut off the ozone generator and sound a local alarm when concentrations above the permissible exposure limit occur.
(3) Ozone generator rooms shall not normally be occupied, and such rooms shall be kept free of combustible and hazardous material storage.
(4) Room access doors shall display an approved sign stating: OZONE GAS GENERATOR — HIGHLY TOXIC — OXIDIZER.

Subsection 54.2.3 requires the monitoring of ambient concentrations of ozone at indoor installations. The off-gas from the ozone contactors generally exceeds the immediately dangerous to life and health (IDLH) level; therefore, the remaining ozone gas has to be recycled or destroyed. The off-gas is first passed through a demister, which traps small water droplets on stainless steel mesh. Then the ozone gas is heated and passed through a destruct unit, which contains a catalyst to speed up the process.

Ozone is a strong oxidant that reacts with human tissues, most notably the lungs, and leads to breathing difficulties. The eyes and nose are also affected; thus, there are requirements for treating the discharge concentration of the ozone.

Unlike cabinet requirements, the ozone generator room is allowed to use an interlocked shutdown system in place of the treatment system. The interlocked shutdown system shuts down the ozone treatment process when the ozone concentrations exceed 50 percent of the IDLH for ozone.

54.3 Piping, Valves, and Fittings

54.3.1 General. Piping, valves, fittings, and related components used to convey ozone shall be in accordance with Section 54.3.

54.3.2 Secondary Containment.

54.3.2.1 Secondary containment, such as double-walled piping or exhausted enclosures, shall be provided for piping, valves, fittings, and related components, unless otherwise permitted by 54.3.2.3.

54.3.2.2 Secondary containment shall be capable of directing a sudden release to an approved treatment system.

54.3.2.3 Secondary containment shall not be required for welded stainless steel piping and tubing.

54.3.3 Materials. Materials shall be compatible with ozone and shall be rated for the design operating pressures.

For compatibility information, refer to the listing for the product to be used in an ozone-exposed environment.

54.3.4 Identification. Piping shall be identified: OZONE GAS — HIGHLY TOXIC — OXIDIZER.

54.4 Automatic Shutdown

Ozone generators shall be designed to automatically shut down when any one of the following occurs:

(1) The dissolved ozone concentration in the water being treated is above saturation when measured at the point where the water is exposed to the atmosphere.
(2) The process using generated ozone is shut down.
(3) The ventilation system for the cabinet or ozone generator room fails.
(4) The gas detection system fails.

54.5 Manual Shutdown

Manual shutdown controls shall be provided at the ozone generator and, if in a room, within 10 ft (3 m) of the main exit or exit access door.

Manual shutdown is a fail-safe effort to allow an operator to shut down the operation before the automatic shutdown procedure takes place or in the event of interlock failure. The controls for manual shutdown must be placed near the point of egress for the operator's safety.

Cleaning and Purging of Flammable Gas Piping Systems

55

55.1 Application

Cleaning and purging activities for new and existing flammable gas piping found in electric generating plants and in industrial, institutional, and commercial applications shall comply with NFPA 56.

NFPA 56*, Standard for Fire and Explosion Prevention During Cleaning and Purging of Flammable Gas Piping Systems,* provides minimum safety requirements for the cleaning and purging procedures of flammable gas piping systems, including cleaning new or existing piping systems, purging piping systems into service, and purging piping systems out of service. The 2017 edition of NFPA 56 is referenced in this edition of the *Code*. The first edition of NFPA 56 was issued as a provisional standard in 2011 with a 2012 edition date. The development and issuance of the document as a provisional standard ensured prompt dissemination of new safety criteria related to the safe conduct of cleaning and purging procedures of flammable and combustible gas piping systems. Within 45 days of its issuance as a provisional standard, the document entered into a complete revision cycle process. The 2014 and 2017 editions then followed.

NFPA 56 was developed in response to an explosion on February 7, 2010, at Kleen Energy, a natural gas–fueled power plant under construction. The explosion was caused by a "gas blow," a commonly used cleaning procedure in natural gas–fueled power plants, where flammable gas is blown through piping at high pressure to remove debris and foreign materials. The gas was being vented into an area where it was unable to dissipate fully and found an ignition source, triggering the explosion. The provisions of NFPA 56 now address the safe procedures that must be followed during cleaning and purging activities for new and existing flammable gas piping in electric generating plants and in industrial, institutional, and commercial applications.

In the 2018 edition of NFPA 1, *Fire Code,* the following chapters have been reserved for future use:

- Chapter 56
- Chapter 57
- Chapter 58
- Chapter 59

60 Hazardous Materials

Chapter 60 provides general requirements for the storage, use, and handling of hazardous materials and is the first in a series of chapters in this *Code* that address provisions specifically related to the protection of areas containing hazardous materials.

Chapter 60 references certain provisions of the 2018 edition of NFPA 5000®, *Building Construction and Safety Code*®, and the 2016 edition of NFPA 400, *Hazardous Materials Code*. The purpose of NFPA 400 is to provide fundamental safeguards for storing, using, and handling certain hazardous materials. The 2010 edition of NFPA 400 was the first edition of this code and marked the combination of several NFPA hazardous materials documents into a single document: NFPA 430, *Code for the Storage of Liquid and Solid Oxidizers;* NFPA 432, *Code for the Storage of Organic Peroxide Formulations;* NFPA 434, *Code for the Storage of Pesticides;* and NFPA 490, *Code for the Storage of Ammonium Nitrate*. Those four codes were then withdrawn as separate documents.

In addition to the subjects covered by the incorporated documents, NFPA 400 covers other hazardous material categories specified in building and fire codes, such as corrosives, flammable solids, pyrophoric substances, toxic and highly toxic materials, unstable materials, and water-reactive materials. Chapter 21 of NFPA 400 also covers compressed gases and cryogenic fluids by including material extracted from NFPA 55, *Compressed Gases and Cryogenic Fluids Code*.

Chapter 60 is organized as follows:

Section 60.1	General requirements
Section 60.2	Special definitions
Section 60.3	Provisions for the classification of hazardous materials and hazardous wastes and for the classification of hazard level
Section 60.4	Permissible storage quantities; permissible locations of use; requirements for control areas
Section 60.5	Basic requirements for control, mitigation, and cleanup of unauthorized releases; emergency response planning and training; hazard communication and signage; control of potential sources of ignition; handling and processing systems, including process equipment, piping systems, and storage vessels; identification of hazardous materials; separation of incompatible materials; general storage and storage cabinets (in other words, any requirements that are not quantity specific and are broadly applicable)
Section 60.6	Requirements for emergency action planning fire control, and handling of chemical hazards for certain materials when in excess of the maximum allowable quantity (MAQ)
Section 60.7	Provisions for use of a performance alternative to the prescriptive controls contained in this chapter

The home and garden warehouse described in the following case study contained chlorinated pool chemicals and pool treatment products. Based on their fire and reactivity characteristics, these materials were classified by NFPA 430 as oxidizers. (The 2000 edition of NFPA 430 was cited in the investigation report referenced in the case study. As noted above, NFPA 430 has since been withdrawn and incorporated into the new NFPA 400.) By their nature, oxidizers increase the burning rate (intensity) of combustible materials. Some oxidizers can also cause spontaneous combustion in such materials.

The storage of oxidizers poses unique hazards for emergency responders. These compounds will react exothermically to varying degrees when contaminated, depending on the specific oxidizer and the nature of the contaminant. Fires involving oxidizers can produce heat, smoke, and harmful products of combustion in greater quantities than would be expected of an equivalent size fire involving only normal combustibles. Gross contamination can cause some oxidizers to undergo an explosive reaction, particularly if they are subjected to confinement and heating. It is imperative that emergency responders be able to recognize the presence of hazardous materials, preferably by advance knowledge consequent to preplanning or by means of visual cues, such as warning placards, hazard identification signs as described by NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response*, and so forth. The responders can then take the appropriate action, which in some cases is to take no action at all and protect exposures (human and structural) and allow the reaction to proceed to its end.

Storage and protection of hazardous materials in accordance with applicable NFPA codes and standards are critical to the protection of life and property and can assist in minimizing the hazards posed by the storage, use, and handling of bulk quantities of hazardous materials. Chapter 60, supplemented by Chapter 61 through Chapter 75, provides the necessary requirements to ensure adequate protection where hazardous materials are present.

This case study provides but one example of the severity of a fire involving hazardous materials and just one class of hazardous material at that. Conditions could have been much worse if other classes of commodities had been involved.

Case Study

In August 2000, the National Fire Protection Association (NFPA) investigated a Phoenix, Arizona, warehouse fire that involved hazardous materials. A summary of the report, as well as key findings related to the presence of hazardous materials, follows. The complete report, "Storage Warehouse, Phoenix, AZ, August 2, 2000," can be downloaded at https://www.nfpa.org/News-and-Research/Resources/Fire-investigations/Non-residential-properties.

On August 2, 2000, a fire was discovered in a multi-tenant 85,000 ft^2 warehouse in Phoenix, Arizona, at 4:58 p.m. By the time the fire was extinguished the next day, it had completely destroyed the facility. The damage to property and the commodities stored inside was estimated at over $100 million.

The warehouse consisted of a single-story main structure, with a two-story office wing on the east side and was fully sprinklered. Two tenants occupied the warehouse: a home and garden supply company and a pharmaceutical distribution operation. The former operation housed merchandise typically found in home improvement retail outlets. Materials were stored in several configurations, including solid and open shelf rack storage and palletized, solid-pile storage. Commodities stored in that part of the building included calcium hypochlorite, referred to in the trade as "calhypo," and other pool sanitizers based on "trichlor," or trichloro-S-triazinetrione.

Storage of merchandise in the pharmaceutical section of the warehouse consisted of open and solid shelf rack storage, in single- and double-row arrangements, as well as palletized solid-pile storage and shelf storage.

The fire began in the home and garden part of the building on the afternoon of August 2, less than an hour after workers had left for the day. A large plume of smoke was spotted coming from the south portion of the warehouse by a Tempe, Arizona, battalion chief traveling on the freeway adjacent to the warehouse. Simultaneously, occupants in the pharmaceutical warehouse reported hearing banging noises from the home and garden supply portion of the building. Some employees, thinking it was a passing thunderstorm, went outside to look and saw a column of smoke rising from the building. (The banging noises were later theorized to be aerosol cans rocketing in the warehouse and striking the concrete wall between the two warehouses or containers rupturing.)

By 12:14 a.m., the fires in the north section of the building were reportedly extinguished. By morning, on August 3, the entire building and all its contents were destroyed. Department of Environmental Quality (DEQ) and Department of Human Services (DHS) representatives were on the scene from the early moments of the incident and throughout the day after the fire, monitoring air and water samples for contaminants.

Investigation into the cause of the fire was continuing as of the publication date of the NFPA report. Fire investigators had tentatively determined the area of origin was in the center of the bulk storage area of the home and garden supply warehouse, where the calhypo and trichlor materials were stored. The source of ignition had not then been determined.

The fire caused the complete destruction of the building. Most tilt-panel concrete walls had collapsed inward or outward by the time the fire was extinguished. Portions of the north wall were deliberately pushed inward with heavy equipment for safety reasons. Portions of the east wall were later demolished for safety reasons. Virtually all the contents of the home and garden warehouse were destroyed in the fire. The majority of the materials stored in the pharmaceutical warehouse were also destroyed. Those materials not destroyed by fire were contaminated by smoke.

60.1 General Requirements

60.1.1 Applicability. Occupancies containing high hazard contents shall comply with this chapter in addition to other applicable requirements of this *Code.* [**5000:**34.1.1.1]

Chapter 60 is the basis for all the requirements regarding hazardous materials and the starting point for the regulation of all hazardous materials. Depending on the materials and their amount, certain sections or all of Chapter 60 might apply. Chapter 60 adapts established regulatory provisions and experience gained from codes and standards application to expand effective protection features. The authorities having jurisdiction (AHJs) have the opportunity to regulate the amount of hazardous material at a location at a level consistent with the perceived risk to public safety presented by the hazardous material, as addressed by the applicable code or standard.

NFPA 1, *Fire Code,* uses an occupancy approach for regulating hazardous materials by allowing quantities of hazardous materials in excess of a regulated amount without a change in the occupancy classification. The occupancy approach is achieved by relying on added passive and active protection features to protect the occupancy from hazards presented by the use of the hazardous material, without posing a risk to the public located outside the occupancy. When faced with hazardous materials within a building or in large-scale industrial facilities, this *Code* refers to applicable NFPA codes and standards for the majority of requirements available to regulate the particular hazardous material(s) involved. Many of the codes and standards are written for application in industrial settings or in storage facilities, where larger quantities of hazardous materials are present because of the operations and processes involved. It is to be expected that the quantities of hazardous materials at those facilities will be greater than would be found in nonmanufacturing facilities. Recognizing that fact, the AHJ reviews or inspects facilities that normally involve the use of hazardous materials on a regular basis, for example, flammable liquids at service stations, which are regulated by NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*.

Chapter 60 includes a number of occupancy-based tables (Table 60.4.2.1.2 through Table 60.4.2.1.10.1) that were originally added in the 2006 edition. Each table provides an MAQ for each hazardous material allowed to be handled, stored, or used within a control area of that particular occupancy *without* having to resort to increased protection measures. This concept provides the designer and the AHJ with a direct understanding of the amount of each hazardous material that is permitted in any one control area without increased regulatory oversight. In conjunction with the occupancy-based tables, a section on the requirements for mercantile and industrial occupancies and storage facilities is also available. The indoor control area limits remain the key factor in the determination of the protection features required for each level of hazard. The MAQs for hazardous materials handled, stored, or used in an outdoor control area are included in Table 60.4.4.1.2.

The MAQ tables are used as a basis for determining when protection is required. Hazardous materials stored or used in amounts below the MAQs require no additional protection other than that required for the occupancy in which the material is located. But, once the MAQ limits are exceeded, the level of protection increases based on the hazardous material. As shown in the tables, some hazardous materials are not permitted within an occupancy even if additional protection is provided.

Outdoor storage, handling, and use have their own set of requirements. Protection of materials or hazards located outside a building is not usually addressed, since the perception is that little hazard exists. The intent of provisions for outdoor storage of hazardous materials is to protect those persons in the vicinity of the material and responding emergency personnel.

60.1.2 Subjects Not Regulated. Buildings, and portions thereof, containing high hazard contents limited to any of the following shall not be required to comply with this chapter:

(1) Flammable and combustible liquids associated with application of flammable finishes and complying with Chapter 43.
(2) Flammable and combustible liquids associated with wholesale and retail sales and storage in mercantile occupancies and complying with Chapter 66
(3) Class IIIA and Class IIIB combustible liquid solvents in closed systems employing listed cleaning equipment complying with Chapter 24
(4) Refrigerants and refrigerant oil contained within closed-cycle refrigeration systems complying with Chapter 53 and the building code
(5) Flammable and combustible liquid beverages in liquor stores and distributors without bulk storage
(6) High hazard contents stored or used in farm buildings or similar occupancies for on-premises agricultural use
(7) Corrosive materials in stationary batteries utilized for facility emergency power, uninterrupted power supply, or similar purposes, provided that the batteries are provided with safety venting caps and ventilation is provided in accordance with Chapter 52
(8) Corrosive materials displayed in original packaging in mercantile occupancies and intended for personal or household use or as building materials
(9) Aerosol products in storage or mercantile occupancies and complying with Chapter 61
(10) Flammable and combustible liquids storage tank buildings meeting the requirements of Chapter 24 of NFPA 30
(11) Flammable and combustible liquids storage tank vaults meeting the requirements of Chapter 25 of NFPA 30
(12) Flammable and combustible liquids process buildings meeting the requirements of Chapter 17 of NFPA 30
(13) Installation of fuel gas distribution systems and associated equipment in accordance with Section 11.4 and Chapter 69

[**5000:**34.1.1.2]

Subsection 60.1.2 identifies high hazard contents or operations that do not require compliance with Chapter 60. Many of the entries refer the user to another chapter of this *Code* or to a specific NFPA document for the purpose of locating the specific requirements and protection features for the identified hazard. Most of the hazardous materials and high hazard uses have been validated by testing and include protection features referenced in other chapters of this *Code*, using extracted provisions from NFPA codes and standards or other sources. In addition, most of the uses have been exempt from the hazardous materials regulation sections of previous editions of NFPA 1 for many years and were not identified as being a specific fire or life safety problem. However, because NFPA 1 has a concern for emergency responder safety and health, the *Code* now addresses additional classes of hazardous materials.

For the benefit of the user, following is a list of hazardous materials and situations that are exempt from the provisions of NFPA 400:

1. Personal storage and use in one- and two-family dwellings
2. Storage and use of explosives and blasting agents (see NFPA 495, *Explosive Materials Code*)
3. Storage and use of fireworks (see NFPA 1124, *Code for the Manufacture, Transportation, and Storage of Fireworks and Pyrotechnic Articles*)
4. Refrigerants and refrigerant oils in closed cycle refrigeration systems that otherwise comply with the local fire and mechanical codes
5. Storage and use of hazardous materials in farm buildings or similar occupancies and in remote locations for on-premises agricultural use
6. Corrosive materials in stationary batteries used for an emergency power supply, an uninterrupted power supply, or a similar purpose, in accordance with this *Code*
7. Storage and use of aerosol products (see NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*)
8. Corrosive materials in original packaging in mercantile occupancies and intended for personal or household use or for use as a building material
9. Flammable and combustible liquids having no other physical or health hazard covered by NFPA 400 (See NFPA 30)
10. Certain organic peroxide formulations that are capable of detonation, as manufactured, or when unpackaged, or in their authorized shipping containers, under conditions of fire exposure, when stored, manufactured, or used in accordance with NFPA 495, *Explosive Materials Code*
11. Combustible metals, as defined in NFPA 484, *Standard for Combustible Metals*
12. LP-gas storage or utilization systems, in compliance with NFPA 58, *Liquefied Petroleum Gas Code*, or NFPA 59, *Utility LP-Gas Plant Code*
13. Where approved, materials that have been satisfactorily demonstrated not to present a potential danger to public health, safety, or welfare, based upon the quantity or condition of storage
14. Off-site transportation where in accordance with U.S. Department of Transportation (DOT) regulations
15. Cellulose nitrate film stored in compliance with NFPA 40, *Standard for the Storage and Handling of Cellulose Nitrate Film*

In item (1), the use of the word *personal* is deliberate and meaningful. The exemption is only for materials that are for the use of the occupants on a day-to-day basis. Storage of any materials that are related to an occupant's business interests would not be included in the context of *personal*.

The systems in items (4), (6), and (12) would be considered building utilities.

The wording is deliberate in item (13). It is expected that the AHJ will review each specific situation and determine whether an exemption is to be granted.

In item (14), the DOT has broad authority to preempt any local or state rule or regulation that encroaches on federal rules for transporting hazardous materials.

60.1.3 Applicability of Sections.

60.1.3.1 Quantities Not Exceeding the Maximum Allowable Quantities per Control Area. Storage, use, and handling of hazardous materials in quantities not exceeding maximum allowable quantities permitted in control areas set forth in Section 60.1.3.1 shall be in accordance with Section 60.1 through Section 60.5.

Paragraph 60.1.3.1 requires the user to follow the requirements for general protection, such as reporting quantities of hazardous materials to local and state jurisdictions and using appropriate signage, even where less than the MAQ is present. This ensures that AHJs are aware of the presence of any hazardous materials on-site and that a special review might be needed to determine the level of risk for the occupancy.

60.1.3.2 Quantities Exceeding the Maximum Allowable Quantities per Control Area. Storage, use, and handling of hazardous materials in quantities in excess of the maximum allowable quantities permitted in control areas set forth in 60.1.3.2 shall comply with Section 60.2 through Section 60.6.

Paragraph 60.1.3.2 implements the protection strategies within Chapter 60. If an amount of hazardous material exceeds the MAQ for storage, use, and handling, the user must follow all the applicable sections of the chapter. This does not include notification, signage, and reporting requirements, but it does include specific protection, construction, and property setback requirements.

60.1.3.3 Limited Applicability of this Chapter for Specific Material Classes. Chapter 60 shall apply in its entirety to all hazardous materials except where Chapters 61 through 73 of this *Code* specify that only certain sections of this chapter shall apply to a specific material classification category.

Paragraph 60.1.3.3 might appear to be in conflict with earlier sections of this chapter, but, in addition to the rest of Chapter 60, it provides guidance to the user to ensure that other chapters of the *Code* are reviewed and followed. Paragraph 60.1.3.3 allows the use of specific protection features and provides direction and limits found in other chapters for use when applicable.

An example of this application involves the use of flammable liquids. Chapter 66 contains specific requirements for the use of storage cabinets for flammable liquids. The user must apply the specific requirements found in Chapter 66 and not follow the general cabinet requirements in Chapter 60. Also, if a specific chapter other than Chapter 60 does not provide direction or protection features for a specific hazardous material use or storage arrangement, then Chapter 60 must be used to regulate that material.

60.1.4 Facility Closure.

60.1.4.1 Where required by the AHJ, no facility storing hazardous materials listed in 1.1.1 of NFPA 400 shall close or abandon an entire storage facility without notifying the AHJ at least 30 days prior to the scheduled closing. [**400:**1.9.1]

This requirement provides a means for local officials to mandate advance notice of the impending closure of a facility, so that they can work with the management of the facility to ensure proper shutdown, safe removal of any hazardous materials remaining on site, proper disposal of any hazardous waste materials, and a final risk assessment. This requirement also provides for an assessment of whether protective measures need to be kept in place. Going one step further, it can serve as notification to emergency responders that there likely will be no on-site assistance from facility personnel should an emergency occur.

60.1.4.2 The AHJ shall be permitted to reduce the 30-day period specified in 60.1.4.1 when there are special circumstances requiring such reduction. [**400:**1.9.2]

60.1.4.3 Facilities Out of Service.

60.1.4.3.1 Facilities Temporarily Out of Service. Facilities that are temporarily out of service shall continue to maintain a permit and be monitored and inspected. [**400:**1.9.3.1]

60.1.4.3.2 Facilities Permanently Out of Service. Facilities for which a permit is not kept current or that are not monitored and inspected on a regular basis shall be deemed to be permanently out of service and shall be closed in accordance with 60.1.4.4.1 through 60.1.4.4.2. [**400:**1.9.3.2]

60.1.4.4 Closure Plan.

60.1.4.4.1 Where required by the AHJ, the permit holder or applicant shall submit a closure plan to the fire department to terminate storage, dispensing, handling, or use of hazardous materials at least 30 days prior to facility closure. [**400:**1.9.4.1]

This paragraph gives the AHJ and the facility owner time to determine whether compliance for closure is regulated and whether the agreements for the protection features are appropriate for the hazard of the materials on-site. The time frame also allows the AHJ or the facility owner to obtain outside assistance if a third-party review is needed. If both parties agree that a shorter notice is workable, this requirement allows for the approved plan to be accepted in less time.

60.1.4.4.2 The plan shall demonstrate that hazardous materials that were stored, dispensed, handled, or used in the facility have been transported, disposed of, or reused in a manner that eliminates the need for further maintenance and any threat to public health and safety. [**400:**1.9.4.2]

60.1.5 Emergency Planning.

60.1.5.1 Emergency Action Plan. An emergency action plan, consistent with the available equipment and personnel, shall be established to respond to fire and other emergencies in accordance with requirements set forth in this Code. [**400:**1.10.1]

60.1.5.2 Activation. The facility responsible for an unauthorized release shall activate the emergency action element of the Hazardous Materials Management Plan. [**400:**1.10.2]

60.1.6 Hazardous Materials Management Plan (HMMP).

60.1.6.1* When required by the AHJ, new or existing facilities that store, use, or handle hazardous materials covered by this *Code* in amounts above the MAQ specified in 60.4.2.1.2 through 60.4.2.1.13 and 5.4.1.2 of NFPA 400 shall submit a hazardous materials management plan (HMMP) to the AHJ. [**400:**1.11.1]

A.60.1.6.1 See Annex D for a model Hazardous Materials Management Plan (HMMP).

A hazardous materials management plan (HMMP) is an optional requirement that can be imposed by the AHJ. A facility or business using a hazardous material should contact the AHJ to determine whether an HMMP is needed and, if so, when it must be submitted. Paragraph 60.1.6.1 and its subparagraphs provide requirements for the management of hazardous materials used at facilities — all key components of a typical HMMP. Additional information and a number of sample HMMP forms can be found in Annex D.

The intent of an HMMP is to provide specific information on the quantities of each hazardous material and its specific use in the process, as well as locations where and how each hazardous material is stored and used. The HMMP should also provide information on spill control and secondary containment features, as well as details of the facility's emergency response plan. Where an HMMP is provided, it must be reviewed by and include input from all parties that might respond to an incident, so that emergency responders know their respective roles. Training drills and site tours should be conducted. The HMMP should be reviewed and updated as facility modifications occur and as key participants change. The commentary following 60.1.6.2(3) is relevant here.

Δ **60.1.6.2** The HMMP shall be reviewed and updated as follows:

(1) Annually
(2) When the facility is modified
(3) When hazardous materials representing a new hazard category not previously addressed are stored, used, or handled in the facility

[**400:**1.11.2]

The situation in 60.1.6.2(3) is known as "management of change" and is deemed critical to safe operations. Management of change strives to ensure that any substantive change in operating conditions, equipment, or materials used is documented and made known to all personnel who might be involved. The HMMP can be thought of as an extension of management of change to local officials and emergency responders.

60.1.6.3 The HMMP shall comply with the requirements of Section 60.5. [**400:**1.11.3]

60.1.7* Hazardous Materials Inventory Statement (HMIS).

A.60.1.7 See Annex D for a model Hazardous Materials Inventory Statement (HMIS).

A hazardous materials inventory statement (HMIS) must be prepared and submitted when required by the AHJ. Sample guidelines and information can be found in Annex D. The form for the HMIS can be modified as necessary by the AHJ to accommodate local and site-specific concerns.

60.1.7.1 When required by the AHJ, a hazardous materials inventory statement (HMIS) shall be completed and submitted to the AHJ. [**400:**1.12.1]

60.2 Special Definitions

60.2.1 Chemical Name. See 3.3.43.

60.2.2 Closed System Use. See 3.3.271.1.

60.2.3 Control Area. See 3.3.14.2.

60.2.4 Dispensing. See 3.3.87.

60.2.5 Flammable Solid. See 3.3.240.2.

60.3 Classification of Materials, Wastes, and Hazard of Contents

Δ **60.3.1* Hazardous Material Classification.** Materials shall be classified into one or more of the following categories of hazardous materials, based on the definitions found in Chapter 3:

(1) Corrosive solids, liquids, or gases
(2) Flammable solids
(3) Flammable gases
(4) Flammable cryogenic fluids
(5) Inert cryogenic fluids
(6) Inert gases
(7) Organic peroxide formulations
(8) Oxidizer solids or liquids
(9) Oxidizing gases
(10) Oxidizing cryogenic fluids
(11) Pyrophoric solids, liquids, or gases
(12) Toxic or highly toxic solids, liquids, or gases
(13) Unstable (reactive) solids, liquids, or gases
(14) Water-reactive solids or liquids

[**400:**4.1]

A.60.3.1 The categorization and classification of hazardous materials enables the code user to determine the applicability of requirements based on hazard category and class related to the physical and health hazards of materials. The current definitions found in Chapter 3 have been developed using a compilation of criteria found in NFPA codes and standards, requirements of the U.S. DOT, and in some cases definitions established by OSHA in 29 CFR. [**400:**A.4.1]

A system known as the Globally Harmonized System of Classification and Labeling of Chemicals (GHS) has been developed based on standards for classification published by the United Nations (UN) Subcommittee of Experts on the GHS. The U.S. continues its efforts to incorporate the GHS in its federal regulatory scheme. OSHA published its revised Hazard Communication Standard (29 CFR 1910.1200) to align with the GHS in March 2012. The revised standard became effective in May 2012. [**400:**A.4.1]

It is anticipated by the Committee that over time, the GHS will be reviewed for applicability and possible integration into the regulatory scheme developed in NFPA 400 for hazardous materials storage, use, and handling. The evolution of this system of classification will be facilitated by the changes associated with classification, labeling, and safety data sheets. It is not anticipated that the GHS will be fully implemented immediately within NFPA 400, recognizing the historical basis that exists for some of the classifications of materials, such as flammable and combustible liquids. [**400:**A.4.1]

An example of the difficulty in fully integrating the Globally Harmonized System of Classification and Labeling of Chemicals (GHS) into NFPA's regulatory scheme lies in the manner in which GHS treats flammable liquids and combustible liquids, as opposed to their treatment in NFPA 30. NFPA broadly defines *flammable liquid* [flash point below 100°F (38°C)] and *combustible liquid* [flash point 100°F (38°C) and above]. NFPA 30 then classifies flammable liquids as Class IA, Class IB, and Class IC, depending on flash point and boiling point, and flammable liquids as Class II, Class IIIA, and Class IIIB, using flash point only. GHS uses only the word *flammable* and establishes only four categories.

Ignoring the boiling point criterion, NFPA 30 Classes IA and IB correspond to GHS Flammable Categories 1 and 2. NFPA 30 Class IIIA corresponds to GHS Flammable Category 4. NFPA 30 Class IIIB liquids, flash points 200°F (93°C) and higher, have no equivalent in GHS and, therefore, are not regulated under GHS.

Of greater concern is the fact that GHS Flammable Category 3 corresponds to *two* NFPA 30 classes: Class IC flammable [flash point 73°F to 100°F (23°C to 38°C)] and Class II combustible [flash point 100°F to 140°F (38°C to 60°C)]. GHS treats these two groups essentially the same, while NFPA 30 imposes stricter requirements on Class IC.

60.3.2 Classification of High-Hazard Contents.

60.3.2.1 General.

60.3.2.1.1 High hazard contents shall include materials defined as hazardous material in Chapter 3, whether stored, used, or handled. [**400:**4.2.1.1]

60.3.2.1.2 High hazard contents shall include those materials defined as hazardous material solids, liquids, or gases limited to the hazard categories specified in 1.1.1 of NFPA 400 and classified in accordance with 60.3.2.1.2.1 through 60.3.2.1.2.4 whether stored, used, or handled. [**400:**4.2.1.2]

Δ **60.3.2.1.2.1 High Hazard Level 1 Contents.** High hazard Level 1 contents shall include materials that present a detonation hazard, including, but not limited to, the following hazard categories:

(1) Class 4 oxidizers
(2) Detonable pyrophoric solids or liquids
(3) Class 3 detonable and Class 4 unstable (reactive) solids, liquids, or gases
(4) Detonable organic peroxides

[**400:**4.2.1.2.1]

Δ **60.3.2.1.2.2 High-Hazard Level 2 Contents.** High-hazard Level 2 contents shall include materials that present a deflagration hazard or a hazard from accelerated burning limited to the following hazard categories:

(1) Combustible dusts stored, used, or generated in a manner creating a severe fire or explosion hazard
(2) Class I organic peroxides
(3) Class 3 solid or liquid oxidizers that are used or stored in normally open containers or systems or in closed containers or systems at gauge pressures of more than 15 psi (103.4 kPa)
(4) Flammable gases
(5) Flammable cryogenic fluids
(6) Nondetonable pyrophoric solids, liquids, or gases
(7) Class 3 nondetonable unstable (reactive) solids, liquids, or gases
(8) Class 3 water-reactive solids and liquids

[**400:**4.2.1.2.2]

Δ **60.3.2.1.2.3 High-Hazard Level 3 Contents.** High-hazard Level 3 contents shall include materials that readily support combustion or present a physical hazard limited to the following hazard categories:

(1) Flammable solids, other than dusts classified as high-hazard Level 2, stored, used, or generated in a manner creating a high fire hazard
(2) Class II and Class III organic peroxides
(3) Class 2 solid or liquid oxidizers
(4) Class 3 solid or liquid oxidizers that are used or stored in normally closed containers or systems at gauge pressures of less than 15 psi (103.4 kPa)
(5) Class 2 unstable (reactive) materials
(6) Class 2 water-reactive solids, liquids, or gases
(7) Oxidizing gases
(8) Oxidizing cryogenic fluids

[**400:**4.2.1.2.3]

Δ **60.3.2.1.2.4 High-Hazard Level 4 Contents.** High-hazard Level 4 contents shall include materials that are acute health hazards limited to the following hazard categories:

(1) Corrosive solids, liquids, or gases
(2) Highly toxic solids, liquids, or gases
(3) Toxic solids, liquids, or gases

[**400:**4.2.1.2.4]

60.3.3 Mixtures. Mixtures shall be classified in accordance with the hazards of the mixture as a whole by an approved, qualified organization, individual, or testing laboratory. [**400:**4.3]

60.3.4* Multiple Hazards. Hazardous materials that have multiple hazards shall conform to the code requirements for each applicable hazard category. [**400:**4.4]

A.60.3.4 Where a conflict exists between applicable requirements, an analysis should be made and the proper applicable requirement should be implemented or conformed to subject to the approval of the AHJ. [**400:**A.4.4]

A material characterized by multiple hazards must be reviewed with extra care. If a hazardous material is classified in one category, the user is required to review the material based on that category and identify the appropriate protection features. If the material falls under two or more categories, the material must be reviewed for each category. Each protection feature identified must be outlined and provided. For example, if a hazardous material is an oxidizer, a suppression system is required but a ventilation system is not; therefore, the user must review the hazardous material to see whether it meets other hazard classifications addressed in this *Code*. If the same hazardous material is also toxic and, due to the classification, a ventilation system is required, both the suppression system and the ventilation system must be provided for this hazardous material.

60.3.5* Classification of Waste. Waste comprised of or containing hazardous materials shall be classified in accordance with 60.3.1 through 60.3.4 as applicable. [**400:**4.5]

Δ **A.60.3.5** The safe handling, collection, and disposal of hazardous waste can be accomplished only if the physical, chemical, and hazardous properties of its components are known and that information is properly applied. The categorization of a material as waste is normally under the purview of the user. In some cases the waste might be contaminated or "off spec" material, or material where the concentration of the hazardous components has been diluted. In other cases the waste might consist of cleaning materials that have become contaminated with a hazardous material. [**400:**A.4.5]

The classifiers of waste are cautioned that the classification of hazardous waste under the requirements of the Environmental Protection Agency (EPA) or Department of Transportation (DOT) for labeling required for shipping purposes might not correspond to the system of classification incorporated into 60.3.1. In addition, some judgment is needed to apply the *Code* in circumstances where the waste material is not in a form that is normally encountered when the hazardous material employed is in its virgin state. For example, a material that might not have been hazardous in its pure form might become hazardous when it becomes contaminated as use occurs. A tank of water used for rinsing parts on a plating line will eventually become contaminated by the materials that are being rinsed from parts as they travel through the line. If the concentration of the material being rinsed from parts becomes high enough, the content of hazardous materials in the rinse tank might be present in a concentration sufficient enough to cause the waste rinse water to be classified as hazardous. See Section B.5 of NFPA 400 for examples on the classification of dilute solutions of common corrosive materials. [**400:**A.4.5]

In many cases the waste material could be a mixture of materials that must be classified in accordance with the requirements of 60.3.3. [**400:**A.4.5]

60.4 Permissible Storage and Use Locations

60.4.1* General.

A.60.4.1 Section 60.4 introduces the concepts of control areas and MAQ. The purpose is to permit limited amounts of hazardous contents in occupancies having minimum controls without triggering the more restrictive Protection Level 1 through Protection Level 4 building requirements. The MAQ in Table 60.4.2.1.1.3, Table 60.4.2.1.2 through Table 60.4.2.1.8, and Table 60.4.2.1.10.1 is based on demonstrated need and historical safe storage and use of hazardous contents. Subsection 60.4.3, however, establishes additional controls for occupancies exceeding the hazardous contents limits prescribed for control areas. [**400:**A.5.1]

All of the hazardous materials within the scope of 1.1.1 of NFPA 400 are high-hazard contents; see 60.3.2.1.1. However, not all of the hazardous materials categories are placed into High-Hazard Levels 1–4 requiring Protection Levels 1–4 are considered to be high-hazard contents, and some of these materials have been recognized as being of low or ordinary hazards, depending on their nature in a fire. In some cases, Class 1 unstable (reactive) materials, Class 1 water-reactive materials, and Class IV and Class V organic peroxides, do not have a MAQ and, therefore, are not required to comply with the requirements for Protection Level 1 through Protection Level 4. Figure A.60.4.1 helps to illustrate the conditions under which the protection level requirements are applicable. [**400:**A.5.1]

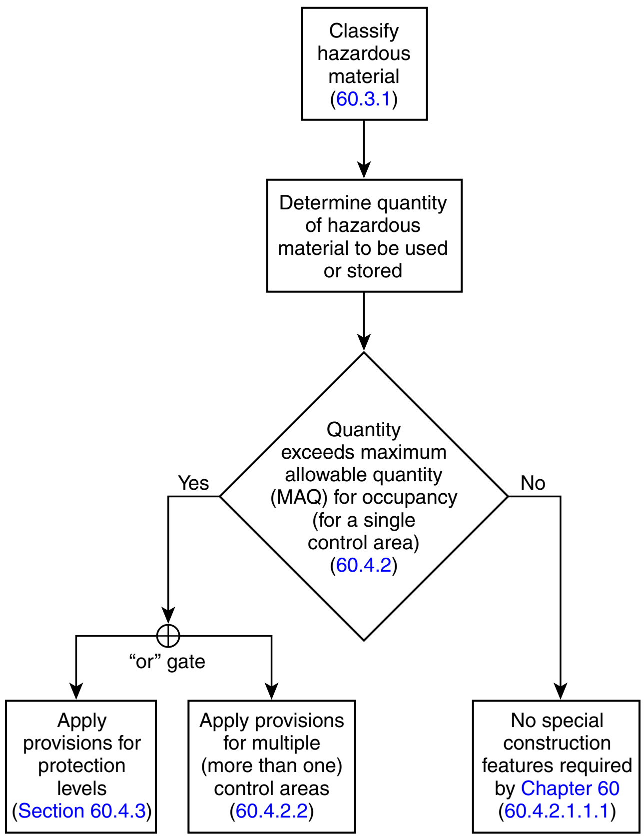

FIGURE A.60.4.1 *Application of Chapter 60 Requirements for Hazardous Materials. [**400:**Figure A.5.1]*

60.4.1.1 Control Areas or Special Protection Required. Hazardous materials shall be stored and used in any of the following:

(1) In control areas complying with 60.4.2
(2) In occupancies complying with requirements for Protection Level 1, Protection Level 2, Protection Level 3, or Protection Level 4 in accordance with 60.4.3
(3) In outdoor areas complying with 60.4.4

[**400:**5.1.1]

60.4.1.2 Weather Protection Structures. Weather protection, when provided, shall comply with 6.2.7.2 of NFPA 400. [**400:**5.1.2]

60.4.1.3 High Hazard Contents. Occupancies in which high hazard contents are stored, used, or handled shall also comply with Chapter 6 of NFPA 400. [**400:**5.1.3]

60.4.2 Control Areas.

60.4.2.1 Hazardous materials shall be permitted to be stored and used in control areas in accordance with 60.4.2.1 and 60.4.2.2. [**400:**5.2.1]

Control area is defined in 3.3.14.2. To paraphrase, it is a building, a part of a building, or an outside area in which one is allowed to store, handle, or use hazardous materials, with the assumption that the quantities involved do not exceed the MAQ specified in this *Code* for each hazardous material present. The concept is that a freestanding building does not require additional protection measures beyond what would normally be required for that occupancy when not more than a given amount of hazardous material (the MAQ) is present. The assumption is that the presence of the MAQ amount does not increase the fire risk. To take this a step further, an area within a building containing the same amount of hazardous material should not require additional protection features if it is isolated from adjacent areas with fire-rated construction.

This approach works well if the separation is durable enough to prevent one incident from impacting adjacent control areas. This approach also works well for additional control areas within the building. At some point, the number of control areas allowed must be limited based on the building's size and associated response time. For example, where material is located on an upper level of a building, direct access might be limited and there will be a delay in response by emergency services.

If hazardous materials are present in amounts greater than the MAQ, the following are true:

1. The quantity is deemed to present a greater hazard than that of a comparable nonhazardous occupancy.
2. Where the material is divided into quantities that are less than the MAQs and moved to separate areas of the building, the risk is the same as for a nonhazardous occupancy due to the fire-rated separation of the hazardous material.

See the also the commentary following A.60.3.4.

60.4.2.1.1 General.

60.4.2.1.1.1 All occupancies shall be permitted to have one or more control areas in accordance with 60.4.2. [**400:**5.2.1.1.1]

60.4.2.1.1.2 The quantity of hazardous materials in an individual control area shall not exceed the maximum allowable quantity (MAQ) for the applicable occupancy set forth in 60.4.2.1.2 through 60.4.2.1.13, except as modified by Table 60.4.2.1.1.3. [**400:**5.2.1.1.2]

Δ **60.4.2.1.1.3** For all occupancies not covered by 60.4.2.1.2 through 60.4.2.1.13, the MAQ of hazardous materials per control area shall be as specified in Table 60.4.2.1.1.3. Ammonium nitrate shall also comply with Chapter 11 of NFPA 400. [**400:**5.2.1.1.3]

Table 60.4.2.1.1.3 presents what can be termed the "general" MAQs. These are maximum quantities of hazardous materials that are considered to be appropriate for industrial, mercantile, or storage occupancies without the need for special protective measures. Table 60.4.2.1.1.3 is used to determine the MAQ for any given material, unless the MAQ for the specific occupancy, as specified in Table 60.4.2.1.2 through Table 60.4.2.1.10.1, is different. In that case, the MAQ in the occupancy-specific table applies. The user should go to the occupancy-specific MAQ table first for information on the relevant occupancy requirements.

It is important to understand a few facts regarding the identified hazardous materials. The following steps should be followed when using Table 60.4.2.1.1.3:

1. The category of the hazardous material should be determined, based on the classification of the material and the definitions within the *Code*. Without this basic information, the limits and protection features cannot be identified. All physical and health hazards associated with the hazardous material must be identified and classified so that each risk can be determined and the protection features or limits can be specified.

2. The use of the hazardous material in a building must be understood so that appropriate limits can be established. These uses are generally categorized as storage, use-closed, and use-open. The storage category is designed for a hazardous material that is intended to enter a building in a container, cylinder, or tank and is not removed from the original container, cylinder, or tank in the storage room or control area. If the hazardous material is shipped to the site, stored, then shipped off-site, only the storage column of the table is used.

3. If the material is used in a process, the process system must be reviewed to determine whether it is classified as use-closed or use-open. Where the process is determined to be closed use, Table 60.4.2.1.1.3 requires that, under normal conditions, the hazardous material not be open to the atmosphere and be kept within a container, a pipe, or equipment that does not allow vapors to escape into the air. These systems include closed piping systems, where a large container of material is transferred through closed piping to smaller containers and sealed for shipping. This condition of use also includes pouring inert material into a vessel, sealing the vessel, and introducing a hazardous material to mix with it, which is then removed under

Δ ***TABLE 60.4.2.1.1.3*** *Maximum Allowable Quantity (MAQ) of Hazardous Materials per Control Area*[a]

N/A: Not applicable. NL: Not limited. NP: Not permitted. UD: Unclassified detonable.

For SI units, 1 lb = 0.454 kg; 1 gal = 3.785 L; 1 scf = 0.0283 Nm^3.

Note: The hazardous material categories and MAQs that are shaded in this table are not regulated by Chapter 60 or NFPA 400 but are provided here for informational purposes. See Chapter 2 for the reference code or standard governing these materials and establishing the MAQs. In accordance with 1.1.1.2 of NFPA 400, materials having multiple hazards that fall within the scope of NFPA 400 shall comply with NFPA 400.

[a]Table values in parentheses correspond to the unit name in parentheses at the top of the column. The aggregate quantity in use and storage is not permitted to exceed the quantity listed for storage.

[b]Measured at NTP or 70°F (21°C) and absolute pressure of 14.7 psi (101.3 kPa).

[c]Quantities are permitted to be increased 100 percent where stored or used in approved cabinets, gas cabinets, exhausted enclosures, gas rooms explosives magazines, or safety cans, as appropriate for the material stored, in accordance with this code. Where footnote d also applies, the increase for both footnote c and footnote d is permitted to be applied accumulatively.

[d]Maximum quantities are permitted to be increased 100 percent in buildings equipped throughout with an automatic sprinkler system in accordance with NFPA 13. Where footnote c also applies, the increase for both footnote c and footnote d is permitted to be applied accumulatively.

[e]The permitted quantities are not limited in a building equipped throughout with an automatic sprinkler system in accordance with NFPA 13.

[f]A maximum quantity of 220 lb (99 kg) of solid or 22 gal (83 L) of liquid Class 3 oxidizer is permitted where such materials are necessary for maintenance purposes, operation, or sanitation of equipment. Storage containers and the manner of storage are required to be approved.

[g]Allowed only where stored or used in gas rooms or approved cabinets, exhausted gas cabinets or exhausted enclosures, as specified in this *Code*. [**5000:** Table 34.1.3.1]

[h]Conversion. Where quantities are indicated in pounds and when the weight per gallon of the liquid is not provided to the AHJ, a conversion factor of 10 lb/gal (1.2 kg/L) shall be used.

[i]Permitted only in buildings equipped throughout with an automatic sprinkler system in accordance with NFPA 13.

[j]None allowed in unsprinklered buildings unless stored or used in gas rooms or in approved gas cabinets or exhausted enclosures, as specified in this *Code*.

[k]With pressure-relief devices for stationary or portable containers vented directly outdoors or to an exhaust hood. [**55:** Table 6.3.1.1]

[l]Flammable gases in the fuel tanks of mobile equipment or vehicles are permitted to exceed the MAQ where the equipment is stored and operated in accordance with this *Code*. [**400:**Table 5.2.1.1.3]

[m]The permitted quantities are not limited in a building equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13 and designed in accordance with the protection criteria contained in Chapter 16 of NFPA 30.

[n]Containing not more than the maximum allowable quantity per control area of Class I-A, Class I-B, or Class I-C flammable liquids, individually.

[o]Medicines, foodstuffs, cosmetics, and other consumer products that contain not more than 50% by volume water-miscible flammable or combustible liquids, with the remainder of the product consisting of components that do not burn, shall not be limited, where packaged in individual containers that do not exceed a 1.3-gallon capacity. [**30:**9.1.4(4)]

[p]Additional storage locations are required to be separated by a minimum of 300 ft (92 m).

[q]In mercantile occupancies, storage of LP-gas is limited to a maximum of 200 lb (91 kg) in nominal 1 lb (0.45 kg) LP-gas containers.

[r]See NFPA 58 for liquefied petroleum gas (LP-gas) requirements. LP-gas is not within the scope of NFPA 400.

a sealed system. This condition of use also applies where mixed finished material is no longer classified as hazardous. Closed use and storage have very similar risks and are treated the same with respect to MAQ.

If a process involves pouring or dispensing into an open vessel, open mixing, transferring, or processing of a hazardous material that is exposed to the atmosphere, the process is classified as open use. This type of activity is considered the most hazardous and, therefore, is most restricted with respect to an MAQ from Table 60.4.2.1.1.3.

4. Apply the appropriate footnotes.

Footnote a contains an important limit and a major component in the proper use of the table. It states that the combination of quantity under use and storage must not exceed the total amount allowed for storage alone. This limit restricts the amount of hazardous material on-site from increasing by simply stating that it is "in use."

Footnote c applies to quantities of most hazardous materials. It allows an increase of 100 percent, or doubling, of the quantity of hazardous materials, where they are stored in an approved cabinet, an exhausted enclosure, an explosive magazine, a safety can, or a gas room. The protection feature used must match the hazard the material presents — for example, putting explosives into a safety cabinet cannot qualify as appropriate protection. As an example, Footnote c allows a flammable solid, which is limited to 125 lb (56.7 kg) in storage, to be increased to 250 lb (115 kg) if it is protected within an approved cabinet. The second sentence of footnote c allows for the increase of some hazardous materials where both footnotes c and d appear with the MAQ value for the particular hazardous material.

Footnote d applies to quantities of hazardous materials that are permitted to increased by 100 percent where the building is completely protected with an automatic sprinkler system. The risk of a problem occurring within the building and spreading to the area where the hazardous material is stored or used is the justification for the increase specified by footnote d. Sprinkler protection that is provided in accordance with footnote d is why materials such as corrosive liquids that are not flammable or combustible are allowed such an increase. Again, footnotes c and d, where indicated, are designed to be added together where both protection measures are present.

EXAMPLE

A warehouse is storing a solid Class III organic peroxide formulation. The material is stored in approved storage cabinets, and the building is fully protected throughout by an automatic sprinkler system designed and installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*. What is the maximum allowable quantity of this commodity that can be stored within the control area without additional protection features?

Based on Table 60.4.2.1.1.3, the base MAQ is 125 lb (56.7 kg). Footnote c would permit a 100 percent increase of the amount, to 250 lb (115 kg), based on the protection afforded by the storage cabinets. Because the building is also protected with an automatic sprinkler system installed in accordance with NFPA 13, footnote d allows an additional 100 percent increase to be applied accumulatively, resulting in a maximum allowable quantity of 500 lb (227 kg) of the Class III organic peroxide per control area.

It should be noted that, if this commodity was found to also have an additional classification, such as being toxic or highly toxic (which would depend on the specific material; see Annex B through Annex H of NFPA 400 for additional information), then the material would also have to conform to the requirements for the applicable additional hazard category.

Footnote e allows a hazardous material to be stored in unlimited quantity if the building is completely protected by an NFPA 13–compliant automatic sprinkler system. At present, Footnote e applies only to one category of hazardous materials addressed by NFPA 400 and NFPA 1: Class 1 oxidizers. NFPA 30 contains a similar provision for Class IIIB liquids: unlimited quantities are allowed if the building is protected throughout with an NFPA 13–compliant sprinkler system that also complies with the provisions of Chapter 16 of NFPA 30.

Footnote f applies specifically to Class 3 oxidizers and limits this class of hazardous material to use for maintenance purposes, operation, or sanitation of equipment.

Footnote i applies to several categories that have been identified as higher risk hazardous materials and are permitted only in buildings protected throughout with an automatic sprinkler system installed in accordance with NFPA 13.

EXAMPLE

Further illustrating the influence of the footnotes to Table 60.4.2.1.1.3 might be helpful to the user.

If a solid material has a classification of oxidizer Class 2, the MAQ is 250 lb (115 kg) for storage per control area. In a one-story building, a designer can designate up to four separate control areas, each with 100 percent of the MAQ, per Table 60.4.2.2.1 This assumes that the control areas are completely separated vertically and horizontally from other control areas with 1-hour fire-resistance-rated fire barriers. This increases the aggregate amount in the building to 1000 lb (454 kg). It must be remembered, however, that footnote a states that the amount of hazardous material in use and storage combined cannot exceed the MAQ for storage.

Footnote c doubles the MAQ per control area if the hazardous material is stored in an approved cabinet, which allows 500 lb (227 kg) per control area, for a total of 2000 lb (907 kg) aggregate in the building (assuming the maximum of four separated control areas as described in the preceding paragraph). The only other footnote that might apply is footnote d, which, again, doubles the MAQ per control area based on the presence of a sprinkler system for the building. With no approved storage cabinet, the sprinkler protection would result, again, in an increase to 500 lb (227 kg) per control area, or 2000 lb (907 kg) for the building. As noted in footnotes c and d, if both are used, the maximum amount is applied cumulatively, which results in 1000 lb (454 kg) per control area, or 4000 lb (1814 kg) for the entire building.

The limits in 60.4.2.1.1.3 as well as in 60.4.2.1.2 through 60.4.2.1.13 must be reviewed to ensure that the special occupancy restrictions are not exceeded.

A review of the MAQs in 60.4.2.1.2 through 60.4.2.1.13 shows that they are, in many cases, less than the corresponding base MAQs in Table 60.4.2.1.1.3 or are designated as NP, i.e., "not permitted." This is deliberate and is based on a determination that the hazards posed by even the base MAQs of certain hazardous materials in certain occupancies is too great without additional protective measures. For example, in health care occupancies, some of the occupants, namely, patients, are not ambulatory and cannot evacuate themselves. For that reason, the user is cautioned that the specific occupancy limits given in Table 60.4.2.1.2 through Table 60.4.2.1.10.1 must be compared against the MAQs specified in Table 60.4.2.1.1.3 to ensure that special occupancy quantity limitations are not exceeded.

Δ **60.4.2.1.2 Assembly Occupancies.** The MAQ of hazardous materials per control area in assembly occupancies shall be as specified in Table 60.4.2.1.2. [**400:**5.2.1.2]

Δ **60.4.2.1.3 Educational Occupancies.** The MAQ of hazardous materials per control area in educational occupancies shall be as specified in Table 60.4.2.1.3. [**400:**5.2.1.3]

Δ **60.4.2.1.4 Day-Care Occupancies.** The MAQ of hazardous materials per control area in day-care occupancies shall be as specified in Table 60.4.2.1.4. [**400:**5.2.1.4]

Δ **60.4.2.1.5 Health Care Occupancies.** The MAQ of hazardous materials per control area in health care occupancies shall be as specified in Table 60.4.2.1.5. [**400:**5.2.1.5]

Δ **60.4.2.1.6 Ambulatory Health Care Occupancies.** The MAQ of hazardous materials per control area in ambulatory health care occupancies shall be as specified in Table 60.4.2.1.6. [**400:**5.2.1.6]

Δ **60.4.2.1.7 Detention and Correctional Occupancies.** The MAQ of hazardous materials per control area in detention and correctional occupancies shall be as specified in Table 60.4.2.1.7. [**400:**5.2.1.7]

Δ **60.4.2.1.8 Residential Occupancies.** The MAQ of hazardous materials per control area in residential occupancies, including lodging and rooming houses, hotels, dormitories, apartments, and residential board and care facilities, shall be as specified in Table 60.4.2.1.8. [**400:**5.2.1.8]

60.4.2.1.9 Mercantile Occupancies. The MAQ of hazardous materials per control area in mercantile occupancies shall be as specified in Table 60.4.2.1.1.3, with increased quantities permitted where storage or display areas comply with 60.4.2.1.13. [**400:**5.2.1.9]

60.4.2.1.10 Business Occupancies.

Δ **60.4.2.1.10.1** The MAQ of hazardous materials per control area in business occupancies, other than laboratories, shall be as specified in Table 60.4.2.1.10.1. [**400:**5.2.1.10.1]

Table 60.4.2.1.2 through Table 60.4.2.1.10.1 provide special quantity limitations for hazardous materials in specific occupancies without the imposition of additional protection features on a new building. In addition, the tables provide guidance for MAQs in existing buildings when new hazardous materials are introduced. The tables also address special conditions, risks, or situations that impact one type of occupancy and not others. For instance, they allow for small amounts of hazardous materials that can be protected by special protection features without putting the total occupancy at risk.

For example, per Table 60.4.2.1.5, the MAQ for Class 2 water-reactive solids in a health care occupancy is 10 lb (4.5 kg) per control area. This is less than the MAQ allowed per Table 60.4.2.1.1.3 [50 lb, (23 kg)]; thus, the more restrictive quantity must be used. Additional explanation is given in the last paragraph of the commentary to 60.4.2.1.1.3.

60.4.2.1.10.2 The MAQ of hazardous materials per control area in laboratories classified as business occupancies shall be as specified in Table 60.4.2.1.1.3. [**400:**5.2.1.10.2]

60.4.2.1.11 Industrial Occupancies. The MAQ of hazardous materials per control area in industrial occupancies shall be as specified in Table 60.4.2.1.1.3, with increased quantities permitted where storage areas comply with 60.4.2.1.13. [**400:**5.2.1.11]

60.4.2.1.12 Storage Occupancies. The MAQ of hazardous materials per control area in storage occupancies shall be as specified in Table 60.4.2.1.1.3, with increased quantities permitted where storage areas comply with 60.4.2.1.13. [**400:**5.2.1.12]

60.4.2.1.13 Special Quantity Limits for Mercantile, Industrial, and Storage Occupancies.

60.4.2.1.13.1 General. Where storage in mercantile, industrial, and storage occupancies is in compliance with all of the special controls set forth in 60.4.2.1.13.2, the MAQ of selected hazardous materials shall be permitted to be increased in accordance with 60.4.2.1.13.3. [**400:**5.2.1.13.1]

Δ **60.4.2.1.13.2 Special Controls Required for Increased Quantities.** Where quantities of hazardous materials are increased in

NTP: Normal temperature and pressure [measured at 70°F (21°C) and 14.7 psi (101 kPa)]. N/A: Not applicable. NP: Not permitted. NL: Not limited.

Note: The hazardous material categories and MAQs that are shaded in this table are not regulated by Chapter 60 or NFPA 400 but are provided here for informational purposes. See Chapter 2 of NFPA 400 for the reference code or standard governing these materials and establishing the MAQs. In accordance with 1.1.1.2 of NFPA 400, materials having multiple hazards that fall within the scope of NFPA 400 shall comply with NFPA 400.

[a]Unlimited amounts of gas are permitted to be used for personal medical or emergency medical use.

[b]Storage in excess of 10 gal (38 L) of Class I and Class II liquids combined or 60 gal (227 L) of Class IIIA liquids is permitted where stored in safety cabinets with an aggregate quantity not to exceed 180 gal (681 L).

[c]Fuel in the tank of operating mobile equipment is permitted to exceed the specified quantity where the equipment is operated in accordance with this *Code*.

[d]The use of explosive materials required by federal, state, or municipal agencies while engaged in normal or emergency performance of duties is not required to be limited. The storage of explosive materials is required to be in accordance with the requirements of NFPA 495.

[e]The storage and use of explosive materials in medicines and medicinal agents in the forms prescribed by the official United States Pharmacopeia or the National Formulary are not required to be limited.

[f]The storage and use of propellant-actuated devices or propellant-actuated industrial tools manufactured, imported, or distributed for their intended purposes are required to be limited to 50 lb (23 kg) net explosive weight.

[g]The storage and use of small arms ammunition, and components thereof, are permitted where in accordance with NFPA 495.

[h]Containers, cylinders, or tanks not exceeding 250 scf (7.1 m^3) content measured at 70°F (21°C) and 14.7 psi (101 kPa) and used for maintenance purposes, patient care, or operation of equipment shall be permitted.

[i]A maximum quantity of 220 lb (99 kg) of solid or 22 gal (83 L) of liquid Class 3 oxidizer is permitted where such materials are necessary for maintenance purposes, operation, or sanitation of equipment. Storage containers and the manner of storage are required to be approved.

[j]Gas cylinders not exceeding 20 scf (0.57 m^3) measured at 70°F (21°C) and 14.7 psi (101 kPa) are permitted in gas cabinets or fume hoods. [**5000:** Table 34.1.3.2(a)]

[k]Conversion. Where quantities are indicated in pounds and when the weight per gallon of the liquid is not provided to the AHJ, a conversion factor of 10 lb/gal (1.2 kg/L) shall be used.

[l]Medicines, foodstuffs, cosmetics, and other consumer products that contain not more than 50% by volume water-miscible flammable or combustible liquids, with the remainder of the product consisting of components that do not burn, shall not be limited, where packaged in individual containers that so not exceed a 1.3-gallon capacity. [**30:**9.1.4(4)]

[**400:** Table 5.2.1.2]

NTP: Normal temperature and pressure [measured at 70°F (21°C) and 14.7 psi (101 kPa)]. N/A: Not applicable. NP: Not permitted. NL: Not limited.

Note: The hazardous material categories and MAQs that are shaded in this table are not regulated by Chapter 60 or NFPA 400 but are provided here for informational purposes. See Chapter 2 of NFPA 400 for the reference code or standard governing these materials and establishing the MAQs. In accordance with 1.1.1.2 of NFPA 400, materials having multiple hazards that fall within the scope of NFPA 400 shall comply with NFPA 400.

[a]Unlimited amounts of gas are permitted to be used for personal medical or emergency medical use.

[b]Storage in excess of 10 gal (38 L) of Class I and Class II liquids combined or 60 gal (227 L) of Class IIIA liquids is permitted where stored in safety cabinets with an aggregate quantity not to exceed 180 gal (681 L).

[c]Fuel in the tank of operating mobile equipment is permitted to exceed the specified quantity where the equipment is operated in accordance with this *Code*.

[d]The use of explosive materials required by federal, state, or municipal agencies while engaged in normal or emergency performance of duties is not required to be limited. The storage of explosive materials is required to be in accordance with the requirements of NFPA 495.

[e]The storage and use of explosive materials in medicines and medicinal agents in the forms prescribed by the official United States Pharmacopeia or the National Formulary are not required to be limited.

[f]The storage and use of propellant-actuated devices or propellant-actuated industrial tools manufactured, imported, or distributed for their intended purposes are required to be limited to 50 lb (23 kg) net explosive weight.

[g]The storage and use of small arms ammunition, and components thereof, are permitted where in accordance with NFPA 495.

[h]Containers, cylinders or tanks not exceeding 250 scf (7.1 m^3) content measured at 70°F (21°C) and 14.7 psi (101 kPa) and used for maintenance purposes, patient care, or operation of equipment shall be permitted.

[i]A maximum quantity of 220 lb (99 kg) or 22 gal (83 L) of liquid Class 3 oxidizer is permitted where such materials are necessary for maintenance purposes, operation, or sanitation of equipment. Storage containers and the manner of storage are required to be approved.

[j]The permitted quantities are not limited in a building protected throughout by automatic sprinkler systems in accordance with NFPA 13.

[k]Storage in laboratories only; additional 20 lb (9 kg) units are permitted where minimum 20 ft (6.1 m) separation is provided.

[l]Gas cylinders not exceeding 20scf (0.57 m^3) measured at 70°F (21°C) and 14.7 psi (101 kPa) are permitted in gas cabinets or fume hoods.

[m]Conversion. Where quantities are indicated in pounds and when the weight per gallon of the liquid is not provided to the AHJ, a conversion factor of 10 lb/gal (1.2 kg/L) shall be used.

[n]Storage shall be permitted to be increased 100% if the building is protected throughout with an automatic sprinkler system installed in accordance with NFPA 13.

[o]Medicines, foodstuffs, cosmetics, and other consumer products that contain not more than 50% by volume water-miscible flammable or combustible liquids, with the remainder of the product consisting of components that do not burn, shall not be limited, where packaged in individual containers that do not exceed 1.3-gallon capacity. NTP: Normal temperature and pressure [measured at 70°F (21°C) and 14.7 psi (101 kPa)]. N/A: Not applicable. NP: Not permitted. NL: Not limited.

Note: The hazardous material categories and MAQs that are shaded in this table are not regulated by NFPA 400 but are provided here for informational purposes. See Chapter 2 of NFPA 400 for the reference code or standard governing these materials and establishing the MAQs. In accordance with 1.1.1.2 of NFPA 400, materials having multiple hazards that fall within the scope of NFPA 400 shall comply with NFPA 400.

[a]Unlimited amounts of gas are permitted to be used for personal medical or emergency medical use.

[b]Storage in excess of 10 gal (38 L) of Class I and Class II liquids combined or 60 gal (227 L) of Class IIIA liquids is permitted where stored in safety cabinets with an aggregate quantity not to exceed 180 gal (681 L).

[c]Fuel in the tank of operating mobile equipment is permitted to exceed the specified quantity where the equipment is operated in accordance with this *Code*.

[d]The use of explosive materials required by federal, state, or municipal agencies while engaged in normal or emergency performance of duties is not required to be limited. The storage of explosive materials is required to be in accordance with the requirements of NFPA 495.

[e]The storage and use of explosive materials in medicines and medicinal agents in the forms prescribed by the official United States Pharmacopeia or the National Formulary are not required to be limited.

[f]The storage and use of propellant-actuated devices or propellant-actuated industrial tools manufactured, imported, or distributed for their intended purposes are required to be limited to 50 lb (23 kg) net explosive weight.

[g]Containers, cylinders, or tanks not exceeding 250 scf (7.1 m^3) content measured at 70°F (21°C) and 14.7 psi (101 kPa and used for maintenance purposes, patient care, or operation of equipment shall be permitted.

[h]The permitted quantities are not limited in a building protected throughout by automatic sprinkler systems in accordance with NFPA 13.

[i]A maximum quantity of 220 lb (99 kg) of solid or 22 gal (83 L) of liquid Class 3 oxidizer is permitted where such materials are necessary for maintenance purposes, operation, or sanitation of equipment. Storage containers and the manner of storage are required to be approved.

[j]Gas cylinders not exceeding 20 scf (0.57 m^3) measured at 70°F (21°C) and 14.7 psi (101 kPa) are permitted in gas cabinets or fume hoods.

[k]Conversion. Where quantities are indicated in pounds and when the weight per gallon of the liquid is not provided to the AHJ, a conversion factor of 10 lb/gal (1.2 kg/L) shall be used.

[l]Storage shall be permitted to be increased 100% if the building is protected throughout with an automatic sprinkler system installed in accordance with NFPA 13.

[m]Medicines, foodstuffs, cosmetics, and other consumer products that contain not more than 50% by volume water-miscible flammable or combustible liquids, with the remainder of the product consisting of components that do not burn, shall not be limited, where packaged in individual containers that do exceed a 1.3-gallon capacity.

[**30:**9.1.4(4)]

[**400:** Table 5.2.1.10.1]

accordance with 60.4.2.1.13.3, such materials shall be stored in accordance with the following limitations:

(1) Storage and display of solids shall not exceed 200 lb/ft^2 (976.4 kg/m^2) of floor area actually occupied by solid merchandise.
(2) Storage and display of liquids shall not exceed 20 gal/ft^2 (76 L/m^2) of floor area actually occupied by liquid merchandise.
(3) Storage and display height shall not exceed 6 ft (1.8 m) above the finished floor.
(4) Individual containers less than 5 gal (19 L) or less than 25 lb (11 kg) shall be stored or displayed on pallets, racks, or shelves.
(5) Racks and shelves used for storage or display shall be in accordance with 60.5.1.13.
(6) Containers shall be listed or approved for the intended use.
(7) Individual containers shall not exceed 100 lb (45.4 kg) capacity for solids or a 10 gal (38 L) capacity for liquids.
(8) Incompatible materials shall be separated in accordance with 60.5.1.12.
(9) Except for surfacing, floors shall be of noncombustible construction.
(10) Aisles 4 ft (1.2 m) in width shall be maintained on three sides of the storage or display area.
(11) Hazard identification signs shall be provided in accordance with 60.5.1.8.

[**400:**5.2.1.13.2]

Δ **60.4.2.1.13.3 Special Maximum Allowable Quantity Increases for Storage in Mercantile, Storage, and Industrial Occupancies.** The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials permitted within a single control area of a mercantile, storage, or industrial occupancy shall be permitted to exceed the MAQ specified in Table 60.4.2.1.1.3, without complying with Protection Level 2, Protection Level 3, or Protection Level 4, provided that the quantities comply with Table 60.4.2.1.13.3(a) and Table 60.4.2.1.13.3(b) and that materials are displayed and stored in accordance with the special limitations in 60.4.2.1.13.2. [**400:**5.2.1.13.3]

Note that, instead of using Table 60.4.2.1.1.3, the user can take advantage of the increased quantity limits in Table 60.4.2.1.13.3(a) and Table 60.4.2.1.13.3(b), at least for certain hazardous materials in certain occupancies, provided the storage requirements of 60.4.2.1.13.2 are met.

If the storage consists of a mixture of hazardous materials, or if the hazardous material has been classified as flammable or combustible, Table 60.4.2.1.13.3(a) and Table 60.4.2.1.13.3(b) cannot be used. Nor can these provisions be used if the hazardous material is in the form of a gas. This does not mean that flammable or combustible liquids or solids or any type of hazardous gas cannot be present, but only that such materials must be protected as required by other sections of this chapter.

Δ ***TABLE 60.4.2.1.13.3(a)** Maximum Allowable Quantity (MAQ) per Indoor and Outdoor Control Area for Selected Hazard Categories in Mercantile, Storage, and Industrial Occupancies*

Hazard Category	Maximum Allowable Quantity[a,b]			
	Solids		Liquids	
	lb	kg	gal	L
Physical Hazard Materials: Nonflammable and Noncombustible Solids and Liquids				
Oxidizers				
Class 3	1,350	616	135	511
Class 2	2,250	1,021	225	852
Class 1	18,000[c]	8,165[c]	1,800[c]	6,814[c]

Note: Maximum quantities for hazard categories not shown are required to be in accordance with Table 60.4.2.1.1.3.

[a]Maximum quantities are permitted to be increased 100 percent in buildings that are sprinklered in accordance with NFPA 13. Where footnote b also applies, the increase for both footnotes is permitted to be applied.

[b]Maximum quantities are permitted to be increased 100 percent where stored in approved storage cabinets in accordance with this *Code*. Where footnote a also applies, the increase for both footnotes is permitted to be applied.

[c]Quantities are not limited in buildings protected by an automatic sprinkler system complying with NFPA 13. [**5000:** Table 34.1.3.3.1(a)] [**400:** Table 5.2.1.13.3(a)]

EXAMPLE

This example of the application of Table 60.4.2.1.13.3(a) should help the user understand the concept. Assume the material is a Class 3 oxidizer in a liquid state (e.g., a calcium hypochlorite solution greater than 50 percent by weight, which is a typical pool chemical), stored in a retail store with one control area. If all the base requirements of 60.4.2.1.13.2 are followed, the retail store can display 135 gal (510 L). Based on footnote a to Table 60.4.2.1.13.3(a), the quantity of this Class 3 oxidizer can be increased by an additional 100 percent if the building is protected with an approved sprinkler system in accordance with NFPA 13. The new amount of stored material permitted would then increase to 270 gal (1022 L).

If footnote b of Table 60.4.2.1.13.3(a) is applied, the quantity of this Class 3 oxidizer can also be increased by 100 percent if the material is stored in an approved storage cabinet. Although materials in a retail setting are unlikely to be displayed in this type of arrangement, this increase would result in an additional allowance of 270 gal (1022 L). Thus, if both footnotes a and b to Table 60.4.2.1.13.3(a) are used, the total amount of Class 3 oxidizer permitted would be 540 gal (2044 L).

TABLE 60.4.2.1.13.3(b) *Maximum Allowable Quantity (MAQ) per Indoor and Outdoor Control Area for Selected Hazard Categories in Mercantile and Storage Occupancies*

Hazard Category	Maximum Allowable Quantity[a,b,c]			
	Solids		Liquids	
	lb	kg	gal	L
Physical Hazard Materials: Nonflammable and Noncombustible Solids and Liquids				
Unstable (reactive)				
Class 3	550	250	55	208
Class 2	1,150	522	115	435
Water-reactive				
Class 3	550	250	55	208
Class 2	1,150	522	115	435
Health Hazard Materials: Nonflammable and Noncombustible Solids and Liquids				
Corrosive	10,000	4,536	1,000	3,785
Highly toxic[d]	20	9	2	8
Toxic[d]	1,000	454	100	378

[a]Maximum quantities for hazard categories not shown are required to be in accordance with Table 60.4.2.1.1.3.

[b]Maximum quantities are permitted to be increased 100 percent in buildings that are sprinklered in accordance with NFPA 13. Where footnote b also applies, the increase for both footnotes can be applied.

[c]Maximum quantities are permitted to be increased 100 percent where stored in approved storage cabinets in accordance with this *Code*. Where footnote a also applies, the increase for both footnotes is permitted to be applied. [**5000:** Table 34.1.3.3.1(b)]

[d]Toxic or highly toxic solids or liquids displayed in original packaging in mercantile or storage occupancies and intended for maintenance, operation of equipment, or sanitation when contained in individual packaging not exceeding 100 lb (45.4 kg) shall be limited to an aggregate of 1200 lb (544.3 kg) or 120 gal (454.2 L). The increases allowed by footnotes a, b, and c shall not apply to highly toxic solids and liquids. [**400:** Table 5.2.1.13.3(b)]

This approach might seem complicated, but, using the special controls for increased quantities of hazardous materials in mercantile occupancies outlined in 60.4.2.1.13.2 for the hazard categories shown in Table 60.4.2.1.13.3(a), the potential risk from increased quantities of Class 3 oxidizer materials is limited.

Many of the retail display arrangements for consumer products have been tested to limit spills or leaks, and the protection features are appropriate for the risk they pose. One of the main reasons this increase is allowed is that the retail industry, with the exception of incidents in bulk retail facilities, has experienced few incidents involving these products in retail settings.

TABLE 60.4.2.2.1 *Design and Number of Control Areas*

Floor Level	Maximum Allowable Quantity per Control Area (%)*	Number of Control Areas per Floor	Fire Resistance Rating for Fire Barriers† (hr)
Above grade			
>9	5.0	1	2
7–9	5.0	2	2
4–6	12.5	2	2
3	50.0	2	1
2	75.0	3	1
1	100.0	4	1
Below grade			
1	75.	3	1
2	50.	2	1
Lower than 2	NP	NP	N/A

NP: Not permitted. N/A: Not applicable.

*Percentages represent the MAQ per control area shown in Table 60.4.2.1.1.3, with all the increases permitted in the footnotes of that table.

†Fire barriers are required to include floors and walls, as necessary, to provide a complete separation from other control areas. [**400:** Table 5.2.2.1]

Historically, spills and leaks have not been a problem, due to the requirement to keep the sales area neat and orderly.

60.4.2.2 Construction Requirements for Control Areas.

60.4.2.2.1 Number of Control Areas. The maximum number of control areas within a building shall be in accordance with Table 60.4.2.2.1. [**400:**5.2.2.1]

Control area is defined in 3.3.14.2 as, essentially, a building, a part of a building, or an outside area in which one is allowed to store, handle, or use hazardous materials, with the assumption that the quantities involved do not exceed a certain specified amount for each hazardous material present. Table 60.4.2.2.1 requires a minimum 1-hour fire barrier around a control area to ensure that an incident in one area does not impact an adjacent area. The table also identifies where the separation needs to be increased to a 2-hour fire barrier, based on the elevation of the control area above grade. This increase in required fire barrier ratings has a direct relationship to the time it would take first responders to set up their equipment and effectively handle the incident. The higher a control area is located within a building, the greater the amount of resources required to handle an incident and the greater the time needed to assemble those resources.

Another feature of Table 60.4.2.2.1 is that, as a control area moves farther above (or below) grade, the MAQ is "derated," that is, the MAQ for any given hazardous material is multiplied by a specified fraction, so only a certain percentage of the base MAQ is allowed. This limit is codified in the asterisk footnote to Table 60.4.2.2.1. The justification for this penalty is the same as for the increase from a 1-hour barrier to a 2-hour barrier: the farther, vertically, from grade, the greater the time required for emergency responders to reach the incident and the greater the difficulty in controlling and resolving it.

The dagger footnote to Table 60.4.2.2.1 clarifies that the fire barrier must completely separate the control area from adjacent spaces. Therefore, rating required for each level applies to walls, floors, and floor/ceiling assemblies, so that an envelope of protection surrounds the control area. If Table 60.4.2.2.1 requires the fire barrier rating to be 1 hour, then that rating also applies to the floor and all walls. If a 2-hour rating is required, as is found on floor level 4 and above, all floor/ceiling assemblies and walls must be 2-hour rated.

Table 60.4.2.2.1 represents a minimum set of construction ratings and cannot be used to reduce construction requirements found in local building codes. For example, if a control area is located on floor level 3 and the local building code requires a 2-hour-rated fire barrier, then Table 60.4.2.2.1 cannot be used to reduce the fire barrier rating to 1 hour; it cannot be used to override any stricter requirements that might apply. As noted under the "below grade" section of the table's "floor level" column, hazardous materials above the MAQ are not allowed to be located on levels more than two levels below grade. The risk to first responders is too great, and the protection features cannot offset the response time needed for an area so far below grade.

The approach for determining the number of control areas and the fire-resistive rating of separation requirements can be demonstrated using the example that follows.

Example

On floor level 1, the user is allowed to have 100 percent of the MAQ in each control area, and up to four control areas are allowed on that floor level. This requirement is the same as in previous editions of the *Code*, in which four was the maximum number of control areas. If flammable solids are stored in the building, this approach allows an MAQ of 125 lb (57 kg) per control area or 500 lb (227 kg) on the first floor level in four control areas, each separated by a 1-hour fire barrier.

The approach of this *Code* is to use the floor level to reduce risk and to increase protection. Protection increases in the following three ways as the building increases in height:

1. The quantity of hazardous material is reduced, because of the percentage factor.
2. The number of control areas per floor is reduced.
3. The fire separation of the control areas is increased.

In this example, on floor level 1 of the building, the user could have 500 lb (227 kg) of flammable solids, but if the same user wanted to have all the flammable solids one level higher or one level lower in the building, the allowable quantity would be reduced. On floor level 2, the amount of material would be reduced to 75 percent of the MAQ, or 94 lb (43 kg), and the number of allowed control areas would be reduced to three. This translates to a reduction in the aggregate amount of material from 500 lb to 282 lb (227 kg to 128 kg).

If the user wanted to use the flammable solids even higher in the building, the allowable quantity would be further limited. For example, applying Table 60.4.2.2.1 to calculate quantities for the same user on floor level 9, the separation of the control areas would increase from a 1-hour to a 2-hour fire barrier, the percentage in the control area would reduce to 5 percent, and only two control areas would be allowed on that floor level. This placement would decrease the allowable amount of flammable solids from 500 lb (227 kg) on floor level 1 to 12.5 lb (5.7 kg) on floor level 9, provided that both control areas contained no more than the maximum amount, or 6.25 lb (2.8 kg), in each control area.

60.4.2.2.2 Where only one control area is present in a building, no special construction provisions shall be required. [**400:**5.2.2.2]

60.4.2.2.3 Where more than one control area is present in a building, control areas shall be separated from each other by fire barriers in accordance with Table 60.4.2.2.1. [**400:**5.2.2.3]

60.4.3 Protection Levels.

Subsection 60.4.3 implements extra protection strategies for quantities of hazardous materials that exceed the MAQ for identified occupancies within Chapter 60. If an amount of hazardous material exceeds the MAQ for storage, the user must follow the applicable sections of Chapter 60, in addition to 60.4.3, and the applicable sections of NFPA 400 for use and handling. If the MAQ is exceeded, additional protection is needed. Specific protection, construction, and property setback requirements are imposed for the higher quantities of hazardous materials that are regulated within this chapter.

Subsection 60.4.3 contains protection requirements that are more restrictive than normal occupancy classification use due to the increased amounts of hazardous materials. If the amount of hazardous material needed for the site cannot be isolated by subdividing the building into separate control areas that contain less hazardous material than allowed by Table 60.4.2.1.1.3, the user must increase the protection features of the building. Table 60.4.2.1.1.3 already includes important provisions that recognize sprinkler protection or approved storage cabinets or special design features; these provisions allow increases in the hazardous materials quantities for the specific occupancy classification beyond the base MAQ. Paragraphs 60.4.3.1 through 60.4.3.7 outline the additional protection features that must be in place to allow even greater quantities of hazardous materials to be stored. If the protection features cannot be provided or are determined not to be an option for the site, then these greater quantities are not allowed, and the MAQs from Table 60.4.2.1.1.3 prevail.

60.4.3.1 Where the quantity of hazardous materials in storage or use exceeds the MAQ for indoor control areas as set forth in 60.4.2, the occupancy shall comply with the requirements for Protection Level 1, Protection Level 2, Protection Level 3, or Protection Level 4, as required for the material in storage or use as defined in 6.2.2 through 6.2.5 of NFPA 400. [**400:**5.3.1]

60.4.3.2 Protection Level 5 shall apply to semiconductor fabrication facilities where required by the building code. [**400:**5.3.2]

60.4.3.3 Protection Level 1.

60.4.3.3.1 Buildings containing quantities of hazardous materials exceeding the MAQ of high hazard Level 1 contents permitted in control areas shall comply with applicable regulations for Protection Level 1, as set forth in the applicable sections of Chapter 6 and Chapters 11 through 21 of NFPA 400, and the building code. [**400:**5.3.3.1]

60.4.3.3.2 High hazard Level 1 contents shall include materials that present a detonation hazard as defined in 60.3.2.1.2.1. [**400:**5.3.3.2]

Protection Level 1 is the highest level of protection and provides the greatest level of protection from the risk provided for by the *Code*. The only way to provide a greater level of protection is to prohibit additional hazardous materials at the site or to move the hazardous materials to a detached building.

High hazard Level 1 contents are unstable materials and can pose a detonation hazard. Many of the facilities using this class of hazardous material would benefit from the option to store it in a detached building or a bunker.

60.4.3.4 Protection Level 2.

60.4.3.4.1 Buildings, and portions thereof, containing quantities of hazardous materials exceeding the MAQ of high-hazard level 2 contents permitted in control areas shall comply with applicable regulations for Protection Level 2, as set forth in the applicable sections of Chapter 6 and Chapters 11 through 21 of NFPA 400, and the building code. [**400:**5.3.4.1]

Protection Level 2 is designed to limit the spread of fire from materials that deflagrate or accelerate burning. Additionally, the protection features are designed to limit the potential for fire to spread from an outside source and affect the hazardous materials in the building.

60.4.3.4.2 High-hazard level 2 contents shall include materials that present a deflagration hazard or a hazard from accelerated burning as defined in 60.3.2.1.2.2. [**400:**5.3.4.2]

60.4.3.5 Protection Level 3.

60.4.3.5.1 Buildings, and portions thereof, containing quantities of hazardous materials exceeding the MAQ of high-hazard level 3 contents permitted in control areas shall comply with applicable regulations for Protection Level 3, as set forth in the applicable sections of Chapter 6 and Chapters 11 through 21 of NFPA 400, and the building code. [**400:**5.3.5.1]

60.4.3.5.2 High-hazard level 3 contents shall include materials that readily support combustion or present a physical hazard as defined in 60.3.2.1.2.3. [**400:**5.3.5.2]

Protection Level 3 is one of the most common protection levels encountered in the general inspection of storage and industrial operations that use hazardous materials. These types of operations and storage facilities normally operate with amounts of hazardous materials greater than the MAQ while conducting business. The protection features should be understood in detail, and the amounts of hazardous materials should be reviewed due to their frequent presence within most jurisdictions. Features for Protection Level 1 through Protection Level 3 are intended primarily to provide protection from physical hazards.

60.4.3.6 Protection Level 4.

60.4.3.6.1 Buildings, and portions thereof, containing quantities of hazardous materials exceeding the MAQ of high-hazard level 4 contents permitted in control areas shall comply with applicable regulations for Protection Level 4, as set forth in the applicable sections of Chapter 6 and Chapters 11 through 21 of NFPA 400, and the building code. [**400:**5.3.6.1]

60.4.3.6.2 High-hazard level 4 contents shall include materials that are acute health hazards as defined in 60.3.2.1.2.4. [**400:**5.3.6.2]

Protection Level 4 is intended to mitigate the acute health hazards resulting from the storage, use, or handling of high hazard Level 4 materials in excess of the predetermined MAQ; these high hazard contents include corrosives, highly toxic materials, and toxic materials. The objective is to protect evacuating occupants and arriving first responders from being injured by these hazardous materials. The MAQ amount is designed to limit the amount to a manageable level without requiring protection features. When the MAQ amount is exceeded, additional protection features must be provided.

Δ **60.4.3.7 Detached Building Required for High-Hazard Level 2 and High Hazard Level 3 Materials.** Buildings required to comply with Protection Level 2 or 3 and containing quantities of high hazard contents exceeding the quantity limits set forth in Table 60.4.3.7 shall be in accordance with 6.2.3.4 or 6.2.4.4 of NFPA 400, as applicable. [**400:**5.3.7]

60.4.4 Outdoor Areas.

An area that is often overlooked is that of protecting hazardous materials stored outdoors. Subsection 60.4.4 addresses the need to limit the amount of material that would be exposed if an incident occurred. Separation between outdoor control areas provides an opportunity for emergency responders to deal with an incident involving a quantity of hazardous material that has been limited to a manageable quantity. It also provides time for the emergency responders to prevent the incident from spreading to adjacent materials, to adjacent buildings, or across property lines to exposed property. See NFPA 400 for additional details.

60.4.4.1 Outdoor Control Areas.

60.4.4.1.1 General.

60.4.4.1.1.1 Hazardous materials shall be permitted to be stored or used in outdoor control areas in accordance with 60.4.4.1.2 and 60.4.4.1.3. [**400:**5.4.1.1.1]

Δ *TABLE 60.4.3.7 Detached Buildings Required Where Quantity of Material Exceeds Amount Shown*

Gas Hazard	Class	Quantity of Material scf	Quantity of Material Nm³*
Individual bulk hydrogen compressed gas systems	N/A	N/A	15,000 (425)
Oxidizers	3	1,200	N/A
	2	2,000	N/A
Organic peroxides	II	25	N/A
	III	50	N/A
Unstable (reactive) materials	3, nondetonable	1	2,000 (57)
	2	25	10,000 (283)
Water-reactive materials	3	1	N/A
	2, deflagrating	25	N/A
Pyrophoric gases		N/A	2,000 (57)

For SI units, 1 ton = 0.9 met ton.
N/A: Not applicable.
*See Table 21.2.5 of NFPA 400. [**400:** Table 5.3.7]

60.4.4.1.1.2 Where storage or use is in an outdoor control area, compliance with the outdoor storage and use requirements in Chapters 11 through 21 of NFPA 400 shall not be required. [**400:**5.4.1.1.2]

Chapters 11 through 21 of NFPA 400 address specific classes of hazardous materials.

60.4.4.1.2 Maximum Allowable Quantity per Outdoor Control Area. Maximum allowable quantities of hazardous materials in an outdoor control area shall be as specified in Table 60.4.2.1.13.3(a) and Table 60.4.2.1.13.3(b) or Table 60.4.4.1.2. [**400:**5.4.1.2]

Table 60.4.4.1.2 presents a list of hazardous materials that are regulated when stored or used outdoors. The amount is not allowed to be increased, because if a release were to occur, it would not be contained within a building and, therefore, might adversely expose occupants trying to egress from an adjacent building.

Outdoor control areas do create exposure problems, but the concept is that 75 percent to 100 percent of the perimeter of the use or storage control area will be open. In addition, no overhead obstruction would be present, except for, perhaps, an approved weather shelter or canopy. Due to this openness of design, outdoor control areas allow for direct access by first responders on multiple sides, with an opportunity for evacuees to exit an adjacent building in other directions. Outdoor control areas also allow gases, vapors, and products of combustion to dissipate, minimizing any adverse exposure to people in the surrounding area. However, this is also a drawback, since these same gases, vapors, and products of combustion might be at harmful levels in the immediate area of the incident.

As residential and commercial development encroaches on industrial sites where hazardous materials are stored and used, and populated areas develop near storage and use areas, approved plans for notification and response will have to be developed and maintained.

60.4.4.1.3 Number of Outdoor Control Areas.

60.4.4.1.3.1 A single outdoor control area shall be permitted on any property. [**400:**5.4.1.3.1]

60.4.4.1.3.2 Where a property exceeds 10,000 ft² (929 m²), a group of two outdoor control areas shall be permitted where approved and where each control area is separated by a minimum distance of 50 ft (15 m). [**400:**5.4.1.3.2]

Paragraph 60.4.4.1.3.2 permits two separate outdoor control areas as an exception to the single control area allowed by 60.4.4.1.3.1. All of the following conditions must be met prior to having two outdoor control areas:

1. The property must be larger than 10,000 ft² (929 m²).
2. The arrangement of hazardous materials and buildings must allow for a 50 ft (15 m) separation between control areas.
3. The "where approved" condition must allow the AHJ the ability to limit the site to one control area if concerns such as limited access, water supply, zoning restriction, or setbacks to adjacent properties are present.

60.4.4.1.3.3 Where a property exceeds 35,000 ft² (3252 m²), additional groups of outdoor control areas shall be permitted where approved, provided that each group is separated by a minimum distance of 300 ft (91 m). [**400:**5.4.1.3.3]

60.4.4.2 Outdoor Storage and Use Areas. Where the quantity of hazardous materials in outdoor storage or use exceeds the MAQ for outdoor control areas as set forth in Table 60.4.4.1.2, the outdoor area shall comply with the applicable outdoor requirements of Chapter 6 and Chapters 11 through 21 of NFPA 400. [**400:**5.4.2]

60.5 Fundamental Requirements

60.5.1 General Requirements.

60.5.1.1 Applicability. Storage, use, and handling of hazardous materials in any quantity shall comply with 60.5.1. [**400:**6.1.1]

Δ **60.5.1.1.1*** Storage of hazardous materials in quantities exceeding the maximum allowable quantity set forth in Section 60.4 and the applicable material specific requirements in Chapters 11 through 21 of NFPA 400. [**400:**6.1.1.1]

A.60.5.1.1.1 Outdoor control areas are not classified with protection levels. [**400:**A.6.1.1.1]

For SI units, 1 lb = 0.454 kg; 1 gal = 3.785 L; 1 scf = 0.0283Nm3.
N/A: Not applicable. NL: Not limited.
Notes:
(1) Table values in parentheses correspond to the unit name in parentheses at the top of the column.
(2) For gallons of liquids, divide the amount in pounds by 10.
(3) The aggregate quantities in storage and use cannot exceed the quantity listed for storage.
(4) The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials allowed in outdoor storage per single property under the same ownership or control used for retail or wholesale sales is permitted to exceed the MAQ where such storage is in accordance with 60.4.2.1.13.3.
*Permitted only where stored or used in approved exhausted gas cabinets, exhausted enclosures, or fume hoods. [**400:** Table 5.4.1.2]

Δ **60.5.1.1.2*** The use, dispensing, and handling of hazardous materials in quantities exceeding the maximum allowable quantity (MAQ) set forth in Section 60.4 shall comply with Section 6.3 of NFPA 400 and the applicable material specific requirements in Chapters 11 through 21 of NFPA 400. [**400:**6.1.1.2]

A.60.5.1.1.2 Outdoor control areas are not classified with protection levels. [**400:**A.6.1.1.2]

60.5.1.2* Safety Data Sheets (SDS). Safety data sheets (SDS) shall be available on the premises for hazardous materials regulated by this code. When approved, SDSs shall be permitted to be retrievable by electronic access. [**400:**6.1.2]

A.60.5.1.2 *Readily available* can mean access to the product manufacturer's or user's paper or electronic copies of SDSs. [**400:**A.6.1.2]

60.5.1.3 Release of Hazardous Materials.

Paragraphs 60.5.1.3.1 through 60.5.1.3.7.2 outline the need to review and prepare for unauthorized or accidental discharges and to provide clear direction identifying that the responsible person, firm, or corporation is financially capable of meeting the cost of the mitigation and cleanup. This process begins with a knowledge of regulations that prohibit releases without permission. The process further requires the user to record the release and to notify all governmental agencies, including the fire department, as required by the regulations. Preparing for an unauthorized or accidental release includes modification to the design of equipment and materials-handling systems and developing procedures for the control and containment of the release.

Δ **60.5.1.3.1 Prohibited Releases.** Hazardous materials shall not be released into a sewer, storm drain, ditch, drainage canal, lake, river, or tidal waterway; upon the ground, a sidewalk, a street, or a highway; or into the atmosphere, unless such release is permitted by the following:

(1) Federal, state, or local governing regulations
(2) Permits of the jurisdictional air quality management board
(3) National Pollutant Discharge Elimination System permit
(4) Waste discharge requirements established by the jurisdictional water quality control board
(5) Sewer pretreatment requirements for publicly or privately owned treatment works

[**400:**6.1.3.1]

60.5.1.3.2 Control and Mitigation of Unauthorized Releases. Provisions shall be made for controlling and mitigating unauthorized releases. [**400:**6.1.3.2]

Provisions might include secondary containment for storage tanks and piping systems; secondary containment in buildings where hazardous materials are used or processed; excess flow valves; appropriately located control valves in piping systems; or alarm systems to warn of a release.

60.5.1.3.3 Records of Unauthorized Releases. Accurate records of the unauthorized release of hazardous materials shall be kept by the permittee. [**400:**6.1.3.3]

60.5.1.3.4* Notification of Unauthorized Releases. The fire department shall be notified immediately or in accordance with approved emergency procedures when an unauthorized release becomes reportable under state, federal, or local regulations. [**400:**6.1.3.4]

A.60.5.1.3.4 There might be additional regulations that must be complied with to notify other agencies. [**400:**A.6.1.3.4]

60.5.1.3.5 Container Failure. When an unauthorized release due to primary container failure is discovered, the involved primary container shall be repaired or removed from service. [**400:**6.1.3.5]

60.5.1.3.6 Overpack Containers. Overpack containers shall be permitted to be used as a means to provide protection for primary containers to be transported for repair or removal from service. [**400:**6.1.3.6]

60.5.1.3.7 Responsibility for Cleanup of Unauthorized Releases.

60.5.1.3.7.1 The person, firm, or corporation responsible for an unauthorized release shall institute and complete all actions necessary to remedy the effects of such unauthorized release, whether sudden or gradual, at no cost to the AHJ. [**400:**6.1.3.7.1]

60.5.1.3.7.2 When deemed necessary by the AHJ, cleanup of an unauthorized release shall be permitted to be initiated by the fire department or by an authorized individual or firm, and costs associated with such cleanup shall be borne by the owner, operator, or other person responsible for the unauthorized release. [**400:**6.1.3.7.2]

60.5.1.4* Personnel Training. Persons in areas where hazardous materials are stored, dispensed, handled, or used shall be trained in the hazards of the materials employed and actions required by the emergency plan. The level of training to be conducted shall be consistent with the responsibilities of the persons to be trained in accordance with 60.5.1.4.1 through 60.5.1.4.5. [**400:**6.1.4]

A.60.5.1.4 The hazard potential of a facility is not dependent on any single factor. Physical size, number of employees, and the quantity and the nature of the hazardous materials are important considerations. The level of training can vary with the complexity of the facility under consideration. [**400:**A.6.1.4]

Paragraph 60.5.1.4 is straightforward, but it addresses an important concept: the basic need and essential requirement to have trained and knowledgeable staff operating in areas where hazardous materials are present. One of the greatest and most cost-effective initial protections against a fire, leak, or spill is a qualified staff. A trained staff provides the needed monitoring and experience to avert or stop an incident before it becomes a major problem. If an incident does occur, the same staff members are an important resource used by the first responders, as outlined in 60.5.1.4.3.

60.5.1.4.1 Awareness. The training provided for persons designated in 60.5.1.4 shall include awareness training in accordance with 60.5.1.4.1.1 through 60.5.1.4.1.3. [**400:**6.1.4.1]

60.5.1.4.1.1 Completion. Initial training shall be completed prior to beginning work in the work area. [**400:**6.1.4.1.1]

60.5.1.4.1.2 Hazard Communications. Training shall be provided prior to beginning work in the work area to enable personnel to recognize and identify hazardous materials stored, dispensed, handled, or used on site and where to find safety information pertaining to the hazards of the materials employed. [**400:**6.1.4.1.2]

60.5.1.4.1.3 Emergency Plan. Training shall be provided prior to beginning work in the work area to enable personnel to implement the emergency plan. [**400:**6.1.4.1.3]

60.5.1.4.2 Operations Personnel. Persons engaged in storing, using, or handling hazardous materials shall be designated as operations personnel and shall be trained in accordance with 60.5.1.4.1 and 60.5.1.4.2.1 through 60.5.1.4.2.6. [**400:**6.1.4.2]

60.5.1.4.2.1 Physical and Health Hazard Properties. Operations personnel shall be trained in the chemical nature of the materials, including their physical hazards and the symptoms of acute or chronic exposure as provided by the safety data sheet (SDS) furnished by the manufacturer or other authoritative sources. [**400:**6.1.4.2.1]

60.5.1.4.2.2 Dispensing, Using, and Processing. Operations personnel shall be trained in the use of specific safeguards applicable to the dispensing, processing, or use of the materials and equipment employed. [**400:**6.1.4.2.2]

60.5.1.4.2.3 Storage. Operations personnel shall be trained in the application of storage arrangements and site-specific limitations on storage for the materials employed. [**400:**6.1.4.2.3]

60.5.1.4.2.4 Transport (Handling). Operations personnel involved in materials handling shall be trained in the requirements for on-site transport of the materials employed. [**400:**6.1.4.2.4]

60.5.1.4.2.5 Actions in an Emergency. Operations personnel shall be trained in the necessary actions to take in the event of an emergency, including the operation and activation of emergency controls prior to evacuation. [**400:**6.1.4.2.5]

Δ **60.5.1.4.2.6 Changes.** Training shall be provided whenever a new hazardous material is introduced into the work area that presents a new physical or health hazard, or when new information is obtained pertaining to physical or health hazards of an existing hazardous material that has not been included in previous training, and when there are changes in any of the following:

(1) Equipment
(2) Operations
(3) Hazardous materials

[**400:**6.1.4.2.6]

This is another element of "management of change," as discussed in the commentary to 60.1.6.2(3).

60.5.1.4.3 Emergency Response Liaison.

60.5.1.4.3.1 Responsible persons shall be designated and trained to be emergency response (ER) liaison personnel. [**400:**6.1.4.3.1]

Δ **60.5.1.4.3.2** Emergency response liaison personnel shall do the following:

(1) Aid emergency responders in pre-planning responses to emergencies
(2) Identify locations where hazardous materials are located
(3) Have access to material safety data sheets
(4) Be knowledgeable in the site emergency response procedures

[**400:**6.1.4.3.2]

60.5.1.4.4* Emergency Responders. Emergency responders shall be trained to be competent in the actions to be taken in an emergency event. [**400:**6.1.4.4]

A.60.5.1.4.4 Emergency responders can include on-site personnel that have been designated and trained to respond to emergencies, persons from the public sector such as fire department personnel, or persons from the private sector that can be contracted or otherwise engaged to perform emergency response duties. *(See Annex I of NFPA 400.)* [**400:**A.6.1.4.4]

60.5.1.4.4.1* Emergency Response Team Leader. Persons acting as ER team leaders shall be trained under the Incident Command System concept or equivalent. [**400:**6.1.4.4.1]

A.60.5.1.4.4.1 OSHA describes an Incident Command System as a standardized on-scene incident management concept designed specifically to allow responders to adopt an integrated organizational structure equal to the complexity and demands of any single incident or multiple incidents without being hindered by jurisdictional boundaries. [**400:**A.6.1.4.4.1]

60.5.1.4.4.2* Response to Incipient Events. Responses to incidental releases of hazardous materials where the material can be absorbed, neutralized, or otherwise controlled at the time of release by employees in the immediate release area, or by maintenance personnel, shall not be considered emergency responses as defined within the scope of this *Code*. [**400:**6.1.4.4.2]

A.60.5.1.4.4.2 Responses to releases of hazardous materials where there is no potential safety or health hazard such as fire, explosion, or chemical exposure are not considered emergency responses as defined within the context of this *Code*. [**400:**A.6.1.4.4.2]

60.5.1.4.4.3* On-Site Emergency Response Team. When an onsite emergency response team is provided, emergency responders shall be trained in accordance with the requirements of the specific site emergency plan or as required by federal, state, or local governmental agencies. [**400:**6.1.4.4.3]

A.60.5.1.4.4.3 Emergency response training will vary depending on the level of emergency response required and by the requirements of the governmental agency. [**400:**A.6.1.4.4.3]

60.5.1.4.5 Training Mandated by Other Agencies. Training required by federal, state, or local regulations that is required based on the quantity or type of hazardous materials stored, dispensed, handled, or used shall be conducted in accordance with the requirements of and under the jurisdiction of the governing agency. [**400:**6.1.4.5]

60.5.1.4.6 Documentation. Training shall be documented and the documentation made available to the AHJ upon written request. [**400:**6.1.4.6]

60.5.1.5 Ignition Source Controls.

Δ **60.5.1.5.1 Smoking.** Smoking shall be prohibited in the following locations:

(1) Within 25 ft (7.6 m) of outdoor storage areas, dispensing areas, or open use areas
(2) In rooms or areas where hazardous materials are stored or dispensed or used in open systems in amounts requiring a permit in accordance with Section 1.8 of NFPA 400

[**400:**6.1.5.1]

Paragraph 60.5.1.5.1 contains a set of minimum requirements that prohibit smoking in areas where hazardous materials are present. If operating conditions are more hazardous due to the hazardous material being used or stored, additional distances could be required to increase the "no smoking" areas. See Section 10.9 for additional guidance on regulating smoking.

60.5.1.5.2 Open Flames and High-Temperature Devices. Open flames and high-temperature devices shall not be used in a manner that creates a hazardous condition. [**400:**6.1.5.2]

60.5.1.5.3 Energy-Consuming Equipment. Energy-consuming equipment with the potential to serve as a source of ignition shall be listed or approved for use with the hazardous materials stored or used. [**400:**6.1.5.3]

Δ **60.5.1.5.3.1* Powered Industrial Trucks.** Powered industrial trucks shall be operated and maintained in accordance with NFPA 505. [**400:**6.1.5.3.1]

Δ **A.60.5.1.5.3.1** The approved powered industrial trucks addressed in NFPA 505 are trucks that are listed by a testing laboratory for the use intended and should be tested and labeled in accordance with ANSI/UL 558, *Standard for Safety Industrial Trucks, Internal Combustion Engine-Powered*, or ANSI/UL 583, *Standard for Safety Electric Battery-Powered Industrial Trucks*. [**505:**1.3.3]

60.5.1.6 Systems, Equipment, and Processes. Processes, methods, specifications, equipment testing and maintenance, design standards, performance, installation, equipment design and construction, and other pertinent criteria shall be in accordance with this section. [**400:**6.1.6]

60.5.1.6.1 Design and Construction of Containers and Tanks. Containers, cylinders, and tanks shall be designed and constructed in accordance with approved standards. Containers, cylinders, tanks, and other means used for containment of hazardous materials shall be of an approved type. [**400:**6.1.6.1]

Δ **60.5.1.6.2 Piping, Tubing, Valves, and Fittings.** Piping, tubing, valves, fittings, and related components used for hazardous materials shall be in accordance with the following:

(1) Piping, tubing, valves, fittings, and related components shall be designed and fabricated from materials compatible with the material to be contained and shall be of a strength and durability to withstand the pressure, structural and seismic stress, and exposure to which they are subject.
(2) Piping and tubing shall be identified in accordance with ASME A13.1, *Scheme for the Identification of Piping Systems,* to indicate the material conveyed.
(3) Accessible manual valves, or fail-safe emergency shutoff valves operated by a remotely located manually or automatically activated shutdown control, shall be installed on supply piping and tubing at the following locations:
    (a) Point of use
    (b) Tank or bulk source
(4) Manual emergency shutoff valves and remotely located manually activated shutdown controls for emergency shutoff valves shall be identified, and the location shall be clearly visible, accessible, and indicated by means of a sign.
(5) Backflow prevention or check valves shall be provided when the backflow of hazardous materials could create a hazardous condition or cause the unauthorized discharge of hazardous materials.
(6) Liquids classified in accordance with NFPA 704 shall be carried in pressurized piping above a gauge pressure of 15 psi (103 kPa) having a hazard ranking as follows:
    (a) Health hazard Class 3 or Class 4
    (b) Flammability Class 4
    (c) Instability Class 3 or Class 4
(7) The pressurized piping specified in 60.5.1.6.2(6) shall be provided with an approved means of leak detection and emergency shutoff or excess flow control in accordance with the following:
    (a) Where the piping originates from within a hazardous material storage room or area, the excess flow control shall be located within the storage room or area.
    (b) Where the piping originates from a bulk source, the excess flow control shall be located at the bulk source.
    (c) Piping for inlet connections designed to prevent backflow shall not be required to be equipped with excess flow control.

[**400:**6.1.6.2]

Δ **60.5.1.6.3 Additional Regulations for Supply Piping for Health Hazard Materials.** Supply piping and tubing for liquids or solids having a health hazard ranking of Class 3 or Class 4 in accordance with NFPA 704 shall be in accordance with ASME B31.3, *Process Piping,* and the following:

(1) Piping and tubing utilized for the transmission of highly toxic, toxic, or highly volatile corrosive liquids shall have welded, threaded, or flanged connections throughout, except for connections located within a ventilated enclosure, or an approved method of drainage or containment.
(2) Piping and tubing shall not be located within corridors, within any portion of a means of egress required to be enclosed in fire resistance–rated construction, or in concealed spaces in areas not classified as Protection Level 1 through Protection Level 4 occupancies.

[**400:**6.1.6.3]

60.5.1.6.4 Equipment, Machinery, and Alarms. Equipment, machinery, and required detection and alarm systems associated with the use, storage, or handling of hazardous materials shall be listed or approved. [**400:**6.1.6.4]

60.5.1.7 Empty Containers and Tanks. Empty containers and tanks previously used for the storage of hazardous materials shall be free from residual material and vapor as defined by DOT, the Resource Conservation and Recovery Act (RCRA), or other regulating authority or shall be maintained as specified for the storage of hazardous material. [**400:**6.1.7]

60.5.1.8 Signs.

Signs that identify hazards and materials are an important means of ensuring safety in areas where hazardous materials are present. The signs should be designed to be identifiable by staff, visitors, and first responders. The requirements of 60.5.1.8 cover the minimum standard size, color, and lettering of signs. Additional signs can be added for specific needs.

60.5.1.8.1 General.

60.5.1.8.1.1 Design and Construction. Signs shall be durable, and the size, color, and lettering of signs shall be in accordance with nationally recognized standards. [**400:**6.1.8.1.1]

60.5.1.8.1.2 Language. Signs shall be in English as the primary language or in symbols permitted by this *Code*. [**400:**6.1.8.1.2]

Δ **60.5.1.8.1.3 Maintenance.** Signs shall meet the following criteria:

(1) They shall not be obscured.
(2) They shall be maintained in a legible condition.
(3) They shall not be removed, unless for replacement.

[**400:**6.1.8.1.3]

60.5.1.8.2 Hazard Materials Identification.

Δ **60.5.1.8.2.1 NFPA 704 Placard.** Visible hazard identification signs in accordance with NFPA 704 shall be placed at the following locations, except where the AHJ has received a hazardous materials management plan and a hazardous materials inventory statement in accordance with 60.1.6 and 60.1.7 and has determined that omission of such signs is consistent with safety:

(1) On stationary aboveground tanks
(2) On stationary aboveground containers
(3) At entrances to locations where hazardous materials are stored, dispensed, used, or handled in quantities requiring a permit
(4) At other entrances and locations designated by the AHJ

[**400:**6.1.8.2.1]

60.5.1.8.2.2 Identification of Containers, Cartons, and Packages. Individual containers, cartons, or packages shall be conspicuously marked or labeled in accordance with nationally recognized standards. [**400:**6.1.8.2.2]

Δ **60.5.1.8.3 No Smoking Signs.** Where "no smoking" is not applicable to an entire site or building, signs shall be provided as follows:

(1) In rooms or areas where hazardous materials are stored or dispensed or used in open systems in amounts requiring a permit in accordance with Section 1.8 of NFPA 400
(2) Within 25 ft (7.6 m) of outdoor storage, dispensing, or open-use areas

[**400:**6.1.8.3]

60.5.1.9 Protection from Vehicles.

The requirements of 60.5.1.9 outline the need for protection of containers and piping containing hazardous materials in areas where vehicular traffic is likely. They describe the most commonly used protection strategy — guard posts — although other approved means such as curbs, landscaping berms, or guardrails can be used.

Δ **60.5.1.9.1** Guard posts or other approved means shall be provided to protect the following where subject to vehicular damage:

(1) Storage tanks and connected piping, valves, and fittings
(2) Storage areas containing tanks or portable containers except where the exposing vehicles are powered industrial trucks used for transporting the hazardous materials
(3) Use areas

[**400:**6.1.9.1]

Δ **60.5.1.9.2** Where guard posts are installed, the posts shall meet the following criteria:

(1) They shall be constructed of steel not less than 4 in. (102 mm) in diameter and concrete filled.
(2) They shall be spaced not more than 4 ft (1.2 m) between posts on center.
(3) They shall be set not less than 3 ft (0.9 m) deep in a concrete footing of not less than a 15 in. (381 mm) diameter.
(4) They shall be set with the top of the posts not less than 3 ft (0.9 m) above ground.
(5) They shall be located not less than 3 ft (0.9 m) from the tank.

[**400:**6.1.9.2]

60.5.1.10 Electrical Wiring and Equipment.

Many hazardous materials are particularly susceptible to ignition or to initiation of a hazardous reaction from exposure to thermal energy. A minor spark can produce a major reaction. Where necessary, electrical wiring and utilization equipment should comply with Chapter 5 of *NFPA 70®*, *National Electrical Code*. The potential for the development of dangerous levels of static electricity should be assessed carefully. The requirements of 60.5.1.10 are a reminder to verify that all wiring and equipment are checked for their appropriateness in the storage or use area.

60.5.1.10.1 General. Electrical wiring and equipment shall be installed in accordance with Section 11.1. [**400:**6.1.10.1]

60.5.1.10.2 Static Accumulation. When processes or use conditions exist where flammable gases, dusts, or vapors can be ignited by static electricity, means shall be provided to prevent the accumulation of a static charge and to dissipate the static charge to ground. [**400:**6.1.10.2]

60.5.1.11 Protection from Light. Materials that are sensitive to light shall be stored in containers designed to protect them from such exposure. [**400:**6.1.11]

60.5.1.12 Separation of Incompatible Materials.

A basic approach to reviewing sites where multiple hazardous materials are present is to determine which materials are compatible for storage or use near other materials. The requirements of 60.5.1.12 are minimum requirements. Each site requires a review of the distances and protection features, because the mixing of incompatible materials can create extremely hazardous and life-threatening incidents. Mixing of incompatible materials can occur at many sites, but one of the most common is a hazardous waste recycling facility, where numerous different materials are separated and stored.

60.5.1.12.1 Incompatible materials in storage and storage of materials incompatible with materials in use shall be separated when the stored materials are in containers having a capacity of more than 5 lb (2.268 kg) or ½ gal (1.89 L). [**400:**6.1.12.1]

Δ **60.5.1.12.2** Separation shall be accomplished by one of the following methods:

(1) Segregating incompatible materials storage by a distance of not less than 20 ft (6.1 m)
(2) Isolating incompatible materials storage by a noncombustible partition extending not less than 18 in. (457 mm) above and to the sides of the stored material or by a noncombustible partition that interrupts the line of sight between the incompatible materials
(3) Storing liquid and solid materials in hazardous materials storage cabinets complying with 60.5.1.18
(4) Storing compressed gases in gas cabinets or exhausted enclosures complying with Chapter 21 of NFPA 400

[**400:**6.1.12.2]

60.5.1.12.3 Materials that are incompatible shall not be stored within the same cabinet or enclosure. [**400:**6.1.12.3]

60.5.1.13 General Storage.

60.5.1.13.1 Storage. The storage arrangement of materials shall be in accordance with this chapter and the material specific requirements of Chapters 11 through 21 of NFPA 400 as applicable. [**400:**6.1.13.1]

60.5.1.13.2 Shelf Storage. Shelving shall be constructed to carry the design loads and shall be braced and anchored in accordance with the seismic design requirements of the applicable building code. [**400:**6.1.13.2]

60.5.1.13.2.1 Shelf Construction.

60.5.1.13.2.1.1 Shelving shall be treated, coated, or constructed of materials that are compatible with the hazardous materials stored. [**400:**6.1.13.2.1.1]

Δ **60.5.1.13.2.1.2** Shelves shall be provided with a lip or guard where used for the storage of individual containers, except under either of the following conditions:

(1) Where storage is located in hazardous materials storage cabinets or laboratory furniture specifically designed for such use
(2) Where amounts of hazardous materials in storage do not exceed the quantity threshold for requiring a permit in accordance with Section 1.8 of NFPA 400

[**400:**6.1.13.2.1.2]

60.5.1.13.2.2 Shelf storage of hazardous materials shall be maintained in an orderly manner. [**400:**6.1.13.2.2]

60.5.1.14* Seismic Protection. Machinery and equipment utilizing hazardous materials in areas subject to seismic activity shall be seismically anchored in accordance with the building code. [**400:**6.1.14]

A.60.5.1.14 For seismic requirements and the seismic zone in which the material is located, see the building code. [**400:**A.6.1.14]

60.5.1.14.1 Shock Padding. Materials that are shock sensitive shall be padded, suspended, or otherwise protected against accidental dislodgement and dislodgement during seismic activity. [**400:**6.1.14.1]

Δ **60.5.1.15 Outdoor Storage and Use Areas.** Outdoor storage and use areas for hazardous materials shall comply with the following:

(1) Outdoor storage and use areas shall be kept free of weeds, debris, and common combustible materials not necessary to the storage or use of hazardous materials.
(2) The area surrounding an outdoor storage and use area shall be kept clear of weeds, debris, and common combustible materials not necessary to the storage or use of hazardous materials for a minimum distance of 15 ft (4.5 m).
(3) Outdoor storage and use areas for hazardous materials shall be located not closer than 20 ft (6.1 m) from a property line that can be built upon, a street, an alley, or a public way, except that a 2-hour fire barrier wall, without openings and extending not less than 30 in. (762 mm) above and to the sides of the storage area, shall be permitted in lieu of such distance.

[**400:**6.1.15]

The provision of 60.5.1.15(1) is intended to prevent a fire from spreading to the outside hazardous materials storage area. Combustible material needed for storage or use (e.g., pallets and cribbing) can be located within the hazardous materials area, but combustible materials that are not associated with the hazardous materials and that are not needed for such storage or use cannot be located in that area. See 10.13.10 for additional guidance.

The provision of 60.5.1.15(2) is intended to ensure that a fire does not spread to the storage or use area from outside the hazardous materials area. This includes combustible materials on-site and off-site within a minimum distance of 15 ft (4.5 m). If the material warrants, a greater setback distance can be required within the wording of 60.5.1.15(2). See 10.13.10 for additional guidance.

The provision of 60.5.1.15(3) provides direction to the user that a minimum of 20 ft (6.1 m) is needed from neighboring buildings and general public areas, such as public ways, streets, and similar areas. The use of a 2-hour fire barrier wall is permitted as an alternative to this minimum separation.

60.5.1.16 Maintenance Required.

60.5.1.16.1* Equipment, machinery, and required detection and alarm systems associated with hazardous materials shall be maintained in an operable condition. [**400:**6.1.16.1]

A.60.5.1.16.1 Maintenance procedures are an important part of any mechanical integrity program. They should contain information on which equipment is covered; what tests and inspections are to be performed; how to perform the tests and inspections in accordance with recognized industry standards and manufacturer's recommendations; what constitutes acceptance of the measured parameters; corrective actions to be taken if the equipment does not meet requirements; and the frequency of the testing and inspection. For examples of additional guidance, refer to *Guidelines for Mechanical Integrity Systems* (AIChE/CCPS); *Guidelines for Safe and Reliable Instrumented Protective Systems* (AIChE/CCPS); and *Guidelines for Writing Effective Operating and Maintenance Procedures* (AIChE/CCPS). [**400:**A.6.1.16.1]

60.5.1.16.2 Stationary tanks not used for a period of 90 days shall be safeguarded or removed in an approved manner. [**400:**6.1.16.2]

60.5.1.16.2.1 The tanks specified in 60.5.1.16.2 shall have the fill line, gauge opening, and pump connection secured against tampering. [**400:**6.1.16.2.1]

60.5.1.16.2.2 Vent lines shall be maintained. [**400:**6.1.16.2.2]

60.5.1.16.2.3* Tanks that are to be placed back in service shall be tested in an approved manner. [**400:**6.1.16.2.3]

A.60.5.1.16.2.3 Testing can include visual inspection, x-ray, spark testing, pressure testing, leak testing, or other nondestructive methods. [**400:**A.6.1.16.2.3]

Δ **60.5.1.16.3** The following shall apply to defective containers, cylinders, and tanks:

(1) They shall be removed from service, repaired, or disposed of in an approved manner.
(2) Overpack containers shall be permitted to be used as a means to provide protection for primary containers that are transported for repair or removal from service.

[**400:**6.1.16.3]

60.5.1.16.4 Defective equipment or machinery shall be removed from service and repaired or replaced. [**400:**6.1.16.4]

60.5.1.16.5 Required detection and alarm systems that are defective shall be replaced or repaired. [**400:**6.1.16.5]

60.5.1.17 Testing.

60.5.1.17.1 The equipment, devices, and systems listed in 60.5.1.17.2.1 shall be tested at one of the intervals listed in 60.5.1.17.2.2. Written records of the tests conducted or maintenance performed shall be maintained. [**400:**6.1.17.1]

Δ **60.5.1.17.2** Testing shall not be required under the following conditions:

(1) Where approved written documentation is provided that testing will damage the equipment, device, or system and the equipment, device, or system is maintained as specified by the manufacturer
(2) Where equipment, devices, and systems fail in a fail-safe manner
(3) Where equipment, devices, and systems self-diagnose and report trouble, with records of the self-diagnosis and trouble reporting made available to the AHJ
(4) Where system activation occurs during the required test cycle for the components activated during the test cycle
(5) Where approved maintenance in accordance with 60.5.1.16.1 is performed not less than annually or in accordance with an approved schedule, in which case the testing requirements set forth in 60.5.1.17.2.1 and 60.5.1.17.2.2 are permitted to apply.

[**400:**6.1.17.2]

Δ **60.5.1.17.2.1 Equipment, Devices, and Systems Requiring Testing.** The following equipment, devices, and systems shall be tested in accordance with 60.5.1.17 and 60.5.1.17.2.2:

(1) Limit control systems for liquid level, temperature, and pressure required by 6.2.1.7 of NFPA 400
(2) Monitoring and supervisory systems required by 6.2.1.1 of NFPA 400

[**400:**6.1.17.2.1]

Δ **60.5.1.17.2.2 Testing Frequency.** The equipment, systems, and devices listed in 60.5.1.17.2.1 shall be tested at one of the following frequencies:

(1) Not less than annually
(2) In accordance with the approved manufacturer's requirements
(3) In accordance with approved recognized industry standards
(4) In accordance with an approved schedule

[**400:**6.1.17.2.2]

Δ **60.5.1.18 Hazardous Materials Storage Cabinets.** When storage cabinets are used to increase maximum allowable quantities per control area or to otherwise comply with a specific provision in Section 60.5, such cabinets shall be in accordance with the following:

(1) Cabinets shall be constructed of metal.
(2) The interior of cabinets shall be treated, coated, or constructed of materials that are nonreactive with the hazardous material stored, and such treatment, coating, or construction shall include the entire interior of the cabinet.
(3) Cabinets shall be either listed as suitable for the intended storage or constructed in accordance with the following:
    (a) Cabinets shall be of steel having a thickness of not less than 0.044 in. (1.12 mm) (18 gauge).
    (b) The cabinet, including the door, shall be double-walled with 1½ in. (38.1 mm) airspace between the walls.
    (c) Joints shall be riveted or welded and shall be tightfitting.
    (d) Doors shall be well fitted, self-closing, and equipped with a self-latching device.
    (e) The bottoms of cabinets utilized for the storage of liquids shall be liquidtight to a minimum height of 2 in. (51 mm).
    (f) For requirements regarding electrical equipment and devices within cabinets used for the storage of hazardous liquids, compressed gases, or cryogenic fluids, see *NFPA 70*.
(4) Cabinets shall be marked in conspicuous lettering that reads as follows: HAZARDOUS — KEEP FIRE AWAY

[**400:**6.1.18]

Isolating and locking hazardous materials in a cabinet can prevent incidents. Hazardous materials storage cabinets allow most MAQs to be doubled or regarded as the same level of protection as that provided by a separate control area. As outlined in the cabinet construction requirements in 60.5.1.18(1) and (2), hazardous materials cabinets are designed so that a fire does not immediately affect the hazardous material in the cabinet, but they also keep the effects of an incident or accident within the cabinet from spreading outside of its protected enclosure. Many premanufactured cabinets are designed and tested for protection of specific hazardous materials, such as flammable and combustible liquids, and carry a product performance listing. If a hazardous material has not been tested in a cabinet, or if a specific cabinet design is required and no listed cabinets are available, a minimum of six essential features as outlined in 60.5.1.18(3) will help a designer create a specialized cabinet and still allow the increase in quantities of hazardous material permitted to be stored using the cabinet for protection. In addition, cabinets are required to be marked with lettering that specifically reads "HAZARDOUS — KEEP FIRE AWAY."

60.5.1.19 Installation of Tanks. Installation of tanks shall be in accordance with 60.5.1.19.1 through 60.5.1.19.2. [**400:**6.1.19]

60.5.1.19.1 Underground Tanks.

60.5.1.19.1.1 Underground tanks used for the storage of liquid hazardous materials shall be provided with secondary containment. [**400:**6.1.19.1.1]

Consideration should be given to using secondary containment-type piping as well.

Δ **60.5.1.19.1.2** In lieu of providing secondary containment for an underground tank, an aboveground tank in an underground vault complying with NFPA 30 shall be permitted. [**400:**6.1.19.1.2]

It is important to note that an underground tank cannot be installed inside a vault. An underground tank is designed to be supported by the backfill placed around it; it cannot accommodate the stresses that would be imposed by support on legs or saddles. Also, underground tanks are not designed to be directly exposed to fire. They are not fitted with emergency vents that relieve the overpressure from an exposure fire.

60.5.1.19.2 Aboveground Tanks. Aboveground stationary tanks installed outdoors and used for the storage of hazardous materials shall be located and protected in accordance with the requirements for outdoor storage of the particular material involved and in accordance with the requirements of Chapters 11 through 21 of NFPA 400. [**400:**6.1.19.2]

Δ **60.5.1.19.2.1** Aboveground tanks that are installed in vaults complying with NFPA 30 shall not be required to comply with location and protection requirements for outdoor storage. [**400:**6.1.19.2.1]

The commentary to 60.5.1.19.1.2 applies here as well.

60.5.1.19.2.2 Aboveground tanks that are installed inside buildings and used for the storage of hazardous materials shall be located and protected in accordance with the requirements for indoor storage of the particular material involved. [**400:**6.1.19.2.2]

60.5.1.19.3 Marking. Aboveground stationary tanks shall be marked as required by 60.5.1.8.2.1. [**400:**6.1.19.2.3]

Δ **60.5.1.20** When required, fire alarm systems and smoke detection systems shall be installed in accordance with *NFPA 72*. [**400:**6.1.20]

Δ **60.5.2** Where permitted by Chapters 11 through 43 of NFPA 101 alcohol-based hand-rub dispensers shall be permitted provided they meet all the following criteria:

(1) The maximum individual dispenser fluid capacity shall be as follows:
  (a) 0.32 gal (1.2 L) for dispensers in corridors and areas open to corridors
  (b) 0.53 gal (2.0 L) for dispensers in rooms or suites of rooms separated from corridors
(2) Where aerosol containers are used, the maximum capacity of the aerosol dispenser shall be 18 oz. (0.51 kg) and shall be limited to Level 1 aerosols as defined in NFPA 30B.
(3) Dispensers shall be separated from each other by horizontal spacing of not less than 48 in. (1220 mm).
(4) Not more than an aggregate 10 gal (37.8 L) of alcohol-based hand-rub solution or 1135 oz (32.2 kg) of Level 1 aerosols, or a combination of liquids and Level 1 aerosols not to exceed, in total, the equivalent of 10 gal (37.8 L) or 1135 oz (32.2 kg,) shall be in use outside of a storage cabinet in a single smoke compartment or fire compartment or story, whichever is less in area. One dispenser complying with 60.5.2(1) per room and located in that room shall not be included in the aggregated quantity.
(5) Storage of quantities greater than 5 gal (18.9 L) in a single smoke compartment or fire compartment or story, whichever is less in area, shall meet the requirements of NFPA 30.
(6) Dispensers shall not be installed in the following locations:
  (a) Above an ignition source for a horizontal distance of 1 in. (25 mm) to each side of the ignition source
  (b) To the side of an ignition source within a 1 in. (25 mm) horizontal distance from the ignition source
  (c) Beneath an ignition source within a 1 in. (25 mm) vertical distance from the ignition source
(7) Dispensers installed directly over carpeted floors shall be permitted only in sprinklered areas of the building.
(8) The alcohol-based hand-rub solution shall not exceed 95 percent alcohol content by volume.
(9) Operation of the dispenser shall comply with the following criteria:
  (a) The dispenser shall not release its contents except when the dispenser is activated, either manually or automatically by touch-free activation.
  (b) Any activation of the dispenser shall only occur when an object is placed within 4 in. (100 mm) of the sensing device.
  (c) An object placed within the activation zone and left in place shall not cause more than one activation.
  (d) The dispenser shall not dispense more solution than the amount required for hand hygiene consistent with label instructions.

(e) The dispenser shall be designed, constructed, and operated in a manner that ensures accidental or malicious activation of the dispensing device is minimized.

(f) The dispenser shall be tested in accordance with the manufacturer's care and use instructions each time a new refill is installed.

[***101:***8.7.3.3]

Subsection 60.5.2 adds guidance on the presence of alcohol-based hand-rub dispensers used in buildings where permitted by the specific occupancy chapter in NFPA *101®, Life Safety Code®*.

Alcohol-based hand-rub dispensers and solutions have been in many buildings for years: office buildings, schools, industrial facilities, hotels, and so on. However, prior to the addition of these requirements in the 2015 edition, NFPA *101* regulated their presence only in health care, ambulatory health care, educational, and day care occupancies. All other occupancies were silent on the issue. Thus, the question arose as to whether or not the *Code* even permitted them in the other occupancies. The addition of 60.5.2 recognizes alcohol-based hand-rub dispensers for any occupancy type, so long as NFPA *101* specifically permits its use in the occupancy.

Subsection 60.5.2 addresses many concerns regarding the presence of alcohol-based hand-rub dispensers, including the maximum capacity per dispenser, aerosol-based hand-rub solutions, location of dispensers, aggregate quantity of solution in use and in storage, and the alcohol content of the solution.

△ 60.6 Emergency Action Planning, Fire Risk Control and Chemical Hazard Requirements for Industrial Processes

Emergency planning, fire risk control, and chemical hazard requirements associated with industrial processes where the quantities of materials in use require compliance with Protection Level 1, Protection Level 2, Protection Level 3, or Protection Level 4 based on materials exceeding the maximum allowable quantities (MAQ) in the following categories shall comply with the requirements of Chapter 7 of NFPA 400:

(1) Unpackaged organic peroxide formulations that are capable of explosive decomposition in their unpackaged state
(2) Oxidizer Class 3 and Class 4: solids and liquids
(3) Pyrophoric solids, liquids, and gases
(4) Unstable reactive Class 3 and Class 4: solids, liquids, and gases
(5) Highly toxic solids, liquids, and gases
(6) Water-reactive liquids, Class 3

△ 60.7 Performance Alternative

In lieu of complying with Chapter 60 in its entirety, occupancies containing high hazard Level 1 to high hazard Level 5 contents shall be permitted to comply with Chapter 10 of NFPA 400.

Section 60.7 offers a performance alternative to Chapter 60 requirements. This section makes reference to Chapter 10 of NFPA 400, which outlines the goals and objectives for a performance-based approach. The performance option of NFPA 400 establishes acceptable levels of risk for facilities (buildings and other structures and the operations associated therewith) as addressed in Section 1.3 of NFPA 400. While the performance option does contain goals, objectives, and performance criteria necessary to provide for an acceptable level of risk, it does not describe how to meet those goals, objectives, and performance criteria. For fire protection designs, the *SFPE Engineering Guide to Performance-Based Fire Protection* provides a framework for such assessments.

Aerosol Products

61

Chapter 61 references NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*. NFPA 30B and Chapter 61 provide minimum requirements for fire prevention and control of fires and explosions in facilities that manufacture, store, or display aerosol products.

61.1 General Provisions

61.1.1 Application.

Δ **61.1.1.1*** The manufacture, storage, use, handling, and display of aerosol products shall comply with the requirements of Chapter 61; NFPA 30B and Sections 60.1 through 60.4 of this *Code*.

Δ **A.61.1.1.1** Chapter 61 provides minimum acceptable requirements for fire prevention and protection in facilities that manufacture and store aerosol products and in mercantile occupancies where aerosol products are displayed and sold. As explained in A.5.1 of NFPA 30B, the hazards presented by each stage of the manufacturing process will vary, depending on the flammability of the base product and on the flammability of the propellant. Considerable judgment will be required of the designer and of the AHJ to provide an adequate level of fire protection. *(See also Annex B of NFPA 30B.)* [**30B:**A.1.2]

Aerosol products in storage or mercantile occupancies complying with this chapter, and covered by 60.1.2(9), are not required to comply with Sections 60.1 through 60.4.

The manufacture and storage of aerosol products present a variety of hazards that need to be addressed through appropriate construction methods, appropriate passive and active fire protection systems, and appropriate fire prevention measures. Aerosol manufacturing facilities include hazards associated with the storage, handling, and dispensing of flammable and combustible liquids and the storage, handling, and use of liquefied flammable gases. Mitigation measures include noncombustible, fire-resistive, and damage-limiting construction. Fire protection systems include automatic sprinkler protection, deflagration suppression systems, and fire alarm and detection systems.

The designer of a manufacturing facility and the authority having jurisdiction (AHJ) must exercise careful judgment to provide for an appropriate level of fire protection for the facility. Information on the properties, safe handling, and storage of liquefied petroleum gases (LP-Gas) is found in Chapter 69 and NFPA 58, *Liquefied Petroleum Gas Code*. Information on the handling and storage of flammable and combustible liquids is found in Chapter 66 and NFPA 30, *Flammable and Combustible Liquids Code*.

The storage of large quantities of aerosol products in a warehouse presents a significant fire challenge that requires the installation of automatic sprinkler systems that are specifically designed to meet the aerosol fire challenge.

61.1.1.2 Where the provisions of Chapter 61 or NFPA 30B conflict with the provisions of Chapter 60, the provisions of Chapter 61 and NFPA 30B shall apply.

61.1.1.3* Chapter 61 shall not apply to the storage and display of containers whose contents are comprised entirely of LP-Gas products. [**30B:**1.1.2]

Δ **A.61.1.1.3** See NFPA 58. [**30B:**A.1.1.2]

61.1.1.4 Chapter 61 shall not apply to post-consumer processing of aerosol containers. [**30B:**1.1.3]

The term *aerosol product* is defined in 3.3.4 as "a combination of a container, a propellant, and a material that is dispensed." Therefore, an aerosol product includes a base product and a propellant. A product whose contents comprise solely of LP-Gas products does not meet this definition. Such products would be regulated as LP-Gas products under the requirements of NFPA 58 and Chapter 69 of this *Code*.

Post-consumer processing of aerosol containers, such as disposal and recycling, is exempt from the requirements of Chapter 61. During post-consumer processing, aerosol containers are assumed to be empty, or nearly so; therefore, the risk of fire or explosion should be minimal.

61.1.1.5* Chapter 61 shall not apply to containers that do not meet the definition of *Aerosol Container* (*see 3.3.2 of NFPA 30B*). [**30B:**1.1.4]

The definition of the term *aerosol container* was revised for the 2011 edition of NFPA 30B to reflect the new requirements from the U.S. Department of Transportation (DOT) allowing the use of plastic aerosol containers up to a maximum size of 1000 ml

(33.8 fl oz). The revised definition prompted changes in several locations of NFPA 30B to accommodate aerosol products in plastic containers. In support of the revised definition of aerosol container, new material that provides several sets of fire test data on the results of testing aerosols in plastic containers was also included in Annex B of NFPA 30B.

The term was further revised for the 2015 edition of NFPA 30B as a pressurized metal or plastic container, up to a maximum size of 1000 ml (33.8 fl oz), or a glass bottle, up to a maximum size of 118 ml (4 fl oz), that is designed and intended to dispense an aerosol.

A.61.1.1.5 Chapter 61 does not apply to products that can be dispensed as aerosolized sprays that are not packaged in aerosol containers as defined in 3.3.2 of NFPA 30B. Chapter 61 is not applicable to other applications such as industrial spray adhesives that are dispensed from large [5–125 gal (18.9 L–475 L)] pressurized gas cylinders. There is no assurance that the protection specified in Chapter 61 will be adequate. [**30B:**A.1.1.4]

61.1.1.5.1 Containers that contain a product that meets the definitions in 3.3.1 and 3.3.3 of NFPA 30B, but are larger than the limits specified in 3.3.2 of NFPA 30B, shall not be classified as aerosol products, and Chapter 61 shall not apply to the manufacture, storage, and display of such products. [**30B:**1.1.4.1]

61.1.2 Permits. Permits, where required, shall comply with Section 1.12.

61.1.3* Classification of Aerosol Products in Metal Containers of Not More Than 33.8 fl oz (1000 ml) and in Plastic or Glass Containers of Not More Than 4 fl oz (118 ml). See Annex E of NFPA 30B. [**30B:**1.7]

A.61.1.3 Tests have shown that aerosol products in plastic containers with a heat of combustion of 10.5 kJ/g have been adequately protected as determined by fire tests. See Annex C of NFPA 30B for a description of the testing of aerosol products in plastic containers. [**30B:**A.1.7]

61.1.3.1 Aerosol products shall be classified by means of the calculation of their chemical or theoretical heats of combustion and shall be designated Level 1, Level 2, or Level 3 in accordance with 61.1.3.2 through 61.1.3.4 and Table 61.1.3.1. [**30B:**1.7.1]

The severity of a fire involving aerosol products depends on the classification of the aerosol products involved. Aerosol products are classified based on a calculation of the chemical or theoretical heats of combustion, taking into account all the constituents of the base product, as well as the propellant. The higher the heat of combustion of the aerosol product, the more severe the fire challenge it poses.

Heat of combustion is expressed in terms of units of heat energy [Btu (kJ)] per units of mass [lb (g)]. Heat of combustion can be determined either theoretically on the basis of the chemical properties of the materials involved or by physical testing in a laboratory.

Annex H of NFPA 30B provides a table of chemical heat of combustion for representative materials. Annex H also provides examples of the chemical heat of combustion calculations required for classifying aerosol products in accordance with 61.1.3 and 61.1.4 of this *Code*.

The protection requirements of NFPA 30B vary depending on an aerosol product's classification. These requirements include automatic sprinkler system design criteria, storage height limitations, and storage arrangements to ensure that sprinkler protection and other protection features provided in the building will adequately control a fire.

The aerosol classification system provided in NFPA 30B is intended to be used only for application of these fire protection requirements. The aerosol level classification system is separate from any consumer product labeling requirements, which are intended as warnings for consumers using the products. Labels on aerosol containers that include such terms as *flammable*, *highly flammable*, or *extremely flammable* are consumer product warning labels, and they are not intended to classify the product for application of NFPA 30B requirements.

TABLE 61.1.3.1 *Aerosol Product Classification*

If the chemical heat of combustion is >	≤	Aerosol Classification Level
0	20 kJ/g (8,600 Btu/lb)	1
20 kJ/g (8,600 Btu/lb)	30 kJ/g (13,000 Btu/lb)	2
30 kJ/g (13,000 Btu/lb)	—	3

[**30B:**Table 1.7.1]

61.1.3.1.1 In lieu of classification by means of the chemical heats of combustion, aerosol products shall be permitted to be classified by means of data obtained from properly conducted full-scale fire tests that utilize a 12-pallet test array. [**30B:**1.7.1.1]

*Exception: This shall not apply to aerosol cooking spray products. (See 61.1.3.5.) [**30B:**1.7.1.1]*

61.1.3.1.2 The fire tests shall be conducted at an approved testing laboratory. *(See Annex C of NFPA 30B for information on the 12-pallet test array.)* [**30B:**1.7.1.2]

61.1.3.2 Level 1 Aerosol Products. Level 1 aerosol products shall be defined as those products with a total chemical heat of combustion that is less than or equal to 20 kJ/g (8600 Btu/lb). [**30B:**1.7.2]

61.1.3.3 Level 2 Aerosol Products. Level 2 aerosol products shall be defined as those products with a total chemical heat of combustion that is greater than 20 kJ/g (8600 Btu/lb), but less than or equal to 30 kJ/g (13,000 Btu/lb). [**30B:**1.7.3]

61.1.3.4 Level 3 Aerosol Products. Level 3 aerosol products shall be defined as those products with a total chemical heat of combustion that is greater than 30 kJ/g (13,000 Btu/lb). [**30B:**1.7.4]

61.1.3.5 Aerosol Cooking Spray Products. Aerosol cooking spray products shall be defined as those aerosol products designed to deliver a vegetable oil or a solid or nonflammable liquid to reduce sticking on cooking and baking surfaces or to be applied to food or both. These products have a chemical heat of combustion that is greater than 20 kJ/g (8600 Btu/lb) and contain not more than 18 percent by weight of flammable propellant. [**30B:**1.7.5]

61.1.3.5.1 If the aerosol cooking spray product has a chemical heat of combustion that does not exceed 20 kJ/g (8600 Btu/lb), it shall be considered a Level 1 aerosol product. [**30B:**1.7.5.1]

61.1.3.5.2 If the aerosol cooking spray product contains more than 18 percent by weight of flammable propellant, it shall be classified in accordance with its chemical heat of combustion, as set forth in Table 61.1.3.1. [**30B:**1.7.5.2]

The classification of aerosol cooking products is new for the 2015 edition of NFPA 30B. Aerosol cooking spray products include those commonly used household products that dispense a vegetable oil or some other nonflammable liquid to reduce sticking of food to cooking or baking surfaces. Aerosol cooking products are characterized by having a chemical heat of combustion greater than 20 kJ/g (8600 Btu/lb) and contain no more than 18 percent of flammable propellant by weight. Where a cooking spray product has a chemical heat of combustion that does not exceed 20 kJ/g (8600 Btu/lb), it should be treated as a Level 1 aerosol product and follow the provisions of NFPA 30B for Level 1 aerosols.

61.1.4 Classification of Aerosol Products in Plastic Containers Greater Than 4 fl oz (118 ml) and Less Than 33.8 oz (1000 ml).

61.1.4.1 Plastic Aerosol 1 Products. Plastic aerosol 1 products shall be defined as those that meet one of the following criteria:

(1) The base product has no fire point when tested in accordance with ASTM D92, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester*, and the propellant is nonflammable.

(2) The base product does not exhibit sustained combustion when tested in accordance with 49 CFR 173, Appendix H, '"Method of Testing for Sustained Combustibility, or the *UN Recommendations on the Transport of Dangerous Goods*, and the propellant is nonflammable.

(3)* The base product contains not more than 20% by volume (15.8% by weight) of ethanol or propanol or mixtures thereof in an aqueous mix and the propellant is nonflammable.

A.61.1.4.1(3) Fire testing with alcohol and water at this percentage in plastic bottles has been successful. Small-scale burn tests of aerosol products in plastic containers have shown the aerosol with a nonflammable propellant to behave the same as the aerosol with no propellant. [**30B:**A.1.8.1(3)]

(4)* The base product contains not more than 4% by weight of an emulsified liquefied flammable gas propellant within an aqueous base, said propellant to remain emulsified for the life of the product. Where such propellant is not permanently emulsified then the propellant shall be nonflammable.

[**30B:**1.8.1]

A.61.1.4.1(4) A fire test with a formula of this type using liquefied petroleum gas was successful. An emulsion, in an aerosol product, would be a mixture of two or more liquids in which one is present as droplets, of microscopic or ultramicroscopic size, distributed throughout the other. Emulsions are formed from the component liquids either spontaneously or, more often, by mechanical means, such as agitation, provided that the liquids that are mixed have no (or a very limited) mutual solubility. Emulsions are stabilized by agents that form films at the surface of the droplets (e.g., soap molecules) or that impart to them a mechanical stability (e.g., colloidal carbon or bentonite). Colloidal distributions or suspension of one or more liquid(s) with another will have a shelf life that varies with the efficiency of the recipe used. [**30B:**A.1.8.1(4)]

61.1.4.2 Plastic Aerosol X Products. Plastic aerosol X products shall be defined as those that do not meet any of the criteria provided in 61.1.4.1. [**30B:**1.8.2]

Paragraph 61.1.4.1 addresses the classification of aerosol products in plastic containers greater than 4 fl oz (118 ml) and less than 33.8 fl oz (1000 ml). This category of aerosol products takes over where the aerosol products in 61.1.4.3 leave off. Also new to the 2015 edition of NFPA 30B was a classification of aerosol products referred to as "Aerosol X." Where an aerosol product does not meet one of the classifications in 61.1.3.1 or 61.1.4.1, it is considered a plastic "aerosol X" product. Requirements for this classification of aerosol are also found throughout Chapter 61 and NFPA 30B.

Commentary Table 61.1 provides a summary of aerosol classifications.

61.1.5 Marking of Packages of Aerosol Products.

This *Code* requires marking of cartons and packages containing aerosol products with their classification level to allow facility operators and AHJs to readily verify that storage is in accordance with building and suppression system design limitations. This marking ensures, for example, that permitted storage heights and sprinkler system design limitations are not exceeded for the specific product.

The intent is not to require such markings to be readable by emergency responders from a distance during an incident. For additional information on identification of hazardous materials for emergency responders, see Chapter 60 and NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response*.

61.1.5.1 Manufacturers of aerosol products shall ensure that all cartons or packages of aerosol products are identified on at least one exterior side with the classification of the aerosol products contained therein, in accordance with 61.1.3 and 61.1.4. [**30B:**1.9.1]

Δ **61.1.5.2** Cartons or packages containing aerosol products in metal containers or glass and plastic containers 4 fl oz (118 ml) or less shall be clearly marked as follows:

Level _____ Aerosols

[**30B:**1.9.2]

COMMENTARY TABLE 61.1 *Classification of Aerosol Products*

Container Type and Size	Aerosol Product	Classification	Section Reference
Metal containers not more than 33.8 fl oz (1000 ml) Plastic or glass containers not more than 4 fl oz (118 ml)	Total chemical heat of combustion ≤20 kJ/g (8,600 Btu/lb)	Level 1	61.1.3.2
	Total chemical heat of combustion >20 kJ/g (8,600 Btu/lb) and ≤30 kJ/g (13,000 Btu/lb)	Level 2	61.1.3.3
	Total chemical heat of combustion >30 kJ/g (13,000 Btu/lb)	Level 3	61.1.3.4
	Cooking spray with chemical heat of combustion >20 kJ/g (8,600 Btu/lb)	Aerosol cooking spray	61.1.3.5
	Cooking spray with chemical heat of combustion ≤20 kJ/g (8,600 Btu/lb)	Level 1	61.1.3.5.1
	Cooking spray with >18% percent flammable propellant by weight	Level 1, 2, or 3 depending on chemical heat of combustion	61.1.3.5.2
Plastic containers larger than 4 fl oz (118 ml) and smaller than 33.8 fl oz (1000 ml)	Meets one of the following: 1. Base product has no fire point when tested to ASTM D92, Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester; nonflammable propellant 2. Base product does not exhibit sustained combustion when tested to 49 CFR 173, Appendix H, "Method of Testing for Sustained Combustibility"; or *UN Recommendations on the Transport of Dangerous Goods*; nonflammable propellant 3. Base product contains not more than 20 percent by volume of ethanol or propanol, or mixtures in an aqueous mix; nonflammable propellant 4. Base product contains not more than 4 percent of emulsified liquefied flammable gas propellant with aqueous base	Plastic aerosol 1	61.1.4.1
	Plastic aerosol product not meeting any of the four criteria listed in 61.1.4.1	Aerosol X	61.1.4.2

N **61.1.5.3** Cartons or packages containing aerosol cooking spray products in metal containers shall be clearly marked as follows:

Aerosol Cooking Spray

[**30B:**1.9.3]

Δ **61.1.5.4** Cartons or packages containing aerosol products in plastic containers greater than 4 fl oz (118 ml) shall be clearly marked on the exterior of the carton as follows:

Plastic Aerosol 1 (or X)

[**30B:**1.9.4]

61.2 Basic Requirements

61.2.1 Site Requirements. Distances between buildings used for the manufacture or storage of aerosol products and adjacent buildings or property lines that are or can be built upon shall be based on sound engineering principles. [**30B:**4.1]

An engineering-based approach to determine the required separation of buildings on the basis of the expected intensity of an exposing fire is described in NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*. For additional provisions on building separation distances, see *NFPA 5000®, Building Construction and Safety Code®*.

61.2.2 Building Construction.

Aerosol product manufacturing facilities are specialized facilities that have specific construction and protection requirements. These facilities include flammable and combustible liquid tank farms, LP-Gas propellant tank farms, flammable and combustible liquid filling lines, and "gas houses" in which the aerosol containers are charged with propellants. All of these different areas of the aerosol manufacturing facility present different hazards, and all require different protection and mitigation strategies.

Chapter 5 of NFPA 30B provides specific requirements for the construction and protection of aerosol manufacturing facilities. These requirements include fire-resistive separations, deflagration venting, automatic sprinkler protection, deflagration suppression systems, gas detection systems, normal and emergency ventilation systems, and equipment interlocks and controls.

61.2.2.1 Openings in fire walls or fire barriers shall be kept to a minimum. [**30B:**4.2.1]

61.2.2.1.1 All openings (i.e., personnel doorways, ductwork, conveyor line, etc.) shall be protected with automatic-closing or self-closing fire doors or dampers. [**30B:**4.2.1.1]

Automatic-closing doors typically are arranged to be held open magnetically and are released automatically upon the detection of smoke by smoke detectors in the vicinity of the door opening. Smoke detectors for door-releasing service must be listed for such use. For details on the placement of smoke detectors for controlling automatic-closing doors, see *NFPA 72®, National Fire Alarm and Signaling Code*, or NFPA 80, *Standard for Fire Doors and Other Opening Protectives*.

Δ **61.2.2.1.2** Fire doors shall be installed in accordance with NFPA 80. [**30B:**4.2.1.2]

Δ **61.2.2.1.3** Fire dampers shall be installed in accordance with manufacturer's instructions and NFPA 90A. [**30B:**4.2.1.3]

61.2.2.2 Means of Egress.

61.2.2.2.1 Means of egress shall comply with applicable provisions of NFPA *101*. [**30B:**4.2.2.1]

61.2.2.2.2 The design and construction of conveyor lines and other physical obstacles, such as in the flammable propellant charging and pump rooms, shall not allow entrapment of personnel and shall provide for direct access to exits. [**30B:**4.2.2.2]

61.2.3 Electrical Installations.

61.2.3.1 All electrical equipment and wiring, including heating equipment, shall be installed in accordance with *NFPA 70*. [**30B:**4.3.1]

61.2.3.1.1 Electrical equipment and wiring in areas where flammable liquids or flammable gases are handled shall meet the additional requirements of Articles 500 and 501 of *NFPA 70*. [**30B:**4.3.1.1]

Articles 500 and 501 of *NFPA 70®, National Electrical Code®*, specify requirements for electrical equipment located in hazardous (classified) locations. Areas in which flammable gases or vapors are, or might be, present in quantities sufficient to produce explosive or ignitible mixtures are considered Class I locations. Electrical equipment in Class I locations must be listed for such use to prevent vapors or gases from coming into contact with potential ignition sources. Numerous protection methods are described in the *National Electrical Code® Handbook*. Also see *Electrical Installations in Hazardous Locations*.

61.2.3.2 Aerosol product storage and display areas shall be considered unclassified for purposes of electrical installation. [**30B:**4.3.2]

61.2.4 Heating Equipment. Heating equipment shall be installed in accordance with the applicable requirements of the following:

(1) NFPA 31, *Standard for the Installation of Oil-Burning Equipment*
(2) NFPA 54, *National Fuel Gas Code*
(3) NFPA 58, *Liquefied Petroleum Gas Code*
(4) NFPA 85, *Boiler and Combustion Systems Hazards Code* [**30B:**4.4]

Δ **61.2.5 Flammable Liquids and Gases.** Areas in which flammable liquids and flammable gases are handled or stored shall meet the applicable requirements of the following:

(1) Chapter 66 and NFPA 30
(2) Chapter 69 and NFPA 58 [**30B:**4.5]

61.2.6 Fire Protection.

Δ **61.2.6.1 Automatic Sprinkler Systems.** Installations of automatic sprinklers, where required by this *Code* and NFPA 30B, shall be installed in accordance with Section 13.3 and NFPA 13 and the provisions of NFPA 30B. [**30B:**4.6.1]

See Section 13.3 for information on automatic sprinkler systems.

Δ **61.2.6.1.1** Where the provisions of Chapter 61 and NFPA 13 differ, the provisions of Chapter 61 shall prevail. [**30B:**4.6.1.1]

Δ **61.2.6.1.2** Where Chapter 61 does not address specific automatic sprinkler protection criteria, the provisions of NFPA 13 shall prevail. [**30B:**4.6.1.2]

N **61.2.6.1.3** Production areas that contain base product fillers, button tippers, valve crimpers, test baths, and aerosol product packaging equipment shall be protected by a wet-pipe automatic sprinkler system installed in accordance with NFPA 13. The sprinkler system shall be designed to protect the highest level of storage or production hazard that is present. [**30B:**5.8.2]

N **61.2.6.1.3.1** Level 2 and Level 3 aerosol products shall be permitted to be stored in production areas, such as staging areas (e.g., awaiting transfer to a warehouse), provided all of the following are met:

(1) They are stacked no more than 5 ft (1.5 m) high.
(2) There is no warehouse storage of aerosol products within 25 ft (7.6 m) of the production line.

[**30B:**5.8.2.1]

N **61.2.6.1.3.1.1** All other storage shall be protected in accordance with Table 6.4.2.7(a) through Table 6.4.2.7(l), of NFPA 30B, as applicable. [**30B:**5.8.2.1.1]

N **61.2.6.1.3.2** Aerosol products in plastic containers of capacity larger than 4 fl oz (118 ml) shall be permitted to be stored in production areas, such as staging areas (e.g., awaiting transfer to a warehouse), up to a maximum quantity of 1000 lb (454 kg), provided all of the following are met:

(1) The aerosol products are not treated as Class III commodities in accordance with Section 6.5 of NFPA 30B.
(2) They are stacked no more than 5 ft (1.5 m) high.
(3) There is no warehouse storage of aerosol products within 25 ft (7.6 m) of the production line.

[**30B:**5.8.2.2]

61.2.6.2 Standpipe and Hose System. Installations of standpipe and hose systems, where required by this *Code* and NFPA 30B, shall be designed and installed in accordance with Section 13.2 and NFPA 14 and with the provisions of NFPA 30B. Only combination or spray hose nozzles shall be used. [**30B:**4.6.2]

61.2.6.3 Portable Fire Extinguishers. Fire extinguishers shall be provided in accordance with Section 13.6. [**30B:**4.6.3]

61.2.6.4 Water Supplies.

Aerosol products can burn with extreme intensity. When exposed to heat, the pressure increase inside a container can cause it to rupture and release its flammable contents, which, under pressure, can cause the container to rocket and ignite combustibles otherwise uninvolved in the fire. Such behavior was observed in a 1982 fire involving aerosol products that destroyed a 1,000,000 ft^2 (92,900 m^2) distribution center in Falls Township, Pennsylvania. Because of this severe fire behavior, fire suppression systems must be provided with a sufficient water supply in terms of flow rates, pressures, and flow duration. Additional fire flow capacity should be provided to allow manual fire-fighting operations to supplement any operating automatic suppression systems. See Section 18.4 for additional guidance on fire flow.

61.2.6.4.1 In addition to the water supply requirements for automatic sprinkler systems, a minimum requirement for hose stream supply for combined inside and outside hose streams shall be provided in accordance with one of the following:

(1) 500 gpm (1900 L/min) for buildings protected with spray and/or control mode specific application (CMSA) sprinkler protection
(2) 250 gpm (950 L/min) for buildings protected with ESFR sprinkler protection
(3) 1000 gpm (3800 L/min) for buildings without automatic sprinkler protection [**30B:**4.6.4.1]

61.2.6.4.1.1 The water supply shall be sufficient to provide the required hose stream demand for a minimum duration of 2 hours, unless otherwise specified in 61.3.4.2. [**30B:**4.6.4.1.1]

Δ **61.2.6.4.1.2** The water supply system shall be designed and installed in accordance with Section 13.5 and NFPA 24. [**30B:**4.6.4.1.2]

61.2.6.4.1.3 The water supply requirements shall be permitted as modified by the provisions of NFPA 30B. [**30B:**4.6.4.1.3]

Δ **61.2.6.4.2** Installations of fire pumps and tanks that are needed to supply the required fire protection water shall be installed in accordance with Section 13.4 and NFPA 20 and NFPA 22. [**30B:**4.6.4.2]

61.2.7 Fire Alarms. Fire alarm systems shall be installed, tested, and maintained in accordance with applicable requirements of Section 13.7 and *NFPA 72*. [**30B:**4.7]

61.2.8 Sources of Ignition.

61.2.8.1 In areas where flammable gases or flammable vapors might be present, precautions shall be taken to prevent ignition by eliminating or controlling sources of ignition. [**30B:**4.8.1]

61.2.8.2 Sources of ignition shall include, but are not limited to, the following:

(1) Open flames
(2) Lightning
(3) Hot surfaces
(4) Radiant heat
(5) Smoking
(6) Cutting and welding
(7) Spontaneous ignition
(8) Frictional heat or sparks
(9) Static electricity
(10) Electrical arcs and sparks
(11) Stray currents
(12) Ovens, furnaces, and other heating equipment
(13) Automotive vehicles
(14) Material-handling equipment [**30B:**4.8.2]

Any designated smoking area should be located well away from an aerosol storage area or filling operation and preferably outside the building. See Section 10.9 for smoking restrictions.

61.3 Storage in Warehouses and Storage Areas

61.3.1 Basic Requirements.

61.3.1.1 The protection criteria in Section 61.3 shall apply to the following:

(1) Level 1 aerosol products in metal containers not more than 33.8 fl oz (1000 ml) capacity, in accordance with 61.3.2
(2) Aerosol cooking spray products in metal containers not more than 33.8 fl oz (1000 ml) capacity, in accordance with 61.3.3
(3) Level 2 and Level 3 aerosol products in metal containers not more than 33.8 fl oz (1000 ml) capacity, in accordance with Section 6.4 of NFPA 30B

(4) Aerosol products in glass and plastic containers not more than 4 fl oz (118 ml) capacity, in accordance with Section 6.4
(5) Aerosol products in plastic containers greater than 4 fl oz (118 ml) capacity and not more than 33.8 fl oz (1000 ml) capacity, in accordance with Section 6.5 of NFPA 30B

[**30B:**6.1.1]

61.3.1.2 All outer packaging of aerosol products, including cartons, trays, shrouds, or other packaging, shall be identified on at least one side with the classification of the aerosol products in accordance with Section 1.9 of NFPA 30B and with one of the following, whichever is appropriate:

(a) Level _____ Aerosols
(b) Aerosol Cooking Spray
(c) Plastic Aerosol 1 (or X)

[**30B:**6.1.2]

61.3.1.3* Fire-retardant cartons shall not be considered an acceptable alternative to the protection requirements of Chapter 6 of NFPA 30B. [**30B:**6.1.3]

A.61.3.1.3 At the present time there have been no fire-retardant packaging systems tested that have demonstrated substantial mitigation of the fire hazards presented by aerosol products. [**30B:**A.6.1.3]

61.3.2* Storage of Level 1 Aerosol Products.

A.61.3.2 Fire tests and fire experience show that Level 1 aerosol products present relatively the same fire hazards as Class III commodities, as these are defined and described in NFPA 13. In some cases, the AHJ or applicable fire or building regulations might require storage of such materials to be protected from fire. If fire protection is by means of automatic sprinklers, then the requirements of NFPA 13 should be used as a design basis. [**30B:**A.6.2]

61.3.2.1 Level 1 aerosol products shall be considered equivalent to Class III commodities, as defined in NFPA 13. [**30B:**6.2.1]

61.3.2.2 In cases where the storage of Level 1 aerosol products is required to be protected, such storage shall be protected in accordance with the requirements for Class III commodities set forth in NFPA 13. [**30B:**6.2.2]

61.3.3 Storage of Aerosol Cooking Spray Products.

61.3.3.1 General.

61.3.3.1.1 Aerosol cooking spray products shall be permitted to be stored in a general-purpose warehouse. [**30B:**6.3.1.1]

61.3.3.1.2 Aerosol cooking spray products shall be permitted to be stored mixed with other higher hazard aerosols as long as the provided isolation, storage height restrictions, and protection are based on the highest hazard aerosol product present. [**30B:**6.3.1.2]

61.3.3.2 Fire Protection.

61.3.3.2.1 Encapsulated storage of cartoned aerosol cooking spray products shall be protected as uncartoned storage. [**30B:**6.3.2.1]

61.3.3.2.2 Stretch-wrapping of cartons of aerosol cooking spray products shall be protected as cartoned storage. [**30B:**6.3.2.2]

61.3.3.2.3 Wet-pipe automatic sprinkler protection shall be provided in accordance with Table 61.3.3.2.3(a) or Table 61.3.3.2.3(b) for cartoned aerosol cooking spray products stored in open frame racks without solid shelves or stored as palletized or solid pile storage. [**30B:**6.3.2.3]

61.3.3.2.4 Rack storage shall be arranged so that a minimum aisle width of 8 ft (2.4 m) is maintained between rows of racks and between racks and adjacent solid pile or palletized storage. [**30B:**6.3.2.4]

61.3.3.2.5 Solid pile and palletized storage shall be arranged so that no storage is more than 25 ft (7.6 m) from an aisle. Aisles shall be not less than 4 ft (1.2 m) wide. [**30B:**6.3.2.5]

61.3.3.2.6 Aerosol cooking spray product that is stored uncartoned shall be protected in accordance with Section 6.4 of NFPA 30B using the criteria for a Level 2 or Level 3 aerosol product, based on the product's chemical heat of combustion. [**30B:**6.3.2.6]

61.3.3.2.7 Protection criteria that are developed based on full-scale fire tests performed at an approved facility shall be considered an acceptable alternative to the protection criteria set forth in Table 61.3.3.2.3(a) or Table 61.3.3.2.3(b). [**30B:**6.3.2.7]

Δ ***TABLE 61.3.3.2.3(a)*** *Rack, Palletized and Solid Pile Storage of Cartoned Aerosol Cooking Spray Products (Metric Units)*

Maximum Ceiling Height (m)	Maximum Storage Height (m)	Ceiling Sprinkler Protection Criteria: Sprinkler Type/Nominal Orifice (L/min/bar$^{0.5}$)	Ceiling Sprinkler Protection Criteria: Response/Nominal Temperature Rating	Ceiling Sprinkler Protection Criteria: Design (# sprinklers @ discharge pressure)	Hose Stream Demand (L/min)	Water Supply Duration (hr)
9.1	7.6	ESFR-pendent K = 200	FR/Ordinary	12 @ 5.2 bar	950	1

[**30B:**Table 6.3.2.3(a)]

△ *TABLE 61.3.3.2.3(b) Rack, Palletized and Solid Pile Storage of Cartoned Aerosol Cooking Spray Products (English Units)*

Maximum Ceiling Height (ft)	Maximum Storage Height (ft)	Ceiling Sprinkler Protection Criteria: Sprinkler Type/Nominal Orifice (gpm/psi$^{0.5}$)	Response/ Nominal Temperature Rating	Design (# sprinklers @ discharge pressure)	Hose Stream Demand (gpm)	Water Supply Duration (hr)
30	25	ESFR-pendent K = 14.0	FR/Ordinary	12 @ 75 psi	250	1

[**30B:**Table 6.3.2.3(b)]

61.3.3.2.8 Storage in occupancies other than warehouses or mercantile occupancies, such as in assembly, business, educational, industrial, and institutional occupancies, shall be permitted up to a maximum of 1000 lb (454 kg) net weight. [**30B:**6.3.2.8]

61.3.3.2.9 Solid pile, palletized, or rack storage of aerosol cooking spray product shall be permitted in a general-purpose warehouse that is either unsprinklered or not protected in accordance with this *Code*, up to a maximum of 2500 lb (1135 kg). [**30B:**6.3.2.9]

Subsection 61.3.3 was new for the 2015 edition of NFPA 30B and provides all the criteria for the storage of aerosol cooking spray products. Aerosol cooking spray was added as a classification of aerosol products in 61.1.3.5.

61.3.4 Storage of Level 2 and Level 3 Aerosol Products.

61.3.4.1 The storage of Level 2 and Level 3 aerosol products shall be in accordance with 61.3.4. [**30B:**6.4.1]

61.3.4.1.1 Level 2 aerosol products in containers whose net weight is less than 1 oz (28 g) shall be considered to be equivalent to cartoned unexpanded Group A plastics, as defined in NFPA 13. [**30B:**6.4.1.1]

61.3.4.1.1.1 In cases where the storage of Level 2 aerosol products in containers whose net weight is less than 1 oz (28 g) is required to be protected, such storage shall be in accordance with the requirements set forth in NFPA 13 for cartoned unexpanded Group A plastics. [**30B:**6.4.1.1.1]

61.3.4.2 Fire Protection — Basic Requirements.

61.3.4.2.1 Storage of Level 2 and Level 3 aerosol products shall not be permitted in basement areas of warehouses. [**30B:**6.4.2.1]

61.3.4.2.1.1 Storage of Level 2 and Level 3 aerosol products shall be permitted as provided for in 6.3.3 of NFPA 30B. [**30B:**6.4.2.1.1]

61.3.4.2.2* Encapsulated storage of cartoned Level 2 and Level 3 aerosol products shall be protected as uncartoned. [**30B:**6.4.2.2]

The term *encapsulated storage* refers to a method of packaging that consists of a plastic sheet that completely encloses the sides and top of a pallet load of combustible commodities. Banding, or stretch wrapping, around only the sides of a pallet load is not considered encapsulation.

A.61.3.4.2.2 Fire testing has not been performed on encapsulated pallets of cartoned aerosol products; however, this type of protection should be appropriate for this condition, based on testing of uncartoned aerosol products. [**30B:**A.6.3.2.2]

61.3.4.2.2.1 Stretch-wrapping of cartons of aerosol products shall be permitted. [**30B:**6.4.2.2.1]

61.3.4.2.2.2 Encapsulated storage of uncartoned Level 2 and Level 3 aerosol products on slip sheets or in trays shall be permitted. [**30B:**6.4.2.2.2]

Aerosol sprinkler test programs that led to the development of the aerosol sprinkler protection criteria did not address uncartoned aerosol products. These same test programs showed the importance of "pre-wetting" of cardboard cartons by sprinkler system discharge in the aerosol storage array. The consensus at that time was that, without the presence of the cardboard carton to provide for this pre-wetting, the sprinkler design criteria provided for cartoned aerosols might not adequately control a fire in a storage array involving uncartoned aerosols.

Encapsulated storage of Level 2 and Level 3 aerosol products on slip sheets or on trays has become popular in some areas, and, therefore, appropriate protection was needed for this aerosol storage method. Additional sprinkler testing was performed on uncartoned aerosol storage arrays. These tests led to new protection criteria for uncartoned aerosol products in earlier editions of NFPA 30B.

61.3.4.2.3 Level 2 and Level 3 aerosol products whose containers are designed to vent at gauge pressures of less than 210 psi (1450 kPa) shall not be stored. [**30B:**6.4.2.3]

61.3.4.2.4 Noncombustible draft curtains shall extend down a minimum of 2 ft (0.61 m) from the ceiling and shall be installed at the interface between ordinary and high-temperature sprinklers. [**30B:**6.4.2.4]

61.3.4.2.5 Storage of mixed commodities within or adjacent to aerosol product storage areas shall meet all applicable requirements of Chapter 6 of NFPA 30B. [**30B:**6.4.2.5]

61.3.4.2.6 Storage of idle or empty pallets shall meet all applicable requirements of NFPA 13. [**30B:**6.4.2.6]

61.3.4.2.7 Where required by Chapter 6 of NFPA 30B, wet-pipe automatic sprinkler protection shall be provided in accordance with Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B and Figure 6.4.2.7(a) through Figure 6.4.2.7(e) of NFPA 30B as designated in the corresponding table(s). Protection shall be based on the highest level of aerosol product present. No protection criteria have been established for the protection of palletized and solid piled storage of uncartoned Level 3 aerosol products. The tables are as follows:

(1) Table 6.4.2.7(a) of NFPA 30B Palletized and Solid Pile Storage of Cartoned Level 2 and Level 3 Aerosol Products (Metric Units)
(2) Table 6.4.2.7(b) of NFPA 30B Palletized and Solid Pile Storage of Cartoned Level 2 and Level 3 Aerosol Products (English Units)
(3) Table 6.4.2.7(c) of NFPA 30B Palletized and Solid Pile Storage of Uncartoned Level 2 Aerosol Products (Metric Units)
(4) Table 6.4.2.7(d) of NFPA 30B Palletized and Solid Pile Storage of Uncartoned Level 2 Aerosol Products (English Units)

[**30B:**6.4.2.7]

Annex B of NFPA 30B provides a summary of the aerosol product fire tests that culminated in the development of the sprinkler protection criteria for aerosol products. This testing included more than a dozen full-scale aerosol product fire tests in the late 1970s and early 1980s, which were conducted by a major insurance company, and more than 50 small-, medium-, and large-scale tests sponsored by the aerosol industry during the 1980s. These test programs led to the body of knowledge that was used to develop the first edition of NFPA 30B in 1990. The sprinkler protection criteria provided in NFPA 30B is based on those original tests, as well as ongoing testing of new sprinkler designs, and new storage and display methods. The tables for rack storage of aerosol products were updated for the 2011 edition of NFPA 30B to clarify the permitted sprinkler type and maximum size orifice permitted for certain storage arrangements.

61.3.4.2.7.1 The protection criteria in Tables 6.4.2.7(a) through 6.4.2.7(l) of NFPA 30B shall only be used with ceilings having a pitch of 2 in 12 or less. [**30B:**6.4.2.7.1]

61.3.4.2.7.2 Fire protection requirements for more demanding commodity and clearance situations shall be permitted to be used for less demanding situations. [**30B:**6.4.2.7.2]

61.3.4.2.7.3 The ordinary-temperature design criteria correspond to ordinary-temperature rated sprinklers and shall be used for sprinklers with ordinary- and intermediate-temperature classification. [**30B:**6.4.2.7.3]

61.3.4.2.7.4 The high-temperature design criteria correspond to high-temperature rated sprinklers and shall be used for sprinklers having a high-temperature rating. [**30B:**6.4.2.7.4]

61.3.4.2.8 Protection criteria that are developed based on full-scale fire tests performed at an approved test facility shall be considered an acceptable alternative to the protection criteria set forth in Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B. Such alternative protection criteria shall be subject to the approval of the AHJ. [**30B:**6.4.2.8]

As indicated in the commentary to 61.3.4.2.7, the sprinkler protection criteria contained in NFPA 30B has been developed based on full-scale test programs. Performing full-scale fire tests to develop appropriate criteria for new sprinkler designs or storage methods is a valid approach to defining appropriate protection for aerosol product storage.

Δ **61.3.4.2.9** Installation of in-rack sprinklers shall be in accordance with NFPA 13 as modified by Table 6.4.2.7(e) through Table 6.4.2.7(l) of NFPA 30B. [**30B:**6.4.2.9]

61.3.4.2.9.1 The in-rack sprinkler water demand shall be based on the simultaneous operation of the most hydraulically remote sprinklers as follows:

(1) Sprinkler design parameters shall be in accordance with Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B, whichever is applicable.
(2) In-rack design flows indicated in Table 6.4.2.7(e) through Table 6.4.2.7(l) of NFPA 30B shall be provided, but in no case shall the end-sprinkler discharge be less than 10 psi (0.69 bar).
(3) Eight (8) sprinklers where only one level of in-rack sprinklers is provided.
(4) Twelve (12) sprinklers [six (6) sprinklers on two levels] where only two levels of in-rack sprinklers are provided.
(5) Eighteen (18) sprinklers [six (6) sprinklers on the top three levels] where more than two levels of in-rack sprinklers are provided.

[**30B:**6.4.2.9.1]

61.3.4.2.9.2 Where in-rack sprinklers are not shielded by horizontal barriers, water shields shall be provided above the sprinklers or listed intermediate level/rack sprinklers shall be used. [**30B:**6.4.2.9.2]

61.3.4.2.9.3 When in-rack sprinklers are necessary to protect a higher hazard commodity that occupies only a portion of the length of a rack, the following shall apply:

(1) In-rack sprinklers shall be extended a minimum of 2.4 m (8 ft) or one bay, whichever is greater, in each direction along the rack on either side of the higher hazard.
(2) The in-rack sprinklers protecting the higher hazard shall not be required to be extended across the aisle.

[**30B:**6.4.2.9.3]

61.3.4.2.9.4 Where a storage rack, due to its length, requires less than the number of in-rack sprinklers specified, only those in-rack sprinklers in a single rack need to be included in the calculation. [**30B:**6.4.2.9.4]

61.3.4.2.9.5* In-rack sprinklers shall be located at an intersection of the transverse and longitudinal flues while not exceeding the maximum spacing rules. [**30B:**6.4.2.9.5]

A.61.3.4.2.9.5 In-rack sprinklers have proven to be the most effective way to fight fires in rack storage. To accomplish this, however, in-rack sprinklers must be located where they will operate early in a fire as well as direct water where it will do the most good. Simply maintaining a minimum horizontal spacing between sprinklers does not achieve this goal, because fires in rack storage develop and grow in transverse and longitudinal flues, and in-rack sprinklers do not operate until flames actually impinge on them. To ensure early operation and effective discharge, in-rack sprinklers in the longitudinal flue of open-frame racks must be located at transverse flue intersections. The commodity loads shown in Figure 6.3.2.7(a) through Figure 6.3.2.7(e) of NFPA 30B are typically 1.2 m (4 ft) cubes. Accounting for flue spaces and vertical clear space between loads, this puts the in-rack sprinklers shown in the figures approximately 1.4 m (4.5 ft) apart horizontally when they are between each load and approximately 2.7 m (9 ft) apart horizontally when they are spaced at every other load. If the length or width of loads exceeds 1.2 m (4 ft), in-rack sprinklers should still be positioned at flue intersections, but additional sprinklers may be necessary between the loads. [**30B:**A.6.3.9.2.5]

61.3.4.2.9.5.1 Where no transverse flues exist, in-rack sprinklers shall not exceed the maximum spacing rules. [**30B:**6.4.2.9.5.1]

61.3.4.2.9.6 A minimum 150 mm (6 in.) vertical clearance shall be maintained between the sprinkler deflectors and the top of the tier of storage. [**30B:**6.4.2.9.6]

61.3.4.2.9.7 Horizontal barriers used in conjunction with in-rack sprinklers to impede vertical fire development shall be constructed of minimum 22 ga sheet metal, 10 mm (⅜ in.) plywood, or similar material and shall extend the full length and depth of the rack. [**30B:**6.4.2.9.7]

61.3.4.2.9.7.1 Barriers shall be fitted within 50 mm (2 in.) horizontally around rack uprights. [**30B:**6.4.2.9.7.1]

61.3.4.2.10 Installations of hose connections shall meet the requirements of NFPA 13. [**30B:**6.4.2.10]

61.3.4.2.10.1 Subject to the approval of the AHJ, hose stations shall not be required to be installed in storage areas. [**30B:**6.4.2.10.1]

61.3.4.2.11 Storage height and building heights shall comply with Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B. [**30B:**6.4.2.11]

61.3.4.2.12 Solid shelving shall comply with 61.3.4.2.12.1 through 61.3.4.2.12.3. [**30B:**6.4.2.12]

61.3.4.2.12.1 Solid shelving that is installed in racks that contain Level 2 and Level 3 aerosol products shall be protected in accordance with Table 6.4.2.7(e) through Table 6.4.2.7(l) of NFPA 30B, whichever is applicable. [**30B:**6.4.2.12.1]

61.3.4.2.12.2 In addition to the in-rack sprinklers shown in Figure 6.4.2.7(a) through Figure 6.4.2.7(e) of NFPA 30B, whichever is applicable, a face sprinkler shall be provided directly below the solid shelf or the elevation of the solid shelf if the face sprinkler is located in a transverse flue. [**30B:**6.4.2.12.2]

61.3.4.2.12.3 The face sprinklers below the shelving required by 61.3.4.2.12.2 shall be not greater than 8 ft (2.4 m) apart as far as the solid shelving level extends. [**30B:**6.4.2.12.3]

61.3.4.2.13 Where spray sprinklers are utilized for ceiling protection, sprinkler spacing shall not exceed 100 ft^2 (9.3 m^2) unless otherwise permitted by 61.3.4.2.14. [**30B:**6.4.2.13]

61.3.4.2.14 Ordinary or intermediate temperature rated K = 25.2 extended-coverage spray sprinklers shall be permitted to be used for all density spray sprinkler design criteria in Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B when installed in accordance with their listing. [**30B:**6.4.2.14]

61.3.4.2.15 The ceiling heights in Table 6.4.2.7(e) through Table 6.4.2.7(l) of NFPA 30B shall be permitted to be increased by a maximum of 10 percent if an equivalent percent increase in ceiling sprinkler design density is provided. This shall only apply to spray sprinkler protection criteria. [**30B:**6.4.2.15]

61.3.4.2.16 Protection systems that are designed and developed based on full-scale fire tests performed at an approved test facility or on other engineered protection schemes shall be considered an acceptable alternative to the protection criteria set forth in Section 6.3 of NFPA 30B. Such alternative protection systems shall be approved by the AHJ. [**30B:**6.4.2.16]

61.3.4.2.17 Rack storage shall be arranged so that a minimum aisle width of 8 ft (2.4 m) is maintained between rows of racks and between racks and adjacent solid pile or palletized storage. [**30B:**6.4.2.17]

61.3.4.2.18 Where protection is provided by ESFR sprinklers, aisle width shall be not less than 4 ft (1.2 m). [**30B:**6.4.2.18]

61.3.4.2.19 Solid pile and palletized storage shall be arranged so that no storage is more than 25 ft (7.6 m) from an aisle. Aisles shall be not less than 4 ft (1.2 m) wide. [**30B:**6.4.2.19]

N **61.3.4.3 Aerosol Products in Plastic Containers Greater Than 4 fl oz (118 ml) and Not More Than 33.8 fl oz (1000 ml).**

N **61.3.4.3.1 Fire Protection — Plastic Aerosol 1 Products.**

N **61.3.4.3.1.1** Plastic aerosol 1 products shall be permitted to be stored in a general-purpose warehouse without isolation. [**30B:**6.5.1.1]

N **61.3.4.3.1.2*** Plastic aerosol 1 products shall be considered equivalent to Class III commodities, as defined in NFPA 13. [**30B:**6.5.1.2.]

N **A.61.3.4.3.1.2** The maximum quantity of storage of plastic aerosol X products is limited to what is provided in 61.3.4.3.1.2 because no demonstrated protection criteria are available.

N **61.3.4.3.1.3** In cases where the storage of plastic aerosol 1 products is required to be protected, they shall be protected in accordance with the requirements of NFPA 13. [**30B:**6.5.1.3]

N **61.3.4.3.2 Fire Protection — Plastic Aerosol X Products.**

N **61.3.4.3.2.1** Storage of plastic aerosol X products in occupancies other than warehouses or mercantile occupancies, such as in assembly, business, educational, industrial, and institutional occupancies, shall be permitted up to a maximum of 100 lb (45 kg) net weight. [**30B:**6.5.2.1]

N **61.3.4.3.2.2** Solid pile, palletized, or rack storage of plastic aerosol X products shall be permitted in a general-purpose warehouse or an aerosol warehouse regardless of protection level up to a maximum of 250 lb (115 kg). [**30B:**6.5.2.2]

61.4 Mercantile Occupancies

61.4.1 Plastic Aerosol X Products. Plastic aerosol X products shall be permitted to be stored in mercantile occupancies up to a maximum quantity of 100 lb (45 kg) net weight. [**30B:**7.1]

61.4.2 Sales Display Areas — Aerosol Product Storage Not Exceeding 8 ft (2.4 m) High.

61.4.2.1 Level 1 aerosol products and plastic aerosol 1 products in sales display areas shall not be limited. [**30B:**7.2.1]

61.4.2.2 Aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall be removed from combustible cartons, or the cartons shall be display-cut, when located in sales display areas. [**30B:**7.2.2]

61.4.2.2.1 Cartoned display of aerosol cooking spray products shall be permitted provided the area is protected in accordance with Table 6.3.2.3(a) or Table 6.3.2.3(b) of NFPA 30B, or the area is protected in accordance with Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B, or the maximum quantity of cartoned display complies with 61.4.2.3.1. [**30B:**7.2.2.1]

61.4.2.2.2 Cartoned display of Level 2 aerosol products and Level 3 aerosol products shall be permitted, provided the area is either protected in accordance with Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B or the maximum quantity of cartoned display complies with 61.4.2.3.1. [**30B:**7.2.2.1]

61.4.2.3 Aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products in sales display areas shall not exceed the maximum quantities given in 61.4.2.3.1 and 61.4.2.3.2 according to the protection provided. [**30B:**7.2.3]

61.4.2.3.1 In sales display areas that are nonsprinklered or whose sprinkler system does not meet the requirements of 61.4.2.3.2, the total aggregate quantity of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall not exceed 2 lb/ft^2 (9.8 kg/m^2) of total sales display area, up to the quantities specified in Table 61.4.2.3.1. [**30B:**7.2.3.1]

61.4.2.3.1.1 No single 10 ft × 10 ft (3 m × 3 m) section of sales display area shall contain an aggregate quantity of more than 1000 lb (454 kg) net weight aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products. [**30B:**7.2.3.1.1]

61.4.2.3.2 In sales display areas that are sprinklered in accordance with NFPA 13, for at least Ordinary Hazard (Group 2) occupancies, the total aggregate quantity aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall not exceed 2 lb/ft^2 (9.8 kg/m^2) of total sales display area. [**30B:**7.2.3.2]

61.4.2.3.2.1 No single 10 ft × 10 ft (3 m × 3 m) section of sales display area shall contain an aggregate quantity of more than 1000 lb (454 kg) net weight of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products. [**30B:**7.1.3.2.1]

61.4.2.4 Aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall be securely stacked to not more than 6 ft (1.8 m) high from base to top of the storage array unless on fixed shelving. [**30B:**7.2.4]

TABLE 61.4.2.3.1 *Maximum Quantity per Floor of Aerosol Cooking Spray Products, Level 2 Aerosol Products, and Level 3 Aerosol Products, and Aerosol Products in Plastic Containers*

	Max. Net Weight per Floor	
Floor	**lb**	**kg**
Basement	Not Permitted	
Ground	2500	1135
Upper	500	227

[**30B:**Table 7.2.3.1]

61.4.2.4.1 Shelving shall be of stable construction and storage shall not exceed 8 ft (2.4 m) in height. [**30B:**7.2.4.1]

61.4.3 Sales Display Areas — Aerosol Products Storage Exceeding 8 ft (2.4 m) High.

The storage and display of aerosol products in bulk retail establishments present additional fire protection challenges beyond those found in separate retail display or storage occupancies. Limitations are provided to allow for the uncartoned display of aerosol products on lower shelving, with palletized, cartoned products displayed above. The sprinkler protection for such facilities is required to comply with the aerosol sprinkler protection criteria provided for warehouses.

61.4.3.1 Storage and display of Level 1 aerosol products and plastic aerosol 1 products in sales display areas shall not be limited. [**30B:**7.3.1]

61.4.3.2 Uncartoned or display-cut (case-cut) aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products that are stored for display no more than 6 ft (1.8 m) above the floor shall be permitted where protection is installed in accordance with 61.4.3.3, based on the highest level of aerosol product in the array and the packaging method of the storage above 6 ft (1.8 m). [**30B:**7.3.2]

61.4.3.3 Protection.

61.4.3.3.1 The storage and display of aerosol cooking spray products in metal containers only shall be protected in accordance with Table 6.3.2.3(a) or Table 6.3.2.3(b) of NFPA 30B, or shall be protected in accordance with Table 6.4.2.7(a) through Table 6.4.2.7(l) of NFPA 30B. The storage and display of Level 2 and Level 3 aerosol products in metal containers only shall be protected in accordance with Table 6.3.2.7(a) through Table 6.3.2.7(l) of NFPA 30B, whichever is applicable. [**30B:**7.3.3.1]

61.4.3.3.1.1 Where in-rack sprinklers are required by Table 6.43.2.7(e) through Table 6.4.2.7(l) of NFPA 30B and where the aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products are stored for display below the 6 ft (1.8 m) level, the first tier of in-rack sprinklers shall be installed above the display, but not more than 6 ft (1.8 m) above the floor level. [**30B:**7.2.3.1.1]

61.4.3.3.2 Noncombustible draft curtains shall extend down a minimum of 2 ft (0.61 m) from the ceiling and shall be installed at the interface between ordinary and high-temperature sprinklers. [**30B:**7.3.3.2]

61.4.3.4 Storage and display of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall not exceed 10,000 lb (4,540 kg) net weight within any 25,000 ft^2 (2,323 m^2) of sales display area. [**30B:**7.2.4]

61.4.3.4.1 Aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol product display areas shall be separated from each other by a minimum of 25 ft (7.6 m). [**30B:**7.2.4.1]

61.4.3.5 The area of the design for the required ceiling sprinkler system shall extend 20 ft (6 m) beyond the area devoted to storage of aerosol cooking spray products or Level 2 aerosol product and Level 3 products. [**30B:**7.3.5]

61.4.3.6 Storage and display of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall be separated from the storage of flammable and combustible liquids by a minimum distance of 25 ft (7.6 m) or by a segregating wall or noncombustible barrier. [**30B:**7.3.6]

The aerosol product sprinkler protection criteria provided in NFPA 30B is based on full-scale testing of aerosol product storage arrays. These tests typically involved a "point" ignition source.

Flammable and combustible liquids stored or displayed in the vicinity of aerosol storage could result in a pool fire exposing the aerosol products. A pool fire exposure is a much more severe ignition scenario than the point ignition source utilized in the aerosol full-scale test programs. Therefore, flammable and combustible liquids need to be physically separated from aerosol product storage, and precautions should be taken to prevent the flow of flammable and combustible liquids underneath the aerosol storage arrays.

61.4.3.6.1 Where aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products are stored within 25 ft (7.6 m) of flammable and combustible liquids, beneath the noncombustible barrier shall be liquidtight at the floor to prevent spilled liquids from flowing beneath the aerosol products. [**30B:**7.3.6.1]

61.4.3.7 The sales display area shall meet the requirements for mercantile occupancies in NFPA *101*. [**30B:**7.3.7]

61.4.4 Back Stock Storage Areas.

61.4.4.1 Where back stock areas are separated from sales display areas by construction having a minimum 1-hour fire resistance rating, storage of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products shall meet the requirements of Chapter 6 of NFPA 30B. [**30B:**7.4.1]

61.4.4.2 Where back stock areas are not separated from sales display areas by construction having a minimum 1-hour fire resistance rating, the quantity of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products in back stock areas shall be included in the total allowable quantities specified in 61.4.2.3 or 61.4.3.4. [**30B:**7.4.2]

61.4.4.2.1 Protection shall be provided in accordance with 61.4.3.3. [**30B:**7.3.2.1]

61.4.4.3 An additional quantity of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products, up to a maximum of 500 lb (227 kg) net weight, shall be permitted in back stock areas where the additional quantities are stored in flammable liquid storage cabinets that meet the requirements of Section 9.5 of NFPA 30. [**30B:**7.4.3]

61.4.4.4 Storage of aerosol cooking spray products, Level 2 aerosol products, and Level 3 aerosol products in separate, inside flammable liquids storage rooms shall meet the requirements of 6.3.7 of NFPA 30B. [**30B:**7.4.4]

61.5 Operations and Maintenance

61.5.1 Means of Egress. Means of egress and exits shall be maintained in accordance with NFPA *101*. [**30B:**8.1]

Means of egress, including doors, stairs, corridors, and aisles, must be maintained clear of obstructions to provide free travel to a safe location outside the building in the event of a fire, without passing through a more hazardous area. Where egress doors are provided with locks or latches, they must be arranged such that they can be opened with not more than one latch- or lock-releasing operation and must not require the use of keys, tools, or special knowledge or effort. For example, egress doors must not be arranged such that an occupant needs to swipe a key card or enter a numerical code to allow the door to open in the direction of egress travel. Special locking arrangements must comply with 14.5.3.

61.5.2 Powered Industrial Trucks.

61.5.2.1 The use and selection of powered industrial trucks shall comply with Section 10.17. [**30B:**8.2.1]

See Section 10.17 for information on powered industrial trucks, which must comply with NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations.*

61.5.2.2 Only trained and authorized operators shall be allowed to operate powered industrial trucks. [**30B:**8.2.2]

61.5.2.3 Operator training shall be equivalent to that specified by ANSI/ASME B56.1, *Safety Standard for Low-Lift and High-Lift Trucks*. [**30B:**8.2.3]

61.5.2.4 Loads.

61.5.2.4.1 If the type of load handled presents a hazard of backward falls, the powered industrial truck shall be equipped with a vertical load backrest extension. [**30B:**8.2.4.1]

61.5.2.4.2 For loads that are elevated above the mast of the truck, the backrest extension shall reach at least halfway into the uppermost pallet load. [**30B:**8.2.4.2]

61.5.3 Control of Ignition Sources.

61.5.3.1 Sources of Ignition.

61.5.3.1.1 In areas where flammable gases or flammable vapors might be present, precautions shall be taken to prevent ignition by eliminating or controlling sources of ignition. Sources of ignition include, but are not limited to, the following:

(1) Open flames
(2) Lightning
(3) Hot surfaces
(4) Radiant heat
(5) Smoking
(6) Cutting and welding
(7) Spontaneous ignition
(8) Frictional heat or sparks
(9) Static electricity
(10) Electrical arcs and sparks
(11) Stray currents
(12) Ovens, furnaces, and other heating equipment
(13) Automotive vehicles
(14) Material-handling equipment [**30B:**8.3.1.1]

61.5.3.2 Smoking shall be strictly prohibited, except in designated smoking areas. [**30B:**8.3.2]

61.5.3.3* Welding, cutting, and similar spark-producing operations shall not be permitted in areas that contain aerosol products, until a written permit authorizing the work has been issued. [**30B:**8.3.3]

A.61.5.3.3 See NFPA 51B for further information. [**30B:**A.8.3.3]

61.5.3.3.1 The permit shall be issued by a person in authority following an inspection of the area to assure that proper precautions have been taken and will be followed until completion of the work. [**30B:**8.3.3.1]

61.5.4 Aisles. Storage in aisles shall be prohibited so as to permit access for fire fighting, salvage, and removal of stored commodities. [**30B:**8.4]

61.5.5 Waste Disposal.

61.5.5.1 Filled or partly filled aerosol containers shall be separated from all other rubbish and trash. [**30B:**8.5.1]

61.5.5.1.1 Filled or partly filled aerosol containers shall be placed in noncombustible waste containers. [**30B:**8.5.1.1]

61.5.5.2 Filled or partly filled aerosol containers shall not be disposed of in compactors, balers, or incinerators that crush the container or heat its contents. [**30B:**8.5.2]

61.5.5.2.1 Equipment and facilities that are specifically designed for the disposal of aerosol containers shall be permitted to dispose of filled or partly filled aerosol containers. [**30B:**8.5.2.1]

61.5.6 Inspection and Maintenance.

61.5.6.1 A written and documented preventive maintenance program shall be developed for equipment, machinery, and processes that are critical to fire-safe operation of the facility. [**30B:**8.6.1]

61.5.6.2 Critical detection systems and their components, emergency trips and interlocks, alarms, and safety shutdown systems shall be inspected on a regularly scheduled basis, and any deficiencies shall be immediately corrected. [**30B:**8.6.2]

61.5.6.2.1 Items in this inspection schedule shall include, but are not limited to, the following:

(1) Gas detection systems
(2) Deflagration suppression systems
(3) Deflagration vent systems
(4) Ventilation and local exhaust systems
(5) Propellant charging room door interlocks
(6) Process safety devices
(7) Fire alarm systems [**30B:**8.6.2.1]

61.5.6.3 Maintenance. [**68:**11.10]

61.5.6.3.1 Vent closure maintenance shall be performed after every act of nature or process upset condition to ensure that the closure has not been physically damaged and there are no obstructions, including but not limited to snow, ice, water, mud, or process material, that could lessen or impair the efficiency of the vent closure. [**68:**11.10.1]

Δ **61.5.6.3.2** An inspection shall be performed in accordance with 11.4.4 of NFPA 68 after every process maintenance turnaround. [**68:**11.10.2]

61.5.6.3.3 If process material has a tendency to adhere to the vent closure, the vent closure shall be cleaned periodically to maintain vent efficiency. [**68:**11.10.3]

61.5.6.3.4 Process interlocks, if provided, shall be verified. [**68:**11.10.4]

61.5.6.3.5 Known potential ignition sources shall be inspected and maintained. [**68:**11.10.5]

61.5.6.3.6 Records shall be kept of any maintenance and repairs performed. [**68:**11.10.6]

61.5.7* Static Electricity. All process equipment and piping involved in the transfer of flammable liquids or gases shall be connected to a static-dissipating earth ground system to prevent accumulations of static charge. [**30B:**8.7]

Δ **A.61.5.7** See NFPA 77. [**30B:**A.8.7]

Where not dissipated to ground, a buildup of static electricity can serve as an ignition source where flammable vapors are present and potentially result in a deflagration. By properly grounding equipment as described in NFPA 77, *Recommended Practice on Static Electricity,* any static charge should be safely dissipated, thus eliminating a potential ignition source.

In the 2018 edition of NFPA 1, *Fire Code,* Chapter 62 is reserved for future use.

Compressed Gases and Cryogenic Fluids

63

Chapter 63 contains requirements for compressed gases and cryogenic fluids. For the 2018 edition of this *Code*, Chapter 63 includes extracts from the 2016 edition of NFPA 55, *Compressed Gases and Cryogenic Fluids Code*.

The 2016 edition of NFPA 55 has the following significant changes from the 2013 edition:

1. Clarification and organization of the requirements in Chapter 10 for gaseous hydrogen systems into three tiers based on the quantity of hydrogen stored: less than or equal to the maximum allowable quantity (MAQ), greater than the MAQ but less than bulk quantity, and bulk systems
2. Changes to the requirements in Chapter 7 for emergency isolation
3. Complete revision of Chapter 13, Insulated Liquid Carbon Dioxide Systems, with a focus on carbon dioxide beverage systems
4. A new chapter on liquid nitrous oxide systems (Chapter 16)

The term *compressed gas* is defined in 3.3.140.1 of this *Code* as "a material, or mixture of materials, that (1) is a gas at 68°F (20°C) or less at an absolute pressure of 14.7 psi (101.3 kPa) and (2) has a boiling point of 68°F (20°C) or less at an absolute pressure of 14.7 psi (101.3 kPa) and that is liquefied, nonliquefied, or in solution, except those gases that have no other health or physical hazard properties are not considered to be compressed until the pressure in the packaging exceeds an absolute pressure of 40.6 psi (280 kPa) at 68°F (20°C)." The states of a compressed gas are categorized as follows:

1. Nonliquefied compressed gases are gases, other than those in solution, that are in packaging under the charged pressure and are entirely gaseous at a temperature of 68°F (20°C).
2. Liquefied compressed gases are gases that, in packaging under the charged pressure, are partially liquid at a temperature of 68°F (20°C).
3. Compressed gases in solution are nonliquefied gases that are dissolved in a solvent.
4. Compressed gas mixtures consist of a mixture of two or more compressed gases contained in packaging, the hazard properties of which are represented by the properties of the mixture as a whole.

Cryogenic fluids represent a transient state of a gas that is created through the use of refrigeration. Cryogenic fluids cannot exist in liquid form or partial liquid form at temperatures of 68°F (20°C); hence, they are not compressed gases as defined.

Chapter 63 covers cylinder and bulk gases and cryogenic fluids at all facilities, including gas manufacturing facilities, bulk oxygen systems, gaseous hydrogen systems, and liquefied hydrogen systems — all at consumer sites.

63.1 General Provisions

63.1.1 Application.

63.1.1.1* The installation, storage, use, and handling of compressed gases and cryogenic fluids in portable and stationary containers, cylinders, equipment, and tanks in all occupancies shall comply with the requirements of Chapter 63; NFPA 55, and Sections 60.1 through 60.4 of this *Code*.

A.63.1.1.1 See A.1.3.2.

63.1.1.2 Where the provisions of Chapter 63 or NFPA 55 conflict with the provisions of Chapter 60, the provisions of Chapter 63 and NFPA 55 shall apply.

63.1.1.3 The requirements in this chapter shall apply to users, producers, distributors, and others who are involved with the storage, use, or handling of compressed gases or cryogenic fluids. [**55:**1.3]

Δ **63.1.1.4 Specific Applications.** Chapter 63 shall not apply to the following:

(1)* Off-site transportation of materials covered by Chapter 63.

A.63.1.1.4(1) For regulations on the transportation of gases, see 49 CFR 100–185, "Transportation" and *Transportation of Dangerous Goods Regulations*. [**55:**A.1.1.2(1)]

(2) Storage, use, and handling of radioactive gases in accordance with NFPA 801, *Standard for Fire Protection for Facilities Handling Radioactive Materials*.

(3)* Use and handling of medical compressed gases at health care facilities in accordance with NFPA 99, *Health Care Facilities Code*.

Δ **A.63.1.1.4(3)** Bulk compressed gas and cryogenic fluid system installations are intended to be covered by the requirements of this *Code*. Instrumentation and alarms that are attendant to the system and designed to interface with the application in a health care facility are to be retained within the purview of NFPA 99. [**55:**A.1.1.2(3)]

Refer to Section 63.11 for requirements for liquid oxygen (LOX) in home health care.

(4) Systems consisting of cylinders of oxygen and cylinders of fuel gas used for welding and cutting in accordance with NFPA 51, *Standard for the Design and Installation of Oxygen–Fuel Gas Systems for Welding, Cutting, and Allied Processes*.

(5)* Flammable gases used as a vehicle fuel when stored on a vehicle.

Δ **A.63.1.1.4(5)** For information, see NFPA 52 or NFPA 58. [**55:**A.1.1.2(5)]

(6)* Storage, use, and handling of liquefied and nonliquefied compressed gases in laboratory work areas in accordance with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*.

A.63.1.1.4(6) The storage and use of compressed gases and cryogenic fluids outside the boundaries of laboratory work areas are covered by NFPA 55. [**55:**A.1.1.2(6)]

(7) Storage, use, and handling of liquefied petroleum gases in accordance with NFPA 58, *Liquefied Petroleum Gas Code*.

(8) Storage, use, and handling of compressed gases within closed-cycle refrigeration systems complying with the mechanical code.

(9) Liquefied natural gas (LNG) storage at utility plants under NFPA 59A, *Standard for the Production, Storage, and Handling of Liquefied Natural Gas (LNG)*.

(10) Compressed natural gas (CNG) and liquefied natural gas (LNG), utilized as a vehicle fuel in accordance with NFPA 52, *Vehicular Gaseous Fuel Systems Code*.

(11)* Compressed hydrogen gas (GH2), or liquefied hydrogen gas (LH2) generated, installed, stored, piped, used, or handled in accordance with NFPA 2, *Hydrogen Technologies Code*, when there are no specific or applicable requirements in NFPA 55.

Δ **A.63.1.1.4(11)** NFPA 55 is used as the source document for the fundamental requirements for compressed hydrogen gas (GH2), or liquefied hydrogen gas (LH2) system installations. Correlation between NFPA 55 and NFPA 2 is the responsibility of the two technical committees involved. The installation requirements for bulk GH2 or LH2 are viewed as fundamental provisions. On the other hand, use-specific requirements for designated applications such as vehicular fueling are not resident in NFPA 55 and are under the purview of the NFPA 2 Technical Committee. Where there are specific provisions or controls included in NFPA 55, the specific controls of NFPA 55 will govern except that modifications made to provisions that have been extracted can be followed when the modifications have been made within NFPA's extract procedure as indicated in the *Manual of Style for NFPA Technical Committee Documents*. [**55:**A.1.1.2(11)]

(12) Nonflammable mixtures of ethylene oxide with other chemicals.

(13) Ethylene oxide in chambers 10 scf (0.283 Nm^3) or less in volume or for containers holding 7.05 oz (200 g) of ethylene oxide or less.

[**55:**1.1.2]

63.1.2 Permits Permits, where required, shall comply with Section 1.12.

For permit requirements for compressed gas facility closures, see 63.1.2.1. A number of permits might be required, depending on the operations using various compressed gases. The principal permit that applies to the hazards covered in Chapter 63, however, is a permit for compressed gases. Also see Section 1.12 for additional provisions regarding permits.

63.1.2.1 The permit applicant shall apply for approval to close storage, use, or handling facilities at least 30 days prior to the termination of the storage, use, or handling of compressed or liquefied gases.

63.1.2.2 Such application shall include any change or alteration of the facility closure plan filed pursuant to 60.1.4.4.

63.1.2.3 This 30-day period shall be permitted to be waived by the AHJ if special circumstances require such waiver.

63.1.2.3.1 Permits shall not be required for routine maintenance.

63.1.2.3.2 For repair work performed on an emergency basis, application for permit shall be made within 2 working days of commencement of work.

63.1.3.52 Valve Protection Cap. See 3.3.282.4.

63.1.3.53 Valve Protection Device. See 3.3.282.5.

63.1.4 Hazardous Materials Classification.

Hazard classification of compressed gases is a critical decision, because the safety requirements are based on the material classification and the amount of material being stored.

Not all hazardous materials are placed into the high hazard category, and some of these materials have been recognized as being of low ordinary hazard, depending on their nature in a fire. Inert compressed gases and cryogenic fluids are two examples; there are others. Compressed gases and cryogenic fluids represent the gas phase of an array of hazardous materials. As the genre of hazardous materials is expanded, there are other materials in hazard categories or hazard classes that may in fact be high hazard materials by definition, but which in some cases do not have an MAQ and, therefore, are not required to comply with the requirements for high hazard occupancies. Examples of such materials are Class IIIB combustible liquids, Class 1 unstable reactive materials (including gases), Class 1 water-reactive solids and liquids, Class 1, 2, and 3 water-reactive gases, Class 1 oxidizing solids and liquids, and Class IV and V organic peroxides.

Δ **63.1.4.1* Pure Gases.** Hazardous materials shall be classified according to hazard categories as follows:

(1) Physical hazards, which shall include the following:
   (a) Flammable gas
   (b) Flammable cryogenic fluid
   (c) Oxidizing gas
   (d) Oxidizing cryogenic fluid
   (e) Pyrophoric gas
   (f) Unstable reactive (detonable) gas, Class 3 or Class 4
   (g) Unstable reactive (nondetonable) gas, Class 3
   (h) Unstable reactive gas, Class 1 or Class 2
(2) Health hazards, which shall include the following:
   (a) Corrosive gas
   (b) Cryogenic fluids
   (c) Highly toxic gas
   (d) Toxic gas

[**55:**5.1.1]

N **A.63.1.4.1** Not all hazardous materials are placed into the high hazard category, and some of these materials have been recognized as being of low ordinary hazard, depending on their nature in a fire. Inert compressed gases and cryogenic fluids are one example; there are others. Compressed gases and cryogenic fluids represent the gas phase of an array of hazardous materials. As the genre of hazardous materials is expanded, there are other materials in hazard categories or hazard classes that may in fact be high hazard materials by definition, but which in some cases do not have a MAQ and, therefore, are not required to comply with the requirements for high hazard occupancies. Examples of such materials are Class IIIB combustible liquids, Class 1 unstable reactive materials (including gases), Class 1 water-reactive solids and liquids, Class 1-3 water-reactive gases, Class 1 oxidizing solids and liquids, and Class IV and V organic peroxides. [**55:**A.5.1.1]

63.1.4.2 Other Hazards. Although it is possible that there are other known hazards, the classification of such gases is not within the scope of Chapter 63 and they shall be handled, stored, or used as an *other gas*. [**55:**5.1.2]

63.1.4.3 Mixtures. Mixtures shall be classified in accordance with the hazards of the mixture as a whole. [**55:**5.1.3]

63.1.4.4 Responsibility for Classification. Classification shall be performed by an approved organization, individual, or testing laboratory. [**55:**5.1.4]

63.1.4.4.1 Toxicity. The toxicity of gas mixtures shall be classified in accordance with CGA P-20, *Standard for the Classification of Toxic Gas Mixtures,* or by testing in accordance with the requirements of 29 CFR 1910.1000, DOT 49 CFR 173, or ISO 10298, *Determination of toxicity of a gas or gas mixture*. [**55:**5.1.4.1]

63.1.4.4.2 Flammability of Gas Mixtures. For gas mixtures other than those containing ammonia and nonflammable gases, flammability of gas mixtures shall be classified in accordance with CGA P-23, *Standard for Categorizing Gas Mixtures Containing Flammable and Nonflammable Components,* or by physical testing in accordance with the requirements of ASTM E681, *Standard Test Method for Concentration Limits of Flammability of Chemicals (Vapors and Gases),* or ISO 10156, *Gases and gas mixtures — Determination of fire potential and oxidizing ability for the selection of cylinder valve outlets*. [**55:**5.1.4.2]

63.2 Building-Related Controls

63.2.1 General.

63.2.1.1 Occupancy.

63.2.1.1.1 Occupancy Requirements. Occupancies containing compressed gases and cryogenic fluids shall comply with Section 63.2 in addition to other applicable requirements of NFPA 55. [**55:**6.1.1.1]

63.2.1.1.2 Occupancy Classification. The occupancy of a building or structure, or portion of a building or structure, shall be classified in accordance with the building code. [**55:**6.1.1.2]

63.2.2 Control Areas.

Δ **63.2.2.1 Construction Requirements.** Control areas shall be separated from each other by fire barriers in accordance with Table 63.2.2.1 [**55:**6.2.1]

Δ **63.2.2.2 Number of Control Areas.** The maximum number of control areas within a building shall be in accordance with Table 63.2.2.1. [**400:**5.2.2.1]

Δ **63.2.2.3** Where only one control area is present in a building, no special construction provisions shall be required. [**400:**5.2.2.2]

63.2.2.4 Quantities Less Than or Equal to the MAQ. Indoor control areas with compressed gases or cryogenic fluids stored or used in quantities less than or equal to those shown in Table 63.2.3.1.1 shall be in accordance with 63.2.1, 63.2.3.1.6, 63.2.3.1.7, 63.2.7, 63.2.8, 63.2.12, 63.2.15, 63.2.16, and the applicable provisions of Chapters 1 through 5 and Chapters 7 through 16 of NFPA 55. [**55:**6.2.4]

63.2.3 Occupancy Protection Levels.

63.2.3.1 Quantity Thresholds for Compressed Gases and Cryogenic Fluids Requiring Special Provisions.

Δ **63.2.3.1.1 Threshold Exceedences.** Where the quantities of compressed gases or cryogenic fluids stored or used within an indoor control area exceed those shown in Table 63.2.3.1.1, the area shall meet the requirements for Protection Levels 1 through 5 in accordance with the building code, based on the requirements of 63.2.3.2. [**55:**6.3.1.1]

Several concepts are important for the user to understand when using Table 63.2.3.1.1. First, the quantities shown in the table are those beneath which no requirements for specific protection levels apply. Therefore, to use the table, the protection level for the materials(s) being stored must be determined. Second, the amounts shown are the quantities per control area, not amounts for the entire facility or building. The provision establishes when the requirements for protection levels are to be applied. Reference to 63.2.3.2 is made in 63.2.3.1.1 in order to determine the specifics regarding the various protection levels.

The listing in the table for nonflammable gas was removed for the 2010 edition of NFPA 55, because it was not a regulatory hazard classification and was replaced by a new row for inert gas to clarify that MAQs are not applicable to gases that are considered to be nonreactive, noncorrosive, or nonflammable. Although there is no limitation on the amount being stored, other requirements still apply to inert gases as a class that must be distinguished from hazardous gases. The change also seeks to clarify circumstances where nonflammable gas — a term that can be used to define oxygen — might have been used in place of an inert agent and created an unintended level of risk.

63.2.3.1.2 Quantities Greater Than the MAQ. Building-related controls in areas with compressed gases or cryogenic fluids stored or used within an indoor area in quantities greater than those shown in Table 63.2.3.1.1 shall be in accordance with the requirements of Section 63.2. [**55:**6.3.1.2]

Δ ***TABLE 63.2.2.1*** *Design and Number of Control Areas*

Floor Level	Maximum Allowable Quantity per Control Area (%)*	Number of Control Areas per Floor	Fire Resistance Rating for Fire Barriers+ (hr)
Above grade			
>9	5.0	1	2
7–9	5.0	2	2
4–6	12.5	2	2
3	50	2	1
2	75	3	1
1	100	4	1
Below grade			
1	75	3	1
2	50	2	1
Lower than 2	NP	NP	N/A

NP: Not Permitted.

N/A: Not Applicable.

*Percentages represent the MAQ per control area shown in Table 60.4.2.1.1.3, with all of the increases permitted in the footnotes of that table.

+Fire barriers are required to include floors and walls, as necessary, to provide a complete separation from other control areas.

[**400:**Table 5.2.2.1]

NA: Not applicable within the context of NFPA 55 (refer to the applicable building or fire code for additional information on these materials).

NL: Not limited in quantity.

Notes:

(1) For use of control areas, see Section 6.2 of NFPA 55.

(2) Table values in parentheses or brackets correspond to the unit name in parentheses or brackets at the top of the column.

(3) The aggregate quantity in use and storage is not permitted to exceed the quantity listed for storage. In addition, quantities in specific occupancies are not permitted to exceed the limits in the building code.

[a]Measured at NTP [70°F (20°C) and 14.7 psi (101.3 kPa)].

[b]None allowed in unsprinklered buildings unless stored or used in gas rooms or in approved gas cabinets or exhausted enclosures, as specified in this code.

[c]With pressure-relief devices for stationary or portable containers vented directly outdoors or to an exhaust hood.

[d]Quantities are permitted to be increased 100 percent where stored or used in approved cabinets, gas cabinets, exhausted enclosures, gas rooms, as appropriate for the material stored. Where Footnote e also applies, the increase for the quantities in both footnotes is permitted to be applied accumulatively.

[e]Maximum quantities are permitted to be increased 100 percent in buildings equipped throughout with an automatic sprinkler system in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*. Where Footnote d also applies, the increase for the quantities in both footnotes is permitted to be applied accumulatively.

[f]Flammable gases in the fuel tanks of mobile equipment or vehicles are permitted to exceed the MAQ where the equipment is stored and operated in accordance with the applicable fire code.

[g]See NFPA 58, *Liquefied Petroleum Gas Code*, and Chapter 69 for requirements for liquefied petroleum gas (LP-Gas). LP-Gas is not within the scope of NFPA 55 or Chapter 63.

[h]Additional storage locations are required to be separated by a minimum of 300 ft (92 m).

[i]In mercantile occupancies, storage of LP-Gas is limited to a maximum of 200 lb (91 kg) in nominal 1 lb (0.45 kg) LP-Gas containers.

[j]Permitted only in buildings equipped throughout with an automatic sprinkler system in accordance with NFPA 13.

[k]Allowed only where stored or used in gas rooms or in approved gas cabinets or exhausted enclosures, as specified in this code.

[**55:**Table 6.3.1.1]

63.2.3.1.3 Aggregate Allowable Quantities. The aggregate quantity in use and storage shall not exceed the quantity listed for storage. [**55:**6.3.1.3]

63.2.3.1.4 Incompatible Materials. When the classification of materials in individual containers requires the area to be placed in more than one protection level, the separation of protection levels shall not be required, provided the area is constructed to meet the requirements of the most restrictive protection level and that the incompatible materials are separated as required by 63.3.1.11.2. [**55:**6.3.1.4]

63.2.3.1.5 Multiple Hazards. Where a compressed gas or cryogenic fluid has multiple hazards, all hazards shall be addressed and controlled in accordance with the provisions for the protection level for which the threshold quantity is exceeded. [**55:**6.3.1.5]

63.2.3.1.6 Flammable and Oxidizing Gases.

63.2.3.1.6.1 Flammable and oxidizing gases shall not be stored or used in other than industrial and storage occupancies. [**55:**6.3.1.6.1]

63.2.3.1.6.2 Cylinders, containers, or tanks not exceeding 250 scf (7.1 Nm^3) content at normal temperature and pressure (NTP) and used for maintenance purposes, patient care, or operation of equipment shall be permitted. [**55:**6.3.1.6.2]

The provision of 63.2.3.1.6.2 applies to all compressed gases; as specified in the language, all cylinders, containers, and tanks are size restricted unless they are dedicated to the uses indicated.

Δ **63.2.3.1.7 Toxic and Highly Toxic Compressed Gases.** Except for containers or cylinders not exceeding 20 scf (0.6 Nm^3) content at NTP stored or used within gas cabinets or exhausted enclosures of educational occupancies, toxic or highly toxic compressed gases shall not be stored or used in other than industrial and storage occupancies. [**55:**6.3.1.7]

63.2.3.2 Classification of Protection Levels. The protection level required shall be based on the hazard class of the material involved as indicated in 63.2.3.2.1 through 63.2.3.2.5. [**55:**6.3.2]

63.2.3.2.1 Protection Level 1. Occupancies used for the storage or use of unstable reactive Class 4 and unstable reactive Class 3 detonable compressed gases in quantities that exceed the quantity thresholds for gases requiring special provisions shall be classified Protection Level 1. [**55:**6.3.2.1]

63.2.3.2.2 Protection Level 2. Occupancies used for the storage or use of flammable, pyrophoric, and nondetonable, unstable reactive Class 3 compressed gases or cryogenic fluids in quantities that exceed the quantity thresholds for gases requiring special provisions shall be classified as Protection Level 2. [**55:**6.3.2.2]

63.2.3.2.3 Protection Level 3. Occupancies used for the storage or use of oxidizing and unstable reactive Class 2 compressed gases or cryogenic fluids in quantities that exceed the quantity thresholds for gases requiring special provisions shall be classified as Protection Level 3. [**55:**6.3.2.3]

For both Protection Level 2 and Protection Level 3 (63.2.3.2.2 and 63.2.3.2.3), Table 63.2.3.1.1 establishes the quantity thresholds for cryogenic fluids as well as compressed gases. The requirements for protection levels apply to certain cryogenic fluids as well as compressed gases.

63.2.3.2.4 Protection Level 4. Occupancies used for the storage or use of toxic, highly toxic, and corrosive compressed gases in quantities that exceed the quantity thresholds for gases requiring special provisions shall be classified as Protection Level 4. [**55:**6.3.2.4]

63.2.3.2.5 Protection Level 5. Buildings and portions thereof used for fabrication of semiconductors or semiconductor research and development and containing quantities of hazardous materials exceeding the maximum allowable quantities of high hazard level 5 contents permitted in control areas shall be classified as Protection Level 5. [**55:**6.3.2.5]

63.2.4 Gas Rooms. Where a gas room is used to increase the threshold quantity for a gas requiring special provisions or where otherwise required by the material- or application-specific requirements of Chapters 7 through 16 of NFPA 55, the room shall meet the requirements of 63.2.4.1 through 63.2.4.5. [**55:**6.4]

63.2.4.1 Pressure Control. Gas rooms shall operate at a negative pressure in relationship to the surrounding area. [**55:**6.4.1]

63.2.4.2 Exhaust Ventilation. Gas rooms shall be provided with an exhaust ventilation system. [**55:**6.4.2]

63.2.4.3 Construction. Gas rooms shall be constructed in accordance with the building code. [**55:**6.4.3]

63.2.4.4 Separation. Gas rooms shall be separated from other occupancies by a minimum of 1-hour fire resistance. [**55:**6.4.4]

63.2.4.5 Limitation on Contents. The function of compressed gas rooms shall be limited to storage and use of compressed gases and associated equipment and supplies. [**55:**6.4.5]

63.2.5* Detached Buildings. Occupancies used for the storage or use of compressed gases, including individual bulk hydrogen compressed gas systems in quantities exceeding those specified in Table 63.2.5, shall be in detached buildings constructed in accordance with the provisions of the building code. [**55:**6.5]

TABLE 63.2.5 *Detached Buildings Required Where Quantity of Material Exceeds Amount Shown*

Gas Hazard	Class	Quantity of Material: scf	Quantity of Material: Nm^3
Individual bulk hydrogen compressed gas systems	NA	15,000	425
Unstable reactive (detonable)	4 or 3	Quantity thresholds for gases requiring special provisions*	
Unstable reactive (nondetonable)	3	2,000	57
Unstable reactive (nondetonable)	2	10,000	283
Pyrophoric gas	NA	2,000	57

NA: Not applicable.

*See Table 63.2.3.1.1

[**55:** Table 6.5]

N **A.63.2.5** Bulk hydrogen compressed gas systems terminate at the source valve. In cylinder filling or packaging operations, cylinders located on filling manifolds located downstream of the source valve are not considered to be part of the bulk gas system. For definitions of source valve and bulk hydrogen compressed gas system, see 3.3.89 and 3.3.94.9.1 [of NFPA 55]. Additional requirements for source valves can be found in 63.2.19. [**55:**A.6.5]

63.2.6 Weather Protection.

Buildings or structures used for weather protection may or may not be independent detached structures. For example, the typical cylinder dock may abut a building used for the production or storage of compressed gas. It is part of the building that is sheltered by overhead cover but is considered as outdoor storage in order to provide relief from requirements such as mechanical ventilation, explosion control, and sprinkler systems in some cases. In order to "earn" the exemption, the area must be maintained substantially open to the surrounds. Some building codes allow for this dispensation, providing the weather-protected area is limited in size and of noncombustible construction. Allowances are made for area increase based on comparable areas of any building, including the use of sprinkler systems (when otherwise not required) and street frontage based on fire separation distance. To determine the allowable area increases, the construction type and occupancy of the sheltered area must first be determined.

Weather protection cannot be obstructed by enclosing it with perimeter walls that substantially block the free movement of air and accessibility. On the other hand, limited obstructions within a given set of prescriptive controls are acceptable. For example, a cylinder dock on the exterior of the building is allowed to abut the exterior building wall, providing the three remaining walls are open to the exterior. The provisions also allow for the obstruction of multiple walls, providing the total area of the perimeter walls that are obstructed does not exceed 25 percent of the total open perimeter area. To determine this mathematically, the designer would calculate the aggregate perimeter area of all open sides of the building or structure used for weather protection and then demonstrate that obstructed areas (covered by abutting buildings or partial walls) do not exceed 25 percent of the aggregate area.

63.2.6.1 For other than explosive materials and hazardous materials presenting a detonation hazard, a weather protection structure shall be permitted to be used for sheltering outdoor storage or use areas, without requiring such areas to be classified as indoor storage or use. [**55:**6.6.1]

63.2.6.2 Weather protected areas constructed in accordance with 63.2.6.4 shall be regulated as outdoor storage or use. [**55:**6.6.2]

63.2.6.3 Weather protected areas that are not constructed in accordance with 63.2.6.4 shall be regulated as indoor storage or use. [**55:**6.6.2.1]

63.2.6.4 Buildings or structures used for weather protection shall be in accordance with the following:

(1) The building or structure shall be constructed of noncombustible materials.
(2) Walls shall not obstruct more than one side of the structure.
(3) Walls shall be permitted to obstruct portions of multiple sides of the structure, provided that the obstructed area does not exceed 25 percent of the structure's perimeter area.
(4) The building or structure shall be limited to a maximum area of 1500 ft^2 (140 m^2), with increases in area allowed by the building code based on occupancy and type of construction.
(5) The distance from the structure constructed as weather protection to buildings, lot lines, public ways, or means of egress to a public way shall not be less than the distance required for an outside hazardous material storage or use area without weather protection based on the hazard classification of the materials contained.
(6) Reductions in separation distance shall be permitted based on the use of fire barrier walls where permitted for specific materials in accordance with the requirements of Chapters 7 through 11 of NFPA 55.

[**55:**6.6.3]

63.2.7* Electrical Equipment. Electrical wiring and equipment shall be in accordance with this subsection and *NFPA 70*. [**55:**6.7]

Δ **A.63.2.7** Electrical and electronic equipment and wiring for use in hazardous locations as defined in Article 500 of *NFPA 70* should meet the requirements of Articles 500 and 501 of *NFPA 70*. Note that Article 505 also details requirements for this equipment and wiring in hazardous locations and uses a zone classification method rather than the division method of Article 500. [**55:**A.6.7]

63.2.7.1 Standby Power.

63.2.7.1.1 Where the following systems are required by NFPA 55 for the storage or use of compressed gases or cryogenic fluids that exceed the quantity thresholds for gases requiring special provisions, such systems shall be connected to a standby power system in accordance with *NFPA 70*:

(1) Mechanical ventilation
(2) Treatment systems
(3) Temperature controls
(4) Alarms
(5) Detection systems
(6) Other electrically operated systems

[**55:**6.7.1.1]

63.2.7.1.2 The requirements of 63.2.7.1.1 shall not apply where emergency power is provided in accordance with 63.2.7.2 and *NFPA 70*. [**55:**6.7.1.2]

Δ **63.2.7.2 Emergency Power.** When emergency power is required, the system shall meet the requirements for a Level 2 system in accordance with NFPA 110. [**55:**6.7.2]

63.2.8* Employee Alarm System. Where required by government regulations, an employee alarm system shall be provided to allow warning for necessary emergency action as called for in the emergency action plan required by 4.2.1.1 of NFPA 55, or for reaction time for safe egress of employees from the workplace or the immediate work area, or both. [**55:**6.8]

A.63.2.8 Under the requirements of 29 CFR 1910.38 established by OSHA regulations, employers must establish an employee alarm system that complies with 29 CFR 1910.165. The requirements of 29 CFR 1910.165 for the employee alarm system include, but are not limited to, systems that are capable of being perceived above ambient noise or light levels by all employees in the affected portions of the workplace. Tactile devices may be used to alert those employees who would not otherwise be able to recognize the audible or visual alarm. The alarm system can be electrically powered or powered by pneumatic or other means. State, local, or other governmental regulations might also establish requirements for employee alarm systems. [**55:**A.6.8]

Δ **63.2.9 Explosion Control.** Explosion control shall be provided as required by Table 63.2.9 in accordance with NFPA 68 or NFPA 69 where amounts of compressed gases in storage or use exceed the quantity thresholds requiring special provisions. [**55:**6.9]

Explosion control is generally triggered when quantities of gas exceed MAQ limits. Once the potential for explosion hazard has been determined, a means of explosion control should be provided, regardless of the quantities involved.

63.2.10* Fire Protection Systems. Except as provided in 63.2.10.1, buildings or portions thereof required to comply with Protection Levels 1 through 5 shall be protected by an approved automatic fire sprinkler system complying with Section 13.3 and NFPA 13. [**55:**6.10]

Δ ***TABLE 63.2.9*** *Explosion Control Requirements*

Material	Class	Explosion Control Methods: Barricade Construction	Explosion Control Methods: Explosion Venting or Prevention Systems
Flammable cryogenic fluid	—	Not required	Required
Flammable gas	Nonliquefied	Not required	Required
	Liquefied	Not required	Required
Pyrophoric gas	—	Not required	Required
Unstable reactive gas	4	Required	Not required
	3 (detonable)	Required	Not required
	3 (nondetonable)	Not required	Required

[**55:** Table 6.9]

A.63.2.10 The intent of this section is to require a water-based fire extinguishing system to keep vessels containing compressed gases cool in the event of an exposure fire, thereby minimizing the likelihood of a release and associated consequences. Accordingly, alternative fire extinguishing systems, such as dry-chemical or gaseous agent systems, should not be substituted. [**55:**A.6.10]

63.2.10.1 Rooms or areas that are of noncombustible construction with wholly noncombustible contents shall not be required to be protected by an automatic fire sprinkler system. [**55:**6.10.1]

63.2.10.2 Sprinkler System Design.

63.2.10.2.1 Where sprinkler protection is required, the area in which compressed gases or cryogenic fluids are stored or used shall be protected with a sprinkler system designed to be not less than that required by 11.2.3.1.1 of NFPA 13 for the Ordinary Hazard Group 2 density/area curve. [**55:**6.10.2.1]

63.2.10.2.2 When sprinkler protection is required, the area in which the flammable or pyrophoric compressed gases or cryogenic fluids are stored or used shall be protected with a sprinkler system designed to be not less than that required by 11.2.3.1.1 of NFPA 13 for the Extra Hazard Group 1 density/area curve. [**55:**6.10.2.2]

63.2.11 Lighting. Approved lighting by natural or artificial means shall be provided for areas of storage or use. [**55:**6.11]

63.2.12 Hazard Identification Signs.

Δ **63.2.12.1 Location.** Hazard identification signs shall be placed at all entrances to locations where compressed gases are produced, stored, used, or handled in accordance with NFPA 704. [**55:**6.12.1]

63.2.12.1.1 Ratings shall be assigned in accordance with NFPA 704. [**55:**6.12.1.1]

• **63.2.12.1.2** The AHJ shall be permitted to waive 63.2.12.1 where consistent with safety. [**55:**6.12.1.2]

63.2.12.2 Application. Signage shall be provided as specified in 63.2.12.2.1 and 63.2.12.2.2. [**55:**6.12.2]

63.2.12.2.1 Signs. Signs shall not be obscured or removed. [**55:**6.12.2.1]

63.2.12.2.2 No Smoking. Signs prohibiting smoking or open flames within 25 ft (7.6 m) of area perimeters shall be provided in areas where toxic, highly toxic, corrosive, unstable reactive, flammable, oxidizing, or pyrophoric gases are produced, stored, or used. [**55:**6.12.2.2]

See Section 10.9 for smoking prohibitions.

63.2.13 Spill Control, Drainage, and Secondary Containment. Spill control, drainage, and secondary containment shall not be required for compressed gases. [**55:**6.13]

63.2.14 Shelving.

63.2.14.1 Shelves used for the storage of cylinders, containers, and tanks shall be of noncombustible construction and designed to support the weight of the materials stored. [**55:**6.14.1]

Compressed gases can be contained in cylinders, containers, and tanks, all of which can be stored on shelves. The provision clearly describes all the container types, thus eliminating any confusion.

63.2.14.2 In seismically active areas, shelves and containers shall be secured from overturning. [**55:**6.14.2]

63.2.15 Vent Pipe Termination. The termination point for piped vent systems serving cylinders, containers, tanks, and gas systems used for the purpose of operational or emergency venting shall be located to prevent impingement exposure on the system served and to minimize the effects of high temperature thermal radiation or the effects of contact with the gas from the escaping plume to the supply system, personnel, adjacent structures, and ignition sources. [**55:**6.15]

63.2.16 Ventilation. Indoor storage and use areas and storage buildings for compressed gases and cryogenic fluids shall be provided with mechanical exhaust ventilation or fixed natural ventilation, where natural ventilation is shown to be acceptable for the material as stored. [**55:**6.16]

Fixed natural ventilation is defined in NFPA 55 as the movement of air into and out of a space through permanent openings that are arranged in such a way that the required ventilation cannot be reduced by operating windows, doors, louvers, or similar devices. The concept of fixed natural ventilation was established in NFPA 51A, *Standard for Acetylene Cylinder Charging Plants,* which was integrated into the 2013 edition of NFPA 55. The revisions to 63.2.16 reflect those changes made to NFPA 55 to incorporate the ventilation concepts from NFPA 51A. The use of 1 scf/min/ft^2 (0.3048 Nm^3/min/m^2) has become the national norm for ventilation systems where hazardous materials are involved.

63.2.16.1 Compressed Air. The requirements of 63.2.16 shall not apply to cylinders, containers, and tanks containing compressed air. [**55:**6.16.1]

63.2.16.2 Ventilation Systems. In addition to the requirements of 63.2.16, ventilation systems shall be designed and installed in accordance with the requirements of the mechanical code. [**55:**6.16.2]

63.2.16.3 Mechanical Exhaust Ventilation. Where mechanical exhaust ventilation is provided, the system shall be operational during the time the building or space is occupied. [**55:**6.16.3]

63.2.16.4 Continuous Operation. When operation of ventilation systems is required, systems shall operate continuously unless an alternative design is approved by the AHJ. [**55:**6.16.3.1]

63.2.16.5 Ventilation Rate Mechanical exhaust or fixed natural ventilation shall be provided at a rate of not less than 1 scf/min/ft^2 (0.3048 Nm^3/min/m^2) of floor area over the area of storage or use. [**55:**6.16.3.2]

The ventilation rate should provide sufficient dilution to keep the concentration of any gas that is leaked into the space well below the concentration threshold at which the gas would have some physiological effect or present a fire or explosion hazard. See 63.3.6 for additional information on reducing fire and explosion hazards resulting from flammable gas leakage in buildings.

63.2.16.6 Shutoff Controls. Where powered ventilation is provided, a manual shutoff switch shall be provided outside the room in a position adjacent to the principal access door to the room or in an approved location. [**55:**6.16.3.3]

63.2.16.7 Manual Shutoff Switch. The switch shall be the break-glass or equivalent type and shall be labeled as follows:

WARNING:
VENTILATION SYSTEM EMERGENCY
SHUTOFF

[**55:**6.16.3.3.1]

63.2.16.8 Inlets to the Exhaust System.

63.2.16.8.1 The exhaust ventilation system design shall take into account the density of the potential gases released. [**55:**6.16.4.1]

63.2.16.8.2* For gases that are heavier than air, exhaust shall be taken from a point within 12 in. (305 mm) of the floor. The use of supplemental inlets shall be allowed to be installed at points above the 12 in. (305 mm) threshold level. [**55:**6.16.4.2]

N **A.63.2.16.8.2** Examples of gases that are heavier than air include, but are not limited to, carbon dioxide, argon, and nitrous oxide. [**55:**A.6.16.4.2]

N **63.2.16.8.3*** For gases that are lighter than air, exhaust shall be taken from a point within 12 in. (305 mm) of the ceiling. The use of supplemental inlets shall be allowed to be installed at points below the 12 in. (305 mm) threshold level. [**55:**6.16.4.3]

When gases that are lighter than air are involved, a high point pickup is normally placed as high in the room as possible. A maximum distance from the ceiling plane was also established in conjunction with the height now established at floor level for continuity.

N **A.63.2.16.8.3** Examples of gases that are lighter than air include, but are not limited to, hydrogen, helium, and methane. [**55:**A.6.16.4.3]

63.2.16.8.4 The location of both the exhaust and inlet air openings shall be designed to provide air movement across all portions of the floor or ceiling of the room to prevent the accumulation of vapors within the ventilated space. [**55:**6.16.4.4]

Δ **63.2.16.9 Recirculation of Exhaust.** Exhaust ventilation shall not be recirculated. [**55:**6.16.5]

Most interior spaces of rooms or buildings have obstructions that prevent complete mixing of recirculated air, so it is important not to recirculate air containing toxic materials. Because complete mixing of recirculated air is unlikely due to the patterns of air circulation, toxic materials can accumulate in areas of the room.

63.2.16.10 Ventilation Discharge. Ventilation discharge systems shall terminate at a point not less than 50 ft (15 m) from intakes of air-handling systems, air-conditioning equipment, and air compressors. [**55:**6.16.6]

This is to prevent air that may contain toxic or flammable materials from being introduced back into a building, where it could pose a hazard to personnel.

63.2.16.11 Air Intakes. Storage and use of compressed gases shall be located not less than 50 ft (15 m) from air intakes. For material-specific requirements, see 63.3.4 through 63.3.10. [**55:**6.16.7]

63.2.17 Gas Cabinets. Where a gas cabinet is required, is used to provide separation of gas hazards, or is used to increase the threshold quantity for a gas requiring special provisions, the gas cabinet shall be in accordance with the requirements of 63.2.17.1 through 63.2.17.5. [**55:**6.17]

63.2.17.1 Construction.

63.2.17.1.1 Materials of Construction. The gas cabinet shall be constructed of not less than 0.097 in. (2.46 mm) (12 gauge) steel. [**55:**6.17.1.1]

63.2.17.1.2 Access to Controls. The gas cabinet shall be provided with self-closing limited access ports or noncombustible windows to give access to equipment controls. [**55:**6.17.1.2]

63.2.17.1.3 Self-Closing Doors. The gas cabinet shall be provided with self-closing doors. [**55:**6.17.1.3]

63.2.17.2 Ventilation Requirements.

63.2.17.2.1 The gas cabinet shall be provided with an exhaust ventilation system designed to operate at a negative pressure relative to the surrounding area. [**55:**6.17.2.1]

This is to prevent, in case of a release, gas from being released into the surrounding area. Any release would be directed through the ventilation system discharge.

63.2.17.2.2 Where toxic, highly toxic, pyrophoric, unstable reactive Class 3 or Class 4, or corrosive gases are contained, the velocity at the face of access ports or windows, with the access port or window open, shall not be less than 200 ft/min (61 · m/min) average, with not less than 150 ft/min (46 m/min) at any single point. [**55:**6.17.2.2]

63.2.17.3 Fire Protection. Gas cabinets used to contain toxic, highly toxic, or pyrophoric gases shall be internally sprinklered. [**55:**6.17.3]

63.2.17.4 Quantity Limits. Gas cabinets shall contain not more than three cylinders, containers, or tanks. [**55:**6.17.4]

63.2.17.5 Separation of Incompatibles. Incompatible gases, as defined by Table 63.3.1.11.2, shall be stored or used within separate gas cabinets. [**55:**6.17.5]

63.2.18 Exhausted Enclosures.

63.2.18.1 Ventilation Requirements. Where an exhausted enclosure is required or used to increase the threshold quantity for a gas requiring special provisions, the exhausted enclosure shall be provided with an exhaust ventilation system designed to operate at a negative pressure in relationship to the surrounding area. [**55:**6.18.1]

The provision in 63.2.18.1 requiring negative pressure is intended to prevent any leaks in the system from releasing gas into the room.

63.2.18.1.1 Control Velocity at Access Openings. Where toxic, highly toxic, pyrophoric, unstable reactive Class 3 or Class 4, or corrosive gases are contained, the velocity at the face openings providing access shall be not less than 200 ft/min (61 m/min) average, with not less than 150 ft/min (46 m/min) at any single point. [**55:**6.18.1.1]

63.2.18.1.2 Separation of Incompatible Gases Within Enclosures. Cylinders, containers, and tanks within enclosures shall be separated in accordance with Table 63.3.1.11.2. [**55:**6.18.1.2]

63.2.18.1.3 Fire Protection. Exhausted enclosures shall be internally sprinklered. [**55:**6.18.1.3]

63.2.18.2 Separation. Incompatible gases, as defined by Table 63.3.1.11.2, shall be stored or used within separate exhausted enclosures. [**55:**6.18.2]

63.2.19* Source Valve. Bulk gas systems shall be provided with a source valve. [**55:**6.19]

A.63.2.19 Figure A.63.2.19 shows three possible locations of the source valve. [**55:**A.6.19]

• **63.2.19.1** The source valve shall be marked. [**55:**6.19.1]

63.2.19.2 The source valve shall be designated on the design drawings for the installation. [**55:**6.19.2]

63.3 Compressed Gases

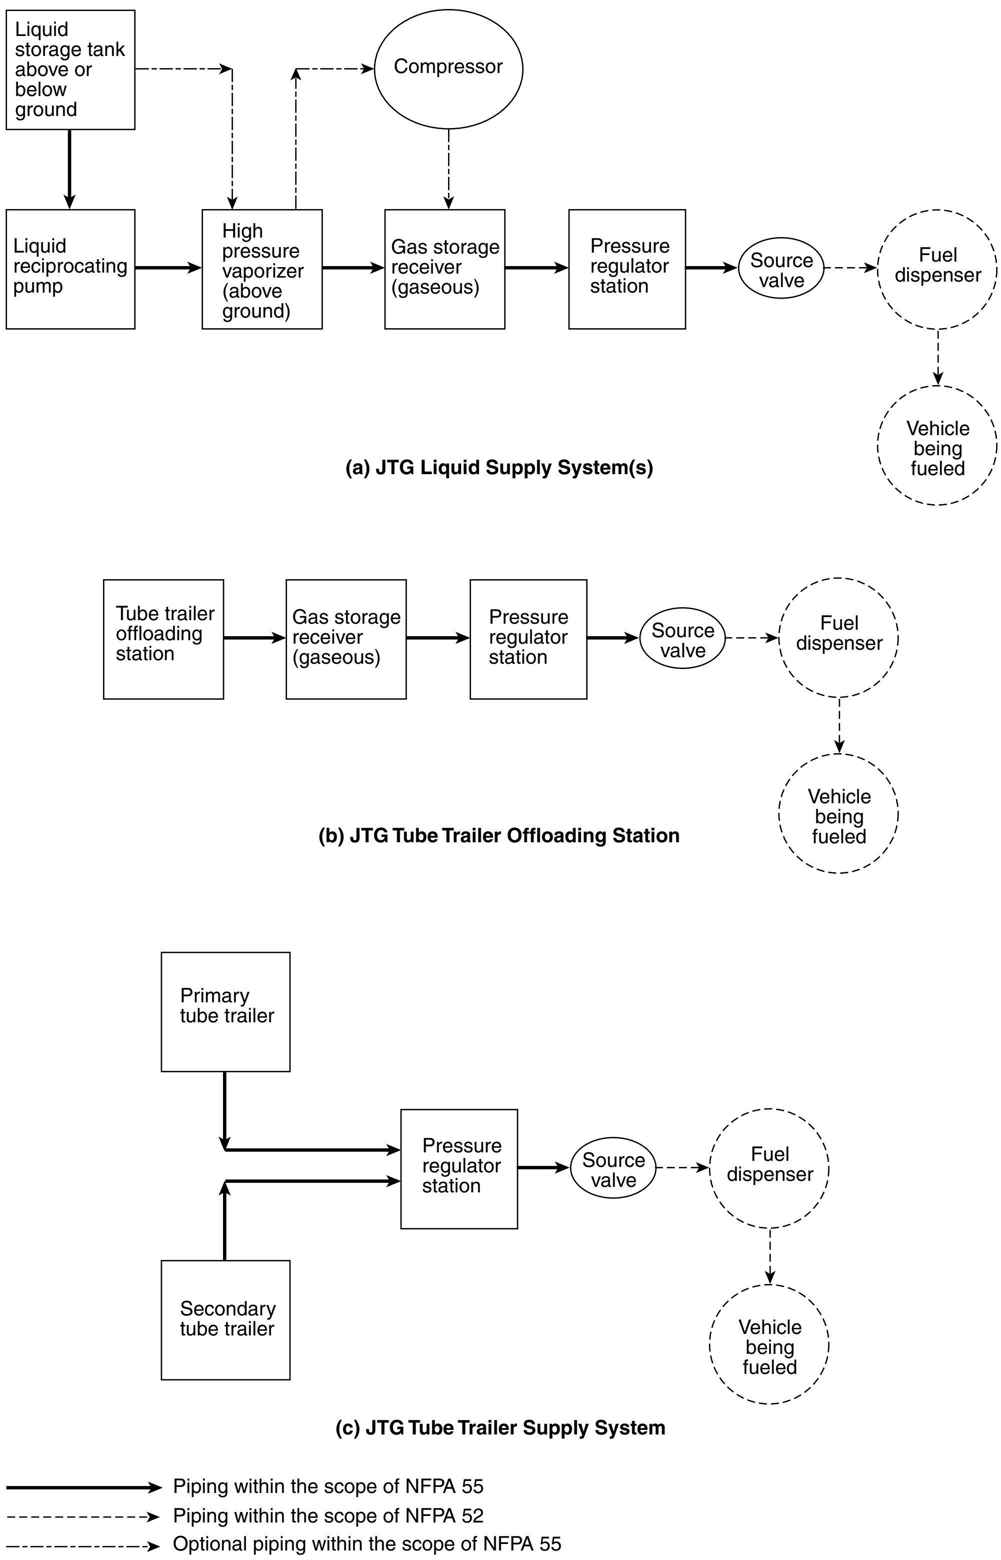
Δ **63.3.1 General.** The storage, use, and handling of compressed gases in cylinders, containers, and tanks shall be in accordance with the provisions of Chapters 1 through 7 of NFPA 55. [**55:**7.1]

63.3.1.1 Compressed Gas Systems.

63.3.1.1.1 Design. Compressed gas systems shall be designed for the intended use and shall be designed by persons competent in such design. [**55:**7.1.2.1]

63.3.1.1.2 Installation. Installation of bulk compressed gas systems shall be supervised by personnel knowledgeable in the application of the standards for their construction and use. [**55:**7.1.2.2]

63.3.1.2 Insulated Liquid Carbon Dioxide Systems. Insulated liquid carbon dioxide systems shall be in accordance with Chapter 13 of NFPA 55. [**55:**7.1.3]



Δ ***FIGURE A.63.2.19*** *Three Examples of Source Valve Locations. [**55:** Figure A.6.19]*

63.3.1.3 Insulated Liquid Nitrous Oxide Systems. (Reserved)

63.3.1.4* Listed or Approved Hydrogen Equipment.

A.63.3.1.4 The compressed gas system equipment referenced is intended to include fuel cell applications, generation of hydrogen from portable or transportable hydrogen generation equipment, batteries, and similar devices and equipment that utilize hydrogen for the purpose of power generation. It does not include hydrogen production facilities intended to produce hydrogen used for distribution or repackaging operations operated by gas producers, distributors, and repackagers. [**55:**A.10.2.8]

63.3.1.4.1 Listed or approved hydrogen–generating and hydrogen–consuming equipment shall be in accordance with the listing requirements and manufacturers' instructions. [**55:**10.2.8.1]

63.3.1.4.2 Such equipment shall not be required to meet the requirements of Chapter 7 of NFPA 55. [**55:**10.2.8.2]

63.3.1.5* Metal Hydride Storage Systems.

Requirements on metal hydride storage systems were added to the 2010 edition of NFPA 55. With the commercial introduction of fuel cell–based power systems and the proliferation of hydrogen as a fuel gas, systems that store hydrogen using alternative methods are becoming more prevalent than those traditionally used for compressed gas and cryogenic liquid. Therefore, there was a need in NFPA 55 for the dissemination of information on these alternative hydrogen storage technologies, as well as a fundamental set of controls to provide guidance to users and enforcement authorities alike.

Because the metal hydride storage system is a closed system that prevents the release of the metal hydride and the hydrogen-absorbing alloy under normal use, the hazard classification of the system considers only the contained hydrogen gas.

The closest analogy that can be made with respect to this approach is that of acetylene — a compressed gas that is dissolved in acetone — or dimethylformamide. These solvents are a Class IB flammable liquid and a Class II combustible liquid, respectively. However, in practice, it is the flammable gas hazard that is regulated; the solvent into which the gas is absorbed has not been independently assessed. The established reason for this approach is that the control strategy for the compressed gas hazard is suitable for that of the solvent hazard.

The control strategy for metal hydride systems, therefore, is heavily dependent on the control strategy for all compressed gases. A number of control procedures have been incorporated into this new section in order to focus on fundamental controls that might otherwise be missed by *Code* users. In addition, provisions have been added to address the refilling of containers, including containers that may be used on powered industrial trucks.

The early use of these systems was as a means to supply power attendant to portable equipment. Specific safeguards have been included to address the security of containers in mobile as well as motorized equipment. Fundamental controls for motorized equipment have been taken, in part, from NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operations*.

A.63.3.1.5 Numerous metal hydrides are currently being tested for gaseous hydrogen storage applications. While certain Class D extinguishing agents have been effective on some metal hydride materials, they have not been tested on the wide range of hydrides. It is crucial to understand any adverse chemical reactions between the hydride and the agent prior to using the fire suppressant. Additionally, it is important to understand that the application should be limited to small incipient stage fires. Larger fires would require the use of personal protective equipment in the application of the extinguishing agent. [**55:**A.10.2.9]

63.3.1.5.1 General Requirements.

63.3.1.5.1.1 Metal Hydride Storage System Requirements. The storage and use of metal hydride storage systems shall be in accordance with 63.3.1.5. [**55:**10.2.9.1.1]

63.3.1.5.1.2 Metal Hydride Systems Storing or Supplying Hydrogen. Those portions of the system that are used as a means to store or supply hydrogen shall also comply with Chapter 7 and Chapter 10 of NFPA 55 as applicable. [**55:**10.2.9.1.2]

63.3.1.5.1.3 Classification. The hazard classification of the metal hydride storage system, as required by 63.1.4.1 and 63.1.4.3, shall be based on the hydrogen stored without regard to the metal hydride content. [**55:**10.2.9.1.3]

63.3.1.5.1.4 Listed or Approved Systems. Metal hydride storage systems shall be listed or approved for the application and designed in a manner that prevents the addition or removal of the metal hydride by other than the original equipment manufacturer. [**55:**10.2.9.1.4]

63.3.1.5.1.5 Containers, Design, and Construction. Compressed gas cylinders, containers, and tanks used for metal hydride storage systems shall be designed and constructed in accordance with 63.3.1.6.1. [**55:**10.2.9.1.5]

63.3.1.5.1.6 Service Life and Inspection of Containers. Metal hydride storage system cylinders, containers, or tanks shall be inspected, tested, and requalified for service at not less than 5-year intervals. [**55:**10.2.9.1.6]

63.3.1.5.1.7 Marking and Labeling. Marking and labeling of cylinders, containers, tanks, and systems shall be in accordance with 63.3.1.6 and the requirements in 63.3.1.5.1.7.1 through 63.3.1.5.1.7.4. [**55:**10.2.9.1.7]

63.3.1.5.1.7.1 System Marking. Metal hydride storage systems shall be marked with the following:

(1) Manufacturer's name
(2) Service life indicating the last date the system can be used
(3) A unique code or serial number specific to the unit
(4) System name or product code that identifies the system by the type of chemistry used in the system

(5) Emergency contact name, telephone number, or other contact information
(6) Limitations on refilling of containers to include rated charging pressure and capacity

[**55:**10.2.9.1.7.1]

63.3.1.5.1.7.2 Valve Marking. Metal hydride storage system valves shall be marked with the following:

(1) Manufacturer's name
(2) Service life indicating the last date the valve can be used
(3) Metal hydride service in which the valve can be used or a product code that is traceable to this information

[**55:**10.2.9.1.7.2]

63.3.1.5.1.7.3 Pressure Relief Device Marking. Metal hydride storage system pressure relief devices shall be marked with the following:

(1) Manufacturer's name
(2) Metal hydride service in which the device can be used or a product code that is traceable to this information
(3) Activation parameters to include temperature, pressure, or both

[**55:**10.2.9.1.7.3]

(A) Pressure Relief Devices Integral to Container Valves. The required markings for pressure relief devices that are integral components of valves used on cylinders, containers, and tanks shall be allowed to be placed on the valve. [**55:**10.2.9.1.7.3(A)]

63.3.1.5.1.7.4 Pressure Vessel Markings. Cylinders, containers, and tanks used in metal hydride storage systems shall be marked with the following:

(1) Manufacturer's name
(2) Design specification to which the vessel was manufactured
(3) Authorized body approving the design and initial inspection and test of the vessel
(4) Manufacturer's original test date
(5) Unique serial number for the vessel
(6) Service life identifying the last date the vessel can be used
(7) System name or product code that identifies the system by the type of chemistry used in the system

[**55:**10.2.9.1.7.4]

63.3.1.5.1.8 Temperature Extremes. Metal hydride storage systems, whether full or partially full, shall not be exposed to artificially created high temperatures exceeding 125°F (52°C) or subambient (low) temperatures unless designed for use under the exposed conditions. [**55:**10.2.9.1.8]

63.3.1.5.1.9 Falling Objects. Metal hydride storage systems shall not be placed in areas where they are capable of being damaged by falling objects. [**55:**10.2.9.1.9]

63.3.1.5.1.10 Piping Systems. Piping, including tubing, valves, fittings, and pressure regulators, serving metal hydride storage systems shall be maintained gastight to prevent leakage. [**55:**10.2.9.1.10]

63.3.1.5.1.10.1 Leaking Systems. Leaking systems shall be removed from service. [**55:**10.2.9.1.10.1]

63.3.1.5.1.11 Refilling of Containers. The refilling of listed or approved metal hydride storage systems shall be in accordance with the listing requirements and manufacturers' instructions. [**55:**10.2.9.1.11]

Δ **63.3.1.5.1.11.1 Industrial Trucks.** The refilling of metal hydride storage systems serving powered industrial trucks shall be in accordance with NFPA 2. [**55:**10.2.9.1.11.1]

63.3.1.5.1.11.2 Hydrogen Purity. The purity of hydrogen used for the purpose of refilling containers shall be in accordance with the listing and the manufacturers' instructions. [**55:**10.2.9.1.11.2]

Δ **63.3.1.5.1.12 Electrical.** Electrical components for metal hydride storage systems shall be designed, constructed, and installed in accordance with *NFPA 70*. [**55:**10.2.9.1.12]

63.3.1.5.2 Portable Containers or Systems.

63.3.1.5.2.1 Securing Containers. Cylinders, containers, and tanks shall be secured in accordance with 63.3.1.9.5. [**55:**10.2.9.2.1]

63.3.1.5.2.1.1 Use on Mobile Equipment. Where a metal hydride storage system is used on mobile equipment, the equipment shall be designed to restrain cylinders, containers, or tanks from dislodgement, slipping, or rotating when the equipment is in motion. [**55:**10.2.9.2.1.1]

63.3.1.5.2.1.2 Motorized Equipment. Metal hydride storage systems used on motorized equipment shall be installed in a manner that protects valves, pressure regulators, fittings, and controls against accidental impact. [**55:**10.2.9.2.1.2]

(A) Protection from Damage. Metal hydride storage systems, including cylinders, containers, tanks, and fittings, shall not extend beyond the platform of the mobile equipment. [**55:**10.2.9.2.1.2(A)]

63.3.1.5.2.2 Valves. Valves on cylinders, containers, and tanks shall remain closed except when containers are connected to closed systems and ready for use. [**55:**10.2.9.2.2]

63.3.1.6 Cylinders, Containers, and Tanks.

63.3.1.6.1 Design and Construction. Cylinders, containers, and tanks shall be designed, fabricated, tested, and marked (stamped) in accordance with regulations of DOT, Transport Canada (TC) *Transportation of Dangerous Goods Regulations*, or the ASME *Boiler and Pressure Vessel Code*, "Rules for the Construction of Unfired Pressure Vessels," Section VIII. [**55:**7.1.5.1]

63.3.1.6.2 Defective Cylinders, Containers, and Tanks.

63.3.1.6.2.1 Defective cylinders, containers, and tanks shall be returned to the supplier. [**55:**7.1.5.2.1]

63.3.1.6.2.2 Suppliers shall repair the cylinders, containers, and tanks, remove them from service, or dispose of them in an approved manner. [**55:**7.1.5.2.2]

63.3.1.6.2.3 Suppliers shall ensure that defective cylinders, containers, and tanks that have been repaired are evaluated by qualified individuals to verify that the needed repairs and any required testing has been performed and that those repaired or tested are in a serviceable condition before returning them to service. [**55:**7.1.5.2.3]

63.3.1.6.3 Supports. Stationary cylinders, containers, and tanks shall be provided with engineered supports of noncombustible material on noncombustible foundations. [**55:**7.1.5.3]

63.3.1.6.4 Cylinders, Containers, and Tanks Containing Residual Gas. Compressed gas cylinders, containers, and tanks containing residual product shall be treated as full except when being examined, serviced, or refilled by a gas manufacturer, authorized cylinder requalifier, or distributor. [**55:**7.1.5.4]

Serious accidents have resulted from users assuming that no material was left in a cylinder that appeared to be empty. If a small amount of gas has been left in a cylinder, the atmosphere in the cylinder might no longer be saturated and could be in the flammable range.

63.3.1.6.5 Pressure Relief Devices.

63.3.1.6.5.1 When required by 63.3.1.6.5.2, pressure relief devices shall be provided to protect containers and systems containing compressed gases from rupture in the event of overpressure from thermal exposure. [**55:**7.1.5.1.1]

63.3.1.6.5.2 Pressure relief devices to protect containers shall be designed and provided in accordance with CGA S-1.1, *Pressure Relief Device Standards — Part 1 — Cylinders for Compressed Gases*, for cylinders; CGA S-1.2, *Pressure Relief Device Standards — Part 2 — Cargo and Portable Tanks for Compressed Gases,* for portable tanks; and CGA S-1.3, *Pressure Relief Device Standards — Part 3 — Stationary Storage Containers for Compressed Gases,* for stationary tanks or in accordance with applicable equivalent requirements in the country of use. [**55:**7.1.5.5.2]

63.3.1.6.5.3 Pressure relief devices shall be sized in accordance with the specifications to which the container was fabricated. [**55:**7.1.5.5.3]

63.3.1.6.5.4 The pressure relief device shall have the capacity to prevent the maximum design pressure of the container or system from being exceeded. [**55:**7.1.5.5.4]

63.3.1.6.5.5 Pressure relief devices shall be arranged to discharge unobstructed to the open air in such a manner as to prevent any impingement of escaping gas upon the container, adjacent structures, or personnel. This requirement shall not apply to DOT specification containers having an internal volume of 2.0 scf (0.057 Nm^3) or less. [**55:**7.1.5.5.5]

63.3.1.6.5.6 Pressure relief devices or vent piping shall be designed or located so that moisture cannot collect and freeze in a manner that would interfere with operation of the device. [**55:**7.1.5.5.6]

63.3.1.7 Cathodic Protection. Where required, cathodic protection shall be in accordance with 63.3.1.7. [**55:**7.1.6]

63.3.1.7.1 Operation. Where installed, cathodic protection systems shall be operated and maintained to continuously provide corrosion protection. [**55:**7.1.6.1]

63.3.1.7.2 Inspection. Container systems equipped with cathodic protection shall be inspected for the intended operation by a cathodic protection tester. The frequency of inspection shall be determined by the designer of the cathodic protection system. [**55:**7.1.6.2]

63.3.1.7.2.1 The cathodic protection tester shall be certified as being qualified by the National Association of Corrosion Engineers, International (NACE). [**55:**7.1.6.2.1]

63.3.1.7.3 Impressed Current Systems. Systems equipped with impressed current cathodic protection systems shall be inspected in accordance with the requirements of the design and 63.3.1.7.2. [**55:**7.1.6.3]

63.3.1.7.3.1 The design limits of the cathodic protection system shall be available to the AHJ upon request. [**55:**7.1.6.3.1]

63.3.1.7.3.2 The system owner shall maintain the following records to demonstrate that the cathodic protection is in conformance with the requirements of the design:

(1) The results of inspections of the system
(2) The results of testing that has been completed

[**55:**7.1.6.3.2]

63.3.1.7.4 Repairs, maintenance, or replacement of a cathodic protection system shall be under the supervision of a corrosion expert certified by NACE. [**55:**7.1.6.4]

63.3.1.7.4.1 The corrosion expert shall be certified by NACE as a senior corrosion technologist, a cathodic protection specialist, or a corrosion specialist or shall be a registered engineer with registration in a field that includes education and experience in corrosion control. [**55:**7.1.6.4.1]

Cathodic protection is a technique used to resist the corrosion of a metal surface by making the surface the cathode of an electrochemical cell. This protection renders a metallic container, piping system, or component negatively charged with respect to its surrounding environment. Provisions for cathodic protection were added to the 2010 edition of NFPA 55 to provide proper maintenance and repair guidelines for cathodic protection systems. It is critical that a corrosion expert, certified by the National Association of Corrosion Engineers, International, is required to provide supervision during repairs, maintenance, or replacement of a cathodic protection system. As part of the certification, the corrosion expert is required to be certified as a senior corrosion technologist, a cathodic protection specialist, or a corrosion specialist. The corrosion expert may also be a registered engineer, but the registration must be in a field that includes education and experience in corrosion control.

63.3.1.8 Labeling Requirements.

63.3.1.8.1 Containers. Individual compressed gas cylinders, containers, and tanks shall be marked or labeled in accordance with DOT requirements or those of the applicable regulatory agency. [**55:**7.1.7.1]

63.3.1.8.2 Label Maintenance. The labels applied by the gas manufacturer to identify the liquefied or nonliquefied compressed gas cylinder contents shall not be altered or removed by the user. [**55:**7.1.7.2]

63.3.1.8.3 Stationary Compressed Gas Cylinders, Containers, and Tanks.

Δ **63.3.1.8.3.1** Stationary compressed gas cylinders, containers, and tanks shall be marked in accordance with NFPA 704. [**55:**7.1.7.3.1]

63.3.1.8.3.2 Markings shall be visible from any direction of approach. [**55:**7.1.7.3.2]

63.3.1.8.4 Piping Systems.

63.3.1.8.4.1 Except as provided in 63.3.1.8.4.2, piping systems shall be marked in accordance with ASME A13.1, *Scheme for the Identification of Piping Systems*, or other applicable approved standards as follows:

(1) Marking shall include the name of the gas and a direction-of-flow arrow.
(2) Piping that is used to convey more than one gas at various times shall be marked to provide clear identification and warning of the hazard.
(3) Markings for piping systems shall be provided at the following locations:
   (a) At each critical process control valve
   (b) At wall, floor, or ceiling penetrations
   (c) At each change of direction
   (d) At a minimum of every 20 ft (6.1 m) or fraction thereof throughout the piping run

[**55:**7.1.7.4.1]

63.3.1.8.4.2 Piping within gas manufacturing plants, gas processing plants, refineries, and similar occupancies shall be marked in an approved manner. [**55:**7.1.7.4.2]

63.3.1.9 Security.

63.3.1.9.1 General. Compressed gas cylinders, containers, tanks, and systems shall be secured against accidental dislodgement and against access by unauthorized personnel. [**55:**7.1.8.1]

63.3.1.9.2* Security of Areas. Storage, use, and handling areas shall be secured against unauthorized entry. [**55:**7.1.8.2]

A.63.3.1.9.2 The goal of this requirement is to prevent unauthorized personnel or those unfamiliar with gas storage systems from tampering with the equipment as well as to prevent the inadvertent or unauthorized removal or use of compressed gases from storage areas. Where the compressed gases are located in an area open to the general public, a common practice is to fence and lock the storage or use area, with access restricted to supplier and user personnel. When the storage or use area is located within the user's secure area and is not accessible by the general public, it is not always necessary to fence or otherwise secure the individual gas storage or use areas. Personnel access patterns may still mandate that the system be fenced, as determined by the supplier and the user. [**55:**A.7.1.8.2]

63.3.1.9.3 Administrative controls shall be allowed to be used to control access to individual storage, use, and handling areas located in secure facilities not accessible by the general public. [**55:**7.1.8.2.1]

63.3.1.9.4 Physical Protection.

63.3.1.9.4.1 Compressed gas cylinders, containers, tanks, and systems that could be exposed to physical damage shall be protected. [**55:**7.1.8.3.1]

63.3.1.9.4.2 Guard posts or other means shall be provided to protect compressed gas cylinders, containers, tanks, and systems indoors and outdoors from vehicular damage in accordance with Section 4.11 of NFPA 55. [**55:**7.1.8.3.2]

Δ **63.3.1.9.5 Securing Compressed Gas Cylinders, Containers, and Tanks.** Compressed gas cylinders, containers, and tanks in use or in storage shall be secured to prevent them from falling or being knocked over by corralling them and securing them to a cart, framework, or fixed object by use of a restraint, unless otherwise permitted by 63.3.1.9.5.1 and 63.3.1.9.5.2. [**55:**7.1.8.4]

Δ **63.3.1.9.5.1** Compressed gas cylinders, containers and tanks in the process of examination, servicing, and refilling shall not be required to be secured. [**55:**7.1.8.4.1]

63.3.1.9.5.2 At cylinder-filling plants, authorized cylinder requalifier's facilities, and distributors' warehouses, the nesting of cylinders shall be permitted as a means to secure cylinders. [**55:**7.1.8.4.2]

63.3.1.10 Valve Protection.

63.3.1.10.1 General. Compressed gas cylinder, container, and tank valves shall be protected from physical damage by means of protective caps, collars, or similar devices. [**55:**7.1.9.1]

63.3.1.10.1.1 Valve protection of individual valves shall not be required to be installed on individual cylinders, containers, or tanks installed on tube trailers or similar transportable bulk gas systems equipped with manifolds that are provided with a means of physical protection that will protect the valves from physical damage when the equipment is in use. Protective systems required by DOT for over the road transport shall provide an acceptable means of protection. [**55:**7.1.9.1.1]

63.3.1.10.1.1.1 Valve protection of individual valves shall not be required on cylinders, containers, or tanks that comprise bulk or non-bulk gas systems where the containers are stationary, or portable equipped with manifolds, that are provided with physical protection in accordance with Section 4.11 of NFPA 55 and 63.3.1.9.4 or other approved means. Protective systems required by DOT for over the road transport shall provide an acceptable means of protection. [**55:**7.1.9.1.1.1]

Paragraph 63.3.1.10.1.1.1 was written as a general requirement for all compressed gases. There are instances in which compressed gas cylinders could be used in a form not anticipated by NFPA 55 and this *Code* when this paragraph was developed. Tube trailers, cylinder packs, and similar arrangements conventionally are not equipped with protective caps, collars, or similar devices. On the other hand, such equipment generally is equipped with safeguards to protect the container valves from impact.

Adding requirements that recognize the requirements for manifold protection resolved the problem with tube trailer systems. Paragraph 63.3.1.10.1.1 addresses systems other than DOT (over the road) type systems, which may include equipment commonly known as 6 packs, 12 packs, and similar items consisting of cylinders equipped with a manifold that are attached to a wheeled frame. Physical protection is typically provided by the framework used as a supporting structure. In addition, stationary storage/use systems are not equipped with valve protection of the type suggested by 63.3.1.10.1. Systems of this nature are usually protected through the use of Section 4.11 of NFPA 55 or 63.3.1.9.4. The "other approved means" is an important consideration and recognizes that every possible circumstance cannot be addressed. Physical protection can be provided by means other than those specifically described in Section 4.11 of NFPA 55 or 7.1.8.3 of NFPA 55. Sufficient guidance is provided to inform the user of the need and of the exceptions to be applied.

63.3.1.10.2 Valve-Protective Caps. Where compressed gas cylinders, containers, and tanks are designed to accept valve-protective caps, the user shall keep such caps on the compressed gas cylinders, containers, and tanks at all times, except when empty, being processed, or connected for use. [**55:**7.1.9.2]

The cylinder valve is one of the most vulnerable points on the cylinder. For that reason, it is important that valve-protective caps are used and that they fit securely over the valve.

63.3.1.10.3 Valve Outlet Caps or Plugs.

63.3.1.10.3.1 Gastight valve outlet caps or plugs shall be provided and in place for all full or partially full cylinders, containers, and tanks containing toxic, highly toxic, pyrophoric, or unstable reactive Class 3 or Class 4 gases that are in storage. [**55:**7.1.9.3.1]

63.3.1.10.3.2 Valve outlet caps and plugs shall be designed and rated for the container service pressure. [**55:**7.1.9.3.2]

63.3.1.11 Separation from Hazardous Conditions.

63.3.1.11.1 General.

63.3.1.11.1.1 Compressed gas cylinders, containers, tanks, and systems in storage or use shall be separated from materials and conditions that present exposure hazards to or from each other. [**55:**7.1.10.1]

One of the most effective techniques for preventing accidents or reducing the severity of accidents is to separate hazardous materials from those materials and conditions that present exposure hazards or to separate hazardous materials from each other. Separation can prevent an incident involving one stored material from propagating to another stored material. Following this basic safety principle can also prevent minor incidents from becoming major incidents.

63.3.1.11.2* Incompatible Materials. Gas cylinders, containers, and tanks shall be separated in accordance with Table 63.3.1.11.2. [**55:**7.1.10.2]

A.63.3.1.11.2 Figure A.63.3.1.11.2 is a schematic showing the separation distances required by 63.3.1.11.2. [**55:**A.7.1.10.2]

63.3.1.11.2.1 Subparagraph 63.3.1.11.2 shall not apply to gases contained within closed piping systems. [**55:**7.1.10.2.1]

63.3.1.11.2.2 The distances shown in Table 63.3.1.11.2 shall be permitted to be reduced without limit where compressed gas cylinders, containers, and tanks are separated by a barrier of noncombustible construction that has a fire resistance rating of at least 0.5 hour and interrupts the line of sight between the containers. [**55:**7.1.10.2.2]

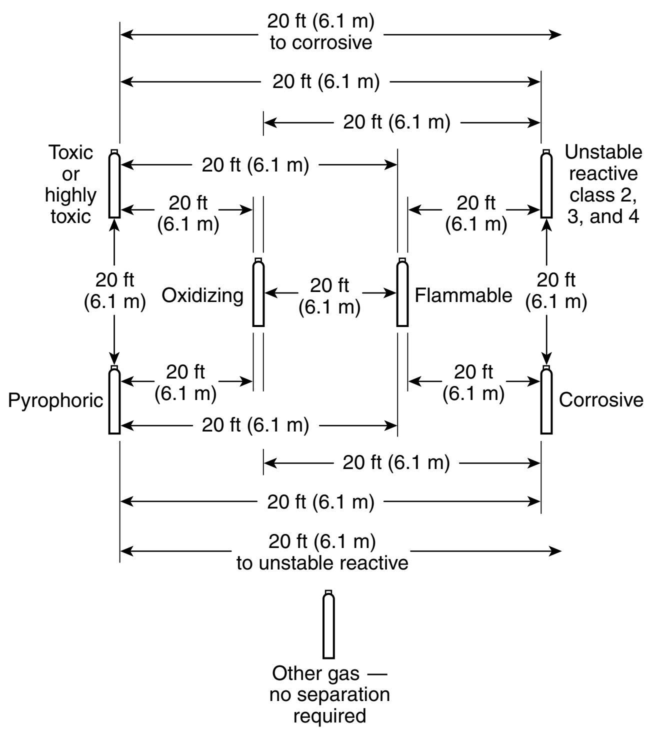
63.3.1.11.2.3 The 20 ft (6.1 m) distance shall be permitted to be reduced to 5 ft (1.5 m) where one of the gases is enclosed in a gas cabinet or without limit where both gases are enclosed in gas cabinets. [**55:**7.1.10.2.3]

63.3.1.11.2.4 Cylinders without pressure relief devices shall not be stored without separation from flammable and pyrophoric gases with pressure relief devices. [**55:**7.1.10.2.4]

Δ ***TABLE 63.3.1.11.2*** *Separation of Gas Cylinders, Containers, and Tanks by Hazard Class*

Gas Category	Other Gas	Unstable Reactive Class 2, Class 3, or Class 4		Corrosive		Oxidizing		Flammable		Pyrophoric		Toxic or Highly Toxic	
		ft	m	ft	m	ft	m	ft	m	ft	m	ft	m
Toxic or highly toxic	NR	20	6.1	20	6.1	20	6.1	20	6.1	20	6.1	—	—
Pyrophoric	NR	20	6.1	20	6.1	20	6.1	20	6.1	—	—	20	6.1
Flammable	NR	20	6.1	20	6.1	20	6.1	—	—	20	6.1	20	6.1
Oxidizing	NR	20	6.1	20	6.1	—	—	20	6.1	20	6.1	20	6.1
Corrosive	NR	20	6.1	—	—	20	6.1	20	6.1	20	6.1	20	6.1
Unstable reactive Class 2, Class 3, or Class 4	NR	—	—	20	6.1	20	6.1	20	6.1	20	6.1	20	6.1
Other gas	—	NR		NR		NR		NR		NR		NR	

NR: No separation required.
[**55:** Table 7.1.10.2]



Δ *FIGURE A.63.3.1.11.2 Separation of Gas Cylinders by Hazard. [55:Figure A.7.1.10.2]*

63.3.1.11.2.5* Spatial separation shall not be required between cylinders deemed to be incompatible in gas production facilities where cylinders are connected to manifolds for the purposes of filling, analysis of compressed gases or, manufacturing procedures, assuming the prescribed controls for the manufacture of gas mixtures are in place. [**55:**7.1.10.2.5]

N **A.63.3.1.11.2.5** Analysis of gas mixtures often includes the analysis of individual cylinders that have been disconnected from the filling manifolds. The analysis procedure is a production step where cylinders of many different types and contents are processed. It is not unusual for an individual gas mixture to contain gases otherwise deemed to be incompatible in the pure state. For example, a mixture of hydrogen and air is routinely manufactured for use as a calibrating gas mixture used to validate the operation of flammable gas detection systems. Analytical operations involving incompatible gases, which may be located within an individual laboratory, typically require that the gases being analyzed be connected to individual work stations or analytical instruments as the process is conducted. The typical analytical process is an attended process where technicians have "hands on" control of the cylinder under examination, which serves to mitigate events that may otherwise occur in unattended operations, including storage or the use of an unattended source of supply. [**55:**A.7.1.10.2.5]

63.3.1.11.3* Clearance from Combustibles and Vegetation. Combustible waste, vegetation, and similar materials shall be kept a minimum of 10 ft (3.1 m) from compressed gas cylinders, containers, tanks, and systems. [**55:**7.1.10.3]

A.63.3.1.11.3 Clearance is required from combustible materials to minimize the effects of exposure fires to the materials stored or used. The requirement to separate the materials from vegetation should not be interpreted to mean that the area is maintained free of all vegetation. In some settings, gas systems are located on grounds that are maintained with formal landscaping. Some judgment must be exercised to determine whether the vegetation poses what might be viewed as an exposure hazard to the materials stored. Cut lawns, formal landscaping, and similar vegetation do not ordinarily present a hazard and should be allowed. On the other hand, tall, dry grass or weeds and vegetation that fringes on the border of an urban–wildland interface might be viewed as a hazard. [**55:**A.7.1.10.3]

Δ **63.3.1.11.3.1** A noncombustible partition without openings or penetrations and extending not less than 18 in. (457 mm) above and to the sides of the storage area shall be permitted in lieu of the minimum distance. [**55:**7.1.10.3.1]

63.3.1.11.3.2 The noncombustible partition shall be either an independent structure or the exterior wall of the building adjacent to the storage area. [**55:**7.1.10.3.2]

63.3.1.11.4 Ledges, Platforms, and Elevators. Compressed gas cylinders, containers, and tanks shall not be placed near elevators, unprotected platform ledges, or other areas where compressed gas cylinders, containers, or tanks could fall distances exceeding one-half the height of the container, cylinder, or tank. [**55:**7.1.10.4]

63.3.1.11.5 Temperature Extremes. Compressed gas cylinders, containers, and tanks, whether full or partially full, shall not be exposed to temperatures exceeding 125°F (52°C) or subambient (low) temperatures unless designed for use under such exposure. [**55:**7.1.10.5]

One of the most significant hazards that compressed gases present is the mechanical energy of compression. The Ideal Gas Law reveals that the pressure of a gas is directly proportional to the temperature of the gas. This law is the reason why it is important not to raise the temperature of the gas, which would then raise the pressure of the gas, increasing the risk of a release of the stored mechanical energy of the gas.

63.3.1.11.5.1 Compressed gas cylinders, containers, and tanks that have not been designed for use under elevated temperature conditions shall not be exposed to direct sunlight outdoors where ambient temperatures exceed 125°F (52°C). The use of a weather protected structure or shaded environment for storage or use shall be permitted as a means to protect against direct exposure to sunlight. [**55:**7.1.10.5.1]

The filling density for compressed gases is related to temperature and pressure. Filling densities and pressures are generally determined at 130°F (54°C). The 125°F (52°C) limitation provides a margin of safety to users of gaseous materials. When ambient temperatures exceed 125°F (52°C), and containers are exposed to direct sunlight, it is possible to exceed the 130°F threshold temperature limit internally, causing containers to become overpressurized and leak, pressure relief valves to release, or in the case of liquefied gas to expand to a point where the container may be subject to extreme hydraulic overpressure. In areas where ambient temperatures are expected to exceed 125°F (52°C), containers stored or used outdoors should be under weather protection, moved inside to a cooler environment, or otherwise provided with shade to avoid direct exposure to sunlight.

63.3.1.11.6 Falling Objects. Compressed gas cylinders, containers, and tanks shall not be placed in areas where they are capable of being damaged by falling objects. [**55:**7.1.10.6]

63.3.1.11.7 Heating. Compressed gas cylinders, containers, and tanks, whether full or partially full, shall not be heated by devices that could raise the surface temperature of the container, cylinder, or tank to above 125°F (52°C). [**55:**7.1.11.7]

63.3.1.11.7.1 Electrically Powered Heating Devices. Electrical heating devices shall be in accordance with *NFPA 70*. [**55:**7.1.10.7.1]

Δ **63.3.1.11.7.2 Fail-Safe Design.** Devices designed to maintain individual compressed gas cylinders, containers, and tanks at constant temperature shall be designed to be fail-safe. [**55:**7.1.10.7.2]

63.3.1.11.8 Sources of Ignition. Open flames and high-temperature devices shall not be used in a manner that creates a hazardous condition. [**55:**7.1.10.8]

63.3.1.11.9 Exposure to Chemicals. Compressed gas cylinders, containers, and tanks shall not be exposed to corrosive chemicals or fumes that could damage cylinders, containers, tanks, or valve-protective caps. [**55:**7.1.10.9]

63.3.1.11.10 Exposure to Electrical Circuits. Compressed gas cylinders, containers, and tanks shall not be placed where they could become a part of an electrical circuit. [**55:**7.1.10.10]

63.3.1.11.10.1* Electrical devices mounted on compressed gas piping, cylinders, containers, or tanks shall be installed, grounded, and bonded in accordance with the methods specified in *NFPA 70* (NEC). [**55:**7.1.10.10.1]

A.63.3.1.11.10.1 Electrical devices can include pressure transducers, signal transmitters, shutoff controls, and similar devices. Some of these devices may be nonincendive and suitable for use in hazardous areas. Flammability of gases is not the only concern with respect to electrical circuits, because piping serving systems in use can act as conductors of electrical energy, exposing unrelated portions of the system to electrical hazards if improperly installed. [**55:**A.7.1.10.10.1]

Δ **63.3.1.12 Service and Repair.** Service, repair, modification, or removal of valves, pressure relief devices, or other compressed gas cylinder, container, and tank appurtenances shall be performed by trained personnel and with the permission of the container owner. [**55:**7.1.11]

63.3.1.13 Unauthorized Use. Compressed gas cylinders, containers, and tanks shall not be used for any purpose other than to serve as a vessel for containing the product for which it was designed. [**55:**7.1.12]

63.3.1.14 Cylinders, Containers, and Tanks Exposed to Fire. Compressed gas cylinders, containers, and tanks exposed to fire shall not be used or shipped while full or partially full until they are requalified in accordance with the pressure vessel code under which they were manufactured. [**55:**7.1.13]

Although a container exposed to fire might not appear to have suffered any structural damage, the structural condition of the container cannot be known until the tank is properly examined.

63.3.1.15 Leaks, Damage, or Corrosion.

63.3.1.15.1 Removal from Service. Leaking, damaged, or corroded compressed gas cylinders, containers, and tanks shall be removed from service. [**55:**7.1.14.1]

63.3.1.15.2 Replacement and Repair. Leaking, damaged, or corroded compressed gas systems shall be replaced or repaired. [**55:**7.1.14.2]

63.3.1.15.3* Handling of Cylinders, Containers, and Tanks Removed from Service. Compressed gas cylinders, containers, and tanks that have been removed from service shall be handled in an approved manner. [**55:**7.1.14.3]

A.63.3.1.15.3 The gas supplier should be consulted for advice under these circumstances. [**55:**A.7.1.14.3]

63.3.1.15.4 Leaking Systems. Compressed gas systems that are determined to be leaking, damaged, or corroded shall be repaired to a serviceable condition or shall be removed from service. [**55:**7.1.14.4]

63.3.1.16 Surfaces.

63.3.1.16.1 To prevent bottom corrosion, cylinders, containers, and tanks shall be protected from direct contact with soil or surfaces where water might accumulate. [**55:**7.1.15.1]

63.3.1.16.2 Surfaces shall be graded to prevent accumulation of water. [**55:**7.1.15.2]

63.3.1.17 Storage Area Temperature.

63.3.1.17.1 Compressed Gas Containers. Storage area temperatures shall not exceed 125°F (52°C). [**55:**7.1.16.1]

63.3.1.18 Underground Piping.

63.3.1.18.1 Underground piping shall be of welded construction without valves, unwelded mechanical joints, or connections installed underground. [**55:**7.1.17.1]

63.3.1.18.1.1 Valves or connections located in boxes or enclosures shall be permitted to be installed underground where such boxes or enclosures are accessible from above ground and where the valves or connections contained are isolated from direct contact with earth or fill. [**55:**7.1.17.1.1]

63.3.1.18.1.1.1 Valve boxes or enclosures installed in areas subject to vehicular traffic shall be constructed to resist uniformly distributed and concentrated live loads in accordance with the building code for areas designated as vehicular driveways and yards, subject to trucking. [**55:**7.1.17.1.1.1]

63.3.1.18.1.2* Piping installed in trench systems located below grade where the trench is open to above shall not be considered to be underground. [**55:**7.1.17.1.2]

A.63.3.1.18.1.2 Underground piping systems are those systems that are buried and in contact with earth fill or similar materials. Piping located in open-top or grated-top trenches is not considered to be underground although it may be below grade. [**55:**A.7.1.17.1.2]

63.3.1.18.2 Gas piping in contact with earth or other material that could corrode the piping shall be protected against corrosion in an approved manner. [**55:**7.1.17.2]

63.3.1.18.2.1 When cathodic protection is provided, it shall be in accordance with 63.3.1.7. [**55:**7.1.17.2.1]

63.3.1.18.3 Underground piping shall be installed on at least 6 in. (150 mm) of well-compacted bedding material. [**30:**27.6.5.1]

63.3.1.18.4 In areas subject to vehicle traffic, the pipe trench shall be deep enough to permit a cover of at least 18 in. (450 mm) of well-compacted backfill material and pavement. [**30:**27.6.5.2]

63.3.1.18.5 In paved areas where a minimum 2 in. (50 mm) of asphalt is used, backfill between the pipe and the asphalt shall be permitted to be reduced to 8 in. (200 mm) minimum. [**30:**27.6.5.3]

63.3.1.18.6 In paved areas where a minimum 4 in. (100 mm) of reinforced concrete is used, backfill between the pipe and the concrete shall be permitted to be reduced to 4 in. (100 mm) minimum. [**30:**27.6.5.4]

Δ **63.3.1.18.7** In areas not subject to vehicle traffic, the pipe trench shall be deep enough to permit a cover of at least 12. in. (300 mm) of well-compacted backfill material. [**55:**7.1.17.7]

63.3.1.18.8 A greater burial depth shall be provided when required by the manufacturer's instructions or where frost conditions are present. [**30:**27.6.5.6]

Greater burial depth is required in areas where the ground is subject to frost heaves, because frost heaves cause upward movement of the soil, which, in turn, subjects piping to bending stresses that could cause failure of pipe joints.

63.3.1.18.9 Piping within the same trench shall be separated horizontally by at least two pipe diameters. Separation shall not need to exceed 9 in. (230 mm). [**30:**27.6.5.7]

63.3.1.18.10 Two or more levels of piping within the same trench shall be separated vertically by a minimum 6 in. (150 mm) of well-compacted bedding material. [**30:**27.6.5.8]

Paragraph 63.3.1.18.10 recognizes the general underground installation of piping containing compressed gases. The provisions for underground installation have been extended to include a requirement for all welded systems. Underground piping systems are those systems that are buried and in contact with earth fill or similar materials. Piping located in open-top or grated-top trenches is not considered to be underground, although it may be belowgrade. An allowance has been provided for the installation of valve boxes that provide access to valves or connections that may be used for operation of the system.

63.3.1.19 Cleaning and Purging of Gas Piping Systems.

On February 7, 2010, a deadly explosion occurred at Kleen Energy, a natural gas–fueled power plant under construction in Middletown, Connecticut. The explosion resulted in 6 fatalities and nearly 50 injuries to workers at the plant. It was determined by the U.S. Chemical Safety Board (CSB) that the explosion was caused by a "gas blow." Gas blows are a commonly used cleaning procedure in natural gas–fueled power plants, where flammable gas is blown through piping at high pressure to remove debris such as welding slag or other foreign materials. Ten minutes before the Kleen Energy explosion, for example, approximately 480,000 scf (13,592 m^3) of natural gas was released, according to the investigation. The gas was being vented from an open-ended pipe into an area where dissipation was impeded by other equipment at the level of discharge before it found an ignition source. Construction of the plant, which was close to completion when the explosion occurred, was heavily regulated, but no standard guided the gas-blowing procedure at the time of explosion.

Exhibit 63.1 is a photo of an earlier gas blow, showing the dirt and debris streaming out of the discharge location. Exhibit 63.2 shows before and after aerial photos of the explosion at the Kleen Energy plant.

As a result of the investigation and urgent recommendations put forth by the CSB, NFPA developed its first provisional standard, NFPA 56 (PS), *Fire and Explosion Prevention During Cleaning and Purging of Flammable Gas Piping Systems*. NFPA 56 (PS) prohibited the use of flammable gas during cleaning procedures while safeguarding a range of activities related to cleaning and repairing piping systems. Since the provisional standard was issued, NFPA 56 has gone through two revision cycles in accordance with the NFPA Regulations Governing Committee Projects and is no longer a provisional standard.

The provisions of NFPA 56 (PS) related to the cleaning and purging of gas piping systems were the basis for a Tentative Interim Amendment (TIA) that was issued on the 2013 edition of NFPA 55 in October 2012. The emergency development of NFPA 56 (PS) brought to light the need to establish fundamental requirements for cleaning and purging relevant to all gases. The TIA issued on NFPA 55 provided a set of fundamental requirements that is applicable across the spectrum of gases regulated by NFPA 55. The TIA was incorporated into the 2016 edition of NFPA 55.

Exhibit 63.1

Gas blow. (Source: U.S. Chemical Safety Board)

Exhibit 63.2

Kleen Energy plant before and after explosion. (Source: U.S. Chemical Safety Board)

Additional language was also added to this *Code*, in Section 63.5 for bulk oxygen systems, Section 63.6 for bulk gaseous hydrogen systems, Section 63.7 for bulk liquified hydrogen systems, Section 63.8 for gas generation systems, and Section 63.10 for the storage, handling, and use of ethylene oxide for sterilization and fumigation. Each of these sections on specific systems refers to 63.3.1.19 for the provisions related to the cleaning and purging of piping systems.

63.3.1.19.1 General.

63.3.1.19.1.1 Piping systems shall be cleaned and purged in accordance with the requirements of 63.3.1.19 when one or more of the following conditions exist:

(1) The system is installed and prior to being placed into service
(2) There is a change in service
(3)* There are alterations or repair of the system involving the replacement of parts or addition to the piping system and prior to returning the system to service

Δ **A.63.3.1.19.1.1(3)** The replacement of parts in a system to repair leaks, the addition of gaskets, and similar routine maintenance is not intended to establish the need for cleaning of the entire piping system. Conversely, when a piping system is extended, or when the system needs to be rendered safe for maintenance purposes, purging the system before disassembly likely will be required as will internal cleaning if new piping or materials of construction are introduced. [**55:**A.7.1.18.1.1(3)]

(4)* The design standards or written procedures specify cleaning and purging

[**55:**7.1.18.1.1]

A.63.3.1.19.1.1(4) Cleaning and purging of piping systems can be conducted as individual functions, that is, just cleaning, just purging, or in combination as required to satisfy the requirements of the procedures. [**55:**A.7.1.18.1.1(4)]

63.3.1.19.1.2 Cleaning and purging of the internal surfaces of piping systems shall be conducted by qualified individuals trained in cleaning and purging operations and procedures, including the recognition of potential hazards associated with cleaning and purging. [**55:**7.1.18.1.2]

63.3.1.19.1.3* A written cleaning or purging procedure shall be provided to establish the requirements for the cleaning and purging operations to be conducted. [**55:**7.1.18.1.3]

A.63.3.1.19.1.3 It is not intended that a new written procedure be required each time the activity occurs within a facility. [**55:**A.7.1.18.1.3]

Δ **63.3.1.19.1.3.1*** An independent or third-party review of the written procedure shall be conducted after the procedure has been written and shall accomplish the following:

(1) Evaluate hazards, errors, and malfunctions related to each step in the procedure
(2) Review the measures prescribed in the procedure for applicability
(3) Make recommendations for additional hazard mitigation measures if deemed necessary

[**55:**7.1.18.1.3.1]

A.63.3.1.19.1.3.1 The review of the written procedures should not be performed solely by the same person(s) responsible for developing the procedures. It can be performed by an independent person or group within the company or department or by a third-party consultant. [**55:**A.7.1.18.1.3.1]

63.3.1.19.1.3.2 The completed written procedure shall be:

(1) Maintained on site by the facility owner/operator
(2) Provided to operating personnel engaged in cleaning or purging operations
(3) Made available to the AHJ upon request

[**55:**7.1.18.1.3.2]

63.3.1.19.1.3.3 Where generic cleaning or purging procedures have been established, a job-specific operating procedure shall not be required. [**55:**7.1.18.1.3.3]

63.3.1.19.1.3.4 Generic procedures shall be reviewed when originally published or when the procedure or operation is changed. [**55:**7.1.18.1.3.4]

63.3.1.19.1.4 Written procedures to manage a change in process materials, technology, equipment, procedures, and facilities shall be established by the facility owner/operator. [**55:**7.1.18.1.4]

63.3.1.19.1.4.1 The management-of-change procedures shall ensure that the following topics are addressed prior to any change in the configuration or design of the piping system:

(1) The technical basis for the proposed change
(2) The safety and health implications
(3) Whether the change is permanent or temporary
(4) Whether modifications to the cleaning and purging procedures are required as a result of the identified changes

[**55:**7.1.18.1.4.1]

63.3.1.19.1.4.2 When modifications to the cleaning and purging procedures are required, the written procedure shall be updated to incorporate any elements identified by the management-of-change procedures. [**55:**7.1.18.1.4.2]

63.3.1.19.1.5 Prior to cleaning or purging, piping systems shall be inspected and tested to determine that the installation, including the materials of construction, and method of fabrication, comply with the requirements of the design standard used and the intended application for which the system was designed. [**55:**7.1.18.1.5]

63.3.1.19.1.5.1 Inspection and testing of piping systems shall not be required to remove a system from service. [**55:**7.1.18.1.5.1]

Δ **63.3.1.19.1.5.2** Purging of piping systems shall not be required for systems that are utilized for operations designated by written operating procedures in accordance with the requirements of the cleaning or purging procedure specified in 63.3.1.19.1.1. [**55:**7.1.18.1.5.2]

63.3.1.19.1.5.3* Personnel in the affected area(s), as determined by the cleaning or purging procedure, shall be informed of the hazards associated with the operational activity and notified prior to the initiation of any such activity. [**55:**7.1.18.1.5.3]

Δ **A.63.3.1.19.1.5.3** The notification is given to warn personnel that such procedures are about to occur so that they will be out of zones potentially affected by the cleaning or purging procedure. The intended notification is to be commensurate with the operation to be conducted, and the timing of the notification should be relevant to the activity conducted so that personnel in the area can respond in a timely manner. Notification could be an audible and/or visible alarm or an announcement over a public address system, private network, radio, or similar and reliable means of electronic transmission. [**55:**A.7.1.18.1.5.3]

Verbal notification can be used in operations where the piping system is limited to the area occupied by those that will be conducting the cleaning or purging procedures and related operating personnel. These areas frequently are found in occupancies where the gas used to charge the piping system is supplied from portable containers, as well as those areas where the piping system is located primarily in the occupied work area. [**55:**A.7.1.18.1.5.3]

63.3.1.19.2* Cleaning. Piping system designs shall be documented to specify the requirements for the internal cleaning of the piping system prior to installation and initial use. [**55:**7.1.18.2]

A.63.3.1.19.2 For additional information on cleaning techniques used for stainless steel parts and equipment, see ASTM A380, *Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment, and Systems*. [**55:**A.7.1.18.2]

63.3.1.19.2.1 The internal surfaces of gas piping systems shall be cleaned to ensure that the required standard of cleanliness specified by the design is met prior to placing the gas piping system into service. [**55:**7.1.18.2.1]

63.3.1.19.2.2* When piping systems are cleaned in stages during installation or assembly, the interior of the cleaned piping shall be protected against the infiltration of unwanted contaminants. [**55:**7.1.18.2.2]

Δ **A.63.3.1.19.2.2** During construction, visual inspection should be performed on sections of pipe as the piping system is being assembled to ensure that no gross contamination is left in the pipe. Where the standard of cleanliness is high, fabrication techniques should be utilized that do not introduce contamination into the pipe. Examples of these techniques can include, but are not limited to, constant inert gas purging, or assembly in a particulate controlled environment. The use of piping and components with a high-quality interior surface finish, and high-quality materials of construction all have an effect on the ability to maintain a high degree of cleanliness. Cleaning after construction can typically be accomplished by one or more of the following methods:

(1) Pigging
(2) Mechanical scraping
(3) High-velocity gas flow
(4) Liquid washing
(5) Use of cleaning media
(6) Application of high vacuum
(7) Solvent cleaning
(8) Water washing
(9) Steam cleaning

[**55:**A.7.1.18.2.2]

63.3.1.19.3* Purging. Piping systems used to contain gases with a physical or health hazard in any of the categories specified by 63.1.4 shall be purged prior to being placed into service for initial use. [**55:**7.1.18.3]

A.63.3.1.19.3 Purging can be accomplished by continuous media or gas flow, evacuation or vacuum, or repeated pressurizing and venting cycles commonly referred to as pulse purging or cycle purging. In some cases, purge procedures can involve more than one type of purging technique. Purging can be accomplished by manual or automatic means. Automated purge panels or manifold systems operated by a programmable logic controller are commonly used as a means to enhance the results of a purging process where high purity gas delivery systems are employed. [**55:**A.7.1.18.3]

Δ **63.3.1.19.3.1** Piping systems shall be purged to remove the internal contents preceding the following activities or operations:

(1) Activating or placing a piping system into service
(2) Deactivating or removing a piping system from service
(3) Changing the service of a piping system from one gas to another, except when such gas is supplied to a manifold or piping system designed for the purpose of filling or otherwise processing cylinders, containers, or tanks in a process with established procedures
(4) Performing service, maintenance, or modifications on a system where personnel or designated areas will potentially be exposed to the internal contents of the piping system
(5) Performing hot work, including but not limited to welding, cutting or brazing on the piping system

[**55:**7.1.18.3.1]

63.3.1.19.3.2 The termination point for the release of purged gases shall be in accordance with 63.2.15. [**55:**7.1.18.3.2]

63.3.1.19.3.2.1 The release of purged gases or mixtures containing any quantity of corrosive, toxic, or highly toxic gases shall be through a treatment system in accordance with the applicable requirements of 63.3.5.3.4 or 63.3.9.3. [**55:**7.1.18.3.2.1]

Δ **63.3.1.19.3.2.2** The termination point for the release of purged gases resultant from the purging of piping systems out of service, other than those in accordance with 63.3.1.19.3.2.1, shall not be required to be in accordance with 63.2.15 where the contained volume of the piping system when released to indoor areas does not result in a concentration in the room or area that will reduce the oxygen concentration in the room or area below a level of 19.5 percent or that exceeds any of the following limits:

(1) Ceiling limit
(2) Permissible exposure limit
(3) Short term exposure limit
(4) Twenty-five percent of the lower flammable limit

[**55:**7.1.18.3.2.2]

63.3.2 Storage.

63.3.2.1 General.

Δ **63.3.2.1.1 Applicability.** The storage of compressed gas cylinders, containers, and tanks shall be in accordance with 63.3.2. [**55:**7.2.1.1]

63.3.2.1.2 Upright Storage Flammable Gas in Solution and Liquefied Flammable Gas. Cylinders, containers, and tanks containing liquefied flammable gases and flammable gases in solution shall be positioned in the upright position. [**55:**7.2.1.2]

63.3.2.1.2.1 Cylinders and Containers of 1.3 Gal (5 L) or Less. Containers with a capacity of 1.3 gal (5 L) or less shall be permitted to be stored in a horizontal position. [**55:**7.2.1.2.1]

63.3.2.1.2.2 Cylinders, Containers, and Tanks Designed for Horizontal Use. Cylinders, containers, and tanks designed for use in a horizontal position shall be permitted to be stored in a horizontal position. [**55:**7.2.1.2.2]

63.3.2.1.2.3 Palletized Cylinders, Containers, and Tanks. Cylinders, containers, and tanks, with the exception of those containing flammable liquefied compressed gases, that are palletized for transportation purposes shall be permitted to be stored in a horizontal position. [**55:**7.2.1.2.3]

63.3.2.1.3 Classification of Weather Protection as an Indoor Versus an Outdoor Area. For other than explosive materials and hazardous materials presenting a detonation hazard, a weather protection structure shall be permitted to be used for sheltering outdoor storage or use areas without requiring such areas to be classified as indoor storage. [**55:**7.2.1.3]

63.3.2.2 Material-Specific Regulations.

63.3.2.2.1 Indoor Storage. Indoor storage of compressed gases shall be in accordance with the material-specific provisions of 63.3.4 through 63.3.10. [**55:**7.2.2.1]

63.3.2.2.2 Exterior Storage.

63.3.2.2.2.1 General. Exterior storage of compressed gases shall be in accordance with the material-specific provisions of 63.3.4 through 63.3.10. [**55:**7.2.2.2.1]

63.3.2.2.2.2 Separation. Distances from property lines, buildings, and exposures shall be in accordance with the material-specific provisions of 63.3.4 through 63.3.10. [**55:**7.2.2.2.2]

63.3.3 Use and Handling.

63.3.3.1 General.

63.3.3.1.1 Applicability. The use and handling of compressed gas cylinders, containers, tanks, and systems shall be in accordance with 63.3.3.1. [**55:**7.3.1.1]

63.3.3.1.2 Controls.

63.3.3.1.2.1 Compressed gas system controls shall be designed to prevent materials from entering or leaving the process at an unintended time, rate, or path. [**55:**7.3.1.2.1]

63.3.3.1.2.2 Automatic controls shall be designed to be fail-safe. [**55:**7.3.1.2.2]

Δ **63.3.3.1.3 Piping Systems.** Piping, tubing, fittings, and related components shall be designed, fabricated, and tested in accordance with the requirements of the applicable parts in ASME B31.3, *Process Piping*. [**55:**7.3.1.3]

63.3.3.1.3.1 Integrity. Piping, tubing, pressure regulators, valves, and other apparatus shall be kept gastight to prevent leakage. [**55:**7.3.1.3.1]

63.3.3.1.3.2 Backflow Prevention. Backflow prevention or check valves shall be provided where the backflow of hazardous materials could create a hazardous condition or cause the unauthorized discharge of hazardous materials. [**55:**7.3.1.3.2]

63.3.3.1.4 Valves.

63.3.3.1.4.1 Valves utilized on compressed gas systems shall be designed for the gas or gases and pressure intended and shall be accessible. [**55:**7.3.1.4.1]

63.3.3.1.4.2 Valve handles or operators for required shutoff valves shall not be removed or otherwise altered to prevent access. [**55:**7.3.1.4.2]

63.3.3.1.5 Vent Pipe Termination.

63.3.3.1.5.1 Venting of gases shall be directed to an approved location. [**55:**7.3.1.5.1]

63.3.3.1.5.2 The termination point for piped vent systems serving cylinders, containers, tanks, and gas systems used for the purpose of operational or emergency venting shall be in accordance with 63.2.15. [**55:**7.3.1.5.2]

63.3.3.1.6 Upright Use.

63.3.3.1.6.1 Compressed gas cylinders, containers, and tanks containing flammable liquefied gas, except those designed for use in a horizontal position and those compressed gas cylinders, containers, and tanks containing nonliquefied gases, shall be used in a "valve end up" upright position. [**55:**7.3.1.6.1]

63.3.3.1.6.2 An upright position shall include a position in which the cylinder, container, or tank axis is inclined as much as 45 degrees from the vertical and in which the relief device is always in direct communication with the gas phase. [**55:**7.3.1.6.2]

63.3.3.1.7 Inverted Use. Cylinders, containers, and tanks containing nonflammable liquefied gases shall be permitted to be used in the inverted position when the liquid phase is used. [**55:**7.3.1.7]

63.3.3.1.7.1 Flammable liquefied gases at processing plants shall be permitted to use this inverted position method while transfilling. [**55:**7.3.1.7.1]

63.3.3.1.7.2 The cylinder, container, or tank shall be secured, and the dispensing apparatus shall be designed for use with liquefied gas. [**55:**7.3.1.7.2]

63.3.3.1.8 Cylinders and Containers of 1.3 Gal (5 L) or Less. Cylinders or containers with a water volume of 1.3 gal (5 L) or less shall be permitted to be used in a horizontal position. [**55:**7.3.1.8]

63.3.3.1.9 Transfer. Transfer of gases between cylinders, containers, and tanks shall be performed by qualified personnel using equipment and operating procedures in accordance with CGA P-1, *Safe Handling of Compressed Gases in Containers*. [**55:**7.3.1.9]

63.3.3.1.10 Use of Compressed Gases for Inflation. Inflatable equipment, devices, or balloons shall only be pressurized or filled with compressed air or inert gases. [**55:**7.3.1.10]

The use of hydrogen, which is a flammable gas, for balloons or other inflatable equipment and devices, is prohibited by NFPA 55.

63.3.3.1.11 Emergency Shutoff Valves.

Δ **63.3.3.1.11.1** Accessible manual or automatic emergency shutoff valves shall be provided to shut off the flow of gas in case of emergency. [**55:**7.3.1.11.1]

63.3.3.1.11.1.1* Manual emergency shutoff valves or the device that activates an automatic emergency shutoff valve on a bulk source or piping system serving the bulk supply shall be identified by means of a sign. [**55:**7.3.1.11.1.1]

A.63.3.3.1.11.1.1 In operations where an automatic emergency shutoff valve is activated by a control system that is operated from a remote station or by remote station software, the software system should be designed to provide a visual indication of the emergency shutdown control system. The visual emergency shutdown function should be able to be identified by trained operators and recognizable to emergency response personnel. [**55:**A.7.3.1.11.1.1]

• **63.3.3.1.11.2** Emergency shutoffs shall be located at the point of use and at the tank, cylinder, or bulk source, and at the point where the system piping enters the building. [**55:**7.3.1.11.2]

63.3.3.1.12 Emergency Isolation.

63.3.3.1.12.1 Where compressed gases having a hazard ranking in one or more of the following hazard classes in accordance with NFPA 704 are carried in pressurized piping above a gauge pressure of 15 psi (103 kPa), an approved method of emergency isolation shall be provided:

(1) Health hazard Class 3 or Class 4
(2) Flammability Class 4
(3) Instability Class 3 or Class 4
[**55:**7.3.1.12.1]

• **63.3.3.1.12.2** Approved means of meeting the requirements for emergency isolation shall include any of the following:

(1) Automatic shutoff valves, located as close to the bulk source as practical, tied to leak detection systems
(2) Attended control stations where trained personnel can monitor alarms or supervisory signals and can trigger emergency responses
(3) A constantly monitored control station with an alarm and remote shut off of the gas supply system
(4) Excess flow valves at the bulk source
[**55:**7.3.1.12.2]

The purpose of excess flow control is to shut down the source of the gas if the piping system ruptures. The use of leak detection and emergency shutoff is a common method of accomplishing a shutdown, and it is used throughout the industry in instances where gases are located in gas cabinets or other enclosed spaces.

There are other portions of the system where excess flow control is not warranted, including those portions of the system designed to prevent the backflow from the source container, as well as for portions of the system serving pressure relief devices.

63.3.3.1.12.3 The requirements of 63.3.3.1.12 shall not be required for the following:

(1) Piping for inlet connections designed to prevent backflow at the source
(2) Piping for pressure relief devices
(3) Where the source of the gas is not in excess of the quantity threshold indicated in Table 63.2.3.1.1
[**55:**7.3.1.12.3]

• **63.3.3.1.12.4 Location Exemptions.** The requirements of 63.3.3.1.12 shall not apply to the following:

(1) Piping for inlet connections designed to prevent backflow
(2) Piping for pressure relief devices
(3) Systems containing 430 scf (12.7 m^3) or less of flammable gas
[**55:**7.3.1.12.4]

63.3.3.2 Material-Specific Regulations.

63.3.3.2.1 Indoor Use. Indoor use of compressed gases shall be in accordance with the requirements of 63.3.4 through 63.3.10. [**55:**7.3.2.1]

63.3.3.2.2 Exterior Use.

63.3.3.2.2.1 General. Exterior use of compressed gases shall be in accordance with the requirements of 63.3.4 through 63.3.10. [**55:**7.3.2.2.1]

63.3.3.2.2.2 Separation. Distances from property lines, buildings, and exposure hazards shall be in accordance with the material-specific provisions of 63.3.4 through 63.3.10. [**55:**7.3.2.2.2]

63.3.3.3 Handling.

Δ **63.3.3.3.1 Applicability.** The handling of compressed gas cylinders, containers, and tanks shall be in accordance with 63.3.3.3. [**55:**7.3.3.1]

63.3.3.3.2 Carts and Trucks.

63.3.3.3.2.1 Cylinders, containers, and tanks shall be moved using an approved method. [**55:**7.3.3.2.1]

Δ **63.3.3.3.2.2** Where cylinders, containers, and tanks are moved by hand cart, hand truck, or other mobile device, such carts, trucks, or devices shall be designed for the secure movement of cylinders, containers, and tanks. [**55:**7.3.3.2.2]

63.3.3.3.3 Lifting Devices. Ropes, chains, or slings shall not be used to suspend compressed gas cylinders, containers, and tanks unless provisions at time of manufacture have been made on the cylinder, container, or tank for appropriate lifting attachments, such as lugs. [**55:**7.3.3.3]

Δ **63.3.4 Medical Gas Systems.** Medical gas systems for health care shall be in accordance with NFPA 99. [**55:**7.4]

63.3.5 Corrosive Gases.

63.3.5.1 General. The storage or use of corrosive compressed gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be in accordance with Chapters 1 through 6 of NFPA 55 and 63.3.1 through 63.3.3 and 63.3.5. [**55:**7.5.1]

63.3.5.2 Distance to Exposures. The outdoor storage or use of corrosive compressed gas shall not be within 20 ft (6.1 m) of buildings not associated with the manufacture or distribution of corrosive gases, lot lines, streets, alleys, public ways, or means of egress. [**55:**7.5.2]

63.3.5.2.1 A 2-hour fire barrier wall without openings or penetrations and that extends not less than 30 in. (762 mm) above and to the sides of the storage or use area shall be permitted in lieu of the 20 ft (6.1 m) distance. [**55:**7.5.2.1]

63.3.5.2.1.1* Where a fire barrier is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.5.2.1.1]

Leaks in a piping system pose a risk for the system. However, the piping system is protected against major failure by the requirements for excess flow control. A protective structure provides a barrier to radiant heat, protecting elements on the side of the structure opposite the compressed gas system and shielding the compressed gas system from exposures on the other side of the structure.

A.63.3.5.2.1.1 Portions of the system upstream of the source valve include the containers or bulk supply as well as control equipment designed to control the flow of gas into a piping system. The piping system downstream of the source valve is protected by excess flow control should failure occur in the piping system and is not required to be protected by the fire barrier. The fire barrier serves to protect those portions of the system that are the most vulnerable along with the necessary controls used to operate the system. [**55:**A.7.5.2.1.1]

63.3.5.2.1.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage or use area. [**55:**7.5.2.1.2]

The use of a 2-hour fire barrier has been recognized as a suitable means to minimize exposure hazards to materials in storage or in use, as well as to act as a protective barrier between the material stored or used and the building structure. See the commentary following 63.3.5.2.1.1.

63.3.5.2.1.3 The 2-hour fire barrier shall be located at least 5 ft (1.5 m) from any exposure. [**55:**7.5.2.1.3]

63.3.5.2.1.4 The 2-hour fire barrier wall shall not have more than two sides at approximately 90 degree (1.57 rad) directions or not more than three sides with connecting angles of approximately 135 degrees (2.36 rad). [**55:**7.5.2.1.4]

63.3.5.3 Indoor Use. The indoor use of corrosive gases shall be provided with a gas cabinet, exhausted enclosure, or gas room. [**55:**7.5.3]

63.3.5.3.1 Gas Cabinets. Gas cabinets shall be in accordance with 63.2.17. [**55:**7.5.3.1]

63.3.5.3.2 Exhausted Enclosures. Exhausted enclosures shall be in accordance with 63.2.18. [**55:**7.5.3.2]

63.3.5.3.3 Gas Rooms. Gas rooms shall be in accordance with 63.2.4. [**55:**7.5.3.3]

63.3.5.3.4 Treatment Systems. Treatment systems, except as provided for in 63.3.5.3.4.1, gas cabinets, exhausted enclosures, and gas rooms containing corrosive gases in use shall be provided with exhaust ventilation, with all exhaust directed to a treatment system designed to process the accidental release of gas. [**55:**7.5.3.4]

63.3.5.3.4.1 Treatment systems shall not be required for corrosive gases in use where provided with the following:

(1) Gas detection in accordance with 63.3.9.3.2.1.1
(2) Fail-safe automatic closing valves in accordance with 63.3.9.3.2.2

[**55:**7.5.3.4.1]

63.3.5.3.4.2 Treatment systems shall be capable of diluting, adsorbing, absorbing, containing, neutralizing, burning, or otherwise processing the release of corrosive gas in accordance with 63.3.9.3.4.1. [**55:**7.5.3.4.2]

63.3.5.3.4.3 Treatment system sizing shall be in accordance with 63.3.9.3.4. [**55:**7.5.3.4.3]

63.3.6 Flammable Gases.

63.3.6.1 Storage, Use, and Handling.

63.3.6.1.1* The storage or use of flammable gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be in accordance with Chapters 1 through 6 of NFPA 55 and 63.3.1 through 63.3.3 and 63.3.6. [**55:**7.6.1.1]

N **A.63.3.6.1.1** All liquefied and nonliquefied flammable compressed gases are regulated by 63.3.6 unless they are specifically indicated as not applicable in accordance with 63.1.1.4. [**55:**A.7.6.1.1]

63.3.6.1.2 Storage, use, and handling of gaseous hydrogen shall be in accordance with 63.3.6.1 and Chapter 10 of NFPA 55. [**55:**7.6.1.2]

N **63.3.6.1.3** Storage, use, and handling of compressed natural gas shall be in accordance with 63.3.6.1. [**55:**7.6.1.3]

The past few years have seen an increase in the use of "portable" compressed natural gas tube trailers being used to provide fuel for heating, steam generation, and so forth. These trailers are used to provide natural gas in locations where pipelines are not available. Empty trailers are swapped out for new ones as needed. Because compressed natural gas (CNG) is a flammable gas under NFPA 55, these installations must be designed and operated per NFPA 55.

Δ **63.3.6.2 Distance to Exposures.** The outdoor storage or use of non-bulk flammable compressed gas shall be located from lot lines, public streets, public alleys, public ways, or buildings not associated with the manufacture or distribution of such gases in accordance with Table 63.3.6.2. [**55:**7.6.2]

63.3.6.2.1 Bulk hydrogen gas installations shall be in accordance with Chapter 10 of NFPA 55. [**55:**7.6.2.1]

63.3.6.2.1.1* Where a protective structure is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.6.2.1.1]

A.63.3.6.2.1.1 See A.63.3.5.2.1.1. [**55:**A.7.6.2.1.1]

63.3.6.2.1.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage or use area. [**55:**7.6.2.1.2]

63.3.6.2.2 Bulk gas systems for flammable gases other than hydrogen shall be in accordance with Table 10.4.2.2.1(a), Table 10.4.2.2.1(b), or Table 10.4.2.2.1(c) of NFPA 55 where the quantity of flammable compressed gas exceeds 5000 scf (141.6 Nm^3). [**55:**7.6.2.2]

63.3.6.2.2.1 Where fire barriers are used as a means of distance reduction, fire barriers shall be in accordance with 10.4.2.2.4 of NFPA 55. [**55:**7.6.2.2.1]

Δ *TABLE 63.3.6.2 Distance to Exposures for Non—Bulk Flammable Gases*

Maximum Amount per Storage Area (scf)	Minimum Distance Between Storage Areas (ft)	Minimum Distance to Lot Lines of Property That Can Be Built Upon (ft)	Minimum Distance to Public Streets, Public Alleys or Public Ways (ft)	Minimum Distance to Buildings on the Same Property		
				Less Than 2-Hour Construction	2-Hour Construction	4-Hour Construction
0–4225	5	5	5	5	0	0
4226–21,125	10	10	10	10	5	0
21,126–50,700	10	15	15	20	5	0
50,701–84,500	10	20	20	20	5	0
84,501–200,000	20	25	25	20	5	0

For SI units, 1 ft = 304.8 mm; 1 scf = 0.02832 Nm^3.

Note: The minimum required distances does not apply where fire barriers without openings or penetrations having a minimum fire–resistive rating of 2 hours interrupt the line of sight between the storage and the exposure. The configuration of the fire barriers shall be designed to allow natural ventilation to prevent the accumulation of hazardous gas concentrations. [**55:** Table 7.6.2]

63.3.6.2.2.2 Mobile acetylene trailer systems (MATS) shall be located in accordance with 15.2.3 of NFPA 55. [**55:**7.6.2.2.2]

63.3.6.2.3 The configuration of the protective structure shall be designed to allow natural ventilation to prevent the accumulation of hazardous gas concentrations. [**55:**7.6.2.3]

63.3.6.2.4 Storage and use of flammable compressed gases shall not be located within 50 ft (15.2 m) of air intakes. [**55:**7.6.2.4]

63.3.6.2.5 Storage and use of flammable gases outside of buildings shall also be separated from building openings by 25 ft (7.6 m). Fire barriers shall be permitted to be used as a means to separate storage areas from openings or a means of egress used to access the public way. [**55:**7.6.2.5]

63.3.6.3 Indoor Non-Bulk Hydrogen Compressed Gas System Location.

Δ **63.3.6.3.1** Hydrogen systems of less than 5000 scf (141.6 Nm^3) and greater than the MAQ, where located inside buildings, shall be in accordance with the following:

(1) In a ventilated area in accordance with the provisions of 63.2.16
(2) Separated from incompatible materials in accordance with the provisions of 63.3.1.11.2
(3) A distance of 25 ft (7.6 m) from open flames and other sources of ignition
(4) A distance of 50 ft (15 m) from intakes of ventilation, air-conditioning equipment, and air compressors located in the same room or area as the hydrogen system
  (a) The distance shall be permitted to be reduced to 10 ft (3.1 m) where the room or area in which the hydrogen system is installed is protected by a listed detection system per Article 500.7(K) of *NFPA 70* and the detection system shuts down the fuel supply in the event of a leak that results in a concentration that exceeds 25 percent of the LFL.
  (b) Emergency shutoff valves shall be provided in accordance with 63.3.3.1.11.
(5) A distance of 50 ft (15 m) from other flammable gas storage
(6) Protected against damage in accordance with the provisions of 63.3.1.9.4.

[**55:**10.3.4.1]

63.3.6.3.2 Systems Installed in One Room.

63.3.6.3.2.1 More than one system of 5000 scf (141.6 Nm^3) or less shall be permitted to be installed in the same room or area, provided the systems are separated by at least 50 ft (15 m) or a full-height fire-resistive partition having a minimum fire resistance rating of 2 hours is located between the systems. [**55:**10.3.4.2.1]

Δ **63.3.6.3.2.2** The separation distance between multiple systems of 5000 scf (141.6 Nm^3) or less shall be permitted to be reduced to 25 ft (7.6 m) in buildings where the space between storage areas is free of combustible materials and protected with a sprinkler system designed for Extra Hazard, Group 1 occupancies in accordance with the requirements of 63.2.10. [**55:**10.3.4.2.2]

63.3.6.3.2.3 The required separation distance between individual portable systems in the process of being filled or serviced in facilities associated with the manufacture or distribution of hydrogen and its mixtures shall not be limited by 63.3.6.3.2.1 or 63.3.6.3.2.2 when such facilities are provided with Protection Level 2 controls and the applicable requirements of Chapters 1 through 7 of NFPA 55. [**55:**10.3.4.2.3]

63.3.6.4 Ignition Source Control. Ignition sources in areas containing flammable gases shall be in accordance with 63.3.6.4. [**55:**7.6.43]

63.3.6.4.1 Static Producing Equipment. Static producing equipment located in flammable gas areas shall be grounded. [**55:**7.6.3.1]

See NFPA 77, *Recommended Practice on Static Electricity*, for additional information on reducing ignition sources related to static electricity.

Δ TABLE 63.3.7.2 *Distance to Exposures for Oxidizing Gases*

Quantity of Gas Stored (at NTP)		Distance to a Building Not Associated with the Manufacture or Distribution of Oxidizing Gases or to a Public Way or Property Line		Minimum Distance Between Storage Areas	
scf	Nm³	ft	m	ft	m
0–50,000	0–1416	5	1.5	5	1.5
50,001–100,000	1417–2832	10	3.0	10	3.0
≤100,001	≤2833	15	4.6	15	4.6

[**55:** Table 7.7.2]

63.3.6.4.2 No Smoking or Open Flame. Signs shall be posted in areas containing flammable gases stating that smoking or the use of open flame, or both, is prohibited within 25 ft (7.6 m) of the storage or use area perimeter. [**55:**7.6.3.2]

See Section 10.9 for detailed guidance on smoking requirements.

63.3.6.4.3 Heating. Heating, where provided, shall be by indirect means. Equipment used for heating applications in rooms or areas where flammable gases are stored or used shall be listed and labeled for use in hazardous environments established by the gases present and shall be installed in accordance with the conditions of the listing and the manufacturer's installation instructions. [**55:**7.6.3.3]

63.3.6.5 Electrical. Areas in which the storage or use of compressed gases exceeds the quantity thresholds for gases requiring special provisions shall be in accordance with *NFPA 70*. [**55:**7.6.4]

63.3.6.6 Maintenance of Piping Systems.

63.3.6.6.1 Maintenance of flammable gas system piping and components shall be performed annually by a qualified representative of the equipment owner. [**55:**7.6.5.1]

63.3.6.6.2 This maintenance shall include inspection for physical damage, leak tightness, ground system integrity, vent system operation, equipment identification, warning signs, operator information and training records, scheduled maintenance and retest records, alarm operation, and other safety-related features. [**55:**7.6.5.2]

63.3.6.6.3 Scheduled maintenance and retest activities shall be formally documented, and records shall be maintained a minimum of 3 years. [**55:**7.6.5.3]

63.3.7 Oxidizing Gases.

63.3.7.1 General. The storage or use of oxidizing compressed gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be in accordance with Chapters 1 through 6 of NFPA 55 and 63.3.1 through 63.3.3 and 63.3.7. [**55:**7.7.1]

63.3.7.2 Distance to Exposures. The outdoor storage or use of oxidizing compressed gas shall be in accordance with Table 63.3.7.2. [**55:**7.7.2]

63.3.7.2.1 The distances shall not apply where fire barriers having a minimum fire resistance of 2 hours interrupt the line of sight between the container and the exposure. [**55:**7.7.2.1]

63.3.7.2.1.1* Where a fire barrier is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.7.2.1.1]

A.63.3.7.2.1.1 See A.63.3.5.2.1.1. [**55:**A.7.7.2.1.1]

63.3.7.2.1.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage or use area. [**55:**7.7.2.1.2]

The use of a 2-hour fire barrier has been recognized as a suitable means to minimize exposure hazards to materials in storage or in use, as well as to act as a protective barrier between the material stored or used and the building structure. See the commentary following 63.3.5.2.1.1.

63.3.7.2.2 The fire barrier shall be at least 5 ft (1.5 m) from the storage or use area perimeter. [**55:**7.7.2.2]

63.3.7.2.3 The configuration of the fire barrier shall allow natural ventilation to prevent the accumulation of hazardous gas concentrations. [**55:**7.7.2.3]

63.3.8 Pyrophoric Gases.

63.3.8.1 General. Pyrophoric compressed gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be stored and used in accordance with Chapters 1 through 6 of NFPA 55 and 63.3.1 through 63.3.3 and 63.3.8. [**55:**7.8.1]

63.3.8.2 Silane and Silane Mixtures. Silane and silane mixtures shall be stored, used, and handled in accordance with the provisions of ANSI/CGA G-13, *Storage and Handling of Silane and Silane Mixtures*. [**55:**7.8.2]

63.3.8.3 Distance to Exposures. The outdoor storage or use of pyrophoric compressed gas shall be in accordance with Table 63.3.8.3. [**55:**7.8.3]

63.3.8.3.1 The distances shall be allowed to be reduced to 5 ft (1.5 m) where fire barriers having a minimum fire resistance of

Δ *TABLE 63.3.8.3 Distance to Exposures for Pyrophoric Gases*

Maximum Amount per Storage Area		Minimum Distance Between Storage Areas		Minimum Distance to Property Lines		Minimum Distance to Public Ways		Minimum Distance to Buildings on the Same Property					
								Less Than 2-Hour Construction		2-Hour Construction		4-Hour Construction	
scf	Nm^3	ft	m	ft	m	ft	m	ft	m	ft	m	ft	m
250	7.1	5	1.5	25	7.6	5	1.5	5	1.5	0	0	0	0
>250 to 2500	>7.1 to 71.0	10	3.0	50	15.2	10	3.0	10	3.0	5	1.5	0	0

[**55:** Table 7.8.3]

2 hours interrupt the line of sight between the container and the exposure. [**55:**7.8.3.1]

63.3.8.3.1.1* Where a fire barrier is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.8.3.1.1]

A.63.3.8.3.1.1 See A.63.3.5.2.1.1. [**55:**A.7.8.3.1.1]

63.3.8.3.1.2 The fire barrier shall be either an independent structure or the exterior wall of the building adjacent to the storage or use area. [**55:**7.8.3.1.2]

See the commentary following 63.3.5.2.1.1.

63.3.8.3.1.3 The fire barrier shall be at least 5 ft (1.5 m) from the storage or use area perimeter. [**55:**7.8.3.1.3]

63.3.8.3.1.4 The configuration of the fire barrier shall allow natural ventilation to prevent the accumulation of hazardous gas concentrations. [**55:**7.8.3.1.4]

63.3.8.3.2 Storage and use of pyrophoric gases outside buildings shall be separated from building openings by 25 ft (7.6 m). [**55:**7.8.3.2]

63.3.8.3.2.1 Fire barriers shall be permitted to be used as a means to separate storage areas from building openings that are used to access the public way. [**55:**7.8.3.2.1]

63.3.9 Toxic and Highly Toxic Gases.

63.3.9.1 General. The storage or use of toxic and highly toxic gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be in accordance with Chapters 1 through 6 of NFPA 55 and 63.3.1 through 63.3.3 and 63.3.9. [**55:**7.9.1]

Because toxic gases can affect people quickly, the storage provisions of 63.3.9.1 are stringent. Many gases do not have an odor and, when they exceed safety thresholds, can incapacitate people before mitigating action can be taken.

63.3.9.2 Ventilation and Arrangement.

63.3.9.2.1 Indoors. The indoor storage or use of highly toxic gases or toxic gases shall be provided with a gas cabinet, exhausted enclosure, or gas room. [**55:**7.9.2.1]

63.3.9.2.1.1 Gas cabinets shall be in accordance with 63.2.17. [**55:**7.9.2.1.1]

63.3.9.2.1.2 Exhausted enclosures shall be in accordance with 63.2.18. [**55:**7.9.2.1.2]

63.3.9.2.1.3 Gas rooms shall be in accordance with 63.2.4. [**55:**7.9.2.1.3]

63.3.9.2.2 Distance to Exposures. The outdoor storage or use of toxic or highly toxic compressed gases shall not be within 75 ft (23 m) of lot lines, streets, alleys, public ways or means of egress, or buildings not associated with such storage or use. [**55:**7.9.2.2]

63.3.9.2.2.1 A 2-hour fire barrier wall without openings or penetrations that extends not less than 30 in. (762 mm) above and to the sides of the storage or use area and that interrupts the line of sight between the storage or use area and the exposure shall be permitted in lieu of the 75 ft (23 m) distance. [**55:**7.9.2.2.1]

63.3.9.2.2.1.1* Where a fire barrier is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.9.2.2.1.1]

A.63.3.9.2.2.1.1 See A.63.3.5.2.1.1. [**55:**A.7.9.2.2.1.1]

See the commentary following 63.3.5.2.1.1.

63.3.9.2.2.1.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage or use area. [**55:**7.9.2.2.1.2]

63.3.9.2.2.1.3 The 2-hour fire barrier wall shall be located at least 5 ft (1.5 m) from any exposure. [**55:**7.9.2.2.1.3]

63.3.9.2.2.1.4 The 2-hour fire barrier wall shall not have more than two sides at approximately 90 degree (1.5 rad) directions or more than three sides with connecting angles of approximately 135 degrees (2.36 rad). [**55:**7.9.2.2.1.4]

63.3.9.2.2.2 Where the storage or use area is located closer than 75 ft (23 m) to a building not associated with the manufacture or distribution of toxic or highly toxic compressed gases, openings in the building other than for piping shall not be permitted above the height of the top of the 2-hour fire barrier wall or within 50 ft

(15 m) horizontally from the storage area, regardless of whether the openings are shielded by a fire barrier. [**55:**7.9.2.2.2]

63.3.9.2.3 Air Intakes. Storage and use of toxic and highly toxic compressed gases shall not be located within 75 ft (23 m) of air intakes. [**55:**7.9.2.3]

Because the dispersion patterns for gases are site specific, preventing toxic gases from entering structures is important.

Gases disperse on the basis of the meteorological conditions (wind speed and temperature), the release velocity and temperature, and the geometric relationship of the discharge point to nearby structures. At some locations, a gas release might move up and away from the release point. At other locations, downwash effects might occur, and the release might be pulled toward the ground (and possibly enter the facility through an opening in the building). Because dispersion patterns are site specific (based on how the parameters mentioned previously vary from site to site) and could require some complex air dispersion modeling, predicting where a release is headed might be difficult.

63.3.9.3 Treatment Systems. Except as provided in 63.3.9.3.1 and 63.3.9.3.2, gas cabinets, exhausted enclosures, and gas rooms containing toxic or highly toxic gases shall be provided with exhaust ventilation, with all exhaust directed to a treatment system designed to process accidental release of gas. [**55:**7.9.3]

Δ **63.3.9.3.1 Storage of Toxic or Highly Toxic Gases.** Treatment systems shall not be required for toxic or highly toxic gases in storage where cylinders, containers, and tanks are provided with the controls specified in 63.3.9.3.1.1 through 63.3.9.3.1.3. [**55:**7.9.3.1]

63.3.9.3.1.1 Valve Outlets Protected. Valve outlets shall be equipped with outlet plugs or caps, or both, rated for the container service pressure. [**55:**7.9.3.1.1]

63.3.9.3.1.2 Handwheels Secured. Where provided, handwheel-operated valves shall be secured to prevent movement. [**55:**7.9.3.1.2]

63.3.9.3.1.3 Containment Devices Provided. Approved cylinder containment vessels or cylinder containment systems shall be provided at an approved location. [**55:**7.9.3.1.3]

Δ **63.3.9.3.2 Use of Toxic Gases.** Treatment systems shall not be required for toxic gases in use where cylinders, containers, and tanks are provided with the controls specified in 63.3.9.3.2.1 and 63.3.9.3.2.2. [**55:**7.9.3.2]

63.3.9.3.2.1 Gas Detection.

63.3.9.3.2.1.1 A gas detection system with a sensing interval not exceeding 5 minutes shall be provided. [**55:**7.9.3.2.1.1]

63.3.9.3.2.1.2 The gas detection system shall monitor the exhaust system at the point of discharge from the gas cabinet, exhausted enclosure, or gas room. [**55:**7.9.3.2.1.2]

63.3.9.3.2.2 Fail-Safe Automatic Closing Valve. An approved automatic-closing fail-safe valve shall be located on or immediately adjacent to and downstream of active cylinder, container, or tank valves. [**55:**7.9.3.2.2]

63.3.9.3.2.2.1 The fail-safe valve shall close when gas is detected at the permissible exposure limit, short-term exposure limit (STEL), or ceiling limit by the gas detection system. [**55:**7.9.3.2.2.1]

63.3.9.3.2.2.2 For attended operations, a manual closing valve shall be permitted when in accordance with 63.3.9.3.4.3. [**55:**7.9.3.2.2.2]

63.3.9.3.2.2.3 For gases used at unattended operations for the protection of public health, such as chlorine at water or wastewater treatment sites, the automatic valve shall close if the concentration of gas detected by a gas detection system reaches one-half of the IDLH. [**55:**7.9.3.2.2.3]

63.3.9.3.2.2.4 The gas detection system shall also alert persons on-site and a responsible person off-site when the gas concentration in the storage/use area reaches the OSHA PEL, OSHA ceiling limit, or OSHA/STEL for the gas employed. [**55:**7.9.3.2.2.4]

Workplace exposures are commonly expressed as time-weighted average (TWA) concentrations that use one of two established terms to define the specific exposure limits permitted for a specific chemical substance: *permissible exposure limit* (PEL) and *threshold limit value* (TLV). Both terms represent the concentration levels that will not cause adverse effects, illness, or disease for persons exposed to a particular hazardous substance in the workplace. The U.S. Department of Labor Occupational Safety and Health Administration (OSHA) establishes the PEL in its regulations for toxic and hazardous substances, which are found in 29 CFR 1910.1000, "Air Contaminants." The PEL includes established limits that are valid on an 8-hour basis (TWA); on a short-term basis [short-term exposure limit (STEL)], which is usually 15 minutes; or as a ceiling concentration level, which means exposures are no longer treated as averages. The TLV, developed by the American Conference of Governmental Industrial Hygienists (ACGIH), essentially follows the same defining criteria to establish values for TWA levels, STEL levels, or ceiling levels for various materials as testing and/or anecdotal data suggest. These data are available from the following primary sources: the ACGIH publication *TLVs® and BEIs®: Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices;* and OSHA, 29 CFR 1910, Subpart Z, "Toxic and Hazardous Substances," for PEL values. In addition to the specific sources identified, these data can also be obtained from the *NIOSH Pocket Guide to Chemical Hazards* and material-specific material safety data sheets (MSDS).

63.3.9.3.3 Treatment System Design and Performance. Treatment systems shall be capable of diluting, adsorbing, absorbing, containing, neutralizing, burning, or otherwise processing stored or used toxic or highly toxic gas, or both. [**55:**7.9.3.3]

63.3.9.3.3.1 Where a total containment system is used, the system shall be designed to handle the maximum anticipated pressure of release to the system when it reaches equilibrium. [**55:**7.9.3.3.1]

63.3.9.3.3.2 Treatment systems shall be capable of reducing the allowable discharge concentrations to one-half the IDLH threshold at the point of discharge. [**55:**7.9.3.3.2]

63.3.9.3.4 Treatment System Sizing.

63.3.9.3.4.1 Worst-Case Release of Gas. Treatment systems shall be sized to process the maximum worst-case release of gas based on the maximum flow rate of release from the largest vessel utilized in accordance with 63.3.9.3.4.2. [**55:**7.9.3.4.1]

63.3.9.3.4.2 Largest Compressed Gas Vessel. The entire contents of the single largest compressed gas vessel shall be considered. [**55:**7.9.3.4.2]

63.3.9.3.4.3 Attended Operations — Alternative Method of System Sizing.

63.3.9.3.4.3.1 Where source cylinders, containers, and tanks are used in attended process operations, with an operator present at the enclosure where the activity occurs, the volume of the release shall be limited to the estimated amount released from the process piping system within a period not to exceed 5 minutes. [**55:**7.9.3.4.3.1]

63.3.9.3.4.3.2 Such process piping systems shall comply with the requirements of 63.3.9.3.4.3.2(A) through 63.3.9.3.4.3.2(E). [**55:**7.9.3.4.3.2]

(A) Local Exhaust. All gas transfer operations shall be conducted within a zone of local exhaust that is connected to a treatment system. [**55:**7.9.3.4.3.2(A)]

Δ **(B) Gas Detection.** Gas detection shall be used to provide a warning to alert the operators to emission of gas into the zone of local exhaust, and the following requirements also shall apply:

(1) The system shall be capable of detecting gas at the permissible exposure limit (PEL) or the ceiling limit for the gas being processed.
(2) Activation of the gas detection system shall provide a local alarm.

[**55:**7.9.3.4.3.2(B)]

(C) Process Shutdown. Operations involving the gas detected shall be shut down and leaks repaired. [**55:**7.9.3.4.3.2(C)]

(D) Piping System Construction. Piping systems used to convey gases shall be of all-welded construction throughout, with the exception of fittings used to connect cylinders, containers, or tanks, or any combination thereof, to the process system. [**55:**7.9.3.4.3.2(D)]

(E) Piping System Accessibility. Piping systems shall be designed to provide for readily accessible manual shutdown controls. [**55:**7.9.3.4.3.2(E)]

63.3.9.3.5 Rate of Release. The time release shall be in accordance with Table 63.3.9.3.5 for the type of container indicated. [**55:**7.9.3.5]

Although Table 63.3.9.3.5 is entitled Rates of Release, the table provides not release rates but the maximum times in which the entire contents of the container can be released. The rate referred to is actually the volume of the container divided by the time given in the table.

TABLE 63.3.9.3.5 *Rates of Release*

	Time Release	
Container Type	**Nonliquefied Gases**	**Liquefied Gases**
Cylinders without restrictive flow orifices	5 minutes	30 minutes
Portable tanks without restrictive flow orifices	40 minutes	240 minutes
All others	Based on peak flow from maximum valve orifice	Based on peak flow from maximum valve orifice

[**55:** Table 7.9.3.5]

63.3.9.3.6* Maximum Flow Rate of Release.

A.63.3.9.3.6 The areas for typical restricted flow orifices are shown in Table A.63.3.9.3.6. [**55:**A.7.9.3.6]

63.3.9.3.6.1 For portable cylinders, containers, and tanks, the maximum flow rate of release shall be calculated based on assuming the total release from the cylinder or tank within the time specified. [**55:**7.9.3.6.1]

63.3.9.3.6.2* When portable cylinders, containers, or tanks are equipped with reduced flow orifices, the worst-case rate of release shall be determined by the maximum achievable flow from the valve based on the following formula:

$$CFM = (767 \times A \times P)\frac{(28.96/MW)^{1/2}}{60} \qquad \textbf{[63.3.9.3.6.2]}$$

where:

CFM = standard cubic feet per minute of gas of concern under flow conditions

A = area of orifice in square inches *(See Table A.63.3.9.3.6 for areas of typical restricted flow orifices.)*

P = supply pressure of gas at NTP in pounds per square inch absolute

MW = molecular weight [**55:**7.9.3.6.2]

TABLE A.63.3.9.3.6 *Typical Orifice Areas*

Orifice Diameter in.	Orifice Diameter cm	Area in.²	Area cm²
0.006	0.015	2.83×10^{-5}	1.83×10^{-4}
0.010	0.025	7.85×10^{-5}	5.06×10^{-4}
0.014	0.036	1.54×10^{-4}	9.93×10^{-4}

[**55:** Table A.7.9.3.6]

A.63.3.9.3.6.2 The formula has been taken from industry publications including the Scott Specialty Gases *Design and Safety Handbook*. It is based on estimated flow rates for air at 70°F (21°C) discharging to normal atmospheric pressure through an average shape and quality orifice. It can be assumed to be ±15 percent accurate. Correction factors have been built into the formula as presented in 63.3.9.3.6.2 to accommodate the use of gases other than air (e.g., use of specific gravity data). [**55:**A.7.9.3.6.2]

The following information is provided courtesy of The Dow Chemical Company to explain how to calculate the derivation of the gas release rate given in 63.3.9.3.6.2.

The gas release rate starts with the following equation:

$$CFM = (767)\,AP\,\frac{(28.96/MW)}{60} \qquad (1)$$

where:

CFM = gas release rate (ft³/min)
A = area of orifice (in.²)
P = pressure of gas (psia)
MW = molecular weight of gas (lb/lb-mole)

The equation is derived as follows:

1. Start the derivation with the equation for choked flow, which is shown as Equation (2):

$$m = C_D A \quad P\rho\gamma \left(\frac{2}{\gamma + 1}\right)^{(\gamma+1)/(\gamma-1)} \qquad (2)$$

where:

m = mass release rate (kg/s)
C_D = discharge coefficient (dimensionless)
A = opening area (m²)
P = pressure of gas (Pascals)
ρ = gas density (kg/m³)
γ = ratio of specific heats (dimensionless)

2. Rewrite gas density based on the Ideal Gas Law, which is shown as Equation (3):

$$\rho = \frac{P(MW)}{RT} \qquad (3)$$

where:

MW = molecular weight (kg/kmole)
R = gas constant (8314 J/°K-kmole)
T = temperature (K)

Substituting Equation (3) into Equation (2),

$$m = C_D AP \quad \frac{1}{T} \quad \frac{MW}{8314} \quad \gamma \left(\frac{2}{\gamma + 1}\right)^{(\gamma+1)/(\gamma-1)} \qquad (4)$$

3. Convert metric units to English:

$$Q = (132.275)(6894.76)(6.452 \times 10^{-4}) \qquad (5)$$

$$C_D AP \quad \frac{1}{T} \quad \frac{MW}{8314} \quad \gamma \left(\frac{2}{\gamma + 1}\right)^{(\gamma+1)/(\gamma-1)}$$

$$Q = (6.45)C_D AP \quad \frac{1}{T} \quad MW \quad \gamma \left(\frac{2}{\gamma + 1}\right)^{(\gamma+1)/(\gamma-1)} \qquad (6)$$

where:

Q = release rate (pounds/minute)
132.275 = conversion factor for lb/min to kg/s
6894.76 = conversion factor for psi to Pascals
6.452×10^{-4} = conversion factor for in.² to m²

4. Solve Equation (6) for the following conditions since Equation (1) is based on air at 70°F (294.26 K):

$$\gamma_{air} = 1.401 \qquad \text{so} \qquad \gamma \left(\frac{2}{\gamma + 1}\right)^{(\gamma+1)/(\gamma-1)} = 0.685$$

$$Q = (6.45) \quad \frac{1}{294.26} \quad 28.96 \; (0.685) = 1.386\, C_D AP \qquad (7)$$

5. Use Equation (1) to determine the value of C_D, by using the *MW* of air to determine a relationship for *CFM* and then ratio the result from Equation (7) to determine the value of C_D:

$$CFM = (767)AP\,\frac{(28.96/MW)}{60} = 12.783\,AP \text{ (for air)}$$

$$Q/CFM = \frac{1.386\, C_D AP}{12.783\, AP} = 0.1084\, C_D$$

Note that at 70°F, air density is 0.0745 lb/ft³, so C_D would need to be 0.687, which is a reasonable value (range typically 0.6 to 1.0), and then calculate the following from Equation (6):

$$Q = (6.45)(0.687)\,AP \quad \frac{1}{294.26} \quad MW \; (0.685) = 0.177\,AP \quad MW \qquad (8)$$

Expressing release rate as volume flow (ft³/min) as follows:

$$Q_v = \frac{0.177\,AP \quad MW}{\rho} \qquad (9)$$

6. The final step in the derivation of the equation shown in Equation (1) is shown below:

Equation (1) is essentially a ratio of the release rate of a gas, compared to the release rate of air. To derive this equation from Equation (9), start with Equation (9) written for air as follows:

$$Q_{air} = \frac{0.177\,AP\ \ 28.96}{\rho_{air}} \quad (10)$$

Then, the ratio of Equation (9) to Equation (10) is calculated as follows:

$$\frac{Q_v}{Q_{air}} = \frac{0.177\,AP\ \ MW/\rho}{0.177\,AP\ \ 28.96/\rho_{air}} = \frac{MW\rho_{air}}{28.96\rho} \quad (11)$$

Substituting Equation (3) into Equation (11) as follows:

$$\frac{Q_v}{Q_{air}} = \frac{MW(28.96)}{(MW)\ \ 28.96} = \frac{28.96}{MW} \quad (12)$$

Therefore, the equation would be as follows:

$$Q_v = Q_{air}\ \frac{28.96}{MW} \quad (13)$$

Substituting Equation (10) into Equation (13), with ρ_{air} = 0.0745 lb/ft^3, gives the following calculation:

$$Q_v = Q_{air}\ \frac{28.96}{MW} = (12.78)\,AP\ \frac{28.96}{MW} = \frac{(767)\,AP\ \frac{28.96}{MW}}{60} \quad (14)$$

where:

Q = release rate (ft^3/min)

A = opening area (in.^{2})

P = pressure (psia)

Hence, the equation is as follows:

$$CFM = (767)\,AP\ \frac{(28.96/MW)}{60}$$

Note that NFPA 55 states that this equation is based on air at 70°F, with some built-in correction factors. Those correction factors are not stated. For gases other than air, the value of γ will be different. For the equation to be valid for other gases, the product of the γ-term and C_D would need to be 0.4705. From the U.S. Environmental Protection Agency document *Risk Management Program Guidance for Offsite Consequence Analysis*, γ ranges from 1.07 to 1.41. This determination would lead to a range of C_D values of 0.686 to 0.756. These values are in the range typically assigned for C_D (0.6 to 1.0). Therefore, the equation in 63.3.9.3.6.2 would be valid for gases other than air.

63.3.9.3.6.3 For mixtures, the average of the molecular weights shall be used. [**55:**7.9.3.6.3]

63.3.9.4 Leaking Cylinders, Containers, and Tanks. When cylinders, containers, or tanks are used outdoors in excess of the quantities specified in Table 63.2.3.1.1 in the column for unsprinklered areas (unprotected by gas cabinets or exhausted enclosures), a gas cabinet, exhausted enclosure, or containment vessel or system shall be provided to control leaks from leaking cylinders, containers, and tanks in accordance with 63.3.9.4.1 through 63.3.9.4.2.3. [**55:**7.9.4]

63.3.9.4.1 Gas Cabinets or Exhausted Enclosures. Where gas cabinets or exhausted enclosures are provided to handle leaks from cylinders, containers, or tanks, exhaust ventilation shall be provided that is directed to a treatment system in accordance with the provisions of 63.3.9.3. [**55:**7.9.4.1]

63.3.9.4.2 Containment Vessels or Systems. Where containment vessels or containment systems are provided, they shall comply with the requirements of 63.3.9.4.2.1 through 63.3.9.4.2.3. [**55:**7.9.4.2]

63.3.9.4.2.1 Performance. Containment vessels or containment systems shall be capable of fully containing or terminating a release. [**55:**7.9.4.2.1]

63.3.9.4.2.2 Personnel. Trained personnel capable of operating the containment vessel or containment system shall be available at an approved location. [**55:**7.9.4.2.2]

63.3.9.4.2.3 Location. Containment vessels or systems shall be capable of being transported to the leaking cylinder, container, or tank. [**55:**7.9.4.2.3]

63.3.9.5 Emergency Power.

63.3.9.5.1 General. Emergency power shall comply with the requirements of 63.3.9.5 in accordance with *NFPA 70*. [**55:**7.9.5.1]

63.3.9.5.2 Alternative to Emergency Power. Emergency power shall not be required where fail-safe engineering is provided for mechanical exhaust ventilation, treatment systems, and temperature control, and standby power is provided to alternative systems that utilize electrical energy. [**55:**7.9.5.2]

63.3.9.5.3 Where Required. Emergency power shall be provided for the following systems:

(1) Exhaust ventilation
(2) Treatment system
(3) Gas detection system
(4) Temperature control system
(5) Required alarm systems

[**55:**7.9.5.3]

63.3.9.5.4 Level. Emergency power systems shall comply with the requirements for a Level 2 system in accordance with NFPA 110. [**55:**7.9.5.4]

63.3.9.6 Gas Detection. Except as provided in 63.3.9.6.1, a continuous gas detection system in accordance with the requirements of 63.3.9.6.2 through 63.3.9.6.6 shall be provided for the indoor storage or use of toxic or highly toxic compressed gases. [**55:**7.9.6]

63.3.9.6.1 Where Gas Detection Is Not Required. A gas detection system shall not be required for toxic gases where the physiological warning properties for the gas are at a level below the accepted PEL or the ceiling limit for the gas. [**55:**7.9.6.1]

63.3.9.6.2 Local Alarm. The gas detection system shall initiate a local alarm that is both audible and visible. [**55:**7.9.6.2]

63.3.9.6.3 Alarm Monitored. The gas detection system shall transmit a signal to a constantly attended control station for quantities exceeding one toxic or highly toxic compressed gas cylinder. [**55:**7.9.6.3]

63.3.9.6.4 Automatic Shutdown.

63.3.9.6.4.1 Activation of the gas detection system shall automatically shut off the flow of gas related to the system being monitored. [**55:**7.9.6.4.1]

63.3.9.6.4.2 An automatic shutdown shall not be required for reactors utilized for the production of toxic or highly toxic gases when such reactors are operated at gauge pressures less than 15 psi (103.4 kPa), constantly attended, and provided with readily accessible emergency shutoff valves. [**55:**7.9.6.4.2]

63.3.9.6.5 Detection Points. Detection shall be provided at the locations specified in 63.3.9.6.5.1 through 63.3.9.6.5.4. [**55:**7.9.6.5]

63.3.9.6.5.1 Treatment System Discharge. Detection shall be provided at the discharge from the treatment system. [**55:**7.9.6.5.1]

63.3.9.6.5.2 Point of Use. Detection shall be provided in the room or area in which the gas is used. [**55:**7.9.6.5.2]

63.3.9.6.5.3 Source. Detection shall be provided at the source cylinder, container, or tank used for delivery of the gas to the point of use. [**55:**7.9.6.5.3]

63.3.9.6.5.4 Storage. Detection shall be provided in the room or area in which the gas is stored. [**55:**7.9.6.5.4]

63.3.9.6.6 Level of Detection. The gas detection system shall detect the presence of gas at or below the PEL or the ceiling limit of the gas for those points identified in 63.3.9.6.5.2 and 63.3.9.6.5.3 and at not less than one-half the IDLH level for points identified in 63.3.9.6.5.1. [**55:**7.9.6.6]

The provision of this requirement specifies that a gas detection system be used along with smoke detection. Advance warning when heat detection is being used in a sprinklered facility provides no specific benefit, because an increase in heat is not an indicator of dangerous levels of gas leakage. The heat being detected is not associated with the hazard of the leaking gas.

63.3.9.7 Automatic Smoke Detection System. An automatic smoke detection system shall be provided for the indoor storage or use of highly toxic compressed gases in accordance with *NFPA 72*. [**55:**7.9.7]

63.3.10 Unstable Reactive Gases (Nondetonable). The storage or use of unstable reactive (nondetonable) gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be in accordance with Chapters 1 through 6 of NFPA 55 and 63.3.1 through 63.3.3 and 63.3.10. [**55:**7.10]

63.3.10.1 Distances to Exposures for Class 2.

63.3.10.1.1 The outdoor storage or use of unstable reactive Class 2 compressed gas shall not be within 20 ft (6 m) of buildings, lot lines, streets, alleys, or public ways or means of egress. [**55:**7.10.1.1]

63.3.10.1.2 A 2-hour fire barrier wall without openings or penetrations shall be permitted in lieu of the 20 ft (6 m) distance required by 63.3.10.1.1. [**55:**7.10.1.2]

63.3.10.1.2.1* Where a fire barrier wall is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.10.1.2.1]

A.63.3.10.1.2.1 See A.63.3.5.2.1.1. [**55:**A.7.10.1.2.1]

A protective structure provides a barrier to radiant heat, protecting elements on the side of the structure opposite the compressed gas system and shielding the compressed gas system from exposures on the other side of the structure.

63.3.10.1.2.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building. [**55:**7.10.1.2.2]

63.3.10.1.2.3 The 2-hour fire barrier wall shall be located at least 5 ft (1.5 m) from any exposure. [**55:**7.10.1.2.3]

63.3.10.1.2.4 The 2-hour fire barrier wall shall not have more than two sides at approximately 90 degree (1.57 rad) directions or not more than three sides with connecting angles of approximately 135 degrees (2.36 rad). [**55:**7.10.1.2.4]

63.3.10.2 Distances to Exposures for Class 3.

63.3.10.2.1 The outdoor storage or use of unstable reactive Class 3 (nondetonable) compressed gas shall not be within 75 ft (23 m) of buildings, lot lines, streets, alleys, or public ways or means of egress. [**55:**7.10.2.1]

63.3.10.2.2 A 2-hour fire barrier wall without openings or penetrations, extending not less than 30 in. (762 mm) above and to the sides of the storage or use area, that interrupts the line of sight between the storage or use and the exposure shall be permitted in lieu of the 75 ft (23 m) distance specified in 63.3.10.2.1. [**55:**7.10.2.2]

63.3.10.2.2.1* Where a fire barrier wall is used to protect compressed gas systems, the system shall terminate downstream of the source valve. [**55:**7.10.2.2.1]

A.63.3.10.2.2.1 See A.63.3.5.2.1.1. [**55:**A.7.10.2.2.1]

See the commentary following 63.3.5.2.1.1.

63.3.10.2.2.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage or use area. [**55:**7.10.2.2.2]

63.3.10.2.2.3 The 2-hour fire barrier wall shall be located at least 5 ft (1.5 m) from any exposure. [**55:**7.10.2.2.3]

63.3.10.2.2.4 The 2-hour fire barrier wall shall not have more than two sides at approximately 90 degree (1.57 rad) directions or more than three sides with connecting angles of approximately 135 degrees (2.36 rad). [**55:**7.10.2.2.4]

63.3.10.3 Storage Configuration.

63.3.10.3.1 Unstable reactive Class 3 compressed gases stored in cylinders, containers, or tanks shall be arranged to limit individual groups of cylinders, containers, or tanks to areas not exceeding 100 ft^2 (9.3 m^2). [**55:**7.10.3.1]

63.3.10.3.2 Multiple areas shall be separated by aisles. [**55:**7.10.3.2]

63.3.10.3.3 Aisle widths shall not be less than the height of the cylinders, containers, or tanks or 4 ft (1.2 m), whichever is greater. [**55:**7.10.3.3]

63.3.10.4 Basements. Unstable reactive compressed gases shall not be stored in basements. [**55:**7.10.4]

63.3.10.5 Unstable Reactive Gases (Detonable).

63.3.10.5.1 Storage or Use. The storage or use of unstable reactive (detonable) gases exceeding the quantity thresholds for gases requiring special provisions as specified in Table 63.2.3.1.1 shall be in accordance with Chapters 1 through 6 of NFPA 55, 63.3.1 through 63.3.3, and 63.3.10.5. [**55:**7.10.5.1]

63.3.10.5.2 Location. The location of storage areas shall be determined based on the requirements of the building code for explosive materials. [**55:**7.10.5.2]

63.4 Cryogenic Fluids

63.4.1 General. This section shall apply to all cryogenic fluids, including those fluids regulated elsewhere in this *Code*, except that where specific requirements are provided in Sections 63.5, 63.7, or 63.11, those specific requirements shall apply in accordance with the applicable chapter. [**55:**8.1]

63.4.1.1 Storage, use, and handling of cryogenic fluids shall be in accordance with Chapters 1 through 6 of NFPA 55 and Section 63.4 as applicable. [**55:**8.1.1]

63.4.2* Containers — Design, Construction, and Maintenance. Containers employed for the storage or use of cryogenic fluids shall be designed, fabricated, tested, marked (stamped), and maintained in accordance with DOT regulations; Transport Canada (TC), *Transportation of Dangerous Goods Regulations*; the ASME *Boiler and Pressure Vessel Code*, "Rules for the Construction of Unfired Pressure Vessels"; or regulations of other administering agencies. [**55:**8.2]

A.63.4.2 Pressure vessels of any type can be subject to additional regulations imposed by various states or other legal jurisdictions. Users should be aware that compliance with DOT or ASME requirements might not satisfy all the required regulations for the location in which the vessel is to be installed or used. [**55:**A.8.2]

63.4.2.1 Aboveground Tanks. Aboveground tanks for the storage of cryogenic fluids shall be in accordance with 63.4.2.1. [**55:**8.2.1]

The requirements of 63.4.2.1 and its subparagraphs were added to the 2010 edition of NFPA 55 to address aboveground tanks storing cryogenic fluids and the construction provisions for both the inner vessel and the vacuum jacket (outer vessel). In addition to the provisions specified, it is mandatory that the inner vessel of storage tanks used in cryogenic fluid service be designed and constructed in accordance with the applicable sections of ASME's *Boiler and Pressure Vessel Code*. Cryogenic fluids are defined as fluids with a boiling point lower than 130°F (90°C) at an absolute pressure of 14.7 psi (101.3 kPa).

63.4.2.1.1 Construction of the Inner Vessel. The inner vessel of storage tanks in cryogenic fluid service shall be designed and constructed in accordance with Section VIII, Division 1 of the ASME *Boiler and Pressure Vessel Code* and shall be vacuum jacketed in accordance with 63.4.2.1.2. [**55:**8.2.1.1]

63.4.2.1.2 Construction of the Vacuum Jacket (Outer Vessel).

63.4.2.1.2.1 The vacuum jacket used as an outer vessel for storage tanks in cryogenic fluid service shall be of welded steel construction designed to withstand the maximum internal and external pressure to which it will be subjected under operating conditions to include conditions of emergency pressure relief of the annular space between the inner vessel and the outer vessel. [**55:**8.2.1.2.1]

63.4.2.1.2.2 The jacket shall be designed to withstand a minimum collapsing pressure differential of 30 psi (207 kPa). [**55:**8.2.1.2.2]

63.4.2.1.2.3 Vacuum Level Monitoring.

63.4.2.1.2.3.1 A connection shall be provided on the exterior of the vacuum jacket to allow measurement of the pressure within the annular space between the inner vessel and the outer vessel. [**55:**8.2.1.2.3.1]

63.4.2.1.2.3.2 The connection shall be fitted with a bellows-sealed or diaphragm-type valve equipped with a vacuum gauge tube that is shielded to protect against damage from impact. [**55:**8.2.1.2.3.2]

63.4.2.2 Nonstandard Containers.

63.4.2.2.1 Containers, equipment, and devices that are not in compliance with recognized standards for design and construction shall be permitted if approved by the AHJ upon presentation of evidence that they are designed and constructed for safe operation. [**55:**8.2.2.1]

63.4.2.2.2 The following data shall be submitted to the AHJ with reference to the deviation from the standard with the application for approval:

(1) Type and use of container, equipment, or device
(2) Material to be stored, used, or transported
(3) Description showing dimensions and materials used in construction
(4) Design pressure, maximum operating pressure, and test pressure
(5) Type, size, and setting of pressure relief devices

[**55:**8.2.2.2]

63.4.2.3 Foundations and Supports. Stationary tanks shall be provided with concrete or masonry foundations or structural steel supports on firm concrete or masonry foundations, and the requirements of 63.4.2.3.1 through 63.4.2.3.5 also shall apply. [**55:**8.2.3]

63.4.2.3.1 Excessive Loads. Stationary tanks shall be supported to prevent the concentration of excessive loads on the supporting portion of the shell. [**55:**8.2.3.1]

63.4.2.3.2 Expansion and Contraction. Foundations for horizontal containers shall be constructed to accommodate expansion and contraction of the container. [**55:**8.2.3.2]

63.4.2.3.3* Support of Ancillary Equipment.

A.63.4.2.3.3 Vaporizers or heat exchangers used to vaporize cryogenic fluids can accumulate a large load of ice during operation. Additional requirements to be considered in the design include snow load for the area where the installation is located as well as the requirements for seismic conditions. The operating conditions of systems vary, and the designer has a responsibility to consider all the loads that might be imposed. Foundations that could be used to support delivery vehicles as well might require special consideration relevant to live loads as well as for the dead loads imposed by the equipment itself. [**55:**A.8.2.3.3]

63.4.2.3.3.1 Foundations shall be provided to support the weight of vaporizers or heat exchangers. [**55:**8.2.3.3.1]

63.4.2.3.3.2 Foundations shall be designed to withstand soil and frost conditions as well as the anticipated seismic, snow, wind, and hydrostatic loading under operating conditions. [**55:**8.2.3.3.2]

63.4.2.3.4 Temperature Effects. Where drainage systems, terrain, or surfaces beneath stationary tanks are arranged in a manner that can subject stationary tank foundations or supports to temperatures below –130°F (–90°C), the foundations or supports shall be constructed of materials that are capable of withstanding the low-temperature effects of cryogenic fluid spillage. [**55:**8.2.3.4]

If cryogenic fluids are released, they will immediately boil. The resulting cold vapor will likely cause water in the air to condense. The result might be a fog or mist that reduces visibility in the area of the release.

63.4.2.3.5 Corrosion Protection. Portions of stationary tanks in contact with foundations or saddles shall be painted to protect against corrosion. [**55:**8.2.3.5]

63.4.2.4 Pressure Relief Devices.

63.4.2.4.1 General.

63.4.2.4.1.1 Pressure relief devices shall be provided to protect containers and systems containing cryogenic fluids from rupture in the event of overpressure. [**55:**8.2.4.1.1]

63.4.2.4.1.2 Pressure relief devices shall be designed in accordance with CGA S-1.1, *Pressure Relief Device Standards — Part 1 — Cylinders for Compressed Gases*, and CGA S-1.2, *Pressure Relief Device Standards — Part 2 — Cargo and Portable Tanks for Compressed Gases,* for portable tanks; and CGA S-1.3, *Pressure Relief Device Standards — Part 3 — Stationary Storage Containers for Compressed Gases,* for stationary tanks. [**55:**8.2.4.1.2]

63.4.2.4.2 Containers Open to the Atmosphere. Portable containers that are open to the atmosphere and are designed to contain cryogenic fluids at atmospheric pressure shall not be required to be equipped with pressure relief devices. [**55:**8.2.4.2]

63.4.2.4.3 Equipment Other Than Containers. Heat exchangers, vaporizers, insulation casings surrounding containers, vessels, and coaxial piping systems in which liquefied cryogenic fluids could be trapped due to leakage from the primary container shall be provided with a pressure relief device. [**55:**8.2.4.3]

63.4.2.4.4 Sizing.

63.4.2.4.4.1 Pressure relief devices shall be sized in accordance with the specifications to which the container was fabricated. [**55:**8.2.4.4.1]

63.4.2.4.4.2 The pressure relief device shall have the capacity to prevent the maximum design pressure of the container or system from being exceeded. [**55:**8.2.4.4.2]

63.4.2.4.5 Accessibility. Pressure relief devices shall be located such that they are accessible for inspection and repair. [**55:**8.2.4.5]

63.4.2.4.5.1* ASME pressure relief valves shall be made to be tamper resistant in order to prevent adjusting of the set pressure by other than authorized personnel. [**55:**8.2.4.5.1]

A.63.4.2.4.5.1 Pressure relief valves typically are spring-loaded valves where the relief pressure is set by adjustment of a spring. Valves should be made to be tamper resistant in order to prevent adjustment by other than authorized personnel typically found at a retest facility. An ASME pressure relief valve is designed to comply with the requirements of the ASME *Boiler and Pressure Vessel Code* and typically is equipped with a wire and lead seal to resist tampering. [**55:**A.8.2.4.5.1]

63.4.2.4.5.2 Non-ASME pressure relief valves shall not be field adjusted. [**55:**8.2.4.5.2]

63.4.2.4.6 Arrangement.

63.4.2.4.6.1 Pressure Relief Devices. Pressure relief devices shall be arranged to discharge unobstructed to the open air in such a manner as to prevent impingement of escaping gas on personnel, containers, equipment, and adjacent structures or its entrance into enclosed spaces. [**55:**8.2.4.6.1]

63.4.2.4.6.2 Portable Containers with Volume Less Than 2.0 scf (0.057 Nm^3).

63.4.2.4.6.2.1 The arrangement of the discharge from pressure relief devices from DOT-specified containers with an internal water volume of 2.0 scf (0.057 Nm^3) or less shall be incorporated in the design of the container. [**55:**8.2.4.6.2.1]

63.4.2.4.6.2.2 Additional safeguards regarding placement or arrangement shall not be required. [**55:**8.2.4.6.2.2]

63.4.2.4.7 Shutoffs Between Pressure Relief Devices and Containers.

63.4.2.4.7.1 General. Shutoff valves installed between pressure relief devices and containers shall be in accordance with 63.4.2.4.7. [**55:**8.2.4.7.1]

63.4.2.4.7.2 Location. Shutoff valves shall not be installed between pressure relief devices and containers unless the valves or their use meet the requirements of 63.4.2.4.7.2.1 or 63.4.2.4.7.2.2. [**55:**8.2.4.7.2]

63.4.2.4.7.2.1* Security. Shutoff valves shall be locked in the open position, and their use shall be limited to service-related work performed by the supplier under the requirements of the ASME *Boiler and Pressure Vessel Code*. [**55:**8.2.4.7.2.1]

N **A.63.4.2.4.7.2.1** The ASME *Boiler and Pressure Vessel Code* requires that full-area stop valves be locked open and provided with manual vent valves for maintaining pressure during maintenance operations. Further, the ASME Code requires that if the full-area stop valve is closed, an operator must be present at all times to maintain the vessel pressure within acceptable limits and must lock the full-area stop valve in the open position before leaving the station. See the ASME *Boiler and Pressure Vessel Code* for complete details and requirements. [**55:**A.8.2.4.7.2.1]

Δ **63.4.2.4.7.2.2 Multiple Pressure Relief Devices.** Shutoff valves controlling multiple pressure relief devices on a container shall be installed so that either the type of valve installed or the arrangement provides the full required flow through the relief devices at all times. [**55:**8.2.4.7.2.2]

63.4.2.4.8 Temperature Limits. Pressure relief devices shall not be subjected to cryogenic fluid temperatures except when operating. [**55:**8.2.4.8]

63.4.3 Pressure Relief Vent Piping.

63.4.3.1 General. Pressure relief vent piping systems shall be constructed and arranged to direct the flow of gas to a safe location and in accordance with 63.4.3. [**55:**8.3.1]

63.4.3.2 Sizing. Pressure relief device vent piping shall have a cross-sectional area not less than that of the pressure relief device vent opening and shall be arranged so as not to restrict the flow of escaping gas. [**55:**8.3.2]

63.4.3.3 Arrangement. Pressure relief device vent piping and drains in vent lines shall be arranged so that escaping gas discharges unobstructed to the open air and does not impinge on personnel, containers, equipment, and adjacent structures or enter enclosed spaces. [**55:**8.3.3]

63.4.3.4 Installation. Pressure relief device vent lines shall be installed in a manner that excludes or removes moisture and condensation to prevent malfunction of the pressure relief device due to freezing or ice accumulation. [**55:**8.3.4]

63.4.3.5 Overfilling. Controls shall be provided to prevent overfilling of stationary containers. [**55:**8.3.5]

63.4.4 Marking.

63.4.4.1 General. Cryogenic containers and systems shall be marked in accordance with nationally recognized standards and in accordance with 63.4.4. [**55:**8.4.1]

63.4.4.1.1 Portable Containers.

63.4.4.1.1.1 Portable cryogenic containers shall be marked in accordance with CGA C-7, *Guide to the Preparation of Precautionary Labeling and Marking of Compressed Gas Containers*. [**55:**8.4.1.1.1]

63.4.4.1.1.2* All DOT-4L/TC-4LM liquid cylinders shall have product identification visible from all directions with minimum 2 in. (51 mm) high letters. [**55:**8.4.1.1.2]

A.63.4.4.1.1.2 An example of this identification is 360 degree wraparound tape. [**55:**A.8.4.1.1.2]

63.4.4.1.2 Stationary Tanks. Stationary tanks shall be marked in accordance with NFPA 704. [**55:**8.4.1.2]

63.4.4.1.3 Identification Signs. Visible hazard identification signs shall be provided in accordance with NFPA 704 at entrances to buildings or areas in which cryogenic fluids are stored, handled, or used. [**55:**8.4.1.3]

63.4.4.2 Identification of Contents. Stationary containers shall be placarded with the identity of their contents to indicate the name of the material contained. [**55:**8.4.2]

The name on the required placard should not be a trade name or other name that would not be readily understood by emergency response personnel (see Exhibit 63.3).

63.4.4.3 Container Specification. Stationary containers shall be marked with the manufacturing specification and maximum allowable working pressure on a permanent nameplate. [**55:**8.4.3]

63.4.4.3.1 The nameplate shall be installed on the container in an accessible location. [**55:**8.4.3.1]

63.4.4.3.2 The nameplate shall be marked in accordance with nationally recognized standards. [**55:**8.4.3.2]

63.4.4.4 Identification of Container Connections.

63.4.4.4.1 Container inlet and outlet connections, liquid-level limit controls, valves, and pressure gauges shall be identified using one of the methods prescribed by 63.4.4.4.1.1 through 63.4.4.4.1.2. [**55:**8.4.4.1]

63.4.4.4.1.1 They shall be marked with a permanent tag or label identifying their function. [**55:**8.4.4.1.1]

63.4.4.4.1.2 They shall be identified by a schematic drawing that indicates their function and designates whether they are connected to the vapor or liquid space of the container. [**55:**8.4.4.1.2]

63.4.4.4.1.2.1 When a schematic drawing is provided, it shall be attached to the container and maintained in a legible condition. [**55:**8.4.4.1.2.1]

Exhibit 63.3

Signage on cryogenic fluid container.

63.4.4.5 Identification of Piping Systems. Piping systems shall be identified in accordance with ASME A13.1, *Scheme for the Identification of Piping Systems*. [**55:**8.4.5]

63.4.4.6 Identification of Emergency Shutoff Valves. Emergency shutoff valves on stationary containers shall be identified, visible, and indicated by means of a sign. [**55:**8.4.6]

63.4.5 Medical Cryogenic Systems.

63.4.5.1 Bulk cryogenic fluid systems in medical gas applications at health care facilities shall be in accordance with Section 63.4, 63.1.1.4(3), and the material-specific requirements of Chapter 9 of NFPA 55 as applicable. [**55:**8.5.1]

63.4.5.1.1 Bulk cryogenic fluid systems shall be in accordance with the following provisions as applicable:

(1) Where located in a court, systems shall be in accordance with 63.4.13.2.7.2.
(2) Where located indoors, systems shall be in accordance with 63.4.14.11.1.
(3) Systems shall be installed by personnel qualified in accordance with CGA M-1, *Guide for Medical Gas Installations at Consumer Sites,* or ASSE 6015, *Professional Qualification Standard for Bulk Medical Gas Systems Installers.*
(4) Systems shall be installed in compliance with Food and Drug Administration Current Good Manufacturing Practices as found in 21 CFR 210 and 21 CFR 211.

[**55:**8.5.1.1]

63.4.5.1.2 The following components of the bulk system shall be accessible and visible to delivery personnel during filling operations:

(1) Fill connection
(2) Top and bottom fill valves
(3) Hose purge valve
(4) Vent valve
(5) Full trycock valve
(6) Liquid level gauge
(7) Tank pressure gauge

[**55:**8.5.1.2]

63.4.5.1.3 Bulk cryogenic fluid systems shall be anchored with foundations in accordance with the provisions of CGA M-1, *Guide for Medical Gas Installations at Consumer Sites*. [**55:**8.5.1.3]

63.4.5.1.4 Bulk cryogenic fluid systems shall consist of the following:

(1) One or more main supply vessel(s), whose capacity shall be determined after consideration of the customer usage requirements, delivery schedules, proximity of the facility to alternative supplies, and the emergency plan
(2) A contents gauge on each of the main vessel(s)
(3) A reserve supply sized for greater than an average day's supply, with the size of vessel or number of cylinders being determined after consideration of delivery schedules, proximity of the facility to alternative supplies, and the facility's emergency plan

(4) At least two main vessel relief valves and rupture discs installed downstream of a three-way (three-port) valve
(5) A check valve located in the primary supply piping upstream of the intersection with a secondary supply or reserve supply

[**55:**8.5.1.4]

63.4.5.1.5 Bulk cryogenic fluid reserve supply systems consisting of either a second cryogenic fluid source or a compressed gas source shall include the following:

(1) When the reserve source is a compressed gas source, the reserve shall be equipped with the following:
   (a) A cylinder manifold having not less than three gas cylinder connections or as otherwise required for an average of one day's gas supply
   (b) A pressure switch to monitor the pressure in the cylinder manifold
(2) When the reserve source is a second cryogenic fluid vessel, the reserve tank shall be equipped with the following:
   (a) An actuating switch or sensor to monitor the internal tank pressure
   (b) A contents gauge to monitor the liquid level
(3) When the reserve source is either a cryogenic fluid or compressed gas source, a check valve shall be provided to prevent backflow into the reserve system

[**55:**8.5.1.5]

63.4.5.1.6 Bulk cryogenic fluid systems shall include a fill mechanism consisting of the following components:

(1) A nonremovable product-specific fill connection in compliance with CGA V-6, *Standard Cryogenic Liquid Transfer Connection*
(2) A means to cap and secure the fill connection inlet
(3) A check valve to prevent product backflow from the fill inlet
(4) A fill hose purge valve
(5) Supports that hold the fill piping off the ground
(6) A secure connection between the bulk tank and the fill piping
(7) Supports as necessary to hold the fill line in position during all operations associated with the filling procedure

[**55:**8.5.1.6]

63.4.5.1.7 Where vaporizers are required to convert cryogenic liquid to the gaseous state, the vaporizer units shall conform to the following:

(1) Be permitted to operate by either ambient heat transfer or external thermal source (e.g., electric heater, hot water, steam)
(2) Be designed to provide capacity for the customer's peak and average flow rates under local conditions, seasonal conditions for weather and humidity, and structures that obstruct air circulation flow and sunlight
(3) If switching is required as part of the system design, have piping and manual/automatic valving configured in such a manner that operating vaporizer(s) or sections of the vaporizer can be switched to nonoperating vaporizer or section of the vaporizer to de-ice through a valving configuration that ensures continuous flow to the facility through either or both vaporizers and/or sections of the vaporizer if valving switchover fails

[**55:**8.5.1.7]

63.4.5.1.8 Where a vaporizer requires an external thermal source, the flow from the source of supply shall be unaffected by the loss of the external thermal source through either of the following:

(1) Reserve ambient heat transfer vaporizers capable of providing capacity for at least one day's average supply and piped so as to be unaffected by flow stoppage through the main vaporizer
(2) A reserve noncryogenic source capable of providing at least one day's average supply

[**55:**8.5.1.8]

63.4.6 Security.

63.4.6.1 General. Cryogenic containers and systems shall be secured against accidental dislodgement and against access by unauthorized personnel in accordance with 63.4.6. [**55:**8.6.1]

63.4.6.2* Security of Areas. Areas used for the storage of containers and systems shall be secured against unauthorized entry. [**55:**8.6.2]

A.63.4.6.2 The purpose of this requirement is to prevent unauthorized personnel or those unfamiliar with cryogenic storage systems from tampering with the equipment. Where the bulk storage system is located in an area open to the general public, a common practice is to fence the system and lock it, with access restricted to supplier personnel and sometimes user personnel. When the bulk storage system is located within the user's secure area and is not open to the general public, it is not always necessary to fence the bulk storage system. Personnel access patterns may still mandate that the system be fenced, as determined by the supplier and the user. [**55:**A.8.6.2]

The Annex A material for 63.4.6.2 provides more specific guidance on fencing of bulk storage systems. As explained in the annex, the primary purpose of security is to prevent tampering and unauthorized use of cryogenic fluids by the general public. Many facilities are either fully fenced or otherwise provided with access control whereby only the users of the materials are permitted access. The intent of NFPA 55 was not to require that any storage or use be under lock and key or that the security provided be such that storage or use by facility employees was hampered by security controls. It is reasonable to expect that facilities that are not accessible by the general public have administrative procedures in place that directs the proper storage and use areas as well as specifying how the materials will be allowed to be used. Paragraph 63.3.1.9.3 does not mandate the use of administrative controls but allows administrative controls to be used as a means to limit access. In areas not accessible by the general public, the user has a choice as to whether to provide physical barriers as a means of protection or to otherwise restrict access through the use of policies and procedures. This flexibility is required by NFPA 55 to address practical application of these requirements.

63.4.6.2.1 Administrative controls shall be allowed to be used to control access to individual storage areas located in secure facilities not accessible by the general public. [**55:**8.6.2.1]

63.4.6.3 Securing of Containers. Stationary containers shall be secured to foundations in accordance with the building code. [**55:**8.6.3]

63.4.6.3.1 Portable containers subject to shifting or upset shall be secured. [**55:**8.6.3.1]

63.4.6.3.2 Nesting shall be permitted as a means of securing portable containers. [**55:**8.6.3.2]

63.4.6.4 Securing of Vaporizers. Vaporizers, heat exchangers, and similar equipment shall be secured to foundations, and their connecting piping shall be designed and constructed to provide for the effects of expansion and contraction due to temperature changes. [**55:**8.6.4]

The intent of 63.4.6.4 is for the design of the piping to accommodate expansion and contraction, so that the piping system does not fracture. In a portion of the system, expansion joints, as well as flexible connectors, can be used as a means of compensating for movement.

63.4.6.5 Physical Protection. Containers, piping, valves, pressure relief devices, regulating equipment, and other appurtenances shall be protected against physical damage and tampering. [**55:**8.6.5]

63.4.7 Separation from Hazardous Conditions.

63.4.7.1 General. Cryogenic containers and systems in storage or use shall be separated from materials and conditions that present exposure hazards to or from each other in accordance with 63.4.7. [**55:**8.7.1]

63.4.7.2* Stationary Cryogenic Containers. Stationary containers located outdoors shall be separated from exposure hazards in accordance with the minimum separation distances indicated in Table 63.4.7.2. [**55:**8.7.2]

TABLE 63.4.7.2 *Minimum Separation Distance Between Stationary Cryogenic Containers and Exposures*

Exposure	Minimum Distance ft	Minimum Distance m
(1) Buildings, regardless of construction type	1	0.3
(2) Wall openings	1	0.3
(3) Air intakes	10	3.1
(4) Property lines	5	1.5
(5) Places of public assembly (assembly occupancies)	50	15
(6) Nonambulatory patient areas	50	15
(7) Combustible materials, (e.g., paper, leaves, weeds, dry grass, debris)	15	4.5
(8) Incompatible hazardous materials	20	6.1
(9) Building exits	10	3.1

[**55:** Table 8.7.2]

A.63.4.7.2 It is not uncommon to have inert cryogenic fluids used to provide stage effects for theatrical performances that are conducted within assembly occupancies. The fluids are sometimes placed within these occupancies with special controls, including ventilation systems, fire detection systems, monitors for oxygen deficiency, warning signs, and remote fill indicating devices that indicate tank volume when a remote filling point is provided and stationary tanks are involved. Such installations are normally permitted on a case-by-case basis under the requirements of Section 1.5 of NFPA 55. [**55:**A.8.7]

Clearance is required from combustible materials to minimize the effects of exposure fires to the materials stored or used. The requirement to separate the materials from vegetation should not be interpreted to mean that the area is maintained free of all vegetation. In some settings, gas systems are located on grounds that are maintained with formal landscaping. Some judgment must be exercised to determine whether the vegetation poses what might be viewed as an exposure hazard to the materials stored. Cut lawns, formal landscaping, and similar vegetation do not ordinarily present a hazard, and should be allowed. On the other hand, tall, dry grass or weeds and vegetation that fringes on the border of an urban–wildland interface might be viewed as a hazard. [**55:**A.8.7.2]

Inert (i.e., nonflammable, nonoxidizing, and nontoxic) cryogenic fluids are used to provide stage effects for theatrical performances conducted within assembly occupancies. The fluids are sometimes used within these occupancies with special controls. In past editions of the *Code,* no requirement precluded the use of an inert cryogenic fluid in any assembly occupancy; however, by including the required separation in Table 63.4.7.2, it can be inferred that such use could be precluded. The provision of A.63.4.7.2 alerts the user and the AHJ to the potential hazards associated with such use without providing a prescriptive list of controls.

Formal landscaping in and around tanks in current modern facilities is not uncommon. Such installations are commonplace in medical and high tech facilities. The real problem is created by indiscriminate placement of waste materials, pallets, and wildland brush. The annex material alerts the user to the type of vegetation allowed.

63.4.7.2.1 Fire Barriers. A 2-hour fire barrier wall shall be permitted in lieu of the distances specified in Table 63.4.7.2 for items 1, 4, 7, 8 and 9, where in accordance with the provisions of 63.4.7.2.1.1 through 63.4.7.2.1.4. [**55:**8.7.2.1]

63.4.7.2.1.1 The fire barrier wall shall be without openings or penetrations. [**55:**8.7.2.1.1]

63.4.7.2.1.1.1 Penetrations of the fire barrier wall by conduit or piping shall be permitted provided that the penetration is protected with a firestop system in accordance with the building code. [**55:**8.7.2.1.1.1]

63.4.7.2.1.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage system. [**55:**8.7.2.1.2]

63.4.7.2.1.3 The fire barrier wall shall be located not less than 5 ft (1.5 m) from any exposure. [**55:**8.7.2.1.3]

63.4.7.2.1.4 The fire barrier wall shall not have more than two sides at 90 degree (1.57 rad) directions or not more than three sides with connecting angles of 135 degrees (2.36 rad). [**55:**8.7.2.1.4]

63.4.7.2.1.4.1* The connecting angles between fire barrier walls shall be permitted to be reduced to less than 135 degrees (2.36 rad) for installations consisting of three walls when in accordance with 63.4.13.2.7.2. [**55:**8.7.2.1.4.1]

A.63.4.7.2.1.4.1 See Figure A.63.4.13.2.7.2.1, which addresses bulk cryogenic systems located in a courtyard. This figure also applies to the case where any or all of the three walls are constructed as fire barrier walls. [**55:**A.8.7.2.1.4.1]

Δ ***TABLE 63.4.7.3*** *Minimum Separation Distance Between Portable Cryogenic Containers and Exposures*

Exposure	Minimum Distance ft	Minimum Distance m
(1) Building exits	10	3.1
(2) Wall openings	1	0.3
(3) Air intakes	10	3.1
(4) Property lines	5	1.5
(5) Room or area exits	3	0.9
(6) Combustible materials, (e.g., paper, leaves, weeds, dry grass, or debris)	15	4.5
(7) Incompatible hazardous materials	20	6.1

[**55:** Table 8.7.3]

63.4.7.2.1.5 Where the requirement of 63.4.7.2.1.4 is met, the bulk system shall be a minimum distance of 1 ft (0.3 m) from the fire barrier wall. [**55:**8.7.2.1.5]

63.4.7.2.2 Point-of-Fill Connections. Point-of-fill connections serving stationary containers filled by mobile transport equipment shall not be positioned closer to exposures than the minimum distances in Table 63.4.7.2. [**55:**8.7.2.2]

63.4.7.2.3 Surfaces Beneath Containers. The surface of the area on which stationary containers are placed, including the surface of the area located below the point at which connections are made for the purpose of filling such containers, shall be compatible with the fluid in the container. [**55:**8.7.2.3]

63.4.7.3 Portable Cryogenic Containers. Portable containers used for cryogenic fluids located outdoors shall be separated from exposure hazards in accordance with Table 63.4.7.3. [**55:**8.7.3]

63.4.7.3.1 Non-bulk portable containers of liquefied hydrogen shall be separated from exposure hazards in accordance with Table 63.4.7.3.1. [**55:**8.7.3.1]

63.4.7.3.2 Fire Barriers. A 2-hour fire barrier wall shall be permitted in lieu of the distances specified by Table 63.4.7.3 or Table 63.4.7.3.1 when in accordance with the provisions of 63.4.7.3.2.1 through 63.4.7.3.2.4. [**55:**8.7.3.2]

63.4.7.3.2.1 The fire barrier wall shall be without openings or penetrations. [**55:**8.7.3.2.1]

63.4.7.3.2.1.1 Penetrations of the fire barrier wall by conduit or piping shall be permitted provided that the penetration is protected with a firestop system in accordance with the building code. [**55:**8.7.3.2.1.1]

Δ ***TABLE 63.4.7.3.1*** *Distance to Exposures for Non-Bulk Liquefied Hydrogen (LH_2)*

Maximum Amount per Storage Area (gal)	Minimum Distance Between Storage Areas (ft)	Minimum Distance to Lot Lines of Property That Can Be Built Upon (ft)	Minimum Distance to Public Streets, Public Alleys, or Public Ways (ft)	Minimum Distance to Buildings on the Same Property: Less than 2-Hour Construction	Minimum Distance to Buildings on the Same Property: 2-Hour Construction	Minimum Distance to Buildings on the Same Property: 4-Hour Construction
0–39.7	5	5	5	5	0	0
39.8–186.9	10	10	10	10	5	0
187–448.7	10	15	15	20	5	0
448.8–747.8	10	20	20	20	5	0
>747.8	20	25	25	20	5	0

For SI units: 1 ft = 305 mm.

Notes:

(1) For requirements on minimum distance to air intakes, see 63.3.6.2.4.

(2) For requirements on minimum distance to building openings including exits, see 63.3.6.2.5.

(3) When 63.4.7.3.2 is used as a means of distance reduction, the configuration of the fire barriers should be designed to allow natural ventilation to prevent the accumulation of hazardous gas concentrations.

[**55:**Table 8.7.3.1]

63.4.7.3.2.2 The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage system. [**55:**8.7.3.2.2]

63.4.7.3.2.3 The fire barrier wall shall be located not less than 5 ft (1.5 m) from any exposure. [**55:**8.7.3.2.3]

63.4.7.3.2.4 The fire barrier wall shall not have more than two sides at approximately 90 degree (1.57 rad) directions, or not more than three sides with connecting angles of approximately 135 degrees (2.36 rad). [**55:**8.7.3.2.4]

63.4.8 Electrical Wiring and Equipment.

63.4.8.1 General. Electrical wiring and equipment shall be in accordance with *NFPA 70* and 63.4.8. [**55:**8.8.1]

63.4.8.2 Location. Containers and systems shall not be located where they could become part of an electrical circuit. [**55:**8.8.2]

63.4.8.3 Electrical Grounding and Bonding. Containers and systems shall not be used for electrical grounding. [**55:**8.8.3]

63.4.8.3.1 When electrical grounding and bonding are required, the system shall be in accordance with *NFPA 70*. [**55:**8.8.3.1]

63.4.8.3.2 The grounding system shall be protected against corrosion, including corrosion caused by stray electrical currents. [**55:**8.8.3.2]

63.4.9 Service and Repair. Service, repair, modification, or removal of valves, pressure relief devices, or other container appurtenances shall be in accordance with nationally recognized codes and standards. [**55:**8.9]

63.4.9.1 Containers. Containers that have been removed from service shall be handled in an approved manner. [**55:**8.9.1]

63.4.9.1.1 Testing. Containers out of service in excess of 1 year shall be inspected and tested as required under 63.4.9.1.2. [**55:**8.9.1.1]

63.4.9.1.2 Pressure Relief Device Testing. The pressure relief devices shall be tested for operability and to determine if they are set at the relief pressure required by the tank design. [**55:**8.9.1.2]

63.4.9.1.3 Containers that have previously been used for flammable cryogenic fluids and have been removed from service shall be purged with an inert gas to remove residual flammable gas and stored with all valves closed and the valve outlets plugged. [**55:**8.9.1.3]

63.4.9.2 Systems. Service and repair of containers or systems shall be performed by trained personnel in accordance with nationally recognized standards and with the permission of the container owner. [**55:**8.9.2]

Repairs to either containers or systems should be performed only when the owner of the container or system has full prior knowledge of the repairs and has given approval for such repairs. Repairs should be completed by personnel who have been trained to recognize standards and can provide adequate proof of such training to the owner of the container or system.

63.4.10 Unauthorized Use. Containers shall not be used for any purpose other than to serve as a vessel for containing the product for which it is designated. [**55:**8.10]

63.4.11 Leaks, Damage, and Corrosion.

63.4.11.1 Leaking, damaged, or corroded containers shall be removed from service. [**55:**8.11.1]

63.4.11.2 Leaking, damaged, or corroded systems shall be replaced, repaired, or removed from service. [**55:**8.11.2]

63.4.12 Lighting. Where required by the AHJ, lighting, including emergency lighting, shall be provided for fire appliances and operating facilities such as walkways, control valves, and gates ancillary to stationary containers. [**55:**8.12]

63.4.13 Storage.

63.4.13.1 Indoor Storage.

63.4.13.1.1 Installation. Stationary containers indoors shall be installed in accordance with Chapters 9 and 11 of NFPA 55 or with ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites*. [**55:**8.13.1.1]

63.4.13.1.2 Stationary Containers. Stationary containers shall be in accordance with 63.4.2. [**55:**8.13.1.2]

63.4.13.1.3 Cryogenic Fluids. Cryogenic fluids in stationary or portable containers stored indoors shall be stored in buildings, rooms, or areas constructed in accordance with the building code. [**55:**8.13.1.3]

63.4.13.1.4 Ventilation. Ventilation shall be in accordance with 63.2.16. [**55:**8.13.1.4]

63.4.13.2 Outdoor Storage.

63.4.13.2.1 General. Cryogenic fluids in stationary or portable containers stored outdoors shall be in accordance with 63.4.13.2. [**55:**8.13.2.1]

63.4.13.2.2 Access. Stationary containers shall be located to provide access by mobile supply equipment and authorized personnel. [**55:**8.13.2.2]

63.4.13.2.2.1 Where exit access is provided to serve areas in which equipment is installed, the minimum width shall be not less than 28 in. (710 mm). [**55:**8.13.2.2.1]

Access is required in and around equipment. Some installations are quite complex, and designers should be aware that they need to provide egress from the area. NFPA *101®, Life Safety Code®*, establishes requirements for exit access.

63.4.13.2.3 Physical Protection. Cryogenic fluid containers, cylinders, tanks, and systems that could be exposed to physical damage shall be protected. [**55:**8.13.2.3]

63.4.13.2.3.1 Guard posts or other means shall be provided to protect cryogenic fluid containers, cylinders, tanks, and systems indoors and outdoors from vehicular damage. *(See Section 4.11 of NFPA 55.)* [**55:**8.13.2.3.1]

63.4.13.2.4 Diked Areas Containing Other Hazardous Materials. Containers of cryogenic fluids shall not be located within diked areas with other hazardous materials. [**55:**8.13.2.4]

63.4.13.2.5* Areas Subject to Flooding. Stationary containers located in flood hazard areas shall be anchored to prevent flotation during conditions of the design flood as designated by the building code. [**55:**8.13.2.5]

A.63.4.13.2.5 Flood hazard areas typically are identified on either (1) the special flood hazard area shown on the flood insurance rate map or (2) the area subject to flooding during the design flood and shown on a jurisdiction's flood hazard map or otherwise legally designated. [**55:**A.8.13.2.5]

Provisions were added to the 2010 edition of NFPA 55 to address elevated tanks and underground tanks in flood-prone areas. Areas subject to flooding are typically identified by the jurisdiction, with anticipated maximum flood levels designated by area. Underground tanks in areas subject to flooding are also of concern, and anchoring underground tanks to resist dislodgment due to buoyancy is an important consideration.

63.4.13.2.5.1 Elevated Tanks. Structures supporting elevated tanks and tanks that are supported at a level above that designated in the design flood shall be anchored to resist lateral shifting due to flood and other hydrostatic effects. [**55:**8.13.2.5.1]

63.4.13.2.5.2 Underground Tanks. Underground tanks in flood hazard areas shall be anchored to prevent flotation, collapse, or lateral movement resulting from hydrostatic loads, including the effects of buoyancy, during conditions of the design flood. [**55:**8.13.2.5.2]

63.4.13.2.6 Drainage.

Allowing spilled cryogens to pool is not a good idea, because pooling can delay evaporation and intensify the hazard. An important practice is to keep containers where such exposure will be limited (see 63.4.13.2.6.2) and to enhance the vaporization process (see 63.4.13.2.6.4) by swirling the liquid on a downgrade.

63.4.13.2.6.1 The area surrounding stationary and portable containers shall be provided with a means to prevent accidental discharge of fluids from endangering personnel, containers, equipment, and adjacent structures and from entering enclosed spaces in accordance with this *Code*. [**55:**8.13.2.6.1]

63.4.13.2.6.2 The stationary container shall not be placed where spilled or discharged fluids will be retained around the container. [**55:**8.13.2.6.2]

Δ **63.4.13.2.6.3** The provisions of 63.4.13.2.6.2 shall be permitted to be altered or waived where the AHJ determines that the container does not constitute a hazard after consideration of special features such as the following:

(1) Crushed rock utilized as a heat sink
(2) Topographical conditions
(3) Nature of occupancy
(4) Proximity to structures on the same or adjacent property
(5) Capacity and construction of containers and character of fluids to be stored

[**55:**8.13.2.6.3]

63.4.13.2.6.4 The grade for a distance of not less than 50 ft (15.2 m) from where cryogenic fluid storage or delivery systems are installed shall be higher than the grade on which flammable or combustible liquids are stored or used. [**55:**8.13.2.6.4]

63.4.13.2.6.4.1* Drainage Control.

(A) Where the grade differential between the storage or delivery system and the flammable or combustible liquids storage or use area is not in accordance with 63.4.13.2.6.4, diversion curbs or other means of drainage control shall be used to divert the flow of flammable or combustible liquids away from the cryogenic system. [**55:**8.13.2.6.4.1(A)]

(B) The means of drainage control shall prevent the flow of flammable or combustible liquid to a distance not less than 50 ft (15.2 m) from all parts of the delivery system. [**55:**8.13.2.6.4.1(B)]

Δ **A.63.4.13.2.6.4.1** The intent of these provisions is to make certain that the cryogenic installation is not exposed to the potential of a pool fire from the release of flammable or combustible liquids. Cryogenic fluids are not diked in order that they are allowed to dissipate should leakage occur. Studies conducted by NASA (NSS 1740.16, *Safety Standard for Hydrogen and Hydrogen Systems*) show that the use of dikes around liquid hydrogen storage facilities serves to prolong ground-level flammable cloud travel and that the dispersion mechanism is enhanced by vaporization-induced turbulence. The travel of spilled or leaked cryogenic fluid to distances greater than a few feet (meters) from the source given the nature of the typical leak is considered to be implausible due to the character of cryogenic fluids and their ability to quickly absorb heat from the surrounding environment. [**55:**A.8.13.2.6.4.1]

63.4.13.2.7 Outdoor Installations.

63.4.13.2.7.1 Enclosed Courts. Stationary containers shall not be installed within enclosed courts. [**55:**8.13.2.7.1]

63.4.13.2.7.2* Courts. Stationary containers shall be sited so that they are open to the surrounding environment except that encroachment by building walls of unlimited height shall be permitted when in accordance with the distances specified by Table 63.4.7.2 or the material-specific tables in Chapters 9, 11, 13, and 16 of NFPA 55. [**55:**8.13.2.7.2]

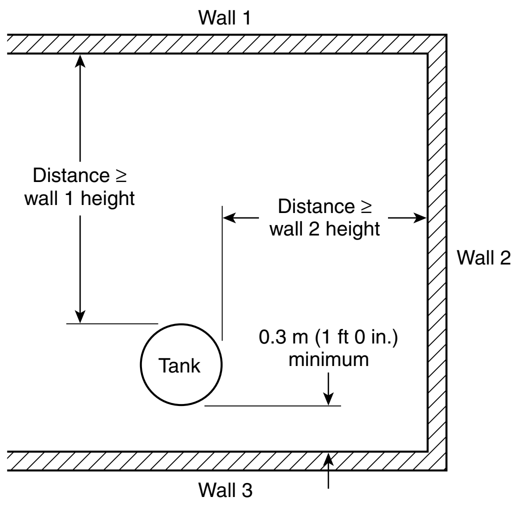
A.63.4.13.2.7.2 The placement of stationary containers is limited with respect to exposure hazards. Table 63.4.7.2 establishes the minimum separation distance between a building and any stationary tank at 1 ft (0.3 m). Additional limitations are placed on wall openings, air intakes, and other exposures. The material-specific tables for liquid hydrogen and liquid oxygen specify increased distances according to the type of construction adjacent to the tank. A problem arises when courtyards are configured so as to interrupt the free movement of air around a tank where an asphyxiation hazard, a flammable hazard, or an oxygen-enriched environment can be created. [**55:**A.8.13.2.7.2]

Placement of stationary containers proximate to the wall of the building served is allowable, provided the minimum separation distances for exposure hazards are met. When additional walls encroach on the installation to form a court, the focus of concern shifts away from the exposure hazards associated with the building itself to the hazards associated with personnel due to hazardous atmospheres that can be created due to the lack of free air movement and ventilation. [**55:**A.8.13.2.7.2]

By specifying the minimum distance between the tank and the encroaching walls that form the court, the circulation of adequate air is ensured. Placing the tank at not less than the height of two of the three encroaching walls results in creating an opening such that the angular dimension between the top of two of the three encroaching walls and the point over which the tank is placed is not greater than 45 degrees, thereby allowing the circulation of air through the space in which the tank is installed. [**55:**A.8.13.2.7.2]

63.4.13.2.7.2.1* Where exterior building walls encroach on the system to form a court, the system shall be located at a distance not less than the height of the wall from at least two court walls. [**55:**8.13.2.7.2.1]

Δ **A.63.4.13.2.7.2.1** The separation distances shown in Figure A.63.4.13.2.7.2.1 are required to provide for ventilation in the space in order to avoid creating a confined space. Chapter 8 of NFPA 55 is a generic chapter used to establish minimum requirements for all cryogens. Material-specific requirements for oxygen, hydrogen, or other gases might require greater separation distances based on the type of construction or the related exposure. For example, wall number 3 shown in Figure A.63.4.13.2.7.2.1 could be an exterior building wall, and the gas could be hydrogen. Refer to Table 63.4.7.2 of this *Code*, Table 9.3.2 and Table 11.3.2.2, Table 13.9.1, and Table 16.2 of NFPA 55 for specific details regarding building walls, wall openings, air intakes, and similar conditions. [**55:**A.8.13.2.7.2.1]



Δ ***FIGURE A.63.4.13.2.7.2.1** Bulk Cryogenic System Located in a Courtyard. [55:Figure A.8.13.2.7.2.1]*

63.4.13.2.7.2.2 The required distance between the exterior walls of the building forming the court and the container shall be determined independently without regard to fire barrier walls used to allow encroachment by fire exposure hazards. [**55:**8.13.2.7.2.2]

63.4.13.2.7.3 Fire Department Access. Fire department access roadways or other approved means shall be in accordance with Section 18.2. [**55:**8.13.2.7.3]

63.4.14 Use and Handling.

63.4.14.1 General. Use and handling of containers and systems shall be in accordance with 63.4.14. [**55:**8.14.1]

63.4.14.1.1 Operating Instructions. Operating instructions shall be provided for installations that require the operation of equipment. [**55:**8.14.1.1]

63.4.14.1.2 Attended Delivery. A qualified person shall be in attendance at all times cryogenic fluid is transferred from mobile supply units to a storage system. [**55:**8.14.1.2]

63.4.14.1.3 Cleaning and Purging of Gas Piping Systems. Cleaning and purging of piping systems shall be in accordance with 63.3.1.19. [**55:**8.14.1.3]

63.4.14.1.4 Inspection.

63.4.14.1.4.1 Cryogenic fluid storage systems shall be inspected and maintained by a qualified representative of the equipment owner as required by the material-specific requirements of Chapters 9, 11, 13, and 16 of NFPA 55. [**55:**8.14.1.4.1]

63.4.14.1.4.2* The interval between inspections other than those specified by material-specific requirements shall be based on nationally recognized good practices or standards. [**55:**8.14.1.4.1.1]

A.63.4.14.1.4.2 ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites*, recommends periodic inspection intervals for inert gas systems. [**55:**A.8.14.1.4.1.1]

63.4.14.1.4.3 A record of the inspection shall be prepared and provided to the user or the AHJ upon request. [**55:**8.14.1.4.2]

63.4.14.1.5 Design.

63.4.14.1.5.1 Nationally Recognized Good Practices. Where nationally recognized good practices or standards have been established for the process employed, such practices and standards shall be followed. [**55:**8.14.1.5.1]

Δ **63.4.14.1.5.2 Piping Systems.** Piping, tubing, fittings, and related components shall be designed, fabricated, and tested in accordance with the requirements of ASME B31.3, *Process Piping*, or other approved standards and shall be in accordance with 63.4.14.2. [**55:**8.14.1.5.2]

63.4.14.2 Piping and Appurtenances.

63.4.14.2.1 Piping systems shall be designed for the use intended through the full range of pressure and temperature to which they will be subjected. [**55:**8.14.2.1]

63.4.14.2.2 Piping systems shall be designed and constructed to allow for expansion, contraction, vibration, settlement, and fire exposure. [**55:**8.14.2.2]

63.4.14.3 Joints. Joints in piping and tubing shall be in accordance with the requirements of ANSI/ASME B31.3, *Process Piping*, or other approved standards. [**55:**8.14.3]

The ASME B31 series standards are nationally recognized as the appropriate standards for use. While ANSI/ASME B31.3, *Process Piping*, is one of the most commonly recognized standards for this application, additional standards other than B31.3 may be appropriate. For example, ASME B31.8, *Gas Transmission and Distribution Pipelines,* can be used for systems designed to address carbon monoxide piping systems. CGA G-5.7, *Carbon Monoxide and Syngas Pipeline Systems,* can also be utilized. A design standard such as B31.3 provides a basic foundation, while the use of other approved standards grants flexibility to designers under the approval process granted by codes without attempting to specify the type of connections that are allowed.

63.4.14.4 Valves and Accessory Equipment. Valves and accessory equipment shall be acceptable for the intended use at the temperatures of the application and shall be designed and constructed to withstand the maximum pressure at the minimum temperature to which they will be subjected. [**55:**8.14.4]

63.4.14.5 Shutoff Valves on Containers. Shutoff valves shall be provided on all container connections, except for pressure relief devices. [**55:**8.14.5]

63.4.14.5.1 Shutoff valves for containers with multiple pressure relief devices shall be permitted in accordance with 63.4.2.4.7. [**55:**8.14.5.1]

63.4.14.5.2 Shutoff valves shall be accessible and located as close as practical to the container. [**55:**8.14.5.2]

63.4.14.6 Shutoff Valves on Piping.

63.4.14.6.1 Shutoff valves shall be installed in piping containing cryogenic fluids where needed to limit the volume of liquid discharged in the event of piping or equipment failure. [**55:**8.14.6.1]

63.4.14.6.2 Pressure relief valves shall be installed where liquid or cold gas can be trapped between shutoff valves in the piping system. *(See 63.4.2.4.)* [**55:**8.14.6.2]

63.4.14.7 Physical Protection and Support.

63.4.14.7.1 Aboveground piping systems shall be supported and protected from physical damage. [**55:**8.14.7.1]

63.4.14.7.2 Piping passing through walls shall be protected from mechanical damage. [**55:**8.14.7.2]

63.4.14.8 Corrosion Protection.

63.4.14.8.1 Aboveground piping that is subject to corrosion shall be protected against corrosion. [**55:**8.14.8.1]

63.4.14.8.2 Belowground piping shall be protected against corrosion. [**55:**8.14.8.2]

63.4.14.9 Cathodic Protection. Where required, cathodic protection shall be in accordance with 63.4.14.9. [**55:**8.14.9]

63.4.14.9.1 Operation. Where installed, cathodic protection systems shall be operated and maintained to continuously provide corrosion protection. [**55:**8.14.9.1]

63.4.14.9.2 Inspection.

63.4.14.9.2.1 Container systems equipped with cathodic protection shall be inspected for the intended operation by a cathodic protection tester. [**55:**8.14.9.2.1]

63.4.14.9.2.2 The cathodic protection tester shall be certified as being qualified by the National Association of Corrosion Engineers, International (NACE). [**55:**8.14.9.2.2]

63.4.14.9.3 Impressed Current Systems.

63.4.14.9.3.1 Systems equipped with impressed current cathodic protection systems shall be inspected in accordance with the requirements of the design and 63.4.14.9.2. [**55:**8.14.9.3.1]

63.4.14.9.3.2 The design limits shall be available to the AHJ upon request. [**55:**8.14.9.3.2]

63.4.14.9.3.3 The system owner shall maintain the following records to demonstrate that the cathodic protection is in conformance with the requirements of the design:

(1) The results of inspections of the system
(2) The results of testing that has been completed

[**55:**8.14.9.3.3]

63.4.14.9.4 Repairs, maintenance, or replacement of a cathodic protection system shall be under the supervision of a corrosion expert certified by NACE. [**55:**8.14.9.4]

63.4.14.9.4.1 The corrosion expert shall be certified by NACE as a senior corrosion technologist, a cathodic protection specialist, or a corrosion specialist or shall be a registered engineer with registration in a field that includes education and experience in corrosion control. [**55:**8.14.9.4.1]

Requirements for cathodic protection are established based on a "when required" provision that is triggered and referenced by material-specific applications when appropriate, including requirements for underground containers or piping systems. Similar provisions are provided for gaseous systems in 63.3.1.7.

63.4.14.10 Testing.

63.4.14.10.1 Piping systems shall be tested and proved free of leaks after installation as required by the codes and standards to which they are designed and constructed. [**55:**8.14.10.1]

63.4.14.10.2 Test pressures shall not be less than 150 percent of the maximum allowable working pressure when hydraulic testing is conducted or 110 percent when testing is conducted pneumatically. [**55:**8.14.10.2]

63.4.14.11 Material-Specific Requirements.

63.4.14.11.1 Indoor Use. Indoor use of cryogenic fluids shall be in accordance with the material-specific provisions of Chapters 9, 11, 13, and 16 of NFPA 55 or with ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites,* and 63.4.14.2. [**55:**8.14.11.1]

63.4.14.11.2 Outdoor Use.

63.4.14.11.2.1 General. Outdoor use of cryogenic fluids shall be in accordance with the material-specific provisions of Chapters 9, 11, 13, and 16 of NFPA 55 or with ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites,* and 63.4.14.2. [**55:**8.14.11.2.1]

63.4.14.11.2.2 Separation. Distances from property lines, buildings, and exposure hazards shall be in accordance with Table 63.4.7.2 and Table 63.4.7.3 and the material-specific provisions of Chapters 9, 11, 13, and 16 of NFPA 55 or with ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites*. [**55:**8.14.11.2.2]

63.4.14.11.2.3 Emergency Shutoff Valves.

63.4.14.11.2.3.1* Accessible manual or automatic emergency shutoff valves shall be provided to shut off the cryogenic fluid supply in case of emergency. [**55:**8.14.11.2.3.1]

(A) Manual emergency shutoff valves or the device that activates an automatic emergency shutoff valve on a bulk source or piping systems serving the bulk supply shall be identified by means of a sign. [**55:**8.14.11.2.3.1(A)]

A.63.4.14.11.2.3.1 In operations where an automatic emergency shutoff valve is activated by a control system that is operated from a remote station or by remote station software, the software system should be designed to provide a visual indication of the emergency shutdown control system. The visual emergency shutdown function should be able to be identified by trained operators and recognizable to emergency response personnel. [**55:**A.8.14.11.2.3.1]

63.4.14.11.2.3.2 Emergency shutoff valves shall be located at the point of use, at the source of supply, and at the point where the system piping enters the building. [**55:**8.14.11.2.3.2]

63.4.14.11.3 Filling and Dispensing.

63.4.14.11.3.1 General. Filling and dispensing of cryogenic fluids shall be in accordance with 63.4.14.1.2. [**55:**8.14.11.3.1]

63.4.14.11.3.2 Dispensing Areas. Dispensing of cryogenic fluids associated with physical or health hazards shall be conducted in approved locations. [**55:**8.14.11.3.2]

63.4.14.11.3.2.1 Indoor Dispensing Areas. Dispensing indoors shall be conducted in areas constructed in accordance with the building code. [**55:**8.14.11.3.2.1]

63.4.14.11.3.2.2 Ventilation. Indoor areas in which cryogenic fluids are dispensed shall be ventilated in accordance with the requirements of 63.2.16 and the mechanical code. [**55:**8.14.11.3.2.2]

63.4.14.11.3.2.3 Piping Systems. Piping systems utilized for filling or dispensing of cryogenic fluids shall be designed and constructed in accordance with 63.4.14.2. [**55:**8.14.11.3.2.3]

63.4.14.11.3.3 Vehicle Loading and Unloading Areas. Loading and unloading areas shall be constructed in accordance with the requirements of Chapter 9 of NFPA 55 for liquid oxygen, Chapter 11 of NFPA 55 for liquid hydrogen, Chapter 13 of NFPA 55 for liquid carbon dioxide, and Chapter 16 of NFPA 55 for liquid nitrous oxide or ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites,* for inert cryogenic fluids, as applicable. [**55:**8.14.11.3.3]

63.4.14.11.3.4* A noncombustible, delivery vehicle spill pad shall be provided when required by the material-specific requirements of Chapter 9 of NFPA 55 for liquid oxygen, Chapter 11 of NFPA 55 for liquid hydrogen, Chapter 13 of NFPA 55 for liquid carbon dioxide, and Chapter 16 of NFPA 55 for liquid nitrous oxide or ANSI/CGA P-18, *Standard for Bulk Inert Gas Systems at Consumer Sites*. [**55:**8.14.11.3.4]

A.63.4.14.11.3.4 The inert cryogens, nitrogen and argon, do not require the installation of a noncombustible spill pad, because they do not typically condense oxygen from the air in sufficient quantities to pose a hazard during transfer. [**55:**A.8.14.11.3.4]

63.4.14.11.3.4.1* A noncombustible spill pad shall be provided for delivery areas where bulk liquid helium is transferred from delivery vehicles. [**55:**8.14.11.3.4.1]

A.63.4.14.11.3.4.1 The noncombustible spill pad is provided for liquid helium transfer operations, because the cryogen is at a temperature that is sufficiently low enough to liquefy oxygen, presenting a hazard when in contact with combustible surfaces. [**55:**A.8.14.11.3.4.1]

63.4.14.11.3.5 Filling Controls. A pressure gauge and full trycock valve shall be provided and shall be visible from the delivery point to allow the delivery operator to monitor the internal pressure and liquid level of stationary containers during filling. [**55:**8.14.11.3.5]

63.4.14.11.3.5.1 When the containers being filled are remote from the delivery point and pressure gauges or full trycock valves are not visible, redundant gauges and valves shall be installed at the filling connection. [**55:**8.14.11.3.5.1]

63.4.14.11.4 Handling.

63.4.14.11.4.1 Applicability. Handling of cryogenic containers shall be in accordance 63.4.14.11.4. [**55:**8.14.11.4.1]

63.4.14.11.4.2 Carts and Trucks.

63.4.14.11.4.2.1 Cryogenic containers shall be moved using an approved method. [**55:**8.14.11.4.2.1]

63.4.14.11.4.2.2 Where cryogenic containers are moved by hand cart, hand truck, or other mobile device, that device shall be designed for the secure movement of the container. [**55:**8.14.11.4.2.2]

63.4.14.11.4.3 Design. Carts and trucks used to transport cryogenic containers shall be designed to provide a stable base for the commodities to be transported and shall have a means of restraining containers to prevent accidental dislodgement. [**55:**8.14.11.4.3]

63.4.14.11.4.4 Closed Containers.

63.4.14.11.4.4.1 Pressurized containers shall be closed while being transported. [**55:**8.14.11.4.4.1]

63.4.14.11.4.4.2 Containers designed for use at atmospheric conditions shall be transported with appropriate loose-fitting covers in place to prevent spillage. [**55:**8.14.11.4.4.2]

63.5 Bulk Oxygen Systems

63.5.1 Bulk oxygen systems shall comply with Chapter 9 of NFPA 55.

63.5.2 Cleaning and Purging of Gas Piping Systems. Cleaning and purging of piping systems shall be in accordance with 63.3.1.19. [**55:**9.4.1.9]

Δ **63.5.3** Cleaning of oxygen systems used in medical gas service shall be in accordance with NFPA 99. *(See also 9.4.3.1 of NFPA 55.)* [**55:**9.4.1.9.1]

63.6 Gas Hydrogen Systems

Bulk gaseous hydrogen systems, bulk liquefied hydrogen systems, and gas generation systems are required to comply with NFPA 2, *Hydrogen Technologies Code*, in addition to the specific chapter of NFPA 55. NFPA 2 provides fundamental safeguards for the generation, installation, storage, piping, use, and handling of hydrogen in compressed gas (GH2) form or cryogenic liquid (LH2) form. In addition, see also 63.3.1.19 and related commentary for additional details regarding the new provisions on cleaning and purging of piping systems also required for these hydrogen systems.

Δ **63.6.1** Bulk hydrogen compressed gas systems shall comply with NFPA 2 and Chapter 10 of NFPA 55.

63.6.2 Cleaning and purging of piping systems shall be in accordance with 63.3.1.19. [**55:**10.2.3.2]

63.7 Bulk Liquefied Hydrogen Systems

Δ **63.7.1** Bulk liquefied hydrogen systems shall comply with NFPA 2 and Chapter 11 of NFPA 55.

63.7.2 Cleaning and purging of piping systems shall be in accordance with 63.3.1.19. [**55:**11.2.3.9]

63.8 Gas Generation Systems

Δ **63.8.1 General.** Gas generation systems shall comply with NFPA 2 and Chapter 12 of NFPA 55.

63.8.2 Process purging and vents shall conform to the following:

(1) Pressure equipment and piping intended to be purged, pressure regulators, relief valves, and other potential sources of combustible gas shall be vented to the outside of the building in accordance with the applicable requirements of 63.2.15 or 63.3.1.19.
(2) The vent shall be designed to prevent entry of water or foreign objects.
(3) The vent gas shall be directed so as to not create additional hazards to the building openings, such as windows, doors, or HVAC intakes.

[**55:**12.3.2.8.5.7]

63.9 Insulated Liquid Carbon Dioxide Systems

Insulated liquid carbon dioxide systems shall comply with Chapter 13 of NFPA 55.

N **63.9.1 General.** The storage, use, and handling of liquid carbon dioxide in insulated systems shall be in accordance with the provisions of Chapter 13 and Chapters 1 through 7 of NFPA 55, as applicable.

N **63.9.2 Permits.**

N **63.9.2.1** For other than vehicles equipped for and using compressed gas as a fuel for propelling the vehicle, an operational permit shall be required for liquid carbon dioxide systems in excess of 100 lb (45.4 kg) of carbon dioxide.

N **63.9.2.2** A construction permit shall be required for the installation of, or modification to, a liquid carbon dioxide (CO_2) system where the quantity exceeds the amount listed in 63.9.2.

N **63.9.2.3** The following information shall be provided to the authority having jurisdiction with the application for permit:

(1) Total aggregate quantity of liquid CO_2 in pounds or cubic feet at normal temperature and pressure
(2) Location and total volume of the room where the liquid CO_2 will be located and whether the room is at or below grade
(3) Location of containers relative to equipment, building openings, and means of egress
(4) Manufacturer's specifications and pressure rating, including cut sheets, of all piping and/or tubing to be used
(5) A piping and instrumentation diagram that shows piping support and remote fill connections
(6) Details of container venting, including, but not limited to, vent line size, material, and termination location
(7) Alarm and detection system and equipment, if applicable
(8) Seismic support for containers

N **63.9.3 Pressure Relief Devices.** Containers used for liquid carbon dioxide shall be equipped with pressure relief devices piped from the uppermost part of the containers and communicating with the vapor space. [**55:**13.3.1]

N **63.9.4 Physical Protection.**

N **63.9.4.1** Pressure relief devices shall be located to minimize tampering, damage, and obstruction to flow. [**55:**13.3.1.1.1]

N **63.9.4.2** The inlet and outlet of the relief devices shall not be blocked by a valve or plug during normal operation. [**55:**13.3.1.1.2]

N **63.9.5 Vent Pipe Systems.** Pressure relief devices shall be piped to the outdoors where the discharge will not impinge on the structure, personnel, or means of egress and will not create a hazardous concentration of carbon dioxide. [**55:**13.3.1.2]

N **63.9.5.1** Pressure relief devices from portable DOT 4L containers that are not a component of a stationary system shall not be required to meet the requirements of 63.9.5. [**55:**13.3.1.2.1]

N **63.9.5.2** Vent piping systems serving pressure relief devices shall be protected from water intrusion to prevent moisture or solid carbon dioxide from collecting and freezing and interfering with the operation of the pressure relief device. [**55:**13.3.1.2.2]

N **63.9.5.3** Vent piping systems serving pressure relief devices shall be designed to prevent backflow restrictions exceeding 10 percent backpressure on the pressure relief device under full flow conditions. [**55:**13.3.1.2.3]

N **63.9.6 Pressure and Level Indicators.**

N **63.9.6.1** Cylinders, containers, and tanks shall be provided with a pressure gauge and a level gauge or device for indicating the quantity of liquid carbon dioxide. [**55:**13.3.2.1]

N **63.9.6.2** These devices shall be designed for the temperatures and pressures associated with liquid carbon dioxide service. [**55:**13.3.2.2]

N **63.9.6.3** Where cylinders, containers, and tanks are in locations remote from the filling connection, a means to determine when the containers have been filled to their design capacity shall be provided and shall be verifiable from the filling connection. [**55:**13.3.2.3]

N **63.9.7 Piping Systems.**

N **63.9.7.1** Carbon dioxide piping shall be located and supported to protect against damage from strain on piping and fittings; the effects of expansion, contraction, and vibration; mechanical damage; and heat sources. [**55:**13.3.3.1]

N **63.9.7.2** Piping, tubing, and hoses and fittings shall be designed to a bursting pressure of at least four times the system design pressure. [**55:**13.3.3.2]

N **63.9.7.3 Materials of Construction.** Materials of construction shall be employed for potential exposure to a temperature of −109.3°F (−78.5°C). [**55:**13.3.4]

N **63.9.7.4 Operating Instructions.** Operating instructions shall account for potential exposure of personnel to extremely low temperatures in accordance with 63.9.12. [**55:**13.5]

N **63.9.8 Safety Measures.**

N **63.9.8.1** Rooms or areas inside assembly, business, educational, institutional, and residential occupancies containing a liquid carbon dioxide (CO_2) system shall comply with the safety measures in 63.9.9.1.

N **63.9.8.2** The provisions of 63.9.9.1 shall not apply to liquid carbon dioxide (CO_2) systems located above grade in outdoor areas with enclosure walls obstructing on no more than 75 percent of the perimeter at ground level.

N **63.9.8.3 Gas Detection System.**

N **63.9.8.3.1** A continuous gas detection system shall be provided in the room or area where container systems are filled and used, and in areas where the heavier-than-air gas can congregate.

N **63.9.8.3.2** Carbon dioxide (CO_2) sensors shall be provided within 12 in. (305 mm) of the floor in the area where the gas is most likely to accumulate or leaks are most likely to occur.

N **63.9.8.3.3** The system shall be designed to detect and notify at a low-level alarm and high-level alarm.

N **63.9.8.4** The threshold for activation of the low-level alarm shall not exceed a carbon dioxide concentration of 5,000 ppm TWA (9,000 mg/m^3). When carbon dioxide is detected at the low-level alarm, the system shall activate a signal at a normally attended location within the building.

N **63.9.8.5** The threshold for activation of the high-level alarm shall not exceed a carbon dioxide concentration of 30,000 ppm (54,000 mg/m^3). When carbon dioxide is detected at the high-level alarm, the system shall activate an audible and visual alarm in an approved location.

N **63.9.9 Signage.**

N **63.9.9.1** Hazard identification signs shall be posted at the entrance to the room and confined to the area where liquid carbon dioxide containers are located. The sign shall be a minimum 8 in. (200 mm) wide and 6 in. (150 mm) high and indicate:

CAUTION — CARBON DIOXIDE GAS
Ventilate the area before entering.
A high carbon dioxide (CO_2) gas concentration
in this area can cause asphyxiation.

N **63.9.10 Performance Design Option.**

N **63.9.10.1** Carbon dioxide (CO_2) systems shall not be required to be provided with a gas detection system where a complete discharge of the stored carbon dioxide cannot result in a concentration exceeding 5,000 ppm in the room where the container is located or the area where the carbon dioxide is likely to congregate. The maximum concentration (ppm) shall be determined as follows:

(1) Calculate the volume (scf) of CO_2 gas at standard temperature and pressure that is contained in the storage containers as follows:
  (a) To convert pounds of liquid to volume (scf) of CO_2 gas, multiply the pounds by 8.741.
  (b) To convert gallons of liquid to volume (scf) of CO_2 gas, multiply the gallons by 74.04.
(2) Calculate the volume of the room containing the CO_2 containers, or the area where the CO_2 is likely to congregate, in cubic feet as follows:
  (a) The volume of the room or area shall be based on a height limitation of 5 ft (1524 mm) or the ceiling, whichever is less.
  (b) The boundary of the area shall be to walls or partitions 5 ft (1524 mm) or more in height that obstruct gas dispersion at the floor level.
  (c) All doors in the boundary walls shall be considered closed.
  (d) CO_2 shall be assumed to congregate in basements, pits, or lower floors where openings are present between the containers and the lower floor.
(3) Divide the volume of CO_2 gas by the volume of the room. If the result does not exceed 0.005 (5,000 ppm), the design meets the performance option criteria.

N 63.9.11 Seismic and Structural Design.

N **63.9.11.1** Liquid carbon dioxide system containers and piping shall comply with the seismic design requirements in accordance with the building code and shall not exceed the floor loading limitation of the building.

N **63.9.11.2** Container foundations or floors in multistoried buildings shall be designed to support the weight of the system at its full capacity in accordance with the building code.

N 63.9.12 Small Insulated Liquid Carbon Dioxide Outdoor Systems.

N **63.9.12.1** Container systems located in enclosed spaces shall be in accordance with 63.9.1 for indoor systems.

N **63.9.12.2** Aboveground outdoor locations shall not be required to be provided with a gas detection and alarm system in accordance with 63.9.1 where the system is unenclosed.

N **63.9.12.3** To be considered unenclosed, enclosures constructed to limit access or otherwise provide a visual or architectural barrier for the installation shall be constructed in accordance with the requirements in Section 6.6 for weather protection or with the following:

(1) The enclosure shall be constructed without a roof or overhead cover.
(2) Supports and walls shall not obstruct more than three sides nor more than 75 percent of the perimeter of the storage or use area, with 25 percent of the perimeter being open to the atmosphere.

[**55:**13.7.1.1]

N **63.9.12.4** Enclosures that do not meet the requirements of 63.9.14.2 shall be permitted when constructed in accordance with the following:

(1) The enclosure shall be constructed without a roof or overhead cover.
(2) Continuous mechanical exhaust ventilation shall be provided.

[**55:**13.7.1.2]

N **63.9.12.5** Where mechanical exhaust ventilation is provided, it shall be in accordance with the following:

(1) The exhaust system shall be installed in accordance with the requirements of the mechanical code.
(2) The exhaust system shall be designed to consider the density of the potential vapors released with exhaust taken from a point within 12 in. (305 mm) of the floor.
(3) The location of both the exhaust and the inlet air openings shall be designed to provide air movement across all portions of the enclosure to prevent the accumulation of vapors.
(4) The rate of exhaust ventilation shall be not less than 1 scf/min/ft^2 (0.028 Nm^3/min/m^2) of floor area within the enclosure.

[**55:**13.7.1.1.2.1]

N 63.9.13 Large Indoor Insulated Liquid Carbon Dioxide Systems. (Reserved)

N 63.9.14 Large Outdoor Insulated Liquid Carbon Dioxide Systems.

N **63.9.14.1 Location.** Outdoor stationary large insulated liquid carbon dioxide systems shall be located in accordance with Table 63.9.14.1. [**55:**13.9.1]

N **63.9.14.2 Point-of-Fill Connections.** Point-of-fill connections serving stationary containers filled by mobile transport equipment shall not be positioned closer to exposures than the minimum distances in Table 63.9.14.1. [**55:**13.9.1.1]

TABLE 63.9.14.1 *Minimum Separation Distance Between Outdoor Stationary Large Insulated Liquid Carbon Dioxide Containers and Exposures*

Exposure	Minimum Distance	
	ft	m
Buildings, regardless of construction type	2	0.6
Wall openings other than building exits	2	0.6
Air intakes	10	3.1
Property lines	5	1.5
Places of public assembly (assembly occupancies)	50	15
Nonambulatory patient areas	50	15
Combustible materials, (e.g., paper, leaves, weeds, dry grass, debris)	15	4.5
Incompatible hazardous materials	20	6.1
Building exits	10	3.1

[**55:**13.9.1]

N **63.9.14.3 Fire Barriers.** A 2-hour fire barrier wall shall be permitted in lieu of the distances specified by Table 63.9.14.1 when in accordance with the provisions of 63.9.15.4 through 63.9.15.8. [**55:**13.9.2]

N **63.9.14.3.1** The fire barrier wall shall be without openings or penetrations. [**55:**13.9.2.1]

N **63.9.14.3.1.1** Penetrations of the fire barrier wall by conduit or piping shall be permitted provided that the penetration is protected with a firestop system in accordance with the Building Code. [**55:**13.9.2.1.1]

N **63.9.14.3.2** The fire barrier wall shall be either an independent structure or the exterior wall of the building adjacent to the storage system. [**55:**13.9.2.2]

N **63.9.14.3.3** The fire barrier wall shall be located not less than 5 ft (1.5 m) from any exposure. [**55:**13.9.2.3]

N **63.9.14.3.4** The fire barrier wall shall not have more than two sides at approximately 90 degree (1.57 rad) directions or not more than three sides with connecting angles of approximately 135 degrees (2.36 rad). [**55:**13.9.2.4]

63.10 Storage, Handling, and Use of Ethylene Oxide for Sterilization and Fumigation

See 63.3.1.19 and related commentary for additional details regarding the language on cleaning and purging of piping systems.

63.10.1 General. Storage, handling, and use of ethylene oxide for sterilization and fumigation shall comply with Chapter 14 of NFPA 55.

63.10.2 Cleaning and Purging of Gas Piping Systems.

63.10.2.1 Cleaning and purging of piping systems shall be in accordance with 63.3.1.19. [**55:**14.4.1.3]

63.10.2.2 Piping and valves that have been used to transport ethylene oxide to or from a sterilizer to the emission control or release point shall be drained and purged in accordance with 63.3.1.19 prior to dismantling. [**55:**14.4.3.1]

63.11 Liquid Oxygen in Home Care

63.11.1 General. The storage and use of liquid oxygen (LOX) in home care shall comply with Sections 63.4 and 63.11.

Δ **63.11.1.1** Gas equipment used in the home for health care shall conform to applicable requirements of NFPA 99.

63.11.2 Information and Instructions. The seller of liquid oxygen shall provide the user with information in written form that includes, but is not limited to, the following:

(1) Manufacturer's instructions and labeling for storage and use of the containers
(2) Locating containers away from ignition sources, exits, electrical hazards, and high temperature devices in accordance with 63.11.3.2
(3) Restraint of containers to prevent falling in accordance with 63.11.3.3
(4) Requirements for handling containers in accordance with 63.11.3.4
(5) Safeguards for refilling of containers in accordance with 63.11.3.5

63.11.3 Containers. Containers of liquid oxygen in home care shall be in accordance with 63.11.3.1 through 63.11.3.5.

63.11.3.1* Containers shall be stored, used, and operated in accordance with the manufacturer's instructions and labeling.

A.63.11.3.1 The seller has a responsibility to provide written instructions to the user in accordance with 63.11.2. In fulfilling this responsibility the seller should explain to the user the use of the equipment being delivered and precautions that are to be taken. The seller's written instructions are intended to make the user aware of the hazards of the material and to provide recommendations that will address the location, restraint, movement, and refill of ambulatory containers when these containers are to be refilled by the user. However, the user has the responsibility to receive, read, and understand the written material regarding storage and use of liquid oxygen and the containers and equipment that is furnished by the seller. In addition to specific information or instructions provided by the seller or equipment manufacturer regarding the storage or use of the equipment and of the liquid oxygen or the containers used, the user remains responsible to see that the containers are used or maintained in accordance with the seller's instructions to ensure that they are as follows:

(1) Located and maintained in accordance with the requirements of 63.11.3.2
(2) Restrained in accordance with the requirements of 63.11.3.3
(3) Handled or transported in accordance with the requirements of 63.11.3.4
(4) When liquid oxygen ambulatory containers are to be refilled by the user, that the containers are refilled in accordance with the requirements of 63.11.3.5 and the manufacturer's instructions

63.11.3.2 Containers shall not be located in areas as follows:

(1) Where they can be overturned due to operation of a door
(2) Where they are in the direct path of egress
(3) Where they are subject to damage from falling objects
(4) Where they can become part of an electrical circuit
(5) Where open flames and high temperature devices could cause a hazard

63.11.3.3* Liquid oxygen home care containers shall be restrained by one of the following methods while in storage or use to prevent falling caused by contact, vibration, or seismic activity:

(1) Restraining containers to a fixed object with one or more restraints
(2) Restraining containers within a framework, stand, or assembly designed to resist container movement
(3) Restraining containers by locating a container against two points of contact

A.63.11.3.3 Two points of contact can be provided by using elements of a room or furnishings in the room such as the walls of a corner of a room or a wall and a furnishing or object such as a table or a desk.

63.11.3.4 Containers shall be transported by use of a cart or hand truck designed for such use.

63.11.3.4.1 Liquid oxygen home care containers equipped with a roller base shall not be required to be transported by use of a cart or truck.

63.11.3.4.2 Liquid oxygen ambulatory containers shall be permitted to be hand carried.

63.11.3.5 The filling of containers shall be in accordance with 63.11.3.5.1 through 63.11.3.5.2:

63.11.3.5.1 Liquid oxygen home care containers shall be filled outdoors.

63.11.3.5.1.1* A drip pan compatible with liquid oxygen shall be provided under home care container filling and vent connections used during the filling process.

A.63.11.3.5.1.1 Drip pans or similar containment devices are used in order to protect against liquid oxygen spillage from coming into contact with combustible surfaces, including asphalt thereby elevating the potential for ignition.

63.11.3.5.2 Liquid oxygen ambulatory containers shall be allowed to be filled indoors when the supply container is designed for filling such containers and written instructions are provided by the container manufacturer.

63.11.3.5.3* The use of open flames and high temperature devices shall be in accordance with the adopted fire prevention code.

A.63.11.3.5.3 Oxygen is not a flammable gas, and ignition of the gas itself is not the primary hazard. When oxygen is present in concentrations that exceed normal ambient concentrations of approximately 21 percent (by volume), ordinary combustible materials can be ignited more easily, and when combustion occurs, the combustion is more vigorous. As a general rule, the higher the concentration of oxygen present, the more likely ignition of ordinary combustibles will occur if ignition sources are present, and the more rapid the combustion process. Fire prevention codes frequently contain general statements cautioning against the use of open flames, and warnings are designed to prevent a hazardous condition caused by ignition sources. On the other hand, these codes assume that the normal ambient atmosphere is present, and they do not typically warn of the hazards of an oxygen-enriched atmosphere, which represents a condition out of the ordinary.

63.11.4 Maximum Quantity. The maximum aggregate quantity of liquid oxygen allowed in storage and in use in a single dwelling unit shall be 31.6 gal (120 L).

63.11.4.1 The maximum aggregate quantity of liquid oxygen allowed in day care occupancies shall be limited by the maximum allowable quantity set forth in the adopted fire prevention code or building code.

63.11.4.2 Where individual sleeping rooms are separated from the remainder of the dwelling unit by fire barriers and horizontal assemblies having a minimum fire-resistance rating of 1 hour in accordance with the adopted building code, the maximum aggregate quantity per dwelling unit shall be allowed to be increased to a maximum of 31.6 gal (120 L) of liquid oxygen per sleeping room.

63.11.5 Smoking. Smoking shall be prohibited in rooms or areas where liquid oxygen is in use.

63.11.5.1* A sign stating "OXYGEN — NO SMOKING" shall be posted in the room or area where the liquid oxygen containers are stored or used.

A.63.11.5.1 A sign prohibiting smoking in areas where oxygen is used may be provided by the seller. However, the posting of the sign within the user's premises and observing the prohibitions and precautionary information printed on the sign remains the responsibility of the user.

Corrosive Solids and Liquids

64

64.1 General

64.1.1 The storage, use, and handling of corrosive solids and liquids shall comply with the requirements of Chapter 60.

Δ **64.1.2** The storage, use, and handling of corrosive solids and liquids in amounts exceeding the maximum allowable quantities permitted in control areas set forth in Chapter 60 shall comply with the requirements of NFPA 400.

The term *corrosive material* is defined in 3.3.180.3 as "a chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the site of contact." Examples of corrosive solids and liquids include acids (carboxylic, peroxy, mineral, and oxidizing), phenol alcohol, sodium, potassium and lithium metals, and bases (sodium carbonate, sodium hydroxide).

For requirements pertaining to the storage, use, and handling of corrosive solids and liquids, users are directed to Chapter 60 on hazardous materials. Where the storage, use, or handling of the corrosive solid or corrosive liquid exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter, they must also comply with the provisions of NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of NFPA 1, *Fire Code*. NFPA 400 combined the NFPA hazardous materials documents into a single code. Rather than extracting the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

Explosives, Fireworks, and Model Rocketry

65

Chapter 65 contains general provisions for regulating the storage, use, and manufacture of explosives, display fireworks, and pyrotechnics before a proximate audience; flame effects before a proximate audience; fireworks manufacturing; and model and high power rocketry.

This chapter covers the wide range of hazards associated with the use of materials that potentially can have disastrous consequences. Numerous incidents have been documented, such as explosions at fireworks manufacturing facilities and storage areas, display fireworks that have landed in a crowd, and special effects that have gone awry. The Station nightclub fire in Rhode Island in 2003 and the fireworks storage accident in Enschede, Netherlands, in 2000 further heightened the fire prevention and protection community's awareness of the hazards of these materials. In October 2017, at least 47 people were killed in explosions at a fireworks factory near Jakarta, Indonesia. A quick search of recent news reports will show many additional incidents involving fireworks and how quickly a situation can turn when they are involved.

See Commentary Table 65.1 for the applicability of NFPA documents to fireworks and rocketry regulation. Commentary Table 65.2 lists the previous and current explosive hazard classifications as of January 1, 1991.

COMMENTARY TABLE 65.1 *NFPA Document Key for Fireworks and Model and High Power Rocketry Applications*

NFPA Document	***Application***
NFPA 1122, *Code for Model Rocketry*	The design, construction, and limitations of propellant mass and power and the reliability of model rocket motors and model rocket motor reloading kits and their components produced commercially for sale to, or for use by, the public for purposes of education, recreation, and sporting competition
NFPA 1123, *Code for Fireworks Display*	The construction, handling, and use of fireworks intended solely for outdoor display, as well as the general conduct and operation of the display
NFPA 1124, *Code for the Manufacture, Transportation, and Storage of Fireworks and Pyrotechnic Articles*	The construction, use, and maintenance of buildings and facilities for manufacture and storage of fireworks, novelties, and pyrotechnic articles and manufacturing facilities; storage of display fireworks, pyrotechnic articles, salute powder, pyrotechnic and explosive compositions, and Black Powder at other than display sites; storage of consumer fireworks at display fireworks storage facilities; transportation on public highways or fireworks, pyrotechnic articles, and components containing pyrotechnic or explosive materials
NFPA 1125, *Code for the Manufacture of Model Rocket and High Power Rocket Motors*	The manufacture of model and high power rocket motors designed, sold, and used for the purpose of propelling recoverable aero models
NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*	The use of pyrotechnic special effects in the performing arts in conjunction with theatrical, musical, or similar productions before a proximate audience, performers, or support personnel
NFPA 1127, *Code for High Power Rocketry*	The design, construction, and limitations of propellant mass and power and the reliability of all high power rocket motors and motor components produced commercially for sale to, or for use by, the certified user for education, recreation, and sporting competition

***COMMENTARY TABLE 65.2** Comparison of Previous and Current Explosive Hazard Classification Names as of January 1, 1991*

Current Classification	***Classification Name Prior to January 1, 1991***
Division 1.1	Class A explosives
Division 1.2	Class A or B explosives
Division 1.3	Class B explosives
Division 1.4	Class C explosives
Division 1.5	Blasting agents
Division 1.6	No applicable hazard class

Source: *Fire Protection Handbook®*, Table 6.15.2.

65.1 General

65.1.1* The storage, use, and handling of explosives, fireworks, and model rocketry shall comply with the requirements of this chapter, NFPA standards referenced within this chapter, and Sections 60.1 through 60.4 of this *Code*.

N **A.65.1.1** Chapter 65 does not contain any prescriptive technical provisions to address the retail sale and associated storage of consumer fireworks. The AHJ can utilize 1.3.2.2 to develop a protection approach for new and existing consumer fireworks retail sale and storage facilities.

65.1.2 Where the provisions of this chapter or NFPA standards referenced herein conflict with the provisions of Chapter 60, the provisions of this chapter and referenced NFPA standards shall apply.

65.2 Display Fireworks

Δ **65.2.1** The construction, handling, and use of fireworks intended solely for outdoor display as well as the general conduct and operation of the display shall comply with the requirements of NFPA 1123.

The purpose of NFPA 1123 is to provide the following:

1. Minimum requirements for outdoor fireworks displays
2. Recommended local permit regulations
3. Recommended regulations for state certifications of display operators

The term *fireworks display* is defined in 3.3.16 of NFPA 1123 as "a presentation of fireworks for a public or private gathering."

Section 1.12 allows the authority having jurisdiction (AHJ) to issue permits for the discharge of fireworks within the jurisdiction. See Table 1.12.8(a) for permit requirements for display fireworks (1.3G). The following recommended regulations for applications for permits for the outdoor display of fireworks are extracted from Annex B of NFPA 1123:

(1) Application for permit to operate a display of outdoor fireworks in conformance with the terms of [*specific regulation*] of the General Laws of [*state or jurisdiction*] should be made in writing on forms provided by the AHJ.

(2) Such application should provide the following information:
   (a) The name, address, email address, and phone number of the individual, group, or organization sponsoring the outdoor fireworks display.
   (b) The name, address, email address, and phone number of the supplier of the fireworks, if different from that of the operator.
   (c) Evidence of financial responsibility by the sponsor of the event or festival and by the operator of the fireworks display. This could take the form of an insurance certificate or other document attesting to coverage or responsibility.
   (d) The date and time of day at which the outdoor fireworks display is to be held, with a proposed rain/wind date and time in the event the display is postponed.
   (e) The exact location planned for the outdoor fireworks display.
   (f) Confirmation of the license of the operator and the number of assistants who are to be present.
   (g) The approximate number and kinds of fireworks to be discharged.
   (h) The manner and place of storage of such fireworks prior to delivery to the outdoor fireworks display site.
   (i) A diagram of the grounds on which the outdoor fireworks display is to be held showing the point at which the fireworks are to be discharged; the display site; the approximate distances from mortars to spectator viewing areas; the location and approximate distances of all buildings, highways, and other lines of communication; the lines behind which the audience is to be restrained; the controls that will be used to maintain audience separation; and the location of other possible overhead obstructions.

(3) Upon receipt of such application ______ days in advance of the date set for this outdoor fireworks display, the AHJ should make or initiate an investigation of the site of the proposed display for the purpose of determining compliance with these regulations in the case of the particular display.

(4) The AHJ should approve or deny the permit application with comments provided to the permit applicant. If the application is denied, the AHJ should specify the reasons for the denial so that the permit

applicant can attempt to address the reasons for a denial with a resubmitted permit application.

Section 1.13 allows the AHJ to require certificates of fitness for individuals or companies performing fireworks displays. See Section 1.13 for information on certificates of fitness, also known as operator licensing requirements.

The following extract of Annex C from NFPA 1123 provides recommended requirements for operator licensing:

C.1 Operator Licensing Requirements.

C.1.1 A requirement of licensing is that the applicant has attained the age of 21 years.

C.1.2 A requirement of licensing is that the applicant has passed a comprehensive written examination covering state laws pertaining to the display of fireworks and this code [NFPA 1123]. At the option of the issuing office, an alternate requirement can be substituted, such as acceptance of competency certification by a national organization or of licensing by another state.

C.1.3 A requirement of licensing is that the applicant has provided evidence of actively participating in the performance of at least five outdoor fireworks displays. At the option of the issuing office, an alternate requirement can be substituted.

C.2 Provisions of Operator Licensing.

C.2.1 The license should be valid for a period of 4 years.

C.2.2 Renewal of the license should be automatic upon provision of proof of active participation in at least three outdoor fireworks displays and 8 hours of continuing education during the prior 4 years.

Δ **65.2.2** All storage of display fireworks shall comply with NFPA 1124.

The purpose of NFPA 1124 is to establish reasonable minimum fire and life safety requirements for the manufacture, transportation, and storage of fireworks, pyrotechnic articles, and any component(s) thereof containing pyrotechnic or explosive compositions. It also applies to:

(1) Testing of fireworks at a manufacturing facility
(2) Testing of pyrotechnic devices used in the entertainment industry
(3) Testing of any component(s) of fireworks or pyrotechnic devices used in the entertainment industry that contain pyrotechnic or explosive compositions

The 2017 edition of NFPA 1124 is referenced in this edition of the *Code*.

65.2.3 Permits. Permits, where required, shall comply with Section 1.12.

65.3 Pyrotechnics Before a Proximate Audience

Δ **65.3.1** The use of pyrotechnic special effects in the performing arts in conjunction with theatrical, musical, or any similar productions before a proximate audience, performers, or support personnel shall comply with NFPA 1126.

The purpose of NFPA 1126 is to provide requirements for the reasonable protection of pyrotechnic operators, performers, support personnel, and proximate audiences viewing a display, including property and buildings where indoor pyrotechnics are used. The requirements of Section 65.3 apply to both indoor and outdoor performances. NFPA 1126 also provides guidelines for the AHJ for approval of the use of pyrotechnics and for the development of requirements for local permits.

NFPA 1126 applies to any outdoor use of pyrotechnics at distances from audiences that are less than those required by NFPA 1123, with the exception of the use of aerial shells, which are required to comply with the provisions of NFPA 1123.

NFPA 1126 also applies to the performance specifications, instructions, notifications, and labeling by the manufacturer of pyrotechnics materials, devices, equipment, and supplies. Annex B of NFPA 1126 provides inspection requirements and an inspection routine that can be used as a model by the AHJ. The AHJ is required to judge the safety of any production. The recommended inspection items are reproduced as a checklist in Exhibit 65.1.

The American Pyrotechnics Association (APA) created a proximate pyrotechnics performance checklist based on

Exhibit 65.1

1. Access
   - ❑ Fire lane clear
   - ❑ Hydrants not blocked
   - ❑ Fire department connections clear
   - ❑ Standpipe connections clear
   - ❑ At least two fire extinguishers provided
   - ❑ Extinguishing equipment charged and in good working order
   - ❑ Warning signs in place
2. Exits
   - ❑ All designated exits clear
   - ❑ Exits visible
3. Pyrotechnic Materials and Devices
   - ❑ Proper and current license in the possession of the pyrotechnic operator
   - ❑ Permit on site
   - ❑ Fire department briefed on proposed activity
   - ❑ Proper ventilation
4. Electrical
   - ❑ Cords and connections in good condition
   - ❑ Power supply safely arranged
   - ❑ Pyrotechnic firing mechanism in good working order
5. Flameproofing
   - ❑ Set and scenic materials treated for flame retardance
   - ❑ Burlap and other protective materials used for rigging treated for flame retardance

Checklist for inspection of pyrotechnics display. (NFPA 1126, Annex B)

Exhibit 65.2

IV. Walkthrough Inspection Checklist (AHJ)
1. Pyrotechnic walkthrough and demonstration
   A. Confirm venue management consent to pyrotechnics
   B. Verify pyrotechnic plot with actual site dimensions/adjustments
2. Type of devices – verify indoor/proximate use and performance specifications (NFPA 1126: 5.1, 5.2, 5.3, 5.4)
3. Verify quantities, locations, and cueing of devices to be used
4. Verify secure areas and methods for restricting unauthorized persons from entering
5. Verify that all devices are securely fixed with proper audience separation
   A. Minimum 15 ft (4.6 m) or 2 times the fallout radius (NFPA 1126: 6.4.1)
   B. Concussion mortars min 25 ft (7.6 m) in secured area (NFPA 1126: 6.4.2)
   C. Trajectory of comets/mines not over audience (NFPA 1126: 6.2.11)
   D. Waterfall effect area to be free of flammable materials (NFPA 1126: 6.2.12)
   E. Wire rocket effects to be properly secured and terminated (NFPA 1126: 6.2.9)
   F. Airbursts over audience to be minimum height of 3 times the diameter of effect, and no sparks within 15 ft (4.6 m) of floor (NFPA 1126: 6.2.14(1) and (2))
6. Check fire-fighting equipment
   A. Minimum of 2 approved water fire extinguishers (NFPA 1126: 6.1.1.1)
   B. Other fire-fighting equipment as needed/required (NFPA 1126: 6.1.1 & 6.1.1.2)
   C. Existing on-site fire-fighting equipment/systems
7. Pyrotechnic firing systems
   A. Verify operational/safety features and functions of systems (NFPA 1126: 6.3.2 and 6.3.3)
   B. Verify operator and spotters have clear view of effects and communication with operator (NFPA 1126: 6.3.5)
8. Determine plan for HVAC/detectors, adjustments and notification of demonstration
9. Determine need for demonstration of representative effects
10. Check plans for approved and secure on-site storage and preparation areas (NFPA 1126: 4.3.2 (l), 6.1.3 and 6.1.4)
    A. Separation from heat/flame sparks (NFPA 1126: 3.3)
    B. No smoking within 25 ft (7.6 m) (signage) (NFPA 1126: 6.5.5)
    C. Materials stored/handled neatly and orderly (NFPA 1126: 6.5.1)
11. Check plan for personal protective equipment for preparation and loading of pyrotechnics (NFPA 1126: 6.5.7)

Proximate pyrotechnics performance checklist. (Courtesy of American Pyrotechnics Association)

NFPA 1126. The portion of the checklist that is specifically applicable to the inspection of a performance for use by AHJs is shown in Exhibit 65.2.

Chapter 1 of this *Code* allows the AHJ to require certificates of fitness for individuals or companies performing fireworks displays. See Section 1.13 for information on provisions relating to certificates of fitness. The following extract of Annex C of NFPA 1126 provides guidelines for the licensing of pyrotechnic operators:

> **C.1 Pyrotechnic Experience.** A license should be granted only to an individual who has actively participated in the setup and loading of at least five performances where pyrotechnic special effects were used. (The issuing office can substitute an alternative number of performances.)
>
> **C.2 Formal Requirements.** A license should be granted only to an individual who has met at least one of the following requirements:
>
> (1) Successful completion of a comprehensive written examination covering this standard [NFPA 1126] and state laws pertaining to the use of pyrotechnic special effects
> (2) Receipt of a competency certificate from a national organization that promotes the safe use of pyrotechnic special effects
> (3) Possession of a license for the use of pyrotechnic special effects issued by another state
>
> **C.3 Provisions for License Renewal.** A license should not be renewed unless the applicant's record proves active participation in at least three pyrotechnic special effect performances during the past four (4) years and that those performances were conducted in a safe manner. The pyrotechnic uses can be of the indoor or outdoor type.

65.3.2 Where any of the following conditions exist, they shall comply with NFPA 1126:

(1) Any indoor display of pyrotechnic special effects
(2) Any outdoor use of pyrotechnic special effects at distances less than those required by NFPA 1123
(3) The use of pyrotechnic special effects during any videotaping, audiotaping, or filming of any television, radio, or movie production if such production is before a proximate audience
(4) The rehearsal of any production in which pyrotechnic special effects are used

65.3.3 Permits. Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the display and use of pyrotechnic materials before a proximate audience. See Table 1.12.8(a).

65.4 Flame Effects Before an Audience

Δ **65.4.1** The use of flame effects before an audience shall comply with NFPA 160.

NFPA 160, *Standard for the Use of Flame Effects Before an Audience*, provides requirements for the protection of property operators, performers, support personnel, and the viewing audiences where flame effects are used indoors or outdoors. The purpose of this standard is to provide minimum requirements to the operators and manufacturers for the safe operation of flame effects.

The circumstances of each show or attraction can be unique and can require individual evaluation when determining the need for protection systems. Factors such as the experience and qualifications of the operations and maintenance personnel, clearance distance between show elements and nonparticipants, visual conditions, and magnitude of the potential hazards are to be weighed in the development and presentation of the production.

NFPA 160 applies to flame effects for entertainment, exhibition, demonstration, or simulation before an audience. NFPA 160 also applies to the following:

1. Use of flame effects before an audience
2. Design, fabrication, installation, testing, control, operation, and maintenance of equipment, materials, procedures, and systems used to produce flame effects
3. Rehearsal, videotaping, audiotaping, or filming of any television, radio, or movie production, if such production is before an audience and includes the use of flame effects
4. Rehearsal of any production incorporating flame effects intended to be presented before an audience
5. Storage and holding at a venue where flammable and combustible materials are to be used to create flame effects
6. That portion or component of any hybrid flame effect that utilizes fuels, materials, devices, and methodologies governed by the standard

NFPA 160 does not apply to the following:

1. Flame effects produced solely by pyrotechnic special effects devices or pyrotechnic material
2. Use of pyrotechnic special effects (See Section 65.3 and NFPA 1126.)
3. Storage of flammable solids, liquids, and gases not to be used to create flame effects (See Chapter 66 and NFPA 30, *Flammable and Combustible Liquids Code*.)
4. Nitrocellulose-based flame projectors
5. Manufacture, off-site storage, and transportation of materials and equipment used to produce flame effects
6. Use of flame effects in fire training (NFPA 160 does apply when the audience is not part of the fire training.)
7. Manufacture, transportation, storage, sale, and use of model or high power rocket motors (See Sections 65.6, 65.7, and 65.8; NFPA 1122; NFPA 1125; and NFPA 1127.)
8. Traditional nontheatrical public display of flames, such as the following:
   a. Use of lighted candles in restaurants or religious services
   b. Fireplaces in areas open to the public
   c. Restaurant cooking visible to the patrons
   d. Listed Group II flame effects
   e. Flame effects used in a fireworks display (See NFPA 1123.)
9. Use of consumer fireworks by the public
10. Use of motor vehicles in races or sanctioned competitive sporting events
11. Use of ground-based effects utilizing explosive, liquid fuels, or other combustibles in air show environments

NFPA 160 identifies and defines the following seven classifications of flame effect:

1. *Group I Flame Effect.* An attended, manually controlled flame effect. Examples of Group I flame effect are handheld burning torches, cigarette lighters, candles, matches, paper lit in ashtrays, burning batons used by jugglers, fire rings that are jumped through by performers, and other fire effects that create the illusion of danger.

An example of the misapplication of the Group I flame effect is local ordinances that permit smoking in a venue for theatrical purposes. At issue is the intent of the definition of the term *Group I flame effect* in NFPA 160. It is not the intent of this *Code* or NFPA 160 to consider this incidental use of a flame as a prop (e.g., to portray smoking by a performer) in a theatrical performance as a Group I flame effect; nor would it be the intent if a few candles were used on stage as props. To assist the users of this *Code* and NFPA 160 in understanding the intent, consider the last line in the first paragraph of item 1, Group I Flame Effect, which concludes "... and other fire effects that create the illusion of danger." Smoking materials or candles used as props on stage are just that, props, and are not being used as special effects that establish some illusion of danger. The AHJ should consider the life safety features of the venue when evaluating the use of any ignition sources or ignited materials. Regarding permit requirements, if the item is not deemed a flame effect, NFPA 160 would not require a permit; however, local AHJ provisions might specify otherwise.

2. *Group II Flame Effect.* An individual or group flame effect designed for unattended operation that is temporarily or permanently installed outside any structure. Examples of Group II flame effect are unattended torches, burning urns, and small fires.

3. *Group III Flame Effect.* An attended, temporarily installed flame effect for a specific production with limited operation and fixed time for removal. Examples of Group III flame effect are effects used by traveling shows and concerts and effects used for limited-duration special events, such as the Olympics. This group also includes a traveling entertainment event that plays various venues, such as, but not limited to, circuses, operas, musicals, stage plays, trade shows, or corporate events. This group effect also includes a nontraveling entertainment event that plays a single venue.
4. *Group IV Flame Effect.* A large individual or group flame effect that is permanently installed inside or outside any structure designed for unattended operation without a main show supervisory control system. Examples of Group IV flame effect are a burning cabin or bonfire and large single or multiple flaming brazier entrance features used to create a theme atmosphere. A stand-alone-type flame effect control system without any significant control supervision by a main show control system is used.
5. *Group V Flame Effect.* A large individual or group flame effect that is temporarily or permanently installed inside or outside any structure and is designed for intermittent or continuous operation under the supervision of a main show control system but without full-time supervision by a technician. An example of Group V flame effect is a simulated building or vehicle explosion that is part of a larger theme-type attraction. The flame effect control system is totally dedicated to the operation of the flame effect elements. The flame effect control system maintains all its internal safety features, with the interface between the flame effect control system and the main show control system limited to those commands and status indicators that cannot alter or override the flame supervisory system control logic.
6. *Group VI Flame Effect.* A large individual or group flame effect that is temporarily or permanently installed inside or outside any structure and is designed for intermittent operation under the supervision of a main show control system and a technical director, with cast members in close proximity to the effect at the time of operation. An example of Group VI flame effect is a live-action stunt show that is part of a larger theme-type attraction. The flame effect control system is totally dedicated to the operation of the flame effect elements. The flame effect control system maintains all its internal safety features, with the interface between the flame effect control system and the main show control system limited to those commands and status indicators that cannot alter or override the flame supervisory system control logic.
7. *Group VII Flame Effect.* An individual flame effect that can be temporarily or permanently installed inside or outside any structure that, due to its unique operating requirements, does not fit into any other classification. An example of Group VII flame effect is a fire created as part of an illusion used to make an item or an individual disappear.

COMMENTARY TABLE 65.3 *Features Included in Flame Effect Groups*

Feature	Flame Effect Group						
	I	II	III	IV	V	VI	VII
Outside	X	X	X	X	X	X	X
Inside	X		X	X	X	X	X
Temporary installation	X	X	X		X	X	X
Permanent installation		X		X	X	X	X
Attended	X		X			X	X
Unattended		X		X	X		X
Visual flame verification	X		X				X
Automatic flame supervision		X		X	X	X	X
Manual fuel controls	X						X
Automatic fuel controls		X	X	X	X	X	X
Main show control					X	X	
Proximate cast			X			X	X

Note: A blank cell in the table means that the feature is not permitted to be in the group.
X — Group feature.
Source: NFPA 160, Table A.3.3.19.

Exhibit 65.3 is a schematic illustration of flame effect control and piping components that can be located at a supervisor station. Commentary Table 65.3 identifies the features of flame effects that are included in the various flame effect groups.

In accordance with A.3.3.19 of NFPA 160, the proximate cast feature applies to flame effect Groups III, VI, and VII, and this revision is shown in Commentary Table 65.3.

65.4.2 Permits. Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the use of flame effects before an audience. See Table 1.12.8(a).

65.5 Fireworks Manufacturing

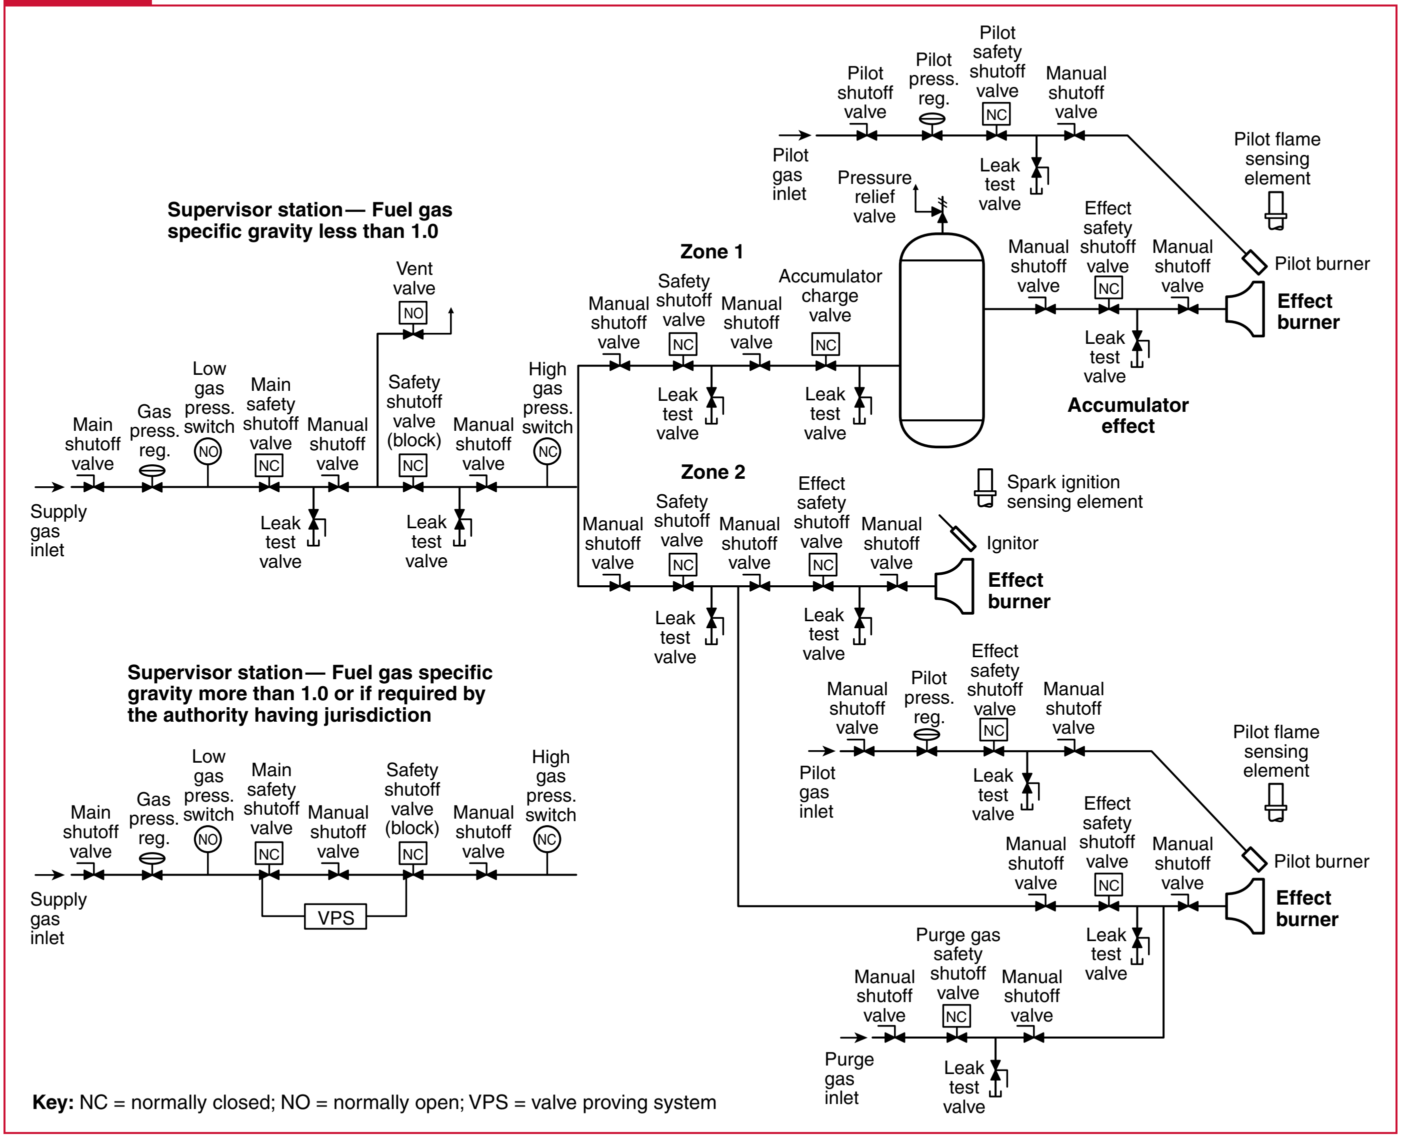
Δ **65.5.1** The manufacture, transportation, or storage of fireworks shall comply with NFPA 1124.

65.5.2 Permits. Permits, where required, shall comply with Section 1.12.

Δ 65.6 Model Rocketry

The design, construction, limitations of propellant mass and power, and reliability of model rocket motors and model rocket motor reloading kits and their components produced commercially for

Exhibit 65.3



Example of various flame effect control and piping components.

sale to or use by the public for purposes of education, recreation, and sporting competition shall comply with NFPA 1122.

The purpose of NFPA 1122 is to ensure the availability of commercial model rocket motors and components that meet standards of safety and reliability and to ensure that the creative and experimental use of model rocket devices by the public is reasonably safe. The intent of NFPA 1122 is also to discourage the creation and launching of homemade rockets and other rocket-like vehicles that are propelled by, or intended to be propelled by, homemade rocket propulsion devices. In addition, experiments with explosive or highly energetic rocket propellants are discouraged by NFPA 1122.

NFPA 1122 addresses not only model rocket motors but also the design and construction of model rockets propelled by model rocket motors and the conduct of launch operations of model rockets.

65.7 Rocketry Manufacturing

Δ **65.7.1** The manufacture of model rocket motors designed, sold, and used for the purpose of propelling recoverable aero models shall comply with NFPA 1125.

The purpose of NFPA 1125 is to provide reasonable safety in the manufacture of model rocket motors and high power rocket motors. The document is designed to supplement existing federal, state, or local regulations.

NFPA 1125 applies to the design, construction, and reliability of model and high power rocket motors and model rocket and high power motor-reloading kits and their components and to the limitation of propellant mass and power. These terms are defined in 3.3.24.2 and 3.3.24.4 of NFPA 1125 as follows:

1. *High Power Rocket Motor*. A rocket motor that has no more than 40,960 N-sec (9209 lb-sec) of total impulse and that does not otherwise meet all the requirements for a model rocket motor set forth in NFPA 1125.
2. *Model Rocket Motor*. A solid-propellant rocket motor that has a total impulse of no greater than 160 N-sec (36 lb-sec), an average thrust of no greater than 80 N (18 lbf), and that otherwise meets the other requirements set forth in NFPA 1125.

Model rocket motors include both assembled reloadable model rocket motors and manufactured expendable model rocket motors.

65.7.2 Permits. Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the manufacture of model rocket motors and a permit for the manufacture, sale, and use of high power rocket motors. See Table 1.12.8(a).

65.8 High Power Rocketry

Δ **65.8.1** The design, construction, limitations of propellant mass and power, and reliability of all high-power rocket motors and motor components produced commercially for sale to or use by the certified user for education, recreation, and sporting competition shall comply with NFPA 1127.

The requirements of NFPA 1127 establish guidelines for reasonably safe operation of high power rockets that protect the user and the public and discourage experimentation with explosive or highly energetic rocket propellants, construction of homemade rocket propulsion motors, or attempted launches or other operation of homemade rocket devices.

NFPA 1127 addresses the design, construction, limitation of propellant mass and power, and reliability of high power rocket motors and motor components produced commercially for sale or for use by a certified user for education, recreation, and sporting competition. NFPA 1127 also covers the design and construction of high power rocket vehicles propelled by high power rocket motors, including the conduct of launch operations of high power rocket vehicles.

65.8.2 Permits. Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the use of high power rockets. See Table 1.12.8(a.

65.9 Explosives

Δ **65.9.1** The manufacture, transportation, storage, sale, and use of explosive materials shall comply with NFPA 495 and NFPA 498.

NFPA 495, *Explosive Materials Code*, applies to, and is intended to provide reasonable safety for the manufacture, transportation, storage, sale, and use of explosive materials. NFPA 495 does not apply to the following:

1. Transportation of explosive materials where they are under the jurisdiction of the U.S. Department of Transportation (DOT). However, NFPA 495 does apply to state and municipal supervision of compliance with 49 CFR, Parts 100–199, "Hazardous Materials Regulations," U.S. Department of Transportation.
2. Transportation and use of military explosives by federal or state military agencies.
3. Transportation and use of explosive materials by federal, state, or municipal agencies while engaged in the performance of normal or emergency duties.
4. Manufacture of explosive materials under the jurisdiction of the U.S. Department of Defense.
5. Distribution of explosive materials to, or storage of explosive materials by, military agencies of the United States.
6. Arsenals, navy yards, depots, or other establishments owned by, operated by, or operated on behalf of the United States.
7. Pyrotechnics such as flares, fuses, and railway torpedoes.
8. Fireworks or pyrotechnic special effects, as defined in NFPA 1123, NFPA 1124, and NFPA 1126.
9. Model and high power rocketry, as defined in NFPA 1122, NFPA 1125, and NFPA 1127.
10. Use of explosive materials in medicines and medicinal agents in the forms prescribed by the United States Pharmacopoeia or the National Formulary.

NFPA 498, *Standard for Safe Havens and Interchange Lots for Vehicles Transporting Explosives*, applies to safe havens that are used for the parking of vehicles transporting explosives and to interchange lots for explosives that are safe havens where less than truckloads of explosives are permitted to be held for transfer from one vehicle to another for continuance in transportation. NFPA 498 also applies to the design and operating features of facilities for motor vehicles that transport explosives, and it provides reasonable requirements for the prevention of fires, theft, and explosion within those facilities.

Facilities for motor vehicles that transport explosives provide safe havens for parking such vehicles and provide interchange areas where less than truckload quantities of explosives are permitted to be transferred from one vehicle to another for further transportation. Some explosives interchange lots also

COMMENTARY TABLE 65.4 *Classifications for Permit to Blast*

Class	Category	Blasting Permitted
A	Unlimited	All types of blasting
B	General aboveground	All phases of blasting operations in quarries, open pit mines, and aboveground construction
C	General underground	All phases of blasting operations in underground mines, shafts, tunnels, and drifts
D	Demolition	All phases of blasting in demolition projects
E	Seismic	All phases of blasting in seismic prospecting
F	Agriculture	All phases of blasting in agriculture but limited to not more than 22.7 kg (50 lb) per blast
G	Special	Special blasting as described on the permit

Source: NFPA 495, Table 4.3.2.

provide temporary holding facilities for less than truckload quantities of explosives.

Facilities for motor vehicles that transport explosives are considered part of the over-the-road transportation of explosives. These facilities not only provide the services previously specified, but they can also provide vehicle maintenance and areas in which drivers can rest.

Motor vehicles that use facilities that transport explosives operate under the regulations of the 49 CFR 100–199, U.S. Department of Transportation. Such vehicles are engaged in transporting explosives and ammunition on government bills of lading, or they often carry commercial explosives.

65.9.2 Permits.

65.9.2.1 Permits, where required, shall comply with Section 1.12.

Subsection 1.12.8 requires a permit for the manufacture, sale, disposal, purchase, storage, use, possession, or transportation of explosives within the jurisdiction, as well as for blasting operations. See Table 1.12.8(a).

65.9.2.2 A separate permit shall be required to conduct blasting operations.

Commentary Table 65.4 shows the classification for blasting permits as required by 65.9.2.2.

Flammable and Combustible Liquids

66

Chapter 66 addresses the storage, use, and handling of flammable and combustible liquids, including waste liquids.

66.1 General

66.1.1* The storage, handling, and use of flammable and combustible liquids, including waste liquids, as herein defined and classified, shall comply with this chapter; NFPA 30, and Sections 60.1 through 60.4 of this *Code*.

A.66.1.1 See A.1.3.2.

66.1.2 Where the provisions of this chapter or NFPA 30 conflict with the provisions of Chapter 60, the provisions of this chapter and NFPA 30 shall apply.

66.1.3 This chapter shall not apply to the following:

(1)* Any liquid that has a melting point of 100°F (37.8°C) or greater

A.66.1.3(1) Liquids that are solid at 100°F (37.8°C) or above, but are handled, used, or stored at temperatures above their flash points, should be reviewed against pertinent sections of this *Code*. [**30:**A.1.1.2(1)]

A material whose melting point is at or above 100°F (37.8°C) is outside the scope of NFPA 30, *Flammable and Combustible Liquids Code*, and can be considered equivalent to a true solid. The provisions of NFPA 30 are not considered to be appropriate for these materials. Certain of these materials (e.g., camphor and naphthalene) are termed *volatile solids* in some technical references and might be reported as having flash points. However, this does not imply that they are liquids within the scope of NFPA 30. It does mean that these materials, like liquids, evolve vapors at ambient temperatures. For this reason, A.66.1.3(1) recommends review of any situation where such materials are handled at temperatures above their putative flash points, because they can take on some of the characteristics of a flammable liquid at elevated temperatures. Under such circumstances, application of specific provisions of NFPA 30 might be prudent, not because they are mandated but because they are simply good fire protection practice.

Conversely, a material that has a melting point below 100°F (37.8°C) is considered by NFPA 30 to be a liquid, even if it is not fluid at the temperature at which it is used or stored. Such a material is within the scope of NFPA 30 because it melts at a relatively low temperature and can then spread or flow toward an ignition source. Some of these materials (e.g., asphalt) do not have distinct melting points, so the dividing line between the liquid state and the solid state is not easily discerned. NFPA 30 defines a liquid as any material that is more fluid than 300 penetration asphalt or that is characterized as a liquid using the test protocol of ASTM D4359, *Standard Test for Determining Whether a Material Is a Liquid or a Solid*. An asphalt graded as 300 penetration is about the consistency of painter's putty or glazing compound, only more cohesive. It is quite resistant to flow.

For purposes of protection of ordinary combustible solid materials in storage, NFPA 13, *Standard for the Installation of Sprinkler Systems*, applies. For flammable solids, as defined by the U.S. Department of Transportation or as defined in 3.3.45 of NFPA 400, *Hazardous Materials Code*, NFPA 400 applies.

(2)* Any liquid that does not meet the criteria for fluidity given in the definition of *liquid* in 3.3.30 of NFPA 30 and Chapter 4 of NFPA 30

A.66.1.3(2) The information in A.66.1.3(1) also applies here. [**30:**A.1.1.2(2)]

(3) Any cryogenic fluid or liquefied gas, as defined in 3.3.140.7

NFPA 30's use of the term *liquid* excludes any material that has a vapor pressure greater than 40 psi (276 kPa) absolute at 100°F (37.8°C). One common material that meets this criterion, thereby excluding it from coverage under NFPA 30, is liquefied petroleum gas (LP-Gas), which is covered in NFPA 58, *Liquefied Petroleum Gas Code*. Other liquefied flammable gases are covered in NFPA 55, *Compressed Gases and Cryogenic Fluids Code*, and NFPA 59A, *Standard for the Production, Storage, and Handling of Liquefied Natural Gas (LNG)*.

(4)* Any liquid that does not have a flash point, but which is capable of burning under certain conditions

A.66.1.3(4) Certain mixtures of flammable or combustible liquids and halogenated hydrocarbons either do not exhibit a flash point using the standard closed-cup test methods or will exhibit elevated flash points. However, if the halogenated hydrocarbon is the more volatile component, preferential evaporation of this component can result in a liquid that does have a flash point or has a flash point that is lower than the original mixture. In order to evaluate the fire hazard of such mixtures, flash point tests should be conducted after fractional evaporation of 10, 20, 40, 60, or even 90 percent of the original sample or other fractions representative of the conditions of use. For systems such as open process tanks or spills in open air, an open-cup test method might be more appropriate for estimating the fire hazard. [**30:**A.1.1.2(4)]

Examples of liquids that do not have flash points but that might be capable of burning under certain conditions (such as being heated in a closed vessel) include methyl bromide, dichloromethane, trichloroethane, and trichloroethylene. NFPA 49, *Hazardous Chemicals Data Compilation*, and NFPA 491, *Compilation of Hazardous Chemical Reactions*, which are available only as part of the *Fire Protection Guide to Hazardous Materials*, 14th edition, can be useful in identifying such materials.

(5)* Any aerosol product

Δ **A.66.1.3(5)** See NFPA 30B. [**30:**A.1.1.2(5)]

(6) Any mist, spray, or foam

Two processes that come under this exclusion are spray finishing using flammable or combustible materials and spray lay-up of glass fiber–reinforced plastic resins, both of which are covered in NFPA 33, *Standard for Spray Application Using Flammable or Combustible Materials*.

(7)* Transportation of flammable and combustible liquids as governed by the U.S. Department of Transportation

A.66.1.3(7) Requirements for transportation of flammable and combustible liquids can be found in NFPA 385 and in the U.S. Department of Transportation's Hazardous Materials Regulations, Title 49, Code of Federal Regulations, Parts 100–199. [**30:**A.1.1.2(7)]

Transportation within the context of NFPA 30 includes the movement of liquids by air, rail, truck, ship, or pipeline beyond the facility from which the liquid is shipped to the point of delivery to the consignee. In this context, transportation does not include movement of liquids within a facility.

NFPA 30 does not apply to transportation. Specific regulations governing transportation of flammable and combustible liquids can be found in the U.S. Department of Transportation's (DOT) Hazardous Materials Transportation Regulations, in 49 CFR 172–179. The DOT has broad preemptive power and any intent by NFPA 30 to govern transportation would be overridden.

NFPA 385, *Standard for Tank Vehicles for Flammable and Combustible Liquids*, is often used as the basis for local and state regulation of intrastate truck shipments, although the DOT regulations specified are more often adopted by reference for the same purpose. Tank vehicles licensed for interstate commerce are always regulated by the DOT, including those operating in intrastate service. The differences between NFPA 385 and the DOT regulations are minor.

In some long-term storage situations, applicability of NFPA 30 depends on how the term *temporary* is defined. A tank vehicle routinely used to store a liquid for periods of time exceeding several days could be considered a storage tank, especially if it never leaves the facility. In that case, Formal Interpretation 84-4 (NFPA 30, 2012 edition) states that the requirements of NFPA 30 would apply. However, the same tank vehicle holding the same liquid but temporarily parked for a few days while it awaits shipment to the consignee would be considered in transportation and, therefore, would not be subject to NFPA 30. Undoubtedly, some situations are not as clear and require the judgment of the authority having jurisdiction (AHJ).

(8)* Storage, handling, and use of fuel oil tanks and containers connected with oil-burning equipment

Δ **A.66.1.3(8)** See NFPA 31. [**30:**A.1.1.2(8)]

NFPA 30 defers to NFPA 31, *Standard for the Installation of Oil-Burning Equipment*, for fuel oil storage tanks where the tanks are inside a building and supply oil-burning appliances such as boilers, hot air furnaces, and hot water heaters. However, NFPA 31 refers to NFPA 30 for outside aboveground fuel oil storage tanks whose capacity exceeds 660 gal (2500 L) and for those that are buried. Historically, the installation of fuel oil storage tanks in buildings to supply fuel to oil-burning appliances has proved to be safe. Although NFPA 31 is the only document referenced in A.66.1.3(8), this exemption applies just as well to fuel tanks installed inside a building under NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*.

(9)* Use and installation of alcohol-based hand rub (ABHR) dispensers. *(See 60.5.2.)*

[**30:**1.1.2]

Δ **A.66.1.3(9)** Requirements for the use and installation of alcohol-based hand rubs are covered in this *Code* and NFPA *101*. [**30:**A.1.1.2(9)]

66.1.4 Installations made in accordance with the applicable requirements of the following standards shall be deemed to be in compliance with this *Code*:

(1) NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*
(2) NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*
(3) NFPA 31, *Standard for the Installation of Oil-Burning Equipment*
(4) NFPA 32, *Standard for Drycleaning Plants*
(5) NFPA 33, *Standard for Spray Application Using Flammable or Combustible Materials*
(6) NFPA 34, *Standard for Dipping, Coating, and Printing Processes Using Flammable or Combustible Liquids*
(7) NFPA 35, *Standard for the Manufacture of Organic Coatings*
(8) NFPA 36, *Standard for Solvent Extraction Plants*

(9) NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*
(10) NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*
(11) NFPA 99, *Health Care Facilities Code*
(12) NFPA *101, Life Safety Code*
[**30:**1.5.3]

NFPA publishes many standards that apply to specific hazards or processes. Compliance with the requirements of the more specifically oriented standards can take precedence over those of NFPA 30. NFPA 30 is a "base" standard for flammable and combustible liquids and applies to a wide range of activities, whereas most of the codes and standards listed in 66.1.4 address narrowly defined situations. Those specific codes and standards can be expected to deal directly with the fire and explosion hazards presented by the process, operation, or occupancy covered.

The exception is this *Code,* which includes a broad-based chapter on hazardous materials (Chapter 60). This *Code* also extracts many provisions of NFPA 30 into Chapter 66. The intent of 66.1.4(1), then, is to exempt from the requirements of NFPA 30 those occupancies in which there are only minor quantities of flammable and combustible liquids. Note that Chapter 9 of NFPA 30 contains basically the same provisions for flammable and combustible liquids as does Chapter 60 of NFPA 1. This allows comprehensive application of NFPA 30 in those jurisdictions where a fire prevention code other than NFPA 1 is used or in jurisdictions where NFPA 30 is referenced directly.

An example of the application of 66.1.4 is appropriate. NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*, generally refers to NFPA 30 for the design and construction of aboveground fuel storage tanks, including any required appurtenances. However, NFPA 30A imposes separation distances between the tanks and property lines and exposures that greatly exceed those imposed by NFPA 30. This is because motor fuel dispensing sites are accessible by the general public, and this unrestricted access presents inherent risks of a vehicle hitting a tank. NFPA 30, on the other hand, anticipates a relatively controlled environment.

A second example involves the manufacturing of coatings, such as lacquers, paints, and inks. For this type of manufacturing, the provisions of NFPA 30, Chapter 17, Processing Facilities, are too generic. NFPA 35, *Standard for the Manufacture of Organic Coatings*, speaks specifically to the operations and processes involved in the manufacture of flammable coatings operations. In addition, NFPA 35 includes fire protection guidance for storage of nitrocellulose, which is used in the manufacture of lacquers. Such information is not found elsewhere in NFPA technical documents.

66.1.5 Permits. Permits, where required, shall comply with Section 1.12.

66.2 Reserved

66.3 Definitions

66.3.1 (Reserved)

66.3.2 (Reserved)

66.3.3 General Definitions.

66.3.3.6* Boil-Over. See 3.3.28.

A.66.3.3.6 See A.3.3.28.

66.3.3.7 Building.

66.3.3.7.1* Important Building. See 3.3.29.7.

A.66.3.3.7.1 See A.3.3.29.7.

66.3.3.7.2 Storage Tank Building. See 3.3.29.11.

66.3.3.8 Chemical Plant. See 3.3.45.

66.3.3.9 Closed-Top Diking. See 3.3.52.

66.3.3.10 Container. Any vessel of 119 gal (450 L) or less capacity used for transporting or storing liquids. [**30,** 2018]

NFPA 30 defines *container* so as to be consistent with the DOT definition of *non-bulk packaging,* in 49 CFR 171.8, part of which reads "a maximum capacity of 450 L (119 gal) or less as a receptacle for liquids." In the same section, DOT defines *bulk packaging*, as it applies to liquids, as packaging that has "a maximum capacity greater than 450 L (119 gal)." Bulk packaging includes transport vehicles (in this case, tank vehicles) and large shipping vessels, such as the ISO intermodal tank shown in Exhibit 66.1. Typical ISO tanks are 8 ft (2.4 m), 20 ft (6 m), and 30 ft (9 m) long, with capacities from 2600 gal (10,000 L) to 9800 gal (37,000 L). For the purpose of applying NFPA 30, ISO tanks are treated the same as fixed tanks, as covered in Chapters 21 through 25 of NFPA 30.

Note, however, that 49 CFR 178.700 includes specifications for what it refers to as an "intermediate bulk container" (IBC), a shipping container that has a capacity of not more than 3 m^3 (793 gal, or 3000 L), but not less than 0.45 m^3 (119 gal, or 450 L). Several types of IBCs are available; a metal IBC is shown in Exhibit 66.2. Most IBCs used in the United States tend to be 275 gal to 330 gal (1040 L to 1250 L) capacity and are about 48 in. × 48 in. × 48 in. (1200 mm × 1200 mm × 1200 mm) in size, although the length in any one dimension can range from

40 in. to 50 in. (1015 mm to 1270 mm). The dimensions are compatible with existing rack storage configurations used in warehouses. IBCs of these sizes occupy the same space as four 55 gal (208 L) drums on a pallet, so they represent a 25 to 50 percent increase in warehouse utilization. IBCs are being used more and more in the United States, having been used extensively in Europe for many years.

To minimize confusion, NFPA 30 uses a convention whereby containers used to store liquids are separated into three categories, as shown in Commentary Table 66.1.

Exhibit 66.2

Typical metal intermediate bulk container (IBC). (Courtesy of National Packaging Services)

COMMENTARY TABLE 66.1 *Container Categories*

Container Type	*Capacity, gal (L)*
Non-bulk container	≤119 (450)
Intermediate bulk container	>119 (450) up to 793 (3,000)
Bulk container	>793 (>3,000)

66.3.3.10.1 Closed Container. See 3.3.70.2.

66.3.3.10.2 Intermediate Bulk Container. See 3.3.70.6.

66.3.3.11 Control Area. For the purposes of this chapter, a building or portion of a building within which flammable and combustible liquids are allowed to be stored, dispensed, and used or handled in quantities that do not exceed the maximum allowable quantity (MAQ). [**30,** 2018]

The concept of *control area* has been adopted by NFPA 30 as a means to establish requirements for managing the quantity of liquids that can be stored in a building or in a portion of a building, but its use in NFPA 30 is limited to flammable and combustible liquids. A control area might be a single room in a building, a floor in a multistory building, or an entire building.

66.3.3.12 Crude Petroleum. See 3.3.77.

66.3.3.13 Cryogenic Fluid. See 3.3.78.

66.3.3.14 Damage-Limiting Construction. See 3.3.83.

66.3.3.15 Distillery. See 3.3.90.

66.3.3.16 Fire Point. See 3.3.127.

66.3.3.17 Flash Point. See 3.3.134.

66.3.3.18* Fugitive Emissions. See 3.3.137.

A.66.3.3.18 See A.3.3.137.

66.3.3.19* Hazardous Material or Hazardous Chemical. Material presenting dangers beyond the fire problems relating to flash point and boiling point. [**30,** 2018]

A.66.3.3.19 Hazardous Material or Hazardous Chemical. These dangers can arise from, but are not limited to, toxicity, reactivity, instability, or corrosivity. [**30,** 2018]

66.3.3.20 Hazardous Materials Storage Locker. See 3.3.151.

66.3.3.21 Hazardous Reaction or Hazardous Chemical Reaction. See 3.3.152.

66.3.3.22 Heat Transfer Fluid (HTF). See 3.3.153.

66.3.3.23 High Hazard Level 2 Contents. Contents that present a deflagration hazard or a hazard from accelerated burning. For the purposes of this chapter, this includes Class I, Class II, or Class IIIA liquids that are used or stored in normally open containers or systems, or in closed containers or systems at gauge pressures 15 psi (103 kPa) or greater. [**30,** 2018]

66.3.3.24 High Hazard Level 3 Contents. Contents that readily support combustion or that present a physical hazard. For the purposes of this chapter, this includes Class I, Class II, or Class IIIA liquids that are used or stored in normally closed containers or in closed systems at gauge pressures of less than 15 psi (103 kPa). [**30,** 2018]

66.3.3.25 Incidental Liquid Use or Storage. See 3.3.161.

66.3.3.26 Liquid.

66.3.3.26.1 Combustible Liquid. See 3.3.169.1.

66.3.3.26.2* Flammable Liquid. See 3.3.169.2.

A.66.3.3.26.2 See A.3.3.169.2.

66.3.3.26.3 Stable Liquid. See 3.3.169.4.

66.3.3.27* Operating Unit (Vessel) or Process Unit (Vessel). See 3.3.196.

A.66.3.3.27 See A.3.3.196.

66.3.3.28 Operations. See 3.3.197.

66.3.3.29* Process or Processing. See 3.3.215.

A.66.3.3.29 See A.3.3.215.

66.3.3.30 Protection for Exposures. See 3.3.218.

66.3.3.31 Refinery. See 3.3.227.

66.3.3.32* Safety Can. See 3.3.233.

A.66.3.3.32 See A.3.3.233.

66.3.3.33 Storage Tank. See 3.3.268.7.

66.3.3.33.1 Aboveground Tank. See 3.3.268.2.

66.3.3.33.1.1 Protected Aboveground Tank. See 3.3.268.2.1.

66.3.3.33.2 Low-Pressure Tank. For the purposes of this chapter, a storage tank designed to withstand an internal pressure above a gauge pressure of 1.0 psig (6.9 kPa) but not more than a gauge pressure of 15 psi (103 kPa) measured at the top of the tank. [**30,** 2018]

Low-pressure storage tanks are constructed in accordance with API 620, *Recommended Rules for the Design and Construction of Large, Welded, Low-Pressure Storage Tanks*, or an equivalent design standard. Low-pressure tanks are used to store commodities that are volatile enough to flash-vaporize or boil at ambient temperature and pressure, but not so volatile that the tank will experience a gauge pressure of 15 psi (gauge pressure of 1 bar or 103 kPa) or greater. Low-pressure tanks do not vent to the atmosphere except under unusual conditions, such as fire exposure.

66.3.3.33.3 Portable Tank. See 3.3.268.4.

66.3.3.33.3.1* Nonmetallic Portable Tank. A portable tank, as herein defined, constructed of plastic, fiber, or a material other than metal. [**30,** 2018]

A.66.3.3.33.3.1 Nonmetallic Portable Tank. Permissible nonmetallic portable tanks for shipping Class I, Class II, and Class IIIA liquids are governed by hazardous materials transportation regulations promulgated by the United Nations (UN) and the U.S. Department of Transportation (DOT). Small tanks for Class IIIB liquids are not governed by either UN or DOT hazardous materials regulations. Fiber portable tanks for Class IIIB liquids include composite designs consisting of a multi-ply corrugated box with a rigid or flexible inner plastic bladder. [**30,** 2018]

66.3.3.33.4 Secondary Containment Tank. See 3.3.268.5.

66.3.3.34 Unit Operation or Unit Process. See 3.3.277.

66.3.3.35 Vapor Pressure. See 3.3.283.

66.3.3.36 Vapor Processing Equipment. Those components of a vapor processing system designed to process vapors or liquids captured during transfer or filling operations. [**30,** 2018]

66.3.3.37* Vapor Processing System. See 3.3.267.15.

A.66.3.3.37 See A.3.3.267.15.

66.3.3.38 Vapor Recovery System. See 3.3.267.16.

66.3.3.39 Vent.

66.3.3.39.1 Emergency Relief Vent. See 3.3.97.

66.3.3.40* Warehouse.

A.66.3.3.40 Warehouse. Warehousing operations referred to in these definitions are those operations not accessible to the public and include general-purpose, merchandise, distribution, and industrial warehouse–type operations. [**30,** 2018]

66.3.3.40.1 General-Purpose Warehouse. See 3.3.286.1.

66.3.3.40.2 Liquid Warehouse. See 3.3.286.2.

66.4 Definition and Classification of Liquids

66.4.1 Definitions Specific to Liquids. For the purposes of this chapter, the terms in this subsection shall have the definitions given. [**30:**4.2]

On May 25, 2012, the U.S. Occupational Safety and Health Administration (OSHA) "Hazard Communication" standard, found in 29 CFR 1910.1200, was updated to align with the United Nations *Globally Harmonized System of Classification and Labelling of Chemicals*, otherwise known as GHS. GHS uses a classification system for liquids that burn that is very different from that used in NFPA 30. For one thing, the term *combustible* is not used at all. Every liquid with a flash point up to 200°F (93°C) is called "flammable."

GHS then assigns each liquid to a specific category, as shown in Commentary Table 66.2.

COMMENTARY TABLE 66.2 *GHS Category*

GHS Category	Flash Point, °C (°F)	Boiling Point, °C (°F)
1	<23 (73)	≤35 (95)
2	<23 (73)	>35 (95)
3	≥23 (73) & ≤60 (140)	NA
4	>60 (140) & ≤93 (200)	NA

NA = Not applicable.

A comparison of the NFPA 30 classification scheme with GHS is shown in Commentary Table 66.3.

There are some differences besides nomenclature between the two systems. For example, while the flash point criteria for NFPA 30 Classes IA and IB match those for GHS Categories I and II, the boiling point criteria are different: 100°F (37.8°C) versus 95°F (35°C). This is relatively minor and could probably be accommodated with little negative effect; also, the flash point range for NFPA 30 Class IIIA is effectively identical with that for GHS Category 4. The problem lies with NFPA 30 Classes IC and II compared with GHS Category 3. NFPA 30 considers Class IC liquids to be ignitible at high ambient temperatures, while Class II liquids seldom are. So, for example, open use of Class IC liquids typically would require such precautions as area ventilation and the use of classified electrical equipment. Such is not required by the *Code* for Class II liquids, unless they are heated to their flash points. However, the OSHA GHS scheme treats these two categories of liquid the same, which likely would cause confusion for users.

66.4.1.1* Boiling Point. See 3.3.27.

A.66.4.1.1 See A.3.3.27.

66.4.1.2 Combustible Liquid. See 3.3.169.1.

66.4.1.3 Flammable Liquid. See 3.3.169.2.

66.4.1.4* Flash Point. See 3.3.134.

A.66.4.1.4 See A.3.3.134.

66.4.1.5 Liquid. See 3.3.172.

66.4.1.6* Vapor Pressure. See 3.3.283.

A.66.4.1.6 See A.3.3.283.

66.4.2* Classification of Liquids. Any liquid within the scope of this *Code* and subject to the requirements of this *Code* shall be classified in accordance with this chapter. [**30:**4.3]

Δ **A.66.4.2** The classification of liquids is based on flash points that have been corrected to sea level, in accordance with the relevant ASTM test procedures. At high altitudes, the actual flash points will be significantly lower than those either observed at sea level or corrected to atmospheric pressure at sea level. Allowances could be necessary for this difference in order to appropriately assess the risk. [**30:**A.4.3]

Table A.66.4.2 presents a comparison of the definitions and classification of flammable and combustible liquids, as set forth in Chapter 66 of this *Code*, with similar definitions and classification systems used by other regulatory bodies. [**30:**A.4.3]

The Hazardous Materials Regulations of the U.S. Department of Transportation (DOT), as set forth in the 49 CFR 173.120(b)(2) and 173.150(f), provide an exception whereby a flammable liquid that has a flash point between 37.8°C (100°F) and 60.5°C (141°F) and does not also meet the definition of any other DOT hazard class can be reclassified as a combustible liquid [i.e., one having a flash point above 60.5°C (141°F)] for shipment by road or rail within the United States. [**30:**A.4.3]

COMMENTARY TABLE 66.3 *NFPA 30 Liquids Classification vs. OSHA Globally Harmonized Standard*

NFPA 30			OSHA GHS		
Liquid Class	Flash Point, °F (°C)	Boiling Point, °F (°C)	Flammable Category	Flash Point, °F (°C)	Boiling Point, °F (°C)
IA	<73 (23)	<100 (38)	1	<73 (23)	≤95 (35)
IB	<73 (23)	≥100 (38)	2	<73 (23)	>95 (35)
IC	73 to <100 (23 to <38)	—	3	73 to 140 (23 to 60)	—
II	100 to <140 (38 to <60)	—			
IIIA	140 to <200 (60 to <93)	—	4	>140 to 200 (> 60 to 93)	—
IIIB	≥200 (93)	—

					Class IIIB†	≥200	≥93

*See A.66.4.3.

†See 29 CFR 1910.106 for Class IIIB liquid exemptions. [**30:** Table A.4.3]

66.4.2.1 Flammable liquids, as defined in 3.3.169.2 and 66.4.1.3, shall be classified as Class I liquids and shall be further subclassified in accordance with the following:

(1) Class IA Liquid — Any liquid that has a flash point below 73°F (22.8°C) and a boiling point below 100°F (37.8°C)
(2) Class IB Liquid — Any liquid that has a flash point below 73°F (22.8°C) and a boiling point at or above 100°F (37.8°C)
(3) Class IC Liquid — Any liquid that has a flash point at or above 73°F (22.8°C), but below 100°F (37.8°C)

[**30:**4.3.1]

66.4.2.2 Combustible liquids, as defined in 3.3.169.1 and 66.4.1.2, shall be classified in accordance with the following:

(1) Class II Liquid — Any liquid that has a flash point at or above 100°F (37.8°C) and below 140°F (60°C)
(2) Class III Liquid — Any liquid that has a flash point at or above 140°F (60°C)
    (a) Class IIIA Liquid — Any liquid that has a flash point at or above 140°F (60°C), but below 200°F (93°C)
    (b) Class IIIB Liquid — Any liquid that has a flash point at or above 200°F (93°C)

[**30:**4.3.2]

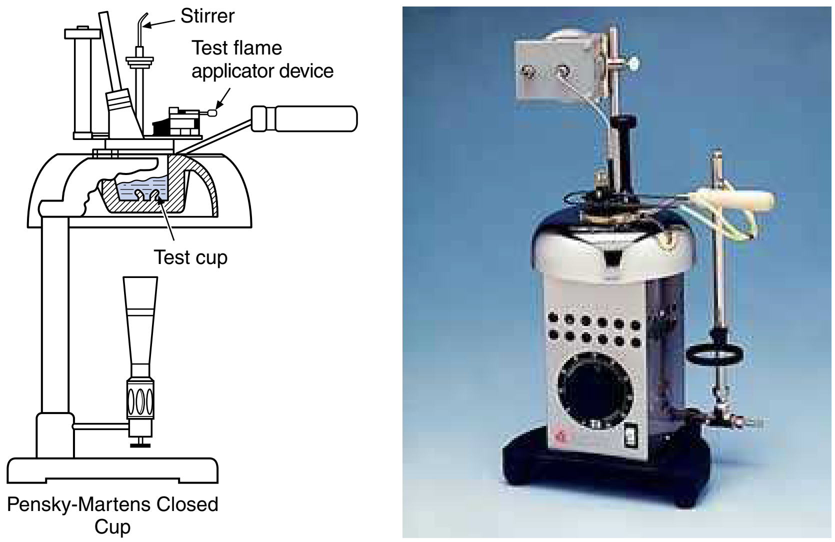
Note that there is no upper bound to the flash point range for Class IIIB liquids. However, if a Class IIIB liquid is diluted to the point where it no longer exhibits a flash point, it would no longer be so classified. That would also be the case for any Class IIIB liquid that is mixed with a noncombustible liquid in proportions in which the mixture does not exhibit a flash point.

66.4.3 Determination of Flash Point. The flash point of a liquid shall be determined according to the methods specified in 66.4.3.1 through 66.4.3.4. [**30:**4.4]

Flash point measurements are made using several different test methods, all sharing a common operation. The liquid being tested is placed in a small sample cup and heated to a certain temperature. A small pilot flame is introduced into the top of the cup, and the operator observes whether the vapor in the cup ignites. If the vapor does not ignite, the liquid is heated to a higher temperature and the pilot flame is reintroduced. These steps are repeated incrementally until ignition occurs. The temperature of the liquid at ignition is the flash point. Exhibit 66.3 shows a cutaway diagram and photograph of a Pensky-Martens closed-cup tester.

Currently, NFPA 30 specifically recognizes only the four closed-cup methods listed in Section 66.4.3. The most common

Exhibit 66.3



Cutaway drawing (left) and photograph (right) of a Pensky-Martens closed-cup flash tester. (Drawing courtesy of ASTM International, Conshohocken, PA; photo courtesy of Koehler Instrument Company, Inc., Bohemia, NY)

manual procedure is described in ASTM D56, *Standard Test Method for Flash Point by Tag Closed Cup Tester*. ASTM D93, *Standard Test Methods for Flash Point by Pensky-Martens Closed Cup Tester*, is used for certain "problem" liquids — those that are viscous and those that tend to form a skin on the surface (experience has shown that the Tag closed-cup tester has difficulties testing those liquids). ASTM D3278, *Standard Test Method for Flash Point of Liquids by Small Scale Closed Cup Apparatus,* and ASTM D3828, *Standard Test Methods for Flash Point by Small Scale Closed Cup Tester,* cover small automated testers that are considerably easier to use and might totally replace the manual units in the future. Exhibit 66.4 shows one such automated tester.

Exhibit 66.4

Automated closed-cup flash point tester. (Courtesy Stanhope-Seta, Surrey, UK)

Using closed-cup procedures and apparatus rather than the open-cup methods offers some advantages. Closed-cup procedures are easier to use; the results are more reproducible, that is, different laboratories will produce the same test results; and closed-cup testers more easily indicate the presence of small amounts of a low flash point component in an otherwise high flash point mixture.

66.4.3.1 Except as specified in 66.4.3.1.1, the flash point of a liquid having a viscosity below 5.5 centiStokes at 104°F (40°C) or below 9.5 centiStokes at 77°F (25°C) shall be determined in accordance with ASTM D56, *Standard Test Method for Flash Point by Tag Closed Cup Tester*. [**30:**4.4.1]

66.4.3.1.1 Cut-back asphalts, liquids that tend to form a surface film, and liquids that contain suspended solids shall not be tested in accordance with ASTM D56, even if they otherwise meet the viscosity criteria. Such liquids shall be tested in accordance with 66.4.3.2. [**30:**4.4.1.1]

66.4.3.2 The flash point of a liquid having a viscosity of 5.5 centiStokes or more at 104°F (40°C) or 9.5 centiStokes or more at 77°F (25°C) or a flash point of 200°F (93.4°C) or higher shall be determined in accordance with ASTM D93, *Standard Test Methods for Flash Point by Pensky-Martens Closed Cup Tester*. [**30:**4.4.2]

66.4.3.3 As an alternative, ASTM D3278, *Standard Test Method for Flash Point of Liquids by Small Scale Closed Cup Apparatus*, shall be permitted to be used for paints, enamels, lacquers, varnishes, and related products and their components that have flash points between 32°F (0°C) and 230°F (110°C) and viscosities below 150 Stokes at 77°F (25°C). [**30:**4.4.3]

66.4.3.4 As an alternative, ASTM D3828, *Standard Test Methods for Flash Point by Small Scale Closed Cup Tester*, shall be permitted to be used for materials other than those for which ASTM D3278 is specifically required. [**30:**4.4.4]

66.5 Reserved

66.6 Fire and Explosion Prevention and Risk Control

66.6.1* Scope. This section shall apply to the hazards associated with storage processing, handling, and use of liquids. This section shall also apply when specifically referenced by another section. [**30:**6.1]

A.66.6.1 These provisions might not provide adequate protection for all operations involving hazardous materials or chemical reactions, nor do they consider health hazards resulting from exposure to such materials. [**30:**A.6.1]

66.6.2 Reserved.

66.6.3* Management of Fire and Explosion Hazards. This chapter shall apply to the management methodology used to identify, evaluate, and control the hazards involved in the processing and handling of flammable and combustible liquids. These hazards include, but are not limited to, preparation, separation, purification, and change of state, energy content, or composition. [**30:**6.3]

Δ **A.66.6.3** The evaluation for management of fire hazards should consider probability of an ignitible mixture, the presence of a credible ignition source, and consequences of an ignition. Where the risk is unacceptable to the AHJ, explosion protection in accordance with NFPA 69 or deflagration venting in accordance with NFPA 68 or a combination of the two should be provided. See also *Guidelines for Chemical Process Quantitative Risk Analysis*, 2nd edition, from the Center for Chemical Process Safety/American Institute of Chemical Engineers. [**30:**A.6.3]

The intent of 66.6.3 is to bring about a holistic approach to the prevention and management of fire and explosion hazards in industries that store or use flammable and combustible liquids. The requirement bridges a gap between NFPA 30 and two important federal rules: OSHA's "Process Safety Management of Highly Hazardous Chemicals" (29 CFR 1910.119) and the U.S. Environmental Protection Agency's (EPA) "Accidental Release Prevention Requirements: Risk Management Programs Under the Clean Air Act," Section 112(r)7 (40 CFR 68). Both of these rules require certain industries and facilities that have the potential for either process-related accidents or release of hazardous materials to the environment to conduct analyses to determine the type, magnitude, and consequences of credible accidents. This information is then used to identify appropriate measures to mitigate the effects of such accidents. The typical means to conduct the analyses include process hazard analysis, what-if analysis, hazard and operability studies, failure modes and effects analysis, fault tree analysis, layer of protection analysis, and event tree analysis.

For further information, see *Guidelines for Hazard Evaluation Procedures*, published by the Center for Chemical Process Safety (CCPS) of the American Institute of Chemical Engineers (AIChE).

66.6.4 Hazards Analysis.

66.6.4.1 General. Operations involving flammable and combustible liquids shall be reviewed to ensure that fire and explosion hazards are addressed by fire prevention, fire control, and emergency action plans.

Exception No. 1: Operations where liquids are used solely for on-site consumption as fuels.

Exception No. 2: Operations where Class II or Class III liquids are stored in atmospheric tanks or transferred at temperatures below their flash points.

*Exception No. 3: Mercantile occupancies, crude petroleum exploration, drillings, and well servicing operations, and normally unoccupied facilities in remote locations. [**30:**6.4.1]*

66.6.4.1.1* The extent of fire prevention and control that is provided shall be determined in consultation with the AHJ or by means of an engineering evaluation of the operation and application of sound fire protection and process engineering principles. This evaluation shall include, but not be limited to, the following:

(1) Analysis of the fire and explosion hazards of the operation
(2) Analysis of emergency relief from process vessels, taking into consideration the properties of the materials used and the fire protection and control measures taken
(3) Analysis of applicable facility design requirements in Chapters 17, 18, 19, 28, and 29 of NFPA 30
(4) Analysis of applicable requirements for liquid handling, transfer, and use, as covered in Chapters 17, 18, 19, 28, and 29 of NFPA 30
(5) Analysis of local conditions, such as exposure to and from adjacent properties and exposure to floods, earthquakes, and windstorms
(6) Analysis of the emergency response capabilities of the local emergency services

[**30:**6.4.1.1]

Δ **A.66.6.4.1.1** The wide range in size, design, and location of liquid-processing facilities precludes the inclusion of detailed fire and hazard prevention and control systems and methods applicable to all such facilities. The user should seek further guidance from documents such as NFPA 551. [**30:**A.6.4.1.1]

The factors listed in 66.6.4.1.1 are not to be considered all-inclusive. Other factors to be considered include environmental exposure, the possible need to evacuate off-site neighboring areas, and the need to isolate each operation from adjacent operations or facilities. Additional useful information might include potential changes to process conditions that would reduce the hazard of the process and possible alternative raw materials that present less hazard.

66.6.4.1.2* Storage, processing, handling, and use of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. [**30:**6.4.1.2]

A.66.6.4.1.2 Storage, processing, handling, and use of Class II and Class III liquids at temperatures above the flash point can produce ignitible vapors if the liquid is released or vessels are vented. Class I liquid requirements address such events to minimize the likelihood of ignition and the consequences if ignition occurs, thus becoming a benchmark for design features when Class II and III liquids are handled above the flash point. However, their characteristics differ from those of Class I liquids. For example, the extent of travel of the Class II and III vapors is limited by the quick condensation of released vapors as they cool to lower temperatures. This might justify a more limited electrical area classification, different ventilation, elimination of explosion venting, and so forth. In addition, the process handling these Class II and III heated liquids may incorporate safety design features that accomplish the intent of NFPA 30, that is to address the hazards of released vapors. Further, the more restrictive building construction requirements in Table 17.6.1 of NFPA 30 might not be necessary for a particular process involving Class II, and III liquids heated above the flash point. The option of conducting an engineering evaluation in accordance with Section 66.6 was included to allow the use of alternative designs to address the level of hazards identified. [**30:**A.6.4.1.2]

This provision addresses an important issue: heating a Class II or Class III combustible liquid up to or beyond its flash point. This results in a risk similar to that presented by a Class I flammable liquid. The intent of this provision is to ensure that any such operation is treated as one involving Class I liquids or that an engineering and safety evaluation is conducted to confirm that such stricter rules are not necessary. This provision is the result of a review of the U.S. Chemical Safety and Hazard Investigation Board's (CSB) report on a serious explosion and fire at an ink and paint manufacturing facility, *Investigation Report: Confined Vapor Cloud Explosion*.

A cautionary note is in order here, having to do with a peculiarity in the OSHA rules for flammable and combustible liquids, as set forth in 29 CFR 1910.106. OSHA requires that, when a Category 3 liquid with a flash point at or above 100°F (37.8°C) is heated for use to within 30°F (16.7°C) of its flash point, it must be handled in accordance with the requirements established by OSHA for a Category 3 liquid with a flash point below 100°F (37.8°C). In terms of NFPA 30, this is equivalent to treating a Class II liquid as a Class IC liquid.

Likewise, when a Category 4 liquid is heated for use to within 30°F (16.7°C) of its flashpoint, OSHA requires that it be handled in accordance with the requirements for a Category 3 liquid whose flash point is at or above 100°F (37.8°C). In terms of NFPA 30, this is equivalent to treating a Class IIIA liquid as a Class II liquid. Conceptually, this is a similar rule to what is stated in 66.6.4.1.2, but it is important to note that the details are quite different.

66.6.4.2 Management of Change. The hazards analysis shall be repeated whenever the hazards leading to a fire or explosion change significantly. Conditions that might require repeating a review shall include, but are not limited to, the following:

(1) When changes occur in the materials in process
(2) When changes occur in process equipment
(3) When changes occur in process control
(4) When changes occur in operating procedures or assignments

[**30:**6.4.2]

66.6.5 Control of Ignition Sources.

Control of potential ignition sources is very important, but primary emphasis should always be on the prevention of the release of ignitible concentrations of vapors.

66.6.5.1 General. Precautions shall be taken to prevent the ignition of flammable vapors by sources such as the following:

(1) Open flames
(2) Lightning
(3) Hot surfaces
(4) Radiant heat
(5) Smoking
(6) Cutting and welding

Generally speaking, 25 percent of the lower flammable limit (LFL) is considered to be the dividing line between a safe condition and one that warrants special attention. For example, in an area where flammable liquids are being used in the open, ventilation would normally be provided to ensure that the concentration of vapor in the adjacent atmosphere is not more than 25 percent of the LFL. A concentration above 25 percent would warrant an alarm condition; a concentration above 50 percent would warrant stopping work.

Where cutting, welding, or similar hot work is involved, a safe condition is typically defined as a concentration of not more than 10 percent vapor in air. The following NFPA standards all use this 10 percent criterion to establish a safe condition for hot work:

- NFPA 306, *Standard for the Control of Gas Hazards on Vessels*
- NFPA 312, *Standard for Fire Protection of Vessels During Construction, Conversion, Repair, and Lay-up*
- NFPA 326, *Standard for the Safeguarding of Tanks and Containers for Entry, Cleaning, or Repair*

A stricter condition is appropriate for hot work because an ignition source is being deliberately introduced where control of ignitable vapors might be a problem.

(7) Spontaneous ignition
(8)* Frictional heat or sparks

A.66.6.5.1(8) With respect to frictional heat or sparks, it is recognized that there is a need to control sources of ignition, including mechanical sparks from hand tools, that have sufficient energy to ignite flammable vapors. Studies, anecdotes, codes, and referenced standards (e.g., API 2214, *Spark Ignition Properties of Hand Tools*) show that there is a potential for hand tool sparks to ignite flammable vapors from a limited number of chemicals and under certain unique conditions. These include flammable liquids with low minimum ignition energies, operations in which flammable or combustible liquids are heated, and atypical spark generation that can occur between specific types of hand tools and struck surfaces (i.e., thermite reactions or impact of steel tools on quartzitic materials). Even spark-resistant tools might not provide suitable protection against ignition. For example, hard metal particles can become imbedded in the relatively soft metal of spark-resistant tools, and these particles can cause sparks when the tools are used. [**30:**A.6.5.1(8)]

NFPA 30 requires analyses, such as job safety analyses or activity hazard analyses, of the hazards and risks of a given task and the application of appropriate protective measures to prevent or mitigate the hazards and risks. This includes identification and mitigation of ignition risk from multiple sources, including hand tools. Due to the complexity of the numerous operations involving flammable liquids, NFPA 30 cannot address all conditions in which spark-resistant tools should be made mandatory, might be advisable, or are unnecessary to help control the ignition risk of any given operation. [**30:**A.6.5.1(8)]

It is recognized that the adoption of the new Globally Harmonized System for labeling by the U.S. Occupational Safety and Health Administration (29 CFR 1910.1200, Appendix C) creates a generalized mandate for the use of spark-resistant tools. However, based on available technical information, this mandate goes beyond what is considered necessary for fire safety, given the fact that it applies to liquids that present little risk of ignition unless heated to or above their flash points. *(See A.66.6.4.1.2.)* [**30:**A.6.5.1(8)]

This Annex A language explains to the user that, although the use of spark-resistant tools is not mandated by the *Code*, there might be situations in which their use is warranted, based on a hazard analysis or job-safety analysis.

The last paragraph of A.66.6.5.1(8) was added in 2015 to explain NFPA 30's position that the new labeling requirements enacted in 29 CFR 1910.1200, Appendix C, also appear to overstate the hazard. In some cases, the mandate for spark-resistant tools applies to liquids that present little risk of ignition unless heated to or above their flash points. Also, experience does not appear to validate the need for spark-resistant tools, given that the incident history is mostly anecdotal.

(9) Static electricity
(10) Electrical sparks
(11) Stray currents
(12) Ovens, furnaces, and heating equipment
[**30:**6.5.1]

66.6.5.2 Smoking. Smoking shall be permitted only in designated and identified areas. [**30:**6.5.2]

66.6.5.3* Hot Work.

Δ **A.66.6.5.3** See NFPA 51B. [**30:**A.6.5.3]

66.6.5.3.1 Welding, cutting, and similar spark-producing operations shall not be permitted in areas containing flammable liquids until a written permit authorizing such work has been issued. [**30:**6.5.3.1]

It is important that no blanket permits be allowed. This responsibility belongs to both the responsible person who issues or approves the permit and the person to whom it is issued. The responsible person who issues or authorizes the permit should ensure that the permit covers only a specific task at one location or on one piece of equipment and should specify on the permit that it is valid only for the duration of the work shift. A new permit should be issued at the beginning of the next shift, because conditions likely will have changed and will need to be reevaluated and because different personnel might be involved.

Any time a significant interruption of work occurs, a new hot work permit should be issued. Separate permits should also be issued for the same task done at several different locations or on different equipment.

The worker(s) who receive the permit should verify that all pertinent restrictions are noted on the permit.

66.6.5.3.2 The permit shall be issued by a person in authority following inspection of the area to ensure that permit requirements have been implemented and will be followed until the job is completed. [**30:**6.5.3.2]

66.6.5.4* Static Electricity.

Δ **A.66.6.5.4** The prevention of electrostatic ignition in equipment is a complex subject. Refer to NFPA 77 for guidance. [**30:**A.6.5.4]

66.6.5.4.1 All equipment such as tanks, machinery, and piping shall be designed and operated to prevent electrostatic ignitions. [**30:**6.5.4.1]

66.6.5.4.2 All metallic equipment such as tanks, machinery, and piping where the potential exists for an ignitible mixture to be present shall be bonded and grounded. [**30:**6.5.4.2]

66.6.5.4.3 The bond and ground shall be physically applied or shall be inherently present by the nature of the installation. [**30:**6.5.4.3]

This requirement simply means that a system might be inherently adequately grounded throughout if all components of the system are in direct metal-to-metal contact with each other and the system is connected to or in contact with the earth at one or more points. If any component is isolated from direct metal contact, it must be connected to the grounded part of the system using a jumper wire.

66.6.5.4.4 Any electrically isolated section of metallic piping or equipment shall be bonded and grounded to prevent hazardous accumulation of static electricity. [**30:**6.5.4.4]

66.6.5.4.5 All nonmetallic equipment and piping where the potential exists for an ignitable mixture to be present shall be designed and operated to prevent electrostatic ignition. [**30:**6.5.4.5]

66.6.5.5 Electrical Systems. Design, selection, and installation of electrical wiring and electrical utilization equipment shall meet the requirements of Section 66.7. [**30:**6.5.5]

66.6.6 Detection and Alarm Systems and Procedures.

66.6.6.1* An approved means shall be provided for prompt notification of fire or other emergency to those identified in the emergency action plan in accordance with Section 66.6.8. [**30:**6.6.1]

Prior to the 2018 edition of this *Code*, 66.6.6.1 applied only to the "plant" itself. It was determined that notification should be made for any situation covered by the emergency action plan and to all entities identified in said plan.

Δ **A.66.6.6.1** One method of complying with this requirement could be through the installation of an automatic and/or manual fire alarm system as covered in *NFPA 72*. [**30:**A.6.6.1]

The 2016 edition of *NFPA 72®, National Fire Alarm and Signaling Code®*, contains information to address the integration of mass notification systems and other systems with fire alarm systems. (See Chapter 24 of *NFPA 72*.)

66.6.6.2 Those areas, including buildings, where a potential exists for a flammable liquid spill shall be monitored as appropriate. The following methods shall be permitted to be used:

(1) Personnel observation or patrol
(2) Process-monitoring equipment that would indicate a spill or leak could have occurred
(3) Provision of gas detectors to continuously monitor the area where facilities are unattended

[**30:**6.6.2]

66.6.7 Fire Protection and Fire Suppression Systems.

66.6.7.1* This section identifies recognized fire protection and fire suppression systems and methods used to prevent or minimize the loss from fire or explosion in liquid-processing facilities. The application of one or a combination of these systems and methods as well as the use of fire-resistive materials shall be determined in accordance with Sections 66.6.3 and 66.6.4. [**30:**6.7.1]

A.66.6.7.1 Other recognized fire prevention and control factors, involving construction, location, and separation, are addressed elsewhere in Section 66.6. [**30:**A.6.7.1]

A presentation of detailed information on fire protection and suppression systems applicable to all the types of facilities covered by this subsection and by Chapter 6 of NFPA 30 is not possible. Each facility is unique in some respects and requires judgment by both the facility operator and the AHJ regarding proper application of NFPA 30's requirements and adequate design of fire protection systems. Often, the assistance of outside consultants and design engineers is necessary.

66.6.7.2 A reliable water supply or other suitable fire control agent shall be available in pressure and quantity to meet the fire demands indicated by the specific hazards of liquids-processing operations, storage, or exposure. [**30:**6.7.2]

66.6.7.3* Permanent connections between the fire water system and any process system shall be prohibited, to prevent contamination of fire water with process fluids. [**30:**6.7.3]

A.66.6.7.3 Permanent connections to process water lines from the fire water system present an opportunity for contamination of the fire water with process fluids. Incidents have occurred where fire water was contaminated with flammable process liquids, with subsequent increased fire damage and, in some cases, injury. Temporary connections are permitted to meet extraordinary needs, as in turnaround and inspection periods, tank cleaning, and so forth. However, care should be taken to address the potential for contamination. Where such use occurs frequently enough to justify a more robust arrangement, double block-and-bleed valves, removable spool pieces, or other means should be used to assure that no contamination can occur. Check valves alone are not sufficient. [**30:**A.6.7.3]

Use of utility water sources, such as boiler feedwater, that are not contaminated, is acceptable for use as a supplemental fire water supply. [**30:**A.6.7.3]

Δ **66.6.7.4** Where required by this chapter, hydrants, with or without fixed monitor nozzles, shall be provided in accordance with this *Code* and NFPA 24. The number and placement shall depend on the hazards of the facility. [**30:**6.7.4]

66.6.7.5 Where the need is indicated by the hazards of liquid processing, storage, or exposure as determined by 66.6.4, fixed protection shall be provided. [**30:**6.7.5]

66.6.7.6 Where provided, fire control systems shall be designed, installed, and maintained in accordance with this *Code* and the following NFPA standards, as applicable:

(1) NFPA 11, *Standard for Low-, Medium-, and High-Expansion Foam*
(2) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*
(3) NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*
(4) NFPA 13, *Standard for the Installation of Sprinkler Systems*
(5) NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*
(6) NFPA 16, *Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems*
(7) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*
(8) NFPA 750, *Standard on Water Mist Fire Protection Systems*
(9) NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*

[**30:**6.7.6]

Δ **66.6.7.7** Where required by this chapter, standpipe and hose systems shall be installed in accordance with Section 13.2 and

NFPA 14 or hose connections from sprinkler systems using combination spray and straight stream nozzles shall be installed in accordance with NFPA 13. [**30:**6.7.7]

66.6.7.8* Where required by this chapter, listed portable fire extinguishers shall be provided in such quantities, sizes, and types as are needed for the specific hazards of operation and storage. [**30:**6.7.8]

Δ **A.66.6.7.8** NFPA 10 provides information on the suitability of various types of extinguishers. [**30:**A.6.7.8]

66.6.7.9 Where provided, mobile foam apparatus and supplies of foam concentrate shall be appropriate to the specific hazards. [**30:**6.7.9]

66.6.8 Emergency Planning and Training.

Emergency planning and training were addressed only briefly in older editions of NFPA 30. Considerably more detail is now provided, but it must still be recognized that each facility requires an individual approach, one that might necessitate considerable judgment and consultation among the operator, the AHJ, and local emergency services.

66.6.8.1 A written emergency action plan that is consistent with available equipment and personnel shall be established to respond to fires and related emergencies. This plan shall include the following:

(1) Procedures to be followed in case of fire or release of liquids or vapors, such as sounding the alarm, notifying the fire department, evacuating personnel, and controlling and extinguishing the fire
(2) Procedures and schedules for conducting drills of these procedures
(3) Appointment and training of personnel to carry out assigned duties, including review at the time of initial assignment, as responsibilities or response actions change, and whenever anticipated duties change
(4) Procedures for maintenance and operation of (a) fire protection equipment and systems, (b) drainage and containment systems, and (c) dispersion and ventilation equipment and systems
(5) Procedures for shutting down or isolating equipment to reduce, mitigate, or stop the release of liquid or vapors, including assigning personnel responsible for maintaining critical plant functions or shutdown of plant processes and safe start-up following isolation or shutdown
(6) Alternate measures for the safety of occupants

[**30:**6.8.1]

Paragraph 66.6.8.1 presents the minimum that should be addressed in an emergency action plan. While the development of an emergency action plan is beyond the scope of NFPA 30, the following references are recommended as starting points:

- NFPA 600, *Standard on Facility Fire Brigades*
- NFPA 601, *Standard for Security Services in Fire Loss Prevention*
- *NFPA 1600®, Standard on Disaster/Emergency Management and Business Continuity/Continuity of Operations Programs*
- "Industrial Fire Loss Prevention," Volume II, Section 12, Chapter 11 of the *Fire Protection Handbook®*
- *Facility Manager's Fire Protection Guide*

66.6.8.2 Personnel responsible for the use and operation of fire protection equipment shall be trained in the use of that equipment. Refresher training shall be conducted at least annually. [**30:**6.8.2]

66.6.8.3 Planning of effective fire control measures shall be coordinated with local emergency response agencies. [**30:**6.8.3]

Many organizations develop a pre-fire plan that contains a site plan and a plan of each floor in each building at the site, showing the location of likely fire occurrences. A pre-fire plan includes fire protection measures, such as installed fixed fire protection systems, manual actuators, and locations of emergency shutdown actuators. The plan is used for annual meetings with operations personnel and local emergency response teams, so that everyone understands the on-site hazards and the best way to work effectively and safely together to address a site emergency. See NFPA 1561, *Standard on Emergency Services Incident Management System and Command Safety*, for more information.

66.6.8.4 Procedures shall be established to provide for safe shutdown of operations under emergency conditions and for safe start-up following cessation of emergencies. Provisions shall be made for training of personnel in shutdown and start-up procedures, and in activation, use, and deactivation of associated alarms, interlocks, and controls. Procedures shall also be established and provisions shall also be made for inspection and testing of associated alarms, interlocks, and controls. [**30:**6.8.4]

66.6.8.5 The emergency procedures shall be kept readily available in the operating areas and shall be updated when conditions change, as identified in 66.6.4.2. [**30:**6.8.5]

66.6.8.5.1 Where premises are likely to be unattended for considerable periods of time, a summary of the emergency plan shall be posted or located in a strategic and accessible location. [**30:**6.8.5.1]

66.6.9 Inspection and Maintenance.

Δ **66.6.9.1** All fire protection equipment shall be properly maintained, and periodic inspections and tests shall be done in accordance with both standard practice and the equipment manufacturers recommendations. Water-based fire protection systems shall be inspected, tested, and maintained in accordance with this *Code* and NFPA 25. [**30:**6.9.1]

Δ **66.6.9.2** Maintenance and operating practices shall be established and implemented to prevent and control leakage and spillage of flammable and combustible liquids. [**30:**6.9.2]

This paragraph has been amended to emphasize prevention of spills, not just control of a spill. Should a spill occur, clean-up operations should be conducted in a manner that minimizes vapor loss. Many commercially available absorbents and adsorbents have been developed, primarily to mitigate environmental damage, but they are still of great benefit. Also, some fire-suppression foams and recently developed vapor-suppression foams are helpful in controlling vapors from large-scale spills.

66.6.9.3 Combustible waste material and residues in operating areas shall be kept to a minimum, stored in covered metal containers, and disposed of daily. [**30:**6.9.3]

66.6.9.4 Ground areas around facilities where liquids are stored, handled, or used shall be kept free of weeds, trash, or other unnecessary combustible materials. [**30:**6.9.4]

66.6.9.5 Aisles established for movement of personnel shall be kept clear of obstructions to permit orderly evacuation and ready access for manual fire-fighting activities. [**30:**6.9.5]

66.6.10 Management of Security. [**30:**6.10]

This section addresses the issue of facility security and the evaluation of how vulnerable a facility is to intrusion with malicious intent, including riots and civil unrest. The focus of this subsection is to provide a basic framework of accepted methods to address security and vulnerability assessments that parallel the regulations imposed by the U.S. Department of Homeland Security's Chemical Facility Anti-Terrorism Standards in 6 CFR 27 and the practices of major industrial groups such as the American Chemistry Council, the American Petroleum Institute (API), and the AIChE. See also Annex G of NFPA 30.

66.6.10.1 Scope. [**30:**6.10.1]

66.6.10.1.1 This section shall apply to the management methodology used to identify, evaluate, and control the security hazards involved in the processing, storage, and handling of flammable and combustible liquids. [**30:**6.10.1.1]

66.6.10.1.2 These hazards include, but are not limited to, vulnerability to terrorist or other malicious attacks. [**30:**6.10.1.2]

66.6.10.2 General. The methodology used shall incorporate a risk-based approach to site security and shall have the following objectives:

(1) Identification and evaluation of security risks
(2) Evaluation of the security performance of the facility
(3) Evaluation of protection for employees, the facility itself, the surrounding communities, and the environment. *(See Annex G of NFPA 30 for more detailed information.)*

[**30:**6.10.2]

66.6.10.3 Specific Requirements. [**30:**6.10.3]

66.6.10.3.1 Operations involving flammable and combustible liquids shall be reviewed to ensure that security vulnerabilities identified during the security vulnerability analysis (SVA) are addressed in a facility security program, with corresponding fire prevention and emergency action plans and drills. [**30:**6.10.3.1]

66.6.10.3.2 The balance of physical, electronic, and personnel techniques used to respond to the SVA shall be determined by means of an engineering evaluation of the operation and application of sound security principles. This evaluation shall include, but not be limited to, the following:

(1) Assessing overall facility
(2) Evaluating vulnerabilities
(3) Assessing threats/consequences
(4) Assessing physical factors/attractiveness
(5) Identifying mitigation factors
(6) Conducting security assessment or gap analysis

[**30:**6.10.3.2]

66.6.10.3.3 A written emergency action plan that is consistent with available equipment and personnel shall be established to respond to fires, security, and related emergencies. This plan shall include the following:

(1) Procedures to be followed such as initiating alarms, notifying appropriate agencies, evacuating personnel, and controlling and extinguishing the fire
(2) Procedures and schedules for conducting drills of these procedures
(3) Appointment and training of personnel to carry out assigned duties
(4) Maintenance of fire protection and response equipment
(5) Procedures for shutting down or isolating equipment to reduce the release of liquid
(6) Alternate measures for the safety of occupants

[**30:**6.10.3.3]

66.6.10.3.4 Specific duties of personnel shall be reviewed at the time of initial assignment, as responsibilities or response actions change, and whenever anticipated duties change. [**30:**6.10.3.4]

66.6.10.3.5 The security management review conducted in accordance with this section shall be repeated under the following conditions:

(1) For an initial review of all new relevant facilities and assets
(2) When substantial changes to the threat or process occur
(3) After a significant security incident
(4) For periodic revalidation of the SVA

[**30:**6.10.3.5]

66.7 Electrical Systems

The purpose of Section 66.7 is to establish the basic first steps to determine the proper classification of the area in which liquids are located for purposes of designing, installing, and maintaining the electrical system. Detailed requirements for the selection of the wiring methods that are allowed and for the selection and installation of electrical utilization equipment are covered in Chapter 5 of *NFPA 70®*, *National Electrical Code®* (*NEC®*).

66.7.1 Scope. This chapter shall apply to areas where Class I liquids are stored or handled and to areas where Class II or Class III liquids are stored or handled at or above their flash points. [**30:**7.1]

Where Class II and Class III liquids are handled at temperatures below their flash points, ignition is not a risk, and ordinary or general-purpose electrical equipment and wiring methods are acceptable. Where this is not the case — such as where a Class II or Class III liquid is handled at temperatures at or above its flash point — the liquid must be treated as if it were a Class I liquid, and the provisions of Section 66.7 might very well apply, unless an engineering evaluation of the installation indicates otherwise.

66.7.2 Reserved.

66.7.3 General Requirements.

66.7.3.1 Electrical utilization equipment and wiring shall not constitute a source of ignition for any ignitible vapor that might be present under normal operation or because of a spill. Compliance with 66.7.3.2 through 66.7.3.7.1 shall be deemed as meeting the requirements of this section. [**30:**7.3.1]

NFPA 70 specifies the types of electrical equipment, electrical equipment enclosures, and wiring methods that are acceptable for various locations, depending on the likelihood that an ignitible atmosphere is present. *NFPA 70* also has responsibility for the schemes by which an area is classified for purposes of proper electrical system installation and for the definitions related to area classification. *NFPA 70* is not responsible for classifying any particular area, nor is it responsible for determining the extent of a classified area. That is the responsibility of other NFPA codes and standards. NFPA 30 is concerned with those locations that might be hazardous due to the presence of ignitible concentrations of vapors from liquids. Such locations are designated as Class I hazardous locations by *NFPA 70*.

Δ **66.7.3.2** All electrical utilization equipment and wiring shall be of a type specified by and installed in accordance with *NFPA 70*. [**30:**7.3.2]

66.7.3.3* Table 66.7.3.3 shall be used to delineate and classify areas for the purpose of installation of electrical utilization equipment and wiring under normal operating conditions. [**30:**7.3.3]

Where ignitible concentrations (concentrations within flammable or explosive limits) are present, the atmosphere can be ignited by an arc, a spark, or high temperature. Hermetic sealing of all electrical equipment is impractical because equipment such as motors, conventional switches, and circuit breakers has movable parts that must be operated through the enclosing case. In addition, access to the inside of enclosures is often necessary for installation, servicing, or alterations. Therefore, it may be necessary to keep equipment in explosionproof enclosures or to use intrinsically safe equipment.

***TABLE 66.7.3.3** Electrical Area Classifications*

Location	NEC Class I Division	NEC Class I Zone	Extent of Classified Area
Indoor equipment installed in accordance with 66.7.3 where flammable vapor–air mixtures can exist under normal operation	1	0	The entire area associated with such equipment where flammable gases or vapors are present continuously or for long periods of time
	1	1	Area within 5 ft of any edge of such equipment, extending in all directions
	2	2	Area between 5 ft and 8 ft of any edge of such equipment, extending in all directions; also, space up to 3 ft above floor or grade level within 5 ft to 25 ft horizontally from any edge of such equipment[1]
Outdoor equipment of the type covered in 66.7.3 where flammable vapor–air mixtures can exist under normal operation	1	0	The entire area associated with such equipment where flammable gases or vapors are present continuously or for long periods of time
	1	1	Area within 3 ft of any edge of such equipment, extending in all directions
	2	2	Area between 3 ft and 8 ft of any edge of such equipment, extending in all directions; also, space up to 3 ft above floor or grade level within 3 ft to 10 ft horizontally from any edge of such equipment
Tank storage installations inside buildings	1	1	All equipment located below grade level
	2	2	Any equipment located at or above grade level

(continues)

TABLE 66.7.3.3 Continued

Location	NEC Class I Division	NEC Class I Zone	Extent of Classified Area
Tank — aboveground, fixed roof	1	0	Inside fixed-roof tank
	1	1	Area inside dike where dike height is greater than the distance from the tank to the dike for more than 50 percent of the tank circumference
	2	2	Within 10 ft from shell, ends, or roof of tank; also, area inside dike up to top of dike wall
	1	0	Area inside of vent piping or vent opening
	1	1	Within 5 ft of open end of vent, extending in all directions
	2	2	Area between 5 ft and 10 ft from open end of vent, extending in all directions
Tank — aboveground, floating roof			
With fixed outer roof	1	0	Area between the floating and fixed-roof sections and within the shell
With no fixed outer roof	1	1	Area above the floating roof and within the shell
Tank vault — interior	1	1	Entire interior volume, if Class I liquids are stored within
Underground tank fill opening	1	1	Any pit, box, or space below grade level, if any part is within a Division 1 or 2 or Zone 1 or 2 classified location
	2	2	Up to 18 in. above grade level within a horizontal radius of 10 ft from a loose fill connection and within a horizontal radius of 5 ft from a tight fill connection
Vent — discharging upward	1	0	Area inside of vent piping or opening
	1	1	Within 3 ft of open end of vent, extending in all directions
	2	2	Area between 3 ft and 5 ft of open end of vent, extending in all directions
Drum and container filling — outdoors or indoors	1	0	Area inside the drum or container
	1	1	Within 3 ft of vent and fill openings, extending in all directions
	2	2	Area between 3 ft and 5 ft from vent or fill opening, extending in all directions; also, up to 18 in. above floor or grade level within a horizontal radius of 10 ft from vent or fill opening
Pumps, bleeders, withdrawal fittings			
Indoor	2	2	Within 5 ft of any edge of such devices, extending in all directions; also, up to 3 ft above floor or grade level within 25 ft horizontally from any edge of such devices
Outdoor	2	2	Within 3 ft of any edge of such devices, extending in all directions; also, up to 18 in. above grade level within 10 ft horizontally from any edge of such devices
Pits and sumps			
Without mechanical ventilation	1	1	Entire area within a pit or sump if any part is within a Division 1 or 2 or Zone 1 or 2 classified location
With adequate mechanical ventilation	2	2	Entire area within a pit or sump if any part is within a Division 1 or 2 or Zone 1 or 2 classified location
Containing valves, fittings, or piping, and not within a Division 1 or 2 or Zone 1 or 2 classified location	2	2	Entire pit or sump

TABLE 66.7.3.3 Continued

Location	NEC Class I Division	NEC Class I Zone	Extent of Classified Area
Drainage ditches, separators, impounding basins			
Outdoor	2	2	Area up to 18 in. above ditch, separator, or basin; also, area up to 18 in. above grade within 15 ft horizontally from any edge
Indoor			Same as pits and sumps
Tank vehicle and tank car[2]			
Loading through open dome	1	0	Area inside of the tank
	1	1	Within 3 ft of edge of dome, extending in all directions
	2	2	Area between 3 ft and 15 ft from edge of dome, extending in all directions
Loading through bottom connections with atmospheric venting	1	0	Area inside of the tank
	1	1	Within 3 ft of point of venting to atmosphere, extending in all directions
	2	2	Area between 3 ft and 15 ft from point of venting to atmosphere, extending in all directions; also, up to 18 in. above grade within a horizontal radius of 10 ft from point of loading connection
Loading through closed dome with atmospheric venting	1	1	Within 3 ft of open end of vent, extending in all directions
	2	2	Area between 3 ft and 15 ft from open end of vent, extending in all directions; also, within 3 ft of edge of dome, extending in all directions
Loading through closed dome with vapor control	2	2	Within 3 ft of point of connection of both fill and vapor lines, extending in all directions
Bottom loading with vapor control or any bottom unloading	2	2	Within 3 ft of point of connections, extending in all directions; also, up to 18 in. above grade within a horizontal radius of 10 ft from point of connections
Storage and repair garage for tank vehicles	1	1	All pits or spaces below floor level
	2	2	Area up to 18 in. above floor or grade level for entire storage or repair garage
Garages for other than tank vehicles	Ordinary		If there is any opening to these rooms within the extent of an outdoor classified location, the entire room shall be classified the same as the area classification at the point of the opening
Outdoor drum storage	Ordinary		
Inside rooms or storage lockers used for the storage of Class I liquids	2	2	Entire room or locker
Indoor warehousing where there is no flammable liquid transfer	Ordinary		If there is any opening to these rooms within the extent of an indoor classified location, the classified location shall extend through the opening to the same extent as if the wall, curb, or partition did not exist
Office and rest rooms	Ordinary		If there is any opening to these rooms within the extent of an indoor classified location, the room shall be classified the same as if the wall, curb, or partition did not exist
Piers and wharves			See Figure 29.3.22 of NFPA 30.

For SI units, 1 in. = 25 mm; 1 ft = 0.3 m.

[1]The release of Class I liquids can generate vapors to the extent that the entire building, and possibly an area surrounding it, should be considered a Class I, Division 2, or Zone 2 location.

[2]When classifying extent of area, consideration should be given to the fact that tank cars or tank vehicles can be spotted at varying points. Therefore, the extremities of the loading or unloading positions should be used. [**30:** Table 7.3.3]

Electrical equipment that could cause ignition-capable arcs or sparks should be kept out of Class I locations, or the equipment must be identified for the appropriate hazardous location. It is practically impossible to make threaded joints gastight. The conduit system and apparatus enclosure "breathe" due to temperature changes, and any flammable gases or vapors in the room could slowly enter the conduit or enclosure, creating an explosive mixture. If an arc occurs, an explosion also could occur.

When an explosion occurs within the enclosure or conduit system, the burning mixture or hot gases must be sufficiently confined within the system to prevent ignition of any explosive mixture outside the system. An enclosure must be designed with sufficient strength to withstand the pressure generated by an internal explosion to prevent rupture and the release of burning or hot gases. During an explosion within an enclosure, gases escape through any paths or openings that exist, but the gases will be sufficiently cooled if they are carried out through an opening that is long in proportion to its width. The function of the joint is the same whether it is flanged, threaded, rabbeted, or any other type designed for this purpose.

The clearance between flat surfaces could increase somewhat under explosion conditions, because the internal pressures created by the explosion tend to force the surfaces apart, as shown in Exhibit 66.5. The amount of increase in the joint clearance depends on the stiffness of the enclosure parts; the size, strength, and spacing of the bolts; and the explosion pressure. When there are no internal pressures, measuring the joint width and the clearance does not indicate the actual clearances under the dynamic conditions of an explosion. Explosion tests are usually needed to demonstrate the acceptability of the design. Exhibit 66.5 illustrates the need to properly install all provided bolts, screws, fittings, and covers. If bolts are missing, it is essential that the manufacturer's specified bolts be used for replacement.

It is important to understand that an explosionproof electrical enclosure is not airtight or watertight, nor can it be considered waterproof or weatherproof. For additional information, see Supplement 3, Electrical Equipment in Hazardous Areas, of the NFPA 30 Handbook.

Table 66.7.3.3 includes two distinct classification systems that indicate the likelihood that a risk of ignition exists: the "Division" system of classification, which originated in and has been used by the United States almost exclusively, and the European "Zone" system. The rules for installations in an area classified by the Division system are located in Article 500 of *NFPA 70*, while those for the Zone system are in Article 505.

It is important to understand that the two systems cannot be comingled. In other words, in any installation or project, the design of the electrical system must be based on either the Division system or the Zone system, but not both. Also, the designer cannot use the Division system for some portions of the design and the Zone system for others.

Commentary Table 66.4 compares the two systems based on relative risk.

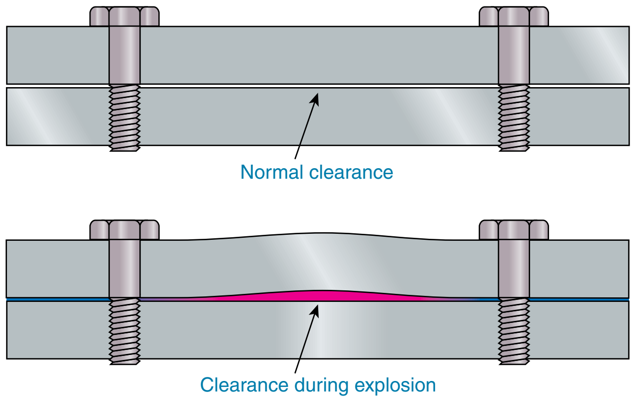
Δ **A.66.7.3.3** For additional information, see NFPA 497. [**30:**A.7.3.3]

Annex material A.66.7.3.3 refers the reader to NFPA 497, *Recommended Practice for the Classification of Flammable Liquids, Gases, or Vapors and of Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*. NFPA 497 basically provides line diagram translations of the area classification tables that appear in this *Code* and in other codes and standards.

An example of these diagrams, and one that illustrates a major difference between the Division and Zone systems, is the guidance given in NFPA 497 for flammable liquids storage tanks. Exhibit 66.6 depicts the area classification for an ordinary cone roof storage tank storing a flammable liquid. Exhibit 66.7 is the equivalent diagram using the Zone system of classification. Note how the inside of the tank is designated Division 1 in Exhibit 66.6 but is designated Zone 0 in Exhibit 66.7.

Chapter 5, Article 500, of *NFPA 70* recognizes two levels of risk with regard to Class I hazardous locations: Division 1 and Division 2. In a Division 1 location, an ignitible atmosphere is

Exhibit 66.5



Effect of internal explosion (bottom) on cover-to-body joint clearance in an explosionproof enclosure. (Courtesy of UL LLC)

COMMENTARY TABLE 66.4 *Comparison of Division and Zone Systems from NFPA 70, National Electrical Code*

Hazard Description	NEC Article 500	NEC Article 505
Flammable materials present continuously or for long periods of time	Division 1	Zone 0
Flammable materials present intermittently during normal operations	Division 1	Zone 1
Flammable materials present only during abnormal operations	Division 2	Zone 2

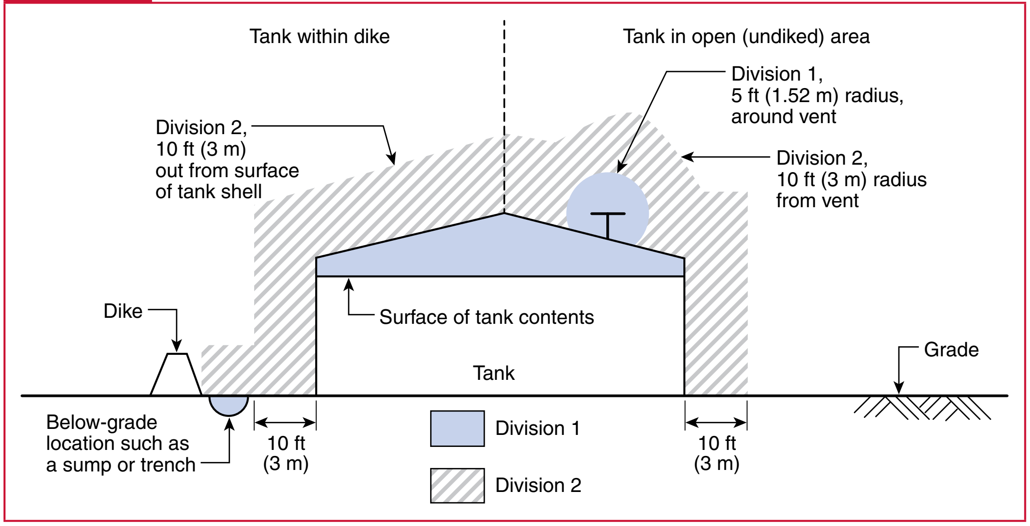
Source: Adapted from LeBlanc, J. A., and Lawrence, W. G., "Benefit from the Three-Zone National Electrical Code," *Chemical Engineering Progress*, American Institute of Chemical Engineers, New York, Dec. 2000, pp. 75–82.

assumed to be present all or most of the time, either because of open handling of liquids or because of frequent leaks or repairs. Therefore, any breakdown or malfunction of the electrical system that results in an arc or a spark will likely lead to an ignition. In a Division 2 location, an ignitible atmosphere is not normally present, but it might be produced because of an abnormal operating condition involving the equipment handling the liquid. Therefore, ignition is considered possible only if there is a simultaneous breakdown of both the process equipment and the electrical system — an unlikely event.

The basic design criteria for electrical equipment suitable for hazardous locations are the following:

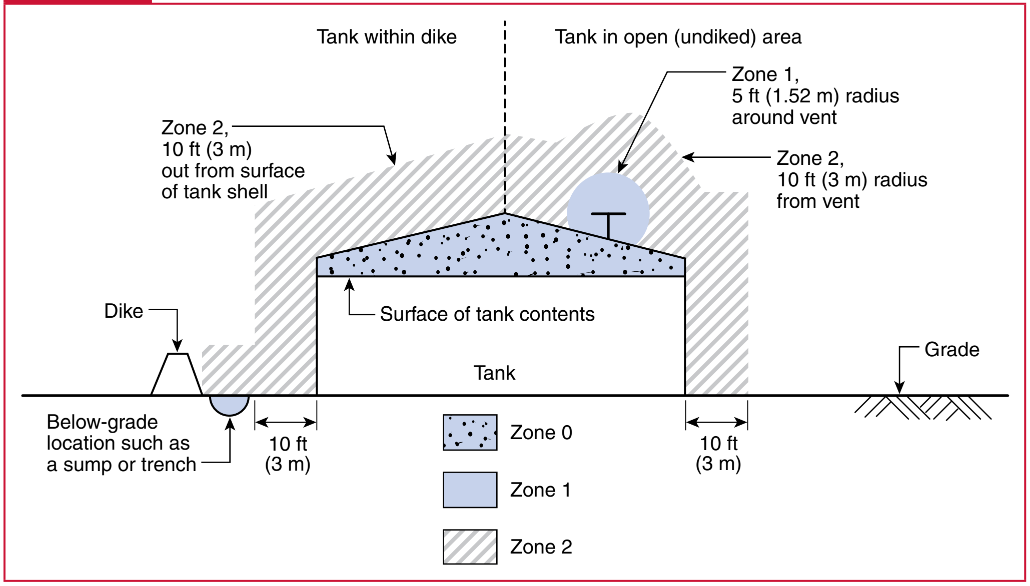
1. Arcing and sparking parts are enclosed.
2. Equipment enclosures are capable of withstanding an internal explosion, in case vapor finds its way inside and is ignited.
3. The hot gases resulting from an internal explosion are cooled by the time they are forced to the outside of the enclosure, so they cannot ignite the surrounding atmosphere.

Exhibit 66.6



Area classification for an aboveground storage tank — Division system.

Exhibit 66.7



Area classification for an aboveground storage tank — Zone system.

66.7.3.4 A classified area shall not extend beyond a floor, wall, roof, or other solid partition that has no openings within the classified area. [**30:**7.3.4]

66.7.3.5 The designation of classes, divisions, and zones shall be as defined in Chapter 5 of *NFPA 70*. [**30:**7.3.5]

66.7.3.6 The area classifications listed in Table 66.7.3.3 are based on the premise that all applicable requirements of this *Code* have been met. If this is not the case, the AHJ shall have the authority to classify the extent of the area. [**30:**7.3.6]

66.7.3.7* Where the provisions of 66.7.3.1 through 66.7.3.6 require the installation of electrical equipment suitable for Class I, Division 1 or 2, or Zone 1 or 2 locations, ordinary electrical equipment, including switchgear, shall be permitted to be used if installed in a room or enclosure that is maintained under positive pressure with respect to the classified area. [**30:**7.3.7]

Δ **A.66.7.3.7** NFPA 496 provides details for these types of installations. [**30:**A.7.3.7]

66.7.3.7.1 Ventilation make-up air shall be taken from an uncontaminated source. [**30:**7.3.7.1]

Δ 66.8 Application of Area Classification

Area classification is used to assure that fixed electrical utilization equipment, electrical fixtures, and wiring are properly installed within Class I, Division 1; Class I, Zone 1; Class I, Division 2; or Class I, Zone 2 designated areas, as defined by Article 500 of *NFPA 70*. [**30:**7.4.1]

Section 66.8 was added in the 2015 edition of the *Code* and is intended to explain the purpose of proper area classification. The important word here is *fixed*; Chapter 7 of NFPA 30 does not attempt to regulate, nor does it apply to, mobile motorized equipment or vehicles, such as industrial trucks or automobiles.

66.9 Storage of Liquids in Containers — General Requirements

Section 66.9 includes information on the following:

- The scope and general requirements involving the storage of flammable and combustible liquids in containers
- The design, construction, and capacity of containers, IBCs, and portable tanks
- The design, construction, and use of flammable liquids storage cabinets
- Control areas and the maximum allowable quantities (MAQs) per control area
- The classification of occupancies
- The design and construction of liquid storage rooms and liquid warehouses
- The general requirements for manual fire protection; electrical systems; containment, drainage, and spill control; ventilation; explosion control; separation of incompatible materials; and the dispensing, handling, and use of liquids in storage areas

The requirements in Section 66.9 are based on studies of fire incidents, research, and full-scale fire tests under various conditions.

66.9.1 Scope.

66.9.1.1 This section shall apply to the storage of flammable and combustible liquids in:

(1) Drums or other containers that do not exceed 119 gal (450 L) individual capacity
(2) Portable tanks that do not exceed 660 gal (2500 L) individual capacity
(3) Intermediate bulk containers that do not exceed 793 gal (3000 L)

[**30:**9.1.1]

The distinct capacity limitations listed in 66.9.1.1 should be kept in mind when applying the provisions of Section 66.9 and Chapter 9 of NFPA 30. Note also that, for the purposes of NFPA 30, portable tanks can be considered to be a subclass of IBCs.

In previous editions of NFPA 30, drum and container sizes were limited to 60 gal (230 L), which created a somewhat confusing gap because the DOT defines an IBC as having a capacity from 119 gal (450 L) to 793 gal (3000 L). The 2008 edition clarified the situation by increasing the size limitations for drums and containers to 119 gal (450 L). Not only did this change eliminate the apparent gap in coverage, it also accommodated environmental recovery drums of 85 gal (322 L) and 95 gal (360 L). Note that the fire protection system design criteria covered in Chapter 16 of NFPA 30 still utilize 60 gal (230 L) as one of the protection criteria limitations, with containers larger than 60 gal (230 L) being protected using the same design criteria as specified for IBCs and portable tanks.

For a number of years, the chemical and distilling industries have been shipping their products in vessels that have capacities up to 5500 gal (20,800 L) and that are built in accordance with DOT specifications. These vessels are referred to as portable tanks by the user industries. Also, the use of large portable vessels of several thousand gallons capacity in intermodal transportation service is common. Because the capacity of these vessels exceeds the 793 gal (3000 L) upper limit for IBCs, they are governed by the applicable requirements of Chapters 21 and 22 of NFPA 30.

66.9.1.2 This section shall also apply to limited transfer of liquids incidental thereto. [**30:**9.1.2]

66.9.1.3 This section shall also apply to overpack drums when used for temporary containment of containers that do not exceed 60 gal (230 L) capacity. Such overpack containers shall be treated as containers as defined in 66.3.3.10. [**30:**9.1.3]

66.9.1.4 This section shall not apply to the following:

(1) Containers, intermediate bulk containers, and portable tanks that are used in operations areas, as covered by Section 66.17
(2) Liquids in the fuel tanks of motor vehicles, aircraft, boats, or portable or stationary engines

The exemption in 66.9.1.4(2) from the provisions of Section 66.9 exists because the use of flammable and combustible fuels and oils stored in fuel tanks is covered by other NFPA standards and codes. See 66.1.4

(3) Beverages where packaged in individual containers that do not exceed 1.3 gal (5 L) capacity
(4) Medicines, foodstuffs, cosmetics, and other consumer products that contain not more than 50 percent by volume of water-miscible flammable or combustible liquids, with the remainder of the product consisting of components that do not burn and where packaged in individual containers that do not exceed 1.3 gal (5 L) capacity

The exemption in 66.9.1.4(4) has been part of the *Code* for many editions. It acknowledges that individually packaged consumer products, such as medicines, foodstuffs, and cosmetics in containers up to 1.3 gal (5 L) with a limited quantity of water-miscible flammable or combustible liquid component in the product, do not present a severe hazard. In the event of a leak or broken package, the amount of liquid spilled would be limited, and the limited quantity of water-miscible flammable or combustible liquid in the product would make ignition difficult. Note that the fire protection system design criteria in Chapter 16 of NFPA 30 generally require a lower sprinkler density when the flammable or combustible liquid concentration within a product is less than or equal to 50 percent, with the rest of the product consisting of components that do not burn.

(5) Liquids that have no fire point when tested in accordance with ASTM D92, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup*, up to the boiling point of the liquid or up to a temperature at which the liquid shows an obvious physical change

The reference to an "obvious physical change" might be a change in state from a liquid to a solid or an obvious change in viscosity. Remember that the *fire point* is the temperature at which sustained burning takes place upon application of an outside ignition source. The fire point is usually several degrees higher than the flash point, but still several hundred degrees lower than the autoignition temperature of the liquid. Liquids meant to be excluded here are those that show flash points when tested in accordance with the Tag or other closed-cup test methods but do not exhibit sustained burning. Water-based paints, which are typically formulated with small amounts of flammable or combustible solvents, are one example. Although these products exhibit a flash point, the end product will not support combustion until the water boils off and the residue becomes very viscous. Note that the fire point has no influence on proper classification of the liquid.

(6) Liquids with a flash point greater than 95°F (35°C) in a water-miscible solution or water-miscible dispersion with a water and noncombustible solids content of more than 80 percent by weight, and which does not sustain combustion when tested in accordance with "Method of Testing for Sustained Combustibility," in accordance with Title 49, Code of Federal Regulations, Part 173, Appendix H, or the UN publication *Recommendations on the Transport of Dangerous Goods*

The exemption in 66.9.1.4(6) acknowledges certain liquids that are quite similar in fire hazard to those addressed in 66.9.1.4(5) but that exhibit opposite behavior in testing, in that no flash point is obtained using closed-cup test methods, but brief burning is exhibited at some point during tests using the Cleveland open-cup method. Overall, the fire hazard is minimal.

(7) Distilled spirits and wines in wooden barrels or casks [**30:**9.1.4]

The exemption in 66.9.1.4(7) acknowledges that even though distilled spirits and wines might be considered flammable liquids, the wooden barrels do not present the same rupture hazard as metal containers or the same spill hazards as plastic containers. When wooden barrels or casks are exposed to fire, they do not fail violently. Rather, the metal hoops on the barrels that secure the staves expand and allow loosening of the staves, which results in leaking distilled spirits adding fuel to the fire. However, sprinkler systems often control the fire before the metal hoops on the barrels are affected. Also, note that the distilled spirits industry and the Distilled Spirits Council of the United States (DISCUS) maintain their own guideline document entitled *Recommended Fire Protection Practices for Distilled Spirits Beverage Facilities*. Exhibit 66.8 shows the storage of wooden barrels containing distilled spirits in a warehouse.

Exhibit 66.8

Distilled spirits stored in wooden barrels in a bonded warehouse.

N **66.9.2 Definitions Specific to Section 66.9.**

N **66.9.2.1* Protected.** For the purposes of Section 66.9, this term shall apply to the storage of containers that meet the appropriate provisions of 66.16 or alternate provisions that have been approved by the authority having jurisdiction *(see 66.16.3.5 and Section 66.16.9)*. [**30:**9.2.1]

N **A.66.9.2.1** The term *protected* indicates that the fire risk is managed so as to control the fire and prevent it from spreading beyond the design area of the automatic fire protection system. [**30:**A.9.2.1]

N **66.9.2.2* Unprotected.** For the purposes of this chapter, this term shall apply to the storage of containers that do not meet the criteria to be considered protected, as defined in 66.9.2.1. [**30:**9.2.2]

N **A.66.9.2.2** The term *unprotected* indicates that the growth of a fire might exceed the capabilities of the automatic fire protection system and extend beyond the design area of the system. In such cases, the total contents of the fire area might become involved in a fire, regardless of the protection features provided. [**30:**A.9.2.2]

The intent of the definitions is to demonstrate that a fire involving any particular storage situation is either capable of being controlled or not capable of being controlled. The phrase "any particular storage situation" means the combination of (1) class of liquid, (2) type and capacity of container, and (3) design and capability of the means of protection. These factors are addressed in the various criteria set forth in Chapter 16 of NFPA 30. The two annex items, A.66.9.2.1 and A.66.9.2.2, explain the rationale for the definitions. The definitions and the Annex A items are repeated in Sections 12.2 and 16.2 of NFPA 30, for the sake of emphasis.

These definitions replace former 66.9.3.4, which previously defined *protected storage* and established an effective date of January 1, 1997, for application of the mandatory fire protection design criteria in Chapter 16 of NFPA 30.

Until the 2018 edition, the *Code* included the following requirements, most recently in 66.9.3.4: "For the purposes of this chapter and Chapters 10, 12, and 16 of NFPA 30, *protected storage* shall mean storage installed after January 1, 1997 that is protected in accordance with Section 66.16. All other storage shall be considered to be unprotected storage unless an alternative means of protection has been approved by the AHJ." To address the need of flexibility, the *Code* specifically allows the AHJ to accept an alternative protection scheme based on, for example, full-scale fire tests. Annex E of NFPA 30 includes information on fire test protocols for situations that are not specifically addressed in Chapter 16 of NFPA 30.

With the adoption of the definitions of *protected* and *unprotected*, 66.9.3.4 was rendered moot and was deleted from the *Code* for the 2018 edition.

66.9.3 General Requirements.

66.9.3.1 The general requirements of this chapter shall be applicable to the storage of liquids in liquid storage areas as covered in Chapters 10 through 14 of NFPA 30, regardless of the quantities being stored.

*Exception: Where more stringent requirements are set forth in Chapters 10 through 14 of NFPA 30, those requirements shall take precedence. [**30:**9.3.1]*

Since the inclusion of the control area concept in the 2008 edition, general requirements have applied to the storage of all flammable and combustible liquids, regardless of the overall quantities stored. Also, specific requirements apply if the quantities stored exceed the MAQs per control area.

The requirements addressed in 66.9.3 are the general requirements and are applicable to the storage of all flammable and combustible liquids. As indicated in the exception to 66.9.3.1, if a more stringent requirement exists in 66.10 through 66.14, that requirement takes precedence.

66.9.3.2 For the purposes of Sections 66.9 through 66.16, unstable liquids shall be treated as Class IA liquids. [**30:**9.3.2]

Unstable liquids might decompose or react vigorously during a fire, causing their containers to overpressure and rupture much more rapidly and violently than would containers of a stable liquid. Class IA liquids, because of their high volatility, would be expected to behave similarly in a fire. Even though most unstable liquids would not be classified as Class IA liquids by virtue of their flash points, additional requirements for their safe storage are deemed necessary, and thus they should be protected as a Class IA liquid would be.

Δ **66.9.3.3** Means of egress shall meet applicable requirements of NFPA *101*. [**30:**9.3.3]

In a liquid storage room or liquid warehouse, some of the more important means of egress requirements to be addressed are the number of exits, the travel distance to an exit, the common path of travel, and dead-end aisles. These requirements are contained in Chapter 42, Storage Occupancies, of NFPA *101*®, *Life Safety Code*®. Additionally, NFPA *101* contains the requirements for the size of door openings, type of doors, emergency lighting, and egress signage.

• **66.9.3.4** Wood of at least 1 in. (25 mm) nominal thickness shall be permitted to be used for shelving, racks, dunnage, scuffboards, floor overlay, and similar installations. [**30:**9.3.4]

Note that no mention is made of metal shelving, nor is there any control over its use. In fact, drum racks used in liquid storage rooms and liquid warehouses are almost always metal. Although wood adds to the fire load in a storage facility, it is preferred by users because it minimizes the chances of damage to or breakage of containers.

66.9.3.5 Class I liquids shall not be permitted to be stored in basements as defined in 3.3.22. [**30:**9.3.5]

Basement storage of Class I flammable liquids presents a firefighting problem. Access to most basements is restricted, and ventilation and removal of smoke and combustion products from the area are usually more difficult to achieve. The storage itself adds to the fire loading and further restricts movement. If the storage of Class I liquids were allowed, any vapors present would create a hazardous situation. For those reasons, the storage of Class I liquids is not allowed, and the storage of Class II and Class IIIA combustible liquids requires that the basement be protected, as stated in 66.9.3.6.

66.9.3.6 Class II and Class IIIA liquids shall be permitted to be stored in basements as defined in 3.3.22, provided the basement is protected in accordance with Section 66.16. [**30:**9.3.6]

66.9.3.7 Class IIIB liquids shall be permitted to be stored in basements as defined in 3.3.22. [**30:**9.3.7]

Class IIIB combustible liquids do not present the same degree of hazards and concerns that Class I flammable liquids do; therefore, Class IIIB liquids are permitted to be stored in basements. Due to their higher flash point, Class IIIB liquids are more difficult to ignite than Class I liquids, and the storage of Class IIIB liquids does not create a hazardous vapor situation in a basement.

66.9.3.8 Where containers, intermediate bulk containers, or portable tanks are stacked, they shall be stacked so that stability is maintained and excessive stress on container walls is prevented. [**30:**9.3.8]

66.9.3.8.1 Portable tanks and intermediate bulk containers stored more than one high shall be designed to stack securely, without the use of dunnage. [**30:**9.3.8.1]

66.9.3.8.2 Materials-handling equipment shall be capable of handling containers, portable tanks, and intermediate bulk containers that are stored at all storage levels. [**30:**9.3.8.2]

Materials-handling equipment, such as power-operated industrial trucks used to lift and place products in the upper levels of storage racks, must have the capability to lift and handle the gross weight of the product, including the weight of the containers and pallets. Also, the equipment's reach must be capable of safely placing the product in the desired storage level.

Δ **66.9.3.8.3*** Power-operated industrial trucks used to move Class I liquids shall be selected, operated, and maintained in accordance with NFPA 505. [**30:**9.3.8.3]

Δ **A.66.9.3.8.3** Section 5.1 of NFPA 505 states "In locations used for the storage of flammable liquids in sealed containers or liquefied or compressed flammable gases in containers, approved power-operated industrial trucks designated as Types CNS, DS, ES, GS, LPS, GS/CNS, or GS/LPS shall be permitted to be used where approved by the AHJ." Compared to the above types, industrial trucks that are designated DY and EE have significantly less potential for igniting flammable vapors (such as might result from a spill of Class I liquid) and should be used in inside liquid storage areas where conditions warrant. [**30:**A.9.3.8.3]

Although the use of ordinary electrical equipment is permitted in liquid warehouses where no Class I flammable liquid transfer operations take place (see Table 66.7.3.3), the use of spark-proof, power-operated industrial trucks is recommended as a minimum for handling containers of Class I flammable liquids. History has shown that power-operated industrial trucks have provided the ignition source for some major warehouse fires.

In some cases, powered industrial trucks might have to be specially selected to ensure that they do not constitute a source of ignition in an area that might be hazardous because of fugitive vapors.

66.9.3.9 Containers, intermediate bulk containers, and portable tanks in unprotected liquid storage areas shall not be stored closer than 36 in. (915 mm) to the nearest beam, chord, girder, or other roof or ceiling member. [**30:**9.3.9]

Because unprotected liquid storage areas might have inadequate sprinkler system designs or no sprinklers at all, the intent of 66.9.3.9 is to ensure that sufficient clearance exists between structural members and the top of storage to allow manual fire fighting using fire hose streams.

66.9.3.10 Liquids used for building maintenance, painting, or other similar infrequent maintenance purposes shall be permitted to be stored in closed containers outside of storage cabinets or inside liquid storage areas, if limited to an amount that does not exceed a 10-day supply at anticipated rates of use. [**30:**9.3.10]

The requirement in 66.9.3.10 acknowledges that situations exist where infrequent building maintenance activities — such as cleaning, painting, floor coating operations, or roof replacements — might require the use of materials that are considered flammable and combustible liquids and that such materials would be present in the facility during the duration of those activities. It is expected that the materials would be stored in an area free of other combustible materials and away from any hazardous processes and areas where hot work is performed. At the completion of the maintenance activity, all materials must be removed from the building or stored in an approved storage cabinet or inside the liquid storage area.

Δ **66.9.3.11** Storage, handling, and use of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. *(See 66.9.4.1.2 and A.66.6.4.1.2.)* [**30:**9.3.11]

66.9.4 Acceptable Containers.

66.9.4.1* Only the following approved containers, intermediate bulk containers, and portable tanks shall be used for Class I, Class II, and Class IIIA liquids:

A.66.9.4.1 It is not the intent of 66.9.4 to regulate containers and packaging systems for Class IIIB liquids, except as required for protected storage in accordance with Chapter 16 of NFPA 30. [**30:**A.9.4.1]

NFPA 30 attempts to reduce fire hazards by setting requirements for the design and construction of containers, IBCs, and portable tanks. Thus, only certain types are allowed. Subsection 66.9.4 specifies what might be considered "approved" and emphasizes that NFPA does not approve individual designs or specifications of containers. That is the responsibility of DOT for shipping containers and organizations such as ASTM, Underwriters Laboratories, and FM Global for consumer use containers and safety cans. Note that items (1), (4), and (6) of 66.9.4.1 reference the United Nations (UN) *Recommendations on the Transport of Dangerous Goods*. Current DOT regulations are compatible with these international rules, and the intent of the reference is to not restrict the use or importation of container types that might not be explicitly authorized by DOT.

Class IIIB liquids are not regulated as to the types of containers allowed, due to their low fire risk.

(1) Metal containers, metal intermediate bulk containers, and metal portable tanks meeting the requirements of and containing products authorized by the U.S. Department of Transportation Hazardous Materials Regulations in 49 CFR 100–199, or by Part 6 of the UN *Recommendations on the Transport of Dangerous Goods*

Item 66.9.4.1(1) is specific to containers and IBCs constructed entirely of metal. (DOT-specification portable tanks are made only of metal.) Some IBCs consist of a thin, flexible polymeric bottle that holds the liquid surrounded by a metal wire "cage," sheet metal, or a heavy corrugated "carton," which gives the assembly some degree of stability. The DOT allows the shipment of some Class IB and IC liquids in such IBCs. However, they do not meet the intent of this *Code* for safe warehousing. IBCs are required to be made completely of metal if they are to be recognized as acceptable "metal" containers under NFPA 30.

Unfortunately, this has led to some confusion regarding what constitutes a metal container. One problem is that the phrase "metal container" implies that the metal is liquidtight. Some drums consist of a rigid plastic container inserted into a metal shell. The metal shell has small weep holes around the bottom to allow moisture that accumulates between the metal and the plastic to drain. Thus, the metal shell cannot be considered to be liquidtight. Yet such a construction is probably just as suitable for the storage of liquids as is a completely liquidtight metal portable tank.

To compound the dilemma, several types of IBCs made of rigid plastic or plastic and metal have gained wide acceptance in the industry because of their durability, their light weight, and particularly their ability to hold corrosive materials without fear of leakage. And, indeed, several types of these IBCs are recognized by NFPA 30 for certain classes of liquid, as discussed in 66.9.4.1(2).

Exhibit 66.9 shows several types and sizes of metal containers. See Exhibit 66.9 for a photo of a metal IBC.

Exhibit 66.9

Metal drums and containers. (Courtesy of Greif, Inc.)

(2) Plastic or metal consumer-use containers meeting the requirements of, and used within the scope of, one or more of the following specifications:
   (a) ASTM F852, *Standard Specification for Portable Gasoline Containers for Consumer Use*
   (b) ASTM F976, *Standard Specification for Portable Kerosene and Diesel Containers for Consumer Use*

In prior editions of the *Code*, 66.9.4.1(2) included both consumer-use containers and industrial-grade safety cans. These two categories are now listed separately, the latter in 66.9.4.1(3).

ASTM F852, *Standard Specification for Portable Gasoline Containers for Consumer Use,* and ASTM F976, *Standard Specification for Portable Kerosene and Diesel Containers for Consumer Use,* cover both metal and high-density polyethylene (HDPE) plastic containers for gasoline and for kerosene and diesel fuel, respectively, although the manufacture of metal containers appears to have ceased. The market demand is now completely met by plastic containers, an example of which is shown in Exhibit 66.10. These containers are quite sturdy for the uses intended, being of thick-wall construction, and are approved by most jurisdictions for storing petroleum products.

(3) Nonmetallic or metallic commercial/industrial safety cans meeting the requirements of, and used with the scope of, one or more of the following specifications:
   (a) ANSI/UL 30, *Standard for Metal Safety Cans*
   (b) ANSI/UL 1313, *Standard for Nonmetallic Safety Cans for Petroleum Products*
   (c) FM Global *Approval Standard for Safety Containers and Filling, Supply, and Disposal Containers* — Class Number 6051 and 6052

Exhibit 66.10

Plastic gasoline can.

(4) Plastic containers that meet requirements set by and contain products authorized by the following:
  (a) The U. S. Department of Transportation Hazardous Materials Regulations in 49 CFR 100–199, or by Part 6 of the UN publication *Recommendations on the Transport of Dangerous Goods*
  (b) Items 256 or 258 of the *National Motor Freight Classification* (NMFC) for liquids that are not classified as hazardous by the U.S. Department of Transportation Hazardous Materials Regulations in 49 CFR 100–199, or by Part 6 of the UN publication *Recommendations on the Transport of Dangerous Goods*

Plastic containers of very thin-wall construction, such as those used for many consumer products and not intended for reuse, should not be used for routine, repeated storage of flammable and combustible liquids. Although these containers are allowed for one-time shipment of some classes of flammable and combustible liquids, they do not meet the rigid requirements established by the standards referenced in 66.9.4.1. See Exhibit 66.11 for some examples of acceptable plastic shipping containers.

(5) Fiber drums that meet the following:
  (a) Requirements of Items 294 and 296 of the *National Motor Freight Classification* (NMFC), or Rule 51 of the *Uniform Freight Classification* (UFC), for Types 2A, 3A, 3B-H, 3B-L, or 4A
  (b) Requirements of, and containing liquid products authorized by, either the U.S. Department of Transportation Hazardous Materials Regulations in 49 CFR Chapter I, or by U.S. Department of Transportation exemption

Exhibit 66.11

Plastic shipping containers. (Courtesy of Greif, Inc.)

(6)* Rigid nonmetallic intermediate bulk containers that meet requirements set by and contain products authorized by the following:
  (a) The U.S. Department of Transportation Hazardous Materials Regulations in 49 CFR 100–199, or by Part 6 of the UN publication *Recommendations on the Transport of Dangerous Goods,* for Classes 31H1, 31H2, and 31HZ1
  (b) The *National Motor Freight Classification* (NMFC), or the International Safe Transit Association for liquids that are not classified as hazardous by the U.S. Department of Transportation Hazardous Materials Regulations in 49 CFR 100–199, or by Part 6 of the UN publication *Recommendations on the Transport of Dangerous Goods*

Δ **A.66.9.4.1(6)** The term *rigid nonmetallic intermediate bulk container* is used to describe intermediate bulk containers that have a plastic vessel that serves as the primary liquid-holding component. This vessel can be enclosed in or encased by an outer structure consisting of a steel cage, a single-wall metal or plastic enclosure, a double wall of foamed or solid plastic, or a paperboard enclosure. These are often called *composite IBCs*, which is the term used by the U.S. Department of Transportation (DOT) to describe them. The term *rigid nonmetallic intermediate bulk container* also denotes an all-plastic single-wall IBC that might or might not have a separate plastic base and for which the containment vessel also serves as the support structure. IBCs that have an outer liquidtight metal structure are considered to be metal IBCs or metal portable tanks by DOT and are defined in 66.9.4.1(1). [**30:**A.9.4.1(6)]

N *TABLE 66.9.4.3 Maximum Allowable Size — Containers, Intermediate Bulk Containers (IBCs), and Portable Tanks*

Container Type	Flammable Liquids			Combustible Liquids	
	Class IA	Class IB	Class IC	Class II	Class IIIA
Glass	1 pt (0.5 L)	1 qt (1 L)	1.3 gal (5 L)	1.3 gal (5 L)	5.3 gal (20 L)
Metal (other than drums) or approved plastic	1.3 gal (5 L)	5.3 gal (20 L)	5.3 gal (20 L)	5.3 gal (20 L)	5.3 gal (20 L)
Safety cans	2.6 gal (10 L)	5.3 gal (20 L)	5.3 gal (20 L)	5.3 gal (20 L)	5.3 gal (20 L)
Metal drum (e.g., UN 1A1/1A2)	119 gal (450 L)	119 gal (450 L)	119 gal (450 L)	119 gal (450 L)	119 gal (450 L)
Approved metal portable tanks and IBCs	793 gal (3000 L)	793 gal (3000 L)	793 gal (3000 L)	793 gal (3000 L)	793 gal (3000 L)
Rigid plastic IBCs (UN 31H1 or 31H2) and composite IBCs with rigid inner receptacle (UN31HZ1)†	NP	NP	NP	793 gal (3000 L)	793 gal (3000 L)
Composite IBCs with flexible inner receptacle (UN31HZ2) DOT/UN-approved flexible IBCs, and NMFC/ISTA-compliant IBCs†	NP	NP	NP	331 gal (1300 L)	331 gal (1300 L)
Non-bulk Bag-in-box	NP	NP	NP	NP	NP
Polyethylene UN1H1 and UN1H2, or as authorized by DOT exemption	1.3 gal (5 L)	5.3 gal (20 L)*	5.3 gal (20 L)*	119 gal (450 L)	119 gal (450 L)
Fiber drum NMFC or UFC Type 2A; Types 3A, 3B-H, or 3B-L; or Type 4A	NP	NP	NP	119 gal (450 L)	119 gal (450 L)

NP: Not permitted for the container categories so classified unless a fire protection system is provided that is developed in accordance with 66.16.3.6 and is approved for the specific container and protection against static electricity is provided.

*See 66.9.4.3.1.

†See 66.9.4.3.2

[**30:** Table 9.4.3]

Several types of IBCs are recognized by NFPA 30. Rigid nonmetallic IBCs have proved to be acceptable for warehouse storage under NFPA 30, having passed a fire exposure test in accordance with 66.9.4.1.1. However, unless protected with the fire protection system design criteria contained in Chapter 16 of NFPA 30, the storage of such containers is considered to be unprotected. Also, these containers are acceptable only for the storage of Class II and Class IIIA liquids as indicated in Table 66.9.4.3.

(7) Glass containers up to the capacity limits stated in Table 66.9.4.3 and in accordance with U.S. Department of Transportation Hazardous Materials Regulations in 49 CFR 100–199

(8) Other nonmetallic intermediate bulk containers that comply with 66.9.4.1.1

[**30:**9.4.1]

Item (8) has been added to allow for nonmetallic IBCs other than those covered by 66.9.4.1(6) that meet the provisions of 66.9.4.1.1, including those constructed of fiberboard.

Δ **66.9.4.1.1** For protected storage, nonmetallic intermediate bulk containers shall comply with Table 66.9.4.3 and shall be listed and labeled in accordance with UL 2389, *Standard for Fire Exposure Testing of Intermediate Bulk Containers or Flammable and Combustible Liquids*; FM Class 6020, *Approval Standard for Intermediate Bulk Containers*; or an equivalent test procedure. [**30:**9.4.1.1]

Paragraph 66.9.4.1.1 specifies the appropriate test protocols to demonstrate acceptable fire performance of nonmetallic IBCs. Addition of the references to the test protocols correlates with requirements stated in Tables 16.5.2.9 and 16.5.2.10 of NFPA 30 and with amendments made to Table 66.9.4.3.

66.9.4.1.2 Medicines, beverages, foodstuffs, cosmetics, and other common consumer products, where packaged according to commonly accepted practices for retail sales, shall be exempt from the requirements of 66.9.4.1 and 66.9.4.3. [**30:**9.4.1.2]

66.9.4.2 Each portable tank or intermediate bulk container shall be provided with one or more devices installed in the top with sufficient emergency venting capacity to limit internal pressure under fire exposure conditions to a gauge pressure of 10 psi (70 kPa) or 30 percent of the bursting pressure of the portable tank, whichever is greater. [**30:**9.4.2]

The portable tanks and IBCs described here generally are cylindrical or rectangular in shape and 225 gal to 375 gal (850 L to 1420 L) in capacity. They are used for transporting many liquid commodities, from coatings to edible oils. Metal portable tanks and IBCs are constructed of steel, aluminum, or alloys containing magnesium. The rigid plastic types are generally made of heavy gauge HDPE, while the composite types consist of a thinner HDPE vessel that is surrounded by a metal wire "cage" or a sheet metal overpack for structural stability. Almost all are designed to nest securely when stacked, without the need for pallets or dunnage.

Vents are installed in the top of portable tanks and IBCs to prevent the discharge of liquid under overpressure situations. Normally, the vents expel any vapors generated by an increase in temperature.

66.9.4.2.1 The total venting capacity shall be not less than that specified in 22.7.3.2 or 22.7.3.4 of NFPA 30. [**30:**9.4.2.1]

The vent requirements stated here attempt to meet the following two objectives:

1. Minimize the overpressure due to normal changes in ambient temperature
2. Provide the emergency relief venting required when the tank is subject to extreme temperature increases such as those generated by a fire

66.9.4.2.2 At least one pressure-actuated vent having a minimum capacity of 6000 ft^3 (170 m^3) of free air per hour at an absolute pressure of 14.7 psi (101 kPa) and 60°F (15.6°C) shall be used. It shall be set to open at not less than a gauge pressure of 5 psi (35 kPa). [**30:**9.4.2.2]

Note, however, that the 6000 ft^3 (170 m^3) of free air per hour specified might not be adequate for unstable liquids, especially if two-phase flow can be expected.

66.9.4.2.3 If fusible vents are used, they shall be actuated by elements that operate at a temperature not exceeding 300°F (150°C). Where plugging of a pressure-actuated vent can occur, such as when used for paints, drying oils, and similar materials, fusible plugs or venting devices that soften to failure at a maximum of 300°F (150°C) under fire exposure shall be permitted to be used for the entire emergency venting requirement. [**30:**9.4.2.3]

Δ **66.9.4.3** The maximum allowable size of a container, intermediate bulk container, or metal portable tank for Class I, Class II, and Class IIIA liquids shall not exceed that specified in Table 66.9.4.3.

*Exception: As provided for in 66.9.1, 66.9.4.3.1, 66.9.4.3.3, and 66.9.4.3.4. [**30:**9.4.3]*

Particular attention should be given to the fact that, for the purposes of NFPA 30, the use of rigid plastic IBCs, composite IBCs, and fiber drums is limited to the particular types specified in Table 66.9.4.3 and must be listed for fire exposure. Also, they are recognized only for storing Class II and Class IIIA liquids, even though some of them might be allowed for transporting liquids of a lower class.

In the 2018 edition, the following changes were made to the table:

- For composite IBCs with flexible inner receptacles (UN31HZ2) and for DOT/UN-approved flexible IBCs, units that have successfully met the criteria of ANSI/UL 2368, *Standard for Fire Exposure Testing of Rigid Nonmetallic and Composite Nonmetallic Intermediate Bulk Containers for Combustible Liquids*; FM 6020, *Approval Standard for Safety Intermediate Bulk Containers*; or an equivalent test procedure, as set forth in 66.9.4.1.1 and 66.9.4.3.2, are permitted for Class II and Class IIIA liquids up to 331 gal (1300 L) maximum capacity.
- Also included in the category described in item (1) are units that are NMFC/ISTA compliant. NMFC refers to the National Motor Freight Classification code, a product of the National Motor Freight Traffic Association, which classifies commodities for purposes of uniform treatment in transportation. ISTA refers to the International Safe Transit Association, an organization that develops testing protocols to ensure performance of packaging in shipment.
- A reference has been added to 66.9.4.3.2, which identifies the test protocols referenced in item (1).

66.9.4.3.1 Class IB and Class IC water-miscible liquids shall be permitted to be stored in plastic containers up to 60 gal (230 L) in size, if stored and protected in accordance with Table 66.16.5.2.7. [**30:**9.4.3.1]

Paragraph 66.9.4.3.1 acknowledges that Class IB and Class IC flammable liquids that are water-miscible, such as alcohols and flavorings, can be safely stored in plastic containers up to 60 gal (230 L), provided they are stored and protected with the fire protection system design criteria contained in Section 66.16.

N **66.9.4.3.2** Nonmetallic intermediate bulk containers shall be listed and labeled in accordance with UL 2368, *Standard for Fire Exposure Testing of Intermediate Bulk Containers for Flammable and Combustible Liquids*; FM Class 6020, *Approval Standard for Intermediate Bulk Containers*; or an equivalent test procedure. [**30:**9.4.3.2]

66.9.4.3.3 Class IA and Class IB liquids shall be permitted to be stored in glass containers of not more than 1.3 gal (5 L) capacity if the required liquid purity (such as American Chemical Society analytical reagent grade or higher) would be affected by storage in metal containers or if the liquid can cause excessive corrosion of a metal container. [**30:**9.4.3.3]

This exception is included to avoid unnecessarily restricting laboratory use of flammable liquids, while still providing an acceptable degree of fire safety.

66.9.4.3.4 Leaking or damaged containers up to 60 gal (230 L) capacity shall be permitted to be stored temporarily in accordance with this section and Chapters 10 through 12 of NFPA 30, provided they are enclosed in overpack containers. [**30:**9.4.3.4]

66.9.4.3.4.1 To be considered protected storage as defined in 66.9.2.1 and in accordance with Section 66.16, an overpack container shall be constructed of the same material as the leaking or damaged container. [**30:**9.4.3.4.1]

66.9.4.3.4.2 Metal overpack containers shall be considered nonrelieving style containers. [**30:**9.4.3.4.2]

66.9.5* Flammable Liquids Storage Cabinets.

A.66.9.5 The requirements in 66.9.5 are based on hazards associated with fixed flammable liquids storage cabinets. They do not address potential hazards associated with mobile storage cabinets (i.e., cabinets with integral wheels) such as the following:

(1) Increased risk of spills
(2) Potential for tipover or blockage of egress
(3) Maintenance of vent and grounding integrity
(4) Variable condition of exposed floor surfaces under the cabinet

[**30:**A.9.5]

A number of commercially available and approved flammable liquids storage cabinets are built to hold flammable and combustible liquids from 4 gal (15 L) up to 120 gal (460 L). Exhibit 66.12 shows a typical flammable liquids storage cabinet for safety cans and small containers. Exhibit 66.13 (left) shows a cabinet designed to store a drum in the vertical position, with room to install a drum pump for dispensing. Exhibit 66.13 (right) shows a cabinet designed to store a drum horizontally, so that the user can gravity dispense from the drum.

The cabinets allow solvents and other flammable and combustible liquids to be stored at workplace locations, saving costly trips to a central liquid storage room. Cabinets are manufactured so they can be located under a counter, wall-mounted, or stacked piggyback style.

Exhibit 66.12

Typical flammable liquids storage cabinet. (Courtesy of Justrite Mfg. Co.)

Exhibit 66.13

A flammable liquids storage cabinet for vertical drum storage (left) and a flammable liquids storage cabinet for horizontal drum storage (right). (Courtesy of Justrite Mfg. Co.)

Although the cabinets are usually referred to as "flammable liquids storage cabinets," combustible liquids are allowed to be stored in them as well. Keep in mind that the liquids stored in a cabinet should be mutually compatible and that the cabinets are designed and constructed for liquid storage only. They are not intended for storing small cylinders of compressed or liquefied gases, especially those that are flammable. Likewise, incompatible materials, whether liquid or solid, should not be stored in these cabinets.

Also, ordinary glass containers exposed to heat will fail at about 212°F (100°C) due to thermally induced stress. Storage cabinets offer protection from radiant heat but only for a limited period of intense fire exposure. Their limitations must be recognized. Specially designed cabinets that provide extra protection for glass containers are available.

66.9.5.1 The volume of Class I, Class II, and Class IIIA liquids stored in an individual storage cabinet shall not exceed 120 gal (460 L). [**30:**9.5.1]

66.9.5.2 The total aggregate volume of Class I, Class II, and Class IIIA liquids in a group of storage cabinets shall not exceed the maximum allowable quantity of flammable and combustible liquids per control area based on the occupancy where the cabinets are located. [**30:**9.5.2]

The control area concept allows for increased storage of liquid quantities within a storage cabinet or multiple storage cabinets.

The number of storage cabinets present in one fire area no longer matters. Previous editions of the *Code* had limited the number of cabinets to three within any one fire area, with exceptions for industrial occupancies that allowed for additional storage cabinets, provided they were separated by 100 ft (30 m) or were located in an area equipped with an automatic sprinkler system. This requirement had an inherent flaw that was recognized by the Technical Committee in that, rather than focus on the number of cabinets, it was more important to consider the volume limitation of the cabinets.

Δ **66.9.5.3** Storage cabinets that meet at least one of the following sets of requirements shall be acceptable for storage of liquids:

(1) Storage cabinets designed and constructed to limit the internal temperature at the center of the cabinet and 1 in. (25 mm) from the top of the cabinet to not more than 325°F (163°C), when subjected to a 10-minute fire test that simulates the fire exposure of the standard time–temperature curve specified in NFPA 251, *Standard Methods of Tests of Fire Resistance of Building and Construction and Materials*, shall be acceptable. All joints and seams shall remain tight and the door shall remain securely closed during the test.

An approved storage cabinet is designed and constructed to protect the contents from external fires; it is not designed or intended to contain a fire. The 10-minute fire test criterion is based on the estimated time for a room or portion of a building to become seriously involved in a fire and, thus, is considered a measure of the time for occupants to evacuate the area. The standard temperature–time curve from which this information is taken can be found in ASTM E152, *Fire Tests of Door Assemblies*, and NFPA 252, *Standard Methods of Fire Tests of Door Assemblies.*

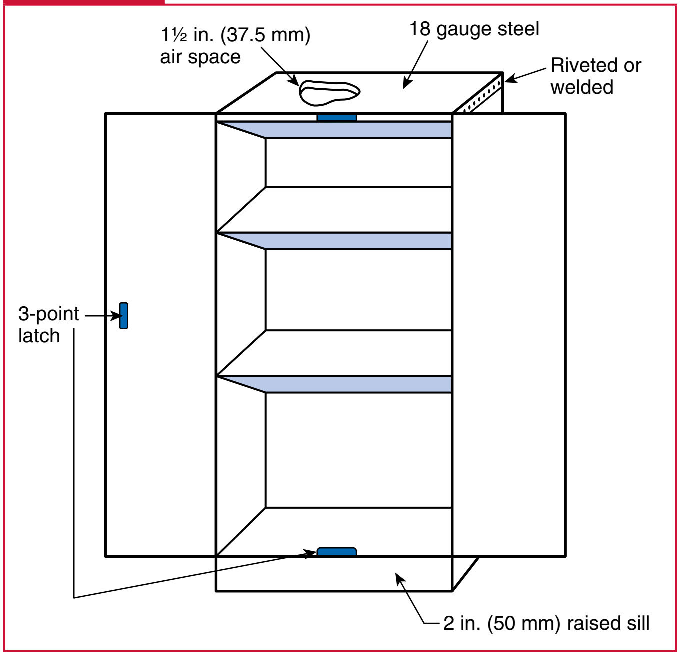
(2) Metal storage cabinets constructed in the following manner shall be acceptable:
   (a) The bottom, top, door, and sides of the cabinet shall be at least No. 18 gauge sheet steel and shall be double-walled, with 1½ in. (38 mm) air space.
   (b) Joints shall be riveted, welded, or made tight by some equally effective means.
   (c) The door shall be provided with a three-point latch arrangement, and the door sill shall be raised at least 2 in. (50 mm) above the bottom of the cabinet to retain spilled liquid within the cabinet.

The three-point latch arrangement on the metal storage cabinet doors is intended to maintain the integrity of the cabinet under fire exposure. Without a three-point latch arrangement, the metal would warp when exposed to a fire, resulting in exposure of the cabinet's contents to the fire. Note that the door is not required to be self-closing, although this feature is often found in commercially available cabinets. Note also that NFPA 30 does not mandate a test for cabinets built in accordance with these requirements. The 2 in. (50 mm) raised sill required here provides for retention of minor spills and leaks. This provision of the *Code* does not prohibit using the bottom of the cabinet for storage. See Exhibit 66.14 for an illustration of acceptable construction of a metal cabinet.

(3) Wooden cabinets constructed in the following manner shall be acceptable:
   (a) The bottom, sides, and top shall be constructed of exterior grade plywood that is at least 1 in. (25 mm) thick and of a type that will not break down or delaminate under fire conditions.
   (b) All joints shall be rabbetted and shall be fastened in two directions with wood screws.
   (c) Where more than one door is used, there shall be a rabbetted overlap of not less than 1 in. (25 mm).
   (d) Doors shall be equipped with a means of latching, and hinges shall be constructed and mounted in such a manner as to not lose their holding capacity when subjected to fire exposure.
   (e) A raised sill or pan capable of containing a 2 in. (50 mm) depth of liquid shall be provided at the bottom of the cabinet to retain spilled liquid within the cabinet.

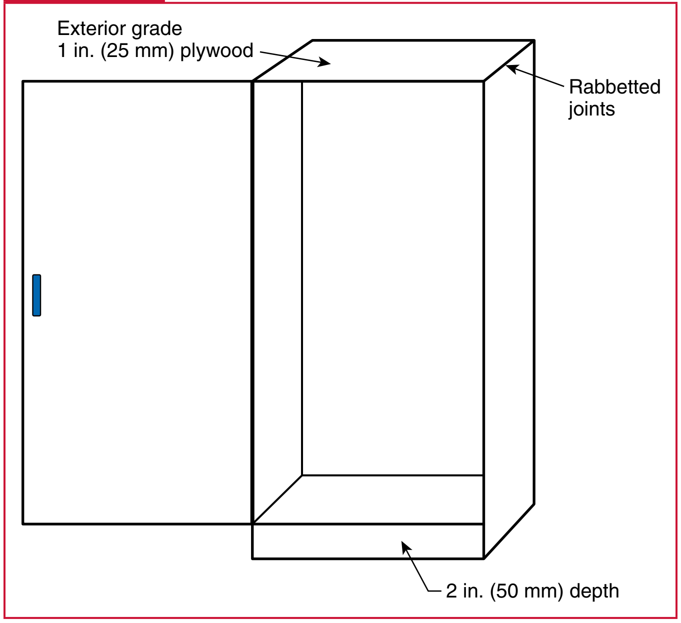
Although not required to do so, a cabinet built to these requirements will meet the test specifications of 66.9.5.3(1). Note that NFPA 30 does not require a three-point latch on wooden doors, because wood does not tend to warp or distort when exposed to fire as metal does. See Exhibit 66.15 for an illustration of acceptable construction of a wooden cabinet. Exhibit 66.16 shows a

Exhibit 66.14



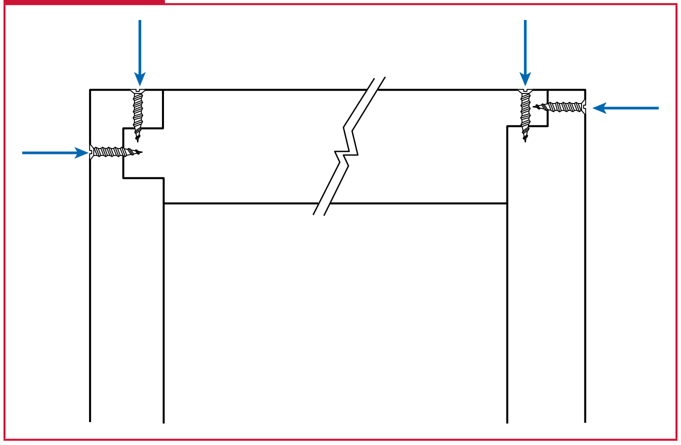
Acceptable construction for metal cabinets.

Exhibit 66.15



Acceptable construction for wooden cabinets.

Exhibit 66.16



Cross-section of two types of rabbetted joints used in construction of wooden cabinets.

cross-section view of a rabbetted joint. These joints, common in high-end cabinetry, are quite strong.

(4) Listed storage cabinets that have been constructed and tested in accordance with UL 1275, *Standard for Flammable Liquid Storage Cabinets*; FM Class Number 6050, *Approval Standard for Storage Cabinets (Flammable and Combustible Liquids)*; or equivalent shall be acceptable.

[**30:**9.5.3]

66.9.5.4* Storage cabinets shall not be required by this *Code* to be ventilated for fire protection purposes. [**30:**9.5.4]

Δ **A.66.9.5.4** Venting of storage cabinets has not been demonstrated to be necessary for fire protection purposes. Additionally, venting a cabinet could compromise the ability of the cabinet to adequately protect its contents from involvement in a fire, because cabinets are not generally tested with any venting. Therefore, venting of storage cabinets is not recommended. [**30:**A.9.5.4]

However, it is recognized that some jurisdictions might require storage cabinets to be vented and that venting can also be desirable for other reasons, such as health and safety. In such cases, the venting system should be installed so as to not affect substantially the desired performance of the cabinet during a fire. Means of accomplishing this can include thermally actuated dampers on the vent openings or sufficiently insulating the vent piping system to prevent the internal temperature of the cabinet from rising above that specified. Any make-up air to the cabinet should also be arranged in a similar manner. [**30:**A.9.5.4]

If vented, the cabinet should be vented from the bottom with make-up air supplied to the top. Also, mechanical exhaust ventilation is preferred and should comply with NFPA 91. Manifolding the vents of multiple storage cabinets should be avoided. [**30:**A.9.5.4]

66.9.5.4.1 If a storage cabinet is not ventilated, the vent openings shall be sealed with the bungs supplied with the cabinet or with bungs specified by the cabinet manufacturer. [**30:**9.5.4.1]

The storage cabinet is not required to be vented for fire protection purposes. However, vent openings are often provided by manufacturers because some jurisdictions mandate that the cabinet be vented to prevent possible vapor accumulation in the cabinet and because some users desire this feature if the cabinet is to be used for the storage of toxic or noxious materials. It should be understood that venting the cabinet might defeat its fire integrity. If it is not necessary nor required that the cabinet be vented, the vent openings should be kept tightly capped with the metal bungs provided for that purpose.

66.9.5.4.2* If a storage cabinet is ventilated for any reason, the vent openings shall be ducted directly to a safe location outdoors or to a treatment device designed to control volatile organic compounds (VOCs) and ignitible vapors in such a manner that will not compromise the specified performance of the cabinet and in a manner that is acceptable to the AHJ. [**30:**9.5.4.2]

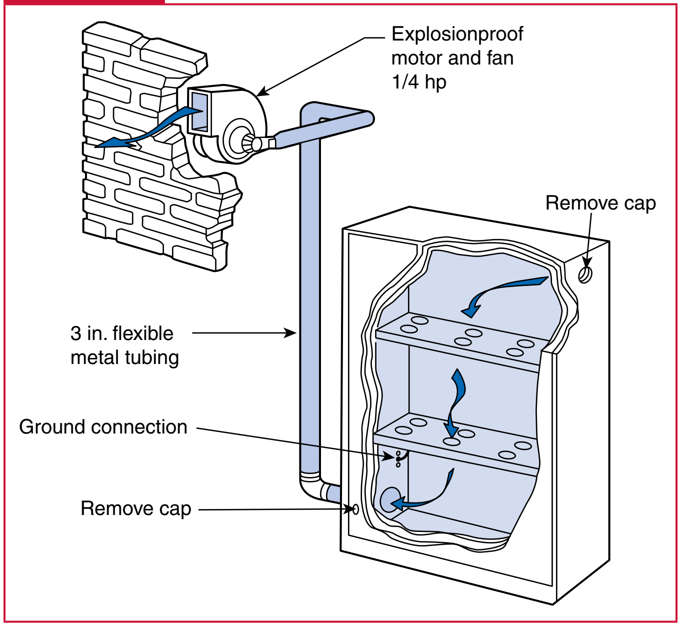
If the cabinet must be vented, the following procedures should be followed (see Exhibit 66.17 for details):

1. Remove both metal bungs and replace them with flash arrester screens (normally provided with the cabinets). The top opening will serve as the fresh air inlet.
2. Connect the bottom opening to an exhaust fan using substantial metal tubing having an inside diameter no smaller than the vent. The tubing should be rigid steel.
3. Position the fan so that it exhausts directly to the outside. The fan should have a nonsparking blade and nonsparking shroud.
4. Ensure that the total run of exhaust duct does not exceed 25 ft (7.6 m).

Venting the interior of a storage cabinet directly to the interior of a standard laboratory hood via flexible plastic duct is improper and dangerous. Not only is the cabinet's integrity violated, but safety of the hood and anyone using it is seriously compromised.

Flammable liquid storage cabinets are not required to be grounded. Notice that Exhibit 66.17 shows a ground connection. This ground connection is provided by the manufacturer for the convenience of the user. For example, the connection can provide a convenient grounding point for a bond wire for containers within the cabinet, which would be useful for containers inside the cabinet that are used to dispense to other smaller containers. Another example: Where a cabinet houses one or two drums of liquid that are equipped with drum pumps or dispensing spigots, the drums and the containers being dispensed to can be bonded to the ground connection.

Exhibit 66.17



Acceptable method to vent a flammable liquids storage cabinet.

A.66.9.5.4.2 A "safe location" should be selected as the location of a vent discharge to minimize the potential for ignitible vapors to travel to a source of ignition after discharge from the vent. Electrical equipment that does not meet the requirements for hazardous locations can serve as an ignition source. The Technical Committee advises that vent discharge locations should consider such factors as the following:

(1) Characteristics of the exhausted material (vapor density, toxicity, velocity of discharge, etc.)
(2) Proximity to potential ignition sources
(3) Building openings such as doors, windows, air intakes, and so forth
(4) Dispersion characteristics (distance to discharge within the flammable range, direction of discharge, atmospheric conditions, and the influence of building and neighboring buildings on discharged vapors)
(5) Likelihood of vapor accumulation following discharge, such as accumulation under building eaves
(6) Likelihood of sufficient discharge volume to allow an ignitible concentration to reach an ignition source

[**30:**A.9.5.4.2]

Historically, NFPA 30 has provided prescriptive guidance, often based on area classification requirements, and results have been acceptable. Closer distances should be accepted only if an analysis by a qualified person justifies closer distances. Similarly, the specified distances might not be acceptable for all installations, thus the guidance provided above. [**30:**A.9.5.4.2]

66.9.5.5* Storage cabinets shall include the following marking: [**30:**9.5.5]

FLAMMABLE
KEEP FIRE AWAY

A.66.9.5.5 ANSI Z535.2.2007, Environmental and Facility Safety Signs, Section 9.2, was used to determine the letter height, based on a safe viewing distance of 25 ft (7.5 m). Markings can be reflective to improve visibility. See ASTM D4956, *Standard Specification for Retroreflective Sheeting for Traffic Control*, for more information on providing reflective surfaces. If international symbols are used, they should be a minimum of 2.0 in. (50 mm) in size. [**30:**A.9.5.5]

The reference to ASTM D4956, *Standard Specification for Retroreflective Sheeting for Traffic Control,* provides the user with specifications for reflective sheeting that can be used for cabinet marking labels to improve visibility in emergency situations such as fires.

66.9.5.5.1 The minimum letter height for FLAMMABLE (signal word) shall be 2.0 in. (50 mm) and the minimum letter height for KEEP FIRE AWAY (message) shall be 1.0 in. (25 mm). [**30:**9.5.5.1]

66.9.5.5.2 All letters shall be uppercase and in contrasting color to the background. [**30:**9.5.5.2]

66.9.5.5.3 The marking shall be located on the upper portion of the cabinet's front door(s) or frame. [**30:**9.5.5.3]

66.9.5.5.4 Use of other languages, the international symbol for "flammable" (a flame in a triangle), the international symbol for "keep fire away" (a burning match in "no" circle) shall be permitted. [**30:**9.5.5.4]

The requirements for marking flammable liquids storage cabinets have been revised to incorporate internationally accepted guidelines for safety signs and to include a reference to ASTM D4956 for information on reflective markings. Specifically, the word "WARNING" is no longer required as part of the marking.

66.9.6 Maximum Allowable Quantities (MAQs) per Control Area.

66.9.6.1 General Occupancy Limits. The MAQs of liquids allowed in each control area shall not exceed the amounts specified in Table 66.9.6.1.

*Exception: As modified by 66.9.6.2 and Chapters 10 through 14 of NFPA 30. [**30:**9.6.1]*

The term *maximum allowable quantities (MAQs) per control area*, as used in *NFPA 5000®, Building Construction and Safety Code®*, and in the model building and fire codes, is perhaps one of the most confusing terms in these codes, in that quantities in excess of the MAQs per control area can — and commonly do — exist. However, when the MAQs per control area are exceeded,

TABLE 66.9.6.1 *MAQ of Flammable and Combustible Liquids per Control Area*

	Liquid Class(es)	Quantity		Notes
		gal	L	
Flammable liquids	IA	30	115	1, 2
	IB and IC	120	460	1, 2
	IA, IB, IC combined	120	460	1, 2, 3
Combustible liquids	II	120	460	1, 2
	IIIA	330	1,265	1, 2
	IIIB	13,200	50,600	1, 2, 4

Notes:
(1) Quantities are permitted to be increased 100 percent where stored in approved flammable liquids storage cabinets or in safety cans in accordance with this *Code*. Where Note 2 also applies, the increase for both notes is permitted to be applied accumulatively.
(2) Quantities are permitted to be increased 100 percent in buildings equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13. Where Note 1 also applies, the increase for both notes is permitted to be applied accumulatively.
(3) Containing not more than the maximum allowable quantity per control area of Class IA, Class IB, or Class IC flammable liquids, individually.
(4) Quantities are not limited in a building equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13 and designed in accordance with the protection criteria contained in Section 66.16 of this *Code*. [**30:** Table 9.6.1]

the occupancy of the area is reclassified to a Protection Level 2 (High-Hazard Level 2) or Protection Level 3 (High-Hazard Level 3) category.

When the volumes of stored flammable and combustible liquids are below the MAQs per control area, the facility's existing occupancy classification is maintained. For example, an industrial or storage occupancy that stores liquids below the MAQs per control area is considered to be an industrial or storage occupancy without further qualification. When such an occupancy stores liquids in excess of the MAQs per control area, it is reclassified as Protection Level 2 (High-Hazard Level 2) or Protection Level 3 (High-Hazard Level 3). In most cases, liquid storage rooms and liquid warehouses store liquids in excess of the MAQs per control area and thus would be considered Protection Level 2 or Protection Level 3 occupancies, because the containers are kept closed.

Class I, Class II, and Class IIIA flammable or combustible liquids that are used or stored in normally open containers or systems or in closed containers or systems at gauge pressures of 15 psi (103 kPa) or greater are considered High-Hazard Level 2 contents, which require protection in accordance with Protection Level 2. Class I, Class II, or Class IIIA liquids that are used or stored in normally closed containers or in closed systems at gauge pressures of less than 15 psi (103 kPa) are considered High-Hazard Level 3 contents, which require protection in accordance with Protection Level 3.

Table 66.9.6.1 contains several general notes that allow the MAQs per control area to be increased from the basic quantity listed in the table. For example, Note (1) allows a 100 percent increase to the basic MAQ when all the liquids are stored in approved flammable liquids storage cabinets or in safety cans. Note (2) allows a 100 percent increase to the basic MAQ when the liquids are stored in a building equipped throughout with an approved automatic sprinkler system. In some situations, both Note (1) and Note (2) can be applicable to a storage situation, in which case both 100 percent increases are applied cumulatively.

Example

Table 66.9.6.1 allows the basic MAQ per control area for a combination of Class IA, Class IB, and Class IC liquids to be 120 gal (460 L). However, if these liquids are stored in approved flammable liquids storage cabinets, then Note (1) allows the MAQ per control area to be increased 100 percent, to a volume of 240 gal (920 L). If the storage cabinets are located in an area provided with an approved automatic sprinkler system, then Note (2) allows the MAQ per control area to be increased another 100 percent. Thus, the 240 gal (920 L) is increased to 480 gal (1840 L) per control area.

In this example, Note (3) is also applicable, which limits the amount of Class IA liquids in the total quantity. Thus, of the total MAQ of 480 gal (1840 L), only 120 gal (460 L) can be a Class IA flammable liquid, based on the basic MAQ for Class IA liquids being 30 gal (115 L), then being increased to 60 gal (230 L) for storage in approved flammable liquids storage cabinets, and then being increased again to 120 gal (460 L) for the cabinets located in an area provided with automatic sprinklers.

Note 4 is applicable only to the storage of Class IIIB combustible liquids in an area provided with a fire protection system that meets the requirements of Chapter 16. In such situations, the quantities are unlimited and no MAQ exists. If the fire protection system does not comply with Chapter 16, then Note (2) applies instead.

66.9.6.2 Special Occupancy Limits.

66.9.6.2.1 For the following occupancies, the MAQs per control area shall not exceed the amounts specified in Table 66.9.6.2.1:

(1) Assembly
(2) Ambulatory health care
(3) Business
(4) Day care
(5) Detention and correctional
(6) Educational
(7) Health care
(8) Residential

[**30:**9.6.2.1]

As indicated in the example given in the commentary to 66.9.6.1, the MAQ per control area for flammable and combustible liquids can be fairly generous [up to 480 gal (1840 L)] when the liquids are stored in approved storage cabinets within an area provided with automatic sprinklers. It was determined that such a generous quantity was excessive for the occupancies listed in 66.9.6.2.1, because those occupancies have normally high occupant loads and generally do not warrant having such quantities of flammable liquids. Thus, the MAQs listed in Table 66.9.6.2.1 represent the reduced quantities that the Technical Committee believes are justified for such occupancies. For the most part, these quantities actually represent the long-standing quantity limitations that existed in previous editions of NFPA 30.

66.9.6.2.2 For the occupancies specified in 66.9.6.2.1, storage in excess of 10 gal (38 L) of Class I and Class II liquids combined or in excess of 60 gal (227 L) of Class IIIA liquids shall be permitted where stored in flammable liquids storage cabinets and where the total aggregate quantity does not exceed 180 gal (680 L). [**30:**9.6.2.2]

TABLE 66.9.6.2.1 *MAQs — Special Occupancy Limits*

Liquid Class(es)	Quantity gal	Quantity L
I and II	10	38
IIIA	60	227
IIIB	120	454

[**30:** Table 9.6.2.1]

Some operations in the special occupancies listed in 66.9.6.2.1 might have a legitimate need for Class I and Class II liquids in excess of 10 gal (38 L) or for Class IIIA liquids in excess of 60 gal (230 L). For that reason, provisions were made in 66.9.6.2.2 to increase the MAQs provided that additional precautions exist, which in this situation requires the excess storage to be in flammable liquids storage cabinets. However, even storage in cabinets does not permit exceeding a maximum total quantity of liquid storage of 180 gal (680 L).

Regarding laboratories that might exist in some of the listed special occupancies, it should be noted that a laboratory stockroom is governed by NFPA 30, specifically the requirements for a liquid storage room, if the quantities exceed the MAQs. The quantities of liquids in the laboratory work area itself are governed by NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*.

66.9.6.2.3 Fuel in the tanks of operating mobile equipment shall be permitted to exceed the quantities specified in Table 66.9.6.1, where the equipment is operated in accordance with this *Code*. [**30:**9.6.2.3]

66.9.6.2.4 For ambulatory health care, day care, educational, and health care occupancies, the MAQ for Class IIIB liquids shall be permitted to be increased 100 percent if the building is protected throughout with an automatic sprinkler system installed in accordance with Section 13.3 and NFPA 13. [**30:**9.6.2.4]

66.9.7 Control Areas.

66.9.7.1 For the purpose of this *Code*, a control area shall be a space within a building where quantities of liquids that do not exceed the maximum quantities allowed by Table 66.9.6.1 or Table 66.9.6.2.1 are stored. [**30:**9.7.1]

Control areas are spaces or rooms within a building or an entire building where the quantities of hazardous materials, including flammable and combustible liquids, do not exceed the MAQs per control area when stored, used, or handled.

The *control area* concept, which encompasses 66.9.7 along with the MAQs addressed in 66.9.6, presents a method for the handling and storage of flammable and combustible liquids without classifying the occupancy as Protection Level 2 (High-Hazard Level 2) or Protection Level 3 (High-Hazard Level 3). To avoid being considered a Protection Level 2 or Protection Level 3 occupancy, the amount of flammable and combustible liquids within any single control area enclosed by fire barriers, horizontal assemblies, fire walls, and exterior walls cannot exceed the MAQ for the specific class of liquids listed in Table 66.9.6.1 or Table 66.9.6.2.1.

Note that some flammable and combustible liquid products might also have primary or secondary classifications that involve other hazardous properties, such as corrosivity or toxicity or that present some other hazard. For such products, the MAQs per control area for the other hazardous materials must also be considered in addition to the MAQs for the specific class of flammable or combustible liquids. The MAQs for other hazardous materials are listed in NFPA 400.

Δ **66.9.7.2** Control areas shall be separated from each other by fire barriers in accordance with Table 66.9.7.2. [**400:**5.2.2.1]

TABLE 66.9.7.2 *Design and Number of Control Areas*

Floor Level	Maximum Allowable Quantity per Control Area (percent)*	Number of Control Areas per Floor	Fire Resistance Rating for Fire Barriers (hr)†
Above grade			
>9	5	1	2
7–9	5	2	2
4–6	12.5	2	2
3	50	2	1
2	75	3	1
1	100	4	1
Below grade			
1	75	3	1
2	50	2	1
Lower than 2	NP	NP	N/A

NP: Not permitted. N/A: Not applicable.

*Percentages represent the MAQ per control area shown in Table 66.9.6.1, with all of the increases permitted in the footnotes of that table.

†Fire barriers are required to include floors and walls, as necessary, to provide a complete separation from other control areas.

[**400:**Table 5.2.2.1]

Control areas are compartments of a building surrounded by fire barrier walls and fire resistance–rated horizontal assemblies. If there are no fire barriers or fire resistance–rated horizontal assemblies, the entire building is considered a single control area. Thus, if the MAQs are exceeded in a building, fire barrier walls can be provided to create additional control areas, subject to the limitations of Table 66.9.7.2, so that the MAQs are not exceeded in any single control area. Doing so avoids classifying the building as Protection Level 2 (High-Hazard Level 2) or Protection Level 3 (High-Hazard Level 3).

Table 66.9.7.2 lists the number of control areas, the percentages of MAQs per control area, and the required fire resistance rating for fire barriers based on the location of the control area within a given floor level with respect to grade.

The noted percentages in the second column (Maximum Allowable Quantity per Control Area) of Table 66.9.7.2 are the percentages of the MAQs permitted per control area as listed in Table 66.9.6.1 and Table 66.9.6.2.1.

Example

For a first-floor control area, Table 66.9.6.1 allows an MAQ per control area of 240 gal (920 L) for Class IC flammable liquids when the building is equipped throughout with an approved automatic sprinkler system. If the control area were located on the second floor, Table 66.9.7.2 would limit the MAQ to 75 percent of that of the first floor, or 180 gal (680 L). Also, the number of control areas on the second floor would be limited to three, whereas four control areas would be permitted on the first floor.

The required fire resistance rating of the horizontal assembly above the control area is dictated by the required fire resistance rating of the fire barrier wall of the control area as listed in Table 66.9.7.2, the purpose of which is to maintain the continuity and integrity of the entire control area enclosure.

66.9.7.3 Control areas located below grade that are considered basements, as defined in 3.3.22, shall not be utilized for the storage of Class I liquids. [**30:**9.7.3]

66.9.8 Classification of Occupancies That Exceed the MAQs of Liquids per Control Area.

When the MAQs per control area are exceeded and no practical or economical options exist for reducing the quantities below the MAQs, the occupancy must be classified as a Protection Level 2 or Protection Level 3 for High-Hazard Level 2 or High-Hazard Level 3 contents, respectively.

Additional information on the protection level occupancy classifications and the high-hazard level content classifications can be found in *NFPA 5000*.

Exceeding the MAQs per control area for flammable and combustible liquids requires storage in a liquid storage room or a liquid warehouse constructed in accordance with Section 9.9 of NFPA 30.

66.9.8.1* Occupancy Classifications. Buildings and portions of buildings where liquids are stored shall be classified as Protection Level 2 or Protection Level 3, as established in this section, when the MAQs per control area are exceeded. [**30:**9.8.1]

Δ **A.66.9.8.1** The Protection Level classifications are taken from *NFPA 5000*. Protection Levels 1, 4, and 5 do not apply to the storage of flammable and combustible liquids and are therefore not extracted here. [**30:**A.9.8.1]

66.9.8.1.1 Protection Level 2. Buildings and portions thereof storing quantities of liquids that are considered as High-Hazard Level 2 liquids and that exceed the maximum allowable quantities per control area shall be classified as Protection Level 2 occupancies. [**30:**9.8.1.1]

Liquid storage rooms generally provide relatively large storage capacity for occupancies whose principal purpose is not the use of flammable and combustible liquids. For example, many hospitals, large university science departments, and private research and development facilities have a liquid storage room for storing bulk quantities of liquids to supply the various points of use throughout the facility. Because of the potential fire threat from inside liquid storage areas to the rest of the building, NFPA 30 sets rigid requirements for the design, construction, and operation of such rooms.

66.9.8.1.2 Protection Level 3. Buildings and portions thereof storing quantities of liquids that are considered as High-Hazard Level 3 liquids and that exceed the maximum allowable quantities per control area shall be classified as Protection Level 3 occupancies. [**30:**9.8.1.2]

Δ **66.9.8.2* Requirements for Specific Occupancies.** Liquids stored in Protection Level 2 or Protection Level 3 occupancies shall meet the applicable requirements for storage in a Liquid Storage Room or Liquid Warehouse as defined in this *Code* and in *NFPA 5000*. [**30:**9.8.2]

Δ **A.66.9.8.2** See *NFPA 5000* for additional requirements. [**30:**A.9.8.2]

66.9.9 Construction Requirements.

66.9.9.1 Storage areas shall be constructed to meet the fire resistance ratings specified in Table 66.9.9.1. Construction assemblies shall comply with the test specifications given in ASTM E119. [**30:**9.9.1]

Table 66.9.9.1 presents the required fire resistance ratings for the various construction elements of liquid storage rooms and liquid warehouses. The hourly ratings shown in the table are those that have been required in previous editions of the *Code*, with the

TABLE 66.9.9.1 *Fire Resistance Ratings for Liquid Storage Areas*

	Fire Resistance Rating (hr)		
Type of Storage Area	**Interior Walls[a], Ceilings, Intermediate Floors**	**Roofs**	**Exterior Walls**
Liquid storage room			
Floor area ≤ 150 ft²	1	—	—
Floor area > 150 ft², but ≤ 500 ft²	2	—	—
Liquid warehouse[b,c,g]	4[d]	—	2[e], 4[f]

For SI units, 1 ft² = 0.09 m².

[a]Between liquid storage areas and any adjacent areas not dedicated to liquid storage.

[b]Fire resistance ratings for liquid warehouses storing only Class IIIB liquids, which are not heated above their flash point, are permitted to be reduced to 2 hours.

[c]Fire resistance ratings for liquid warehouses protected in accordance with Section 66.16 are permitted to be reduced to 2 hours.

[d]This shall be a fire wall as defined in NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*.

[e]For exposing walls that are located more than 10 ft (3 m) but less than 50 ft (15 m) from an important building or line of adjoining property that can be built upon.

[f]For exposing walls that are located 10 ft (3 m) or less from an important building or line of adjoining property that can be built upon.

[g]For accessory use areas in protected liquid warehouses, such as offices and restrooms, whose combined area is less than 10 percent of the area of the warehouse, no fire resistance rating shall be required for the interior walls and ceilings.

[**30:** Table 9.9.1]

requirements for a liquid storage room being the same as those associated with the formerly used term *inside room*.

Liquid storage rooms cannot exceed 500 ft^2 (46 m^2) in area. This restriction limits the quantity of liquid present in any single liquid storage room, thus limiting the size of a potential fire (see also Table 12.6.1.1 of NFPA 30). Note that liquid storage rooms are not required to have direct access from outside the building. Thus, reaching any fire or related emergency situation within the room could be delayed, so it is reasonable to limit the quantity of liquid and the size of the area that will be involved.

Liquid warehouses must meet more restrictive construction standards than liquid storage rooms. This reflects the fact that the total quantity of liquid allowed to be stored in a protected liquid warehouse is not limited.

Note that at least 25 percent of the perimeter walls of a liquid warehouse must be an exterior wall (or walls) and any exterior wall area that exposes another building or another property line (that can be built on) is required to be of 4-hour fire-resistive construction if the adjacent building or property line is within 10 ft (3 m) and of 2-hour fire-resistive construction if the adjacent building or property line is more than 10 ft (3 m) but less than 50 ft (15 m) away. This requirement reflects the fact that a flammable or combustible liquid fire presents a greater-than-normal threat to exposed structures. A rating of 2- or 4-hour construction provides a lateral barrier to the transmission of thermal radiation to the exposed structures. Note that the requirement for fire-resistive exterior walls applies only if the separation distance between the liquid warehouse and the exposed property is 50 ft (15 m) or less.

66.9.9.2 Openings in interior walls to adjacent rooms or buildings and openings in exterior walls with fire resistance ratings shall be provided with normally closed, listed fire doors with fire protection ratings that correspond to the fire resistance rating of the wall as specified in Table 66.9.9.2. [**30:**9.9.2]

Note that for attached liquid warehouses requiring an interior 4-hour fire-resistive-rated wall in accordance with NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls,* one 3-hour-rated fire door is required on each side of any interior opening. This requirement is intended to ensure the integrity of the fire barrier even if the roof should collapse on the fire-exposed side of the wall. If the fire door on the exposed side is torn off its track, as is likely if roof collapse occurs, the door on the unexposed face of the wall would still protect the opening.

Δ ***TABLE 66.9.9.2*** *Protection Ratings for Fire Doors*

Fire Resistance Rating of Wall as Required by Table 66.9.9.1 (hr)	Fire Protection Rating of Door (hr)
1	¾
2	1½
4	3*

*One fire door required on each side of interior openings for attached liquid warehouses. [**30:** Table 9.9.2]

66.9.9.2.1 Such doors shall be permitted to be arranged to stay open during material-handling operations if the doors are designed to close automatically in a fire emergency by provision of listed closure devices. [**30:**9.9.2.1]

Δ **66.9.9.2.2** Fire doors shall be installed in accordance with NFPA 80. [**30:**9.9.2.2]

66.9.9.3 Exterior walls shall be constructed to provide ready access for fire-fighting operations by means of access openings, windows, or lightweight, noncombustible wall panels.

Exception: This requirement does not apply to liquid storage rooms totally enclosed within a building. [30:9.9.3]

66.9.10 Fire Protection.

66.9.10.1 Protected Storage. Fire protection requirements for protected storage shall meet the requirements of 66.9.10.2 and Section 66.16. [**30:**9.10.1]

66.9.10.2 Manual Fire Protection.

66.9.10.2.1 Portable fire extinguishers shall be provided in accordance with Section 13.6 and NFPA 10. [**30:**9.10.2.1]

Δ **66.9.10.2.2** Portable fire extinguishers shall meet the following requirements:

(1) At least one portable fire extinguisher having a capability of not less than 40:B shall be located outside of, but not more than 10 ft (3 m) from, the door opening into a liquid storage area.
(2) At least one portable fire extinguisher having a capability of not less than 40:B shall be located within 30 ft (9 m) of any Class I or Class II liquids located outside of a liquid storage area, or at least one portable fire extinguisher having a capacity of 80:B shall be located within 50 ft (15 m) of such a storage area.

[**30:**9.10.2.2]

Portable fire extinguishers are required to be located outside but relatively close to the liquid storage area because fires involving Class I and Class II liquids are likely to escalate rapidly. If the fire extinguisher is inside or too close to the storage area, it might be impossible to get to it once the fire has started.

66.9.10.2.3 Where provided, hose connections supplied from sprinkler systems shall be installed in accordance with Section 13.3 and NFPA 13. [**30:**9.10.2.3]

66.9.10.2.4 Where provided, hose connections supplied by a standpipe system shall be installed in accordance with Section 13.2 and NFPA 14. [**30:**9.10.2.4]

66.9.10.2.5 Where provided, hose connections shall also meet the following requirements:

(1) Hose connections shall be provided in protected general-purpose warehouses and in protected liquid warehouses.
(2) Where preconnected hose is provided, it shall be either 1½ in. (38 mm) lined fire hose or 1 in. (25 mm) hard rubber hose, using combination spray and straight stream nozzles.

[**30:**9.10.2.5]

66.9.10.2.6 Where hose connections are provided, the water supply shall be sufficient to meet the fixed fire protection demand plus a total of at least 500 gpm (1900 L/min) for inside and outside hose connections for at least 2 hours, unless otherwise specified in Section 66.16. [**30:**9.10.2.6]

The intent of 66.9.10.2.6 is to establish the minimum total water supply required for the entire storage area or facility. The 500 gpm (1900 L/min) for inside and outside hose streams is intended to be the combined demand, as opposed to 500 gpm (1900 L/min) for each.

66.9.11 Emergency Control Systems. (Reserved)

66.9.12 Electrical Systems.

66.9.12.1 Electrical area classification shall not be required for liquid storage areas where all containers, intermediate bulk containers, and portable tanks are sealed and are not opened, except as provided for in 66.9.12.2. [**30:**9.12.1]

66.9.12.2 For liquid storage rooms that are totally enclosed within the building, electrical wiring and utilization equipment for Class I liquid storage shall be Class I, Division 2 (Zone 2), and electrical wiring and utilization equipment in inside rooms used for the storage of Class II and Class III liquids shall be suitable for ordinary purpose.

*Exception: Class I, Division 2 (Zone 2) requirements shall apply to Class II and Class III liquids when stored at temperatures above their flash points. [**30:**9.12.2]*

In smaller liquid storage rooms utilized for the storage of Class I flammable liquids, particularly those rooms totally enclosed within a building (i.e., having no exterior walls), the provision of electrical wiring and utilization equipment for Class I, Division 2 (Zone 2) is necessary because of the potential for ignition of flammable vapors from a spill or leaking container.

Additionally, Class II and Class III combustible liquids handled at temperatures above their flash points have the combustibility characteristics of Class I flammable liquids and must be treated accordingly with respect to the choice of electrical equipment and wiring methods.

It is also noted that Class I, Division 1 electrical equipment must be used in the immediate vicinity of any points where ignitible vapor releases are expected, such as areas involving transfer operations.

Not all "vaporproof" types of lighting fixtures are suitable for use in atmospheres containing ignitible vapors. This designation often refers only to the fixture's capability to prevent moisture from entering its interior. Approved fixtures are properly labeled for their use and are indicated as being "vaportight" or "explosionproof."

66.9.13* Containment, Drainage, and Spill Control.

A.66.9.13 Spill containment can be accomplished by any of the following:

(1) Noncombustible, liquidtight raised sills, curbs, or ramps of suitable height at exterior openings
(2) Noncombustible, liquidtight raised sills, curbs, or ramps of suitable height, or other flow-diverting structures at interior openings
(3) Sloped floors
(4) Open-grate trenches or floor drains that are connected to a properly designed drainage system
(5) Wall scuppers that discharge to a safe location or to a properly designed drainage system
(6) Other means that are acceptable to the AHJ

[**30:**A.9.13]

Where sills, curbs, or ramps are used, the appropriate height will depend on a number of factors, including the maximum expected spill volume, the floor area, and the existence of any drainage systems. Historically, curbs and sills have been 4 in. (100 mm) high. [**30:**A.9.13]

A variety of curb, sill, and ramp heights can be used to obtain the desired containment volume. As a guide, 1 ft^2 of water at a depth of 1 in. equals 0.6 gal (1 m^2 of water @ 25 mm = 25 L). Once the total quantity of liquid containment has been established, the necessary curb, sill, or ramp height can then be calculated. [**30:**A.9.13]

Where open-grate trenches are used, the volume of the trench should be able to contain the maximum expected spill volume or otherwise be connected to a properly designed drainage system. [**30:**A.9.13]

It should be noted that these containment and drainage provisions address only fire protection concerns. Consult the appropriate environmental regulations for other restrictions that could apply. [**30:**A.9.13]

The containment, drainage, and spill control requirements of Section 9.13 apply to the storage of liquids in containers greater than 10 gal (38 L) stored in all liquid storage rooms and liquid warehouses, with the exception of those liquids covered in 66.9.13.4 and 66.9.13.5, which do not require containment, drainage, or spill control.

The primary concerns of the requirements in 66.9.13 are the mitigation of fire hazard resulting from a spill and the prevention of spilled liquids and contaminated fire water from reaching public waterways, public sewers, or adjoining property. The intent is also to prevent a spill from migrating to other parts of the facility where it might be ignited. If the spill has already been ignited, there is also concern that sprinkler discharge will float burning liquid beyond the immediate area.

Spill control must be sized for the largest credible spill. In most cases, this will constitute the single largest container present. Note that containment or drainage is not required if the individual containers do not exceed 10 gal (38 L). The Technical Committee on Storage and Warehousing of Containers and Portable Tanks is not convinced that justification exists for imposing such costly requirements on facilities that store such minimal quantities.

66.9.13.1 Storage areas shall be designed and operated to prevent the discharge of liquids to public waterways, public sewers, or adjoining property, unless such discharge has been specifically approved. [**30:**9.13.1]

66.9.13.1.1 Where the drainage system discharges to private or public sewers or waterways, the drainage system shall be equipped with traps and separators. [**30:**9.13.1.1]

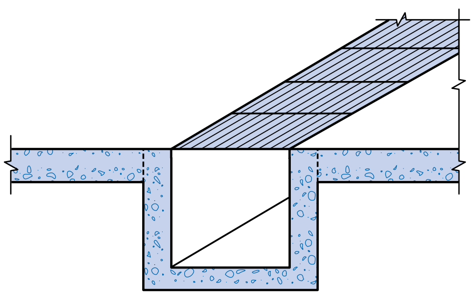
66.9.13.2 Where individual containers exceed 10 gal (38 L), curbs, scuppers, drains, or other suitable means shall be provided to prevent flow of liquids under emergency conditions into adjacent building areas. [**30:**9.13.2]

The intent of 66.9.13.2 is to prevent the flow of burning liquids to uninvolved parts of a building due to sprinkler discharge. This accomplishes two objectives: (1) By limiting the spread of burning liquid, adjacent storage arrays do not become involved in the fire; and (2) by preventing the spread of fire, sprinkler actuation is limited to those sprinklers directly over and adjacent to the principal fire area, thus minimizing the chance that the sprinkler system will be overtaxed. Because most liquids that are immiscible with water are also lighter than water, it is important that the capacity of the drainage system be sufficient to drain the water from the fire protection system and hose streams, as well as the flammable liquid itself. Curbs and sills are the most common method of meeting the requirement. If an open-grated trench is used, it must extend across the entire opening (door) into the room and must be located on the inside of the room. Use of a trench is sometimes preferred where there is an extensive need to transfer flammable liquids into and out of the room by means of hand trucks. Exhibit 66.18 illustrates some design features of trenches.

66.9.13.3 Containment or drainage to an approved location shall be provided. [**30:**9.13.3]

Depending on the estimated size of a spill and expected sprinkler discharge, any means used to contain a spill might need some means to transport the spilled liquid and sprinkler discharge out of the containment and to a safe place where it can be held. This consideration is obviously true for a drainage system or a doorway trench. The containment/drainage design in such cases must include some means to collect the spill and associated runoff in a place where the runoff will not expose either the facility itself or neighboring facilities, public roads, streams, and so on. Where expected quantities of runoff are reasonably small, one or more catch tanks can be used. These would typically be underground tanks. Where catch tanks are deemed impractical, an impoundment of some type should be used. In either case, environmental regulations must be considered. Although not intended for the use described here, some helpful information on impoundments can be found in 66.22.11.1.

Exhibit 66.18



Drainage trench with steel grating cover

Drainage trench details.

66.9.13.3.1 Where a drainage system is used, it shall also have sufficient capacity to carry the expected discharge of water from fire protection systems. [**30:**9.13.3.1]

66.9.13.4 Where only Class IIIB liquids are stored, spill control, containment, and drainage shall not be required. [**30:**9.13.4]

66.9.13.5 Where only unsaturated polyester resins (UPRs) containing not more than 50 percent by weight of Class IC, Class II, or Class IIIA liquid constituents are stored and are protected in accordance with 66.16.5.2.11, spill control, containment, and drainage shall not be required. [**30:**9.13.5]

66.9.13.6 Where storage is protected in accordance with Section 66.16, spill control, containment, and drainage shall also meet the requirements of 66.16.8. [**30:**9.13.6]

66.9.14 Ventilation. Liquid storage areas where dispensing is conducted shall be provided with ventilation that meets the requirements of 66.18.6. [**30:**9.14]

Ventilation is vital to the prevention of flammable liquid fires and explosions. In a room where the potential accumulation of vapors could fall within the flammable range of the stored material, every effort must be made to confine, remove, or dilute the vapors, thereby reducing the probability of ignition. The vapors from most liquids are denser than air, which is the reason for requiring exhaust ventilation to be initiated at or near the floor level. See 66.18.6 for more information.

66.9.15 Exhausted Enclosures. (Reserved)

66.9.16 Explosion Control.

Δ **66.9.16.1*** Where Class IA liquids are stored in containers larger than 1 gal (4 L), areas shall be provided with a means of explosion control that meets the requirements of NFPA 69. An approved engineered damage limiting construction design shall also be permitted.

*Exception: This shall not apply to a liquid storage room totally enclosed within a building. [**30:**9.16.1]*

Δ **A.66.9.16.1** Release of a Class IA liquid into a room or enclosure can result in the evolution of large quantities of flammable vapor. The ignition of this flammable mixture can result in a significant pressure rise, the production of hot combustion gases, and flame. Failure to adequately design a room or building for this type of event can result in the failure of the room or building walls and/or roof and the uncontrolled release of the hot combustion gases, flames, and pressure. An acceptable method of protection against this type of event is the use of damage-limiting construction consisting of a combination of pressure-relieving construction and pressure-resistant construction as described in NFPA 68. [**30:**A.9.16.1]

66.9.16.2* Where unstable liquids are stored, an approved engineered construction method that is designed to limit damage from a deflagration or detonation, depending on the liquid stored, shall be used. [**30:**9.16.2]

A.66.9.16.2 Unstable liquids can create deflagration or detonation hazards. A complete engineering review of the type of explosion event that might be produced by an unstable liquid is needed to define the necessary protection measures. Protection measures for detonations require construction features such as barricades. [**30:**A.9.16.2]

66.9.17 Separation from Incompatible Materials.

66.9.17.1 Except as provided for in 66.9.17.3, liquids shall be separated from incompatible materials where the stored materials are in containers having a capacity of more than 5 lb (2.268 kg) or ½ gal (1.89 L). [**30:**9.17.1]

A number of materials are incompatible with flammable and combustible liquids and must not be stored in the same area because a hazardous and/or exothermic reaction could occur upon contact. Such reactions could act as a potential ignition source.

The safety data sheet for each liquid should include information identifying any materials with which the liquid is incompatible. Another useful source of information is NFPA 491, *Compilation of Hazardous Chemical Reactions*, which is a part of the *Fire Protection Guide to Hazardous Materials*. See also 46 CFR 150, "Compatibility of Cargoes," for the U.S. Coast Guard's chemical incompatibility chart, which is used to isolate incompatible cargoes on marine vessels.

66.9.17.1.1 Separation shall be accomplished by one of the following methods:

(1) Segregating incompatible materials storage by a distance of not less than 20 ft (6.1 m)
(2) Isolating incompatible materials storage by a noncombustible partition extending not less than 18 in. (460 mm) above and to the sides of the stored materials
(3) Storing liquid materials in flammable liquids storage cabinets in accordance with 66.9.5

[**30:**9.17.1.1]

Δ **66.9.17.2** Liquids shall be separated from Level 2 and Level 3 aerosols in accordance with Chapter 61 and NFPA 30B. [**30:**9.17.2]

NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products,* contains several requirements that cover the storage of flammable liquids in areas used mainly for aerosol storage. One such requirement, involving the segregated storage of aerosols, requires flammable and combustible liquids to be separated from the aerosol storage area by a minimum distance of 25 ft (7.6 m). Another such requirement allows the storage of flammable and combustible liquids in metal containers of 1 qt (0.9 L) capacity or less in an aerosol warehouse if automatic sprinkler protection, as required for this situation by NFPA 30B, is provided.

66.9.17.3 Flammable and combustible liquids shall be separated from oxidizers by at least 25 ft (7.6 m). [**30:**9.17.3]

Δ **66.9.17.4** Materials that are water-reactive, as described in NFPA 704 shall not be stored in the same control area with liquids. [**30:**9.17.4]

Materials that are water-reactive can generate heat or become combustible when exposed to water or other liquids, which could result in a potential ignition source. For that reason, water-reactive materials must not be stored in the same area or room with flammable or combustible liquids.

66.9.18 Dispensing, Handling, and Use of Liquids in Storage Areas.

66.9.18.1 Dispensing, handling, and use of liquids shall meet all applicable requirements of Section 66.18. [**30:**9.18.1]

66.9.18.2 Dispensing of Class I liquids or Class II and Class III liquids at temperatures at or above their flash points shall not be permitted in storage areas that exceed 1000 ft^2 (93 m^2) in floor area unless the dispensing area is separated from the storage areas in accordance with Table 66.9.9.1 and meets all other requirements of 66.9.9. [**30:**9.18.2]

The rationale of 66.9.18.2 is that dispensing of liquids would introduce an additional hazard to the storage area. Therefore, the size of the room where dispensing is allowed is restricted. Where dispensing takes place, other restrictions are imposed in addition to the limitation on room size.

66.9.19 Outdoor Storage of Liquids. Storage of liquids outside of buildings shall meet the requirements of Section 66.14 or 66.15, whichever is applicable. [**30:**9.19]

66.13 Reserved

66.14 Hazardous Materials Storage Lockers

66.14.1* Scope. This section shall apply to the storage of liquids in movable, modular, prefabricated storage lockers, also known as hazardous materials storage lockers (hereinafter referred to as lockers), specifically designed and manufactured for storage of hazardous materials, in the following:

(1) Containers that do not exceed 119 gal (450 L) individual capacity
(2) Portable tanks that do not exceed 660 gal (2500 L) individual capacity
(3) Intermediate bulk containers that do not exceed 793 gal (3000 L) individual capacity

[**30:**14.1]

Δ **A.66.14.1** Environmental concerns have dictated special handling of hazardous materials, chemicals, and wastes. Some of these have flammable and combustible liquid characteristics, in addition to their environmental and health problems, thus causing some questions as to how they should be stored and handled. [**30:**A.14.1]

Several manufacturers have met this problem by designing and manufacturing movable, modular prefabricated storage lockers, working diligently with various building officials and AHJs. This results in a product that is intended to meet government standards and regulations for hazardous materials storage. Several municipalities have passed model ordinances covering the design, construction, and location of hazardous materials storage lockers. Design features can include, but are not limited to, the following:

(1) Secondary spill containment sumps
(2) Deflagration venting
(3) Ventilation requirements, including mechanical ventilation where dispensing operations are expected
(4) Electrical equipment for hazardous locations in accordance with *NFPA 70*
(5) Static electricity control
(6) Fire suppression systems (dry chemical or sprinklers)
(7) Heavy structural design for the following:
    (a) Security provisions
    (b) Doors that lock and permit pallet loading
    (c) Wind load, snow load, and storage load conditions
    (d) Anchorage provisions
    (e) Skid design, permitting relocation using lift trucks
(8) Fire-related exterior walls, if required
(9) Interior partitions to segregate incompatible materials
(10) Size limits to limit quantities that can be stored within preassembled or ready-to-assemble designs
(11) Nonsparking floors
(12) Shelving, if required
(13) Heating or cooling units, if needed
(14) Corrosion protection as required
(15) Employee safety provisions (eye/face wash)
(16) NFPA 704 hazard symbols

[**30:**A.14.1]

Features provided are determined by specific storage requirements and needs of the owner, keeping in mind applicable regulations and ordinances that apply and the approval requirements of the AHJ. [**30:**A.14.1]

Several testing laboratories have developed internal procedures for the examination, testing, and listing or labeling of hazardous materials storage lockers submitted by manufacturers. [**30:**A.14.1]

Exhibit 66.19

Exhibit 66.20

A larger version of the locker shown in Exhibit 66.19. This model offers four times the storage capacity in addition to the same features as the locker shown in Exhibit 66.19. (Courtesy of DENIOS, Inc.)

Examples of hazardous materials storage lockers are shown in Exhibit 66.19 and Exhibit 66.20.

66.14.2 Reserved.

66.14.3 General Requirements.

66.14.3.1 Lockers that are used as liquid storage rooms shall meet the requirements of Section 66.9. [**30:**14.3.1]

A hazardous materials storage locker is an excellent means of providing a liquid storage room, particularly in manufacturing facilities where the room might have to be relocated to accommodate changes in the manufacturing process, such as in an automotive assembly plant where the assembly line might have to be changed. Where used as a liquid storage room inside a building, the walls and roof of the locker need to have a 1-hour or 2-hour fire rating, in accordance with Table 66.9.9.1. Note that a locker used outdoors is not required to be fire rated, although reductions from the separation distances imposed by Table 66.14.5.2 are allowed where the lockers are fire rated.

66.14.3.2 Lockers that are located outside shall meet the requirements of Sections 14.4 through 14.6 of NFPA 30. [**30:**14.3.2]

66.14.4 Design and Construction of Hazardous Materials Storage Lockers.

66.14.4.1 The design and construction of a locker shall meet all applicable local, state, and federal regulations and requirements and shall be subject to the approval of the AHJ. [**30:**14.4.1]

There are no construction standards, per se, for hazardous materials storage lockers. In most cases, they will be used as (or as a substitute for) a permanent building or structure. Therefore, they might have to meet certain local building code requirements. They must also meet all applicable federal requirements for the safe storage of hazardous materials.

66.14.4.2 Movable prefabricated structures that have been examined, listed, or labeled by an organization acceptable to the AHJ for use as a hazardous materials storage facility shall be acceptable. [**30:**14.4.2]

66.14.4.3 Lockers shall not exceed 1500 ft^2 (140 m^2) gross floor area. [**30:**14.4.3]

The largest locker currently manufactured is about 12 ft × 40 ft (3.7 m × 12 m), or about the size of the typical van semi-trailer. However, the concept of these lockers is so attractive that larger modular units could well be offered. These units likely would be supplied as a single large unit or in two or more modular sections that are connected on site, in much the same manner as modular housing is constructed and transported. In any case, it was felt that 1500 ft^2 (140 m^2) was a reasonable maximum size. If a larger structure is required, it should be a permanent structure meeting the requirements of an attached building or liquid warehouse.

66.14.4.4 Vertical stacking of lockers shall not be permitted. [**30:**14.4.4]

66.14.4.5 Where electrical wiring and equipment are required, they shall comply with Section 66.7 and 66.9.12. [**30:**14.4.5]

66.14.4.6 Where dispensing or filling is permitted inside a locker, operations shall comply with the provisions of Section 66.18. [**30:**14.4.6]

66.14.4.7 Ventilation shall be provided in accordance with 66.18.6. [**30:**14.4.7]

66.14.4.8 Lockers shall include a spill containment system to prevent the flow of liquids from the locker under emergency conditions. [**30:**14.4.8]

The word *structure* has been replaced with the word *locker* to ensure that this requirement is interpreted as applying to the locker itself and not to a building in which a locker might be located.

66.14.4.8.1 The containment system shall have sufficient capacity to contain 10 percent of the volume of containers allowed in the locker or the volume of the largest container, whichever is greater. [**30:**14.4.8.1]

The 10 percent retention capacity requirement is based on and equal to the EPA Resource Conservation and Recovery Act (RCRA) requirement for hazardous waste storage facilities. Because it was anticipated that these lockers would be used mainly (at least initially) for RCRA compliance, the 10 percent spill retention capability has become a de facto design standard.

66.14.5 Designated Sites for Hazardous Materials Storage Lockers.

66.14.5.1 Lockers shall be located on a designated approved site on the property. [**30:**14.5.1]

66.14.5.2 The designated site shall be arranged to provide the minimum separation distances specified in Table 66.14.5.2 between individual lockers, from locker to property line that is or can be

Δ ***TABLE 66.14.5.2*** *Designated Sites*

	Minimum Separation Distance (ft)		
Area of Designated Site[a] (ft^2)	Between Individual Lockers	From Locker to Property Line That Is or Can Be Built Upon[b]	From Locker to Nearest Side of Public Way or to Important Buildings on Same Property[b,c]
≤100	5	10	5
>100 and ≤500	5	20	10
>500 and ≤1500[d]	5	30	20

For SI units, 1 ft = 0.3 m; 1 ft^2 = 0.09 m^2.

Note: If the locker is provided with a fire resistance rating of not less than 4 hours and deflagration venting is not required in accordance with 66.9.15, all distances required by Table 66.14.5.2 are permitted to be waived.

[a]Site area limits are intended to differentiate the relative size and thus the number of lockers that are permitted in one designated site.

[b]Distances apply to properties that have protection for exposures, as defined. If there are exposures and such protection for exposures does not exist, the distances should be doubled.

[c]When the exposed building has an exterior wall, facing the designated site, that has a fire resistance rating of at least 2 hours and has no openings to above grade areas within 10 ft (3 m) horizontally and no openings to below grade areas within 50 ft (15 m) horizontally of the designated area, the distances can be reduced to half of those shown in the table, except they should never be less than 5 ft (1.5 m).

[d]When a single locker has a gross single story floor area that will require a site area limit of greater than 1500 ft^2 (140 m^2) or when multiple units exceed the area limit of 1500 ft^2 (140 m^2), the AHJ should be consulted for approval of distances. [**30:** Table 14.5.2]

built upon, and from locker to nearest side of public ways or to important buildings on the same property. [**30:**14.5.2]

As stated in footnote a to Table 66.14.5.2, the required separation distance between two adjacent lockers and the setback distances from property lines, public ways, and adjacent buildings are based on the relative sizes of lockers currently available. If the area available for a "designated site" is limited, it might well dictate the maximum size and/or the number of lockers that can be used in a given situation. Conversely, if a certain storage capacity is needed, then sufficient space must be found for the designated site.

Footnote c is similar to the provisions in 66.15.4.1 for outside storage and allows some leniency in siting where the exposure to the adjacent structure is minimal.

Footnote d establishes some additional flexibility. Obviously, if a single unit has the maximum gross floor area allowed — 1500 ft^2 (140 m^2) — the designated site must exceed the maximum allowable size given in the table. The same problem arises if several large units are located adjacent to each other. The AHJ should deal with such situations on a case-by-case basis.

Exhibit 66.21 illustrates application of the provisions of Table 66.14.5.2.

66.14.5.3 Once the designated site is approved, it shall not be changed without the approval of the AHJ. [**30:**14.5.3]

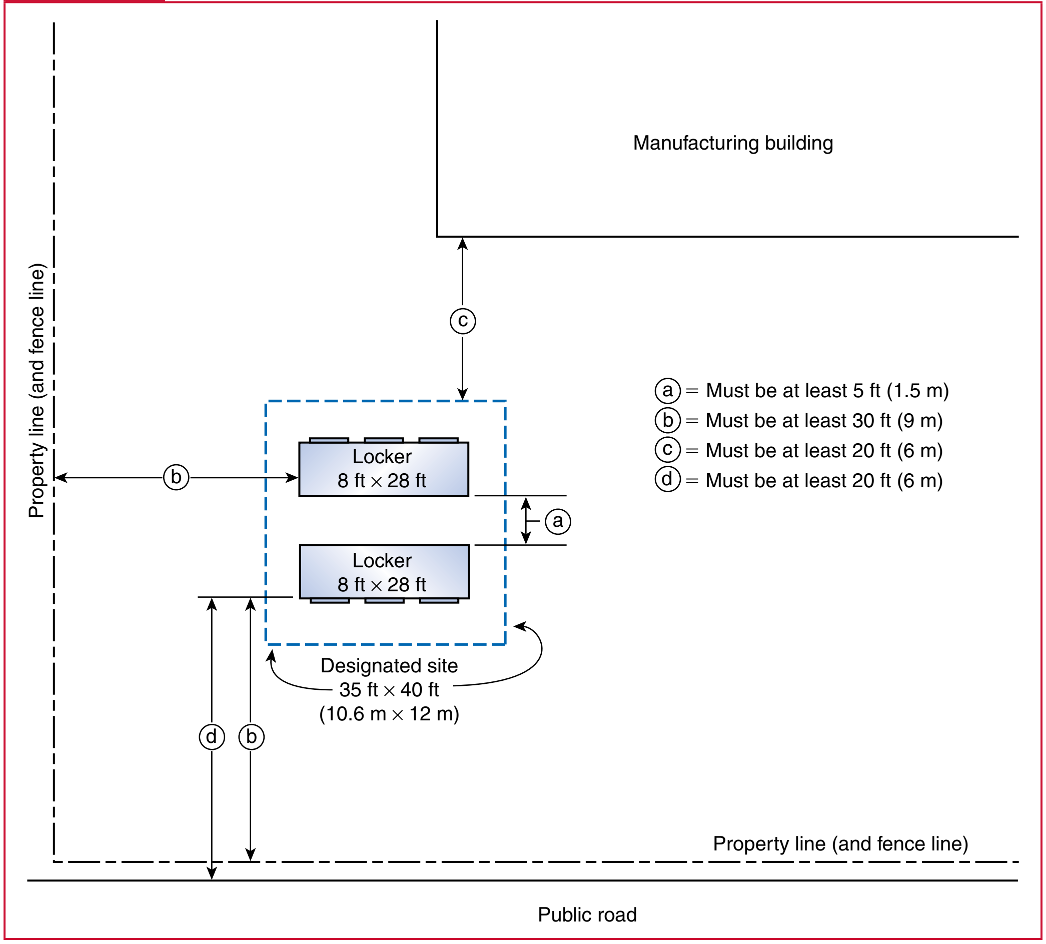
Because the lockers are movable, it is appropriate to establish a rule that, once the designated site has been chosen and approved by the AHJ, it cannot be changed or altered without the further consultation and approval of the AHJ.

66.14.5.4 More than one locker shall be permitted on a designated site, provided that the separation distance between individual lockers is maintained in accordance with Table 66.14.5.2. [**30:**14.5.4]

66.14.5.5 Where the approved designated storage site is accessible to the general public, it shall be protected from tampering or trespassing. [**30:**14.5.5]

The provision in 66.14.5.5 is an important requirement for these lockers. Even though the lockers are relatively secure by design, it was deemed necessary to protect the site from trespassing and vandalism. Compliance will likely require that the site be enclosed by a fence or a barricade, although the exact means is not specified by the *Code*.

Exhibit 66.21



Separation distances for hazardous materials storage lockers, in accordance with Table 66.14.5.2.

66.14.6 Storage Requirements.

66.14.6.1 Containers of liquid in their original shipping packages shall be permitted to be stored either palletized or solid piled within the locker. [**30:**14.6.1]

66.14.6.2 Unpackaged containers shall be permitted to be stored on shelves or directly on the floor of the locker. [**30:**14.6.2]

66.14.6.3 Containers over 30 gal (114 L) capacity storing Class I or Class II liquids shall not be stored more than two containers high. [**30:**14.6.3]

Stacking of larger containers is not allowed due to the potential for toppling of containers. Where storage needs dictate, a locker specifically designed for two-tier storage should be selected.

66.14.6.4 In all cases, the storage arrangement shall provide unrestricted access to and egress from the locker. [**30:**14.6.4]

Special attention needs to be paid to safe storage practices that maintain unrestricted movement of personnel when they are inside the locker. Space will typically be at a premium. Clear space needs to be provided for access for emergency activities should they be necessary. Likewise, anyone who is inside the locker must be able to evacuate quickly in an emergency.

66.14.6.5 Miscellaneous combustible materials, including but not limited to idle pallets, excessive vegetation, and packing materials, shall not be permitted within 5 ft (1.5 m) of the designated site approved for lockers. [**30:**14.6.5]

66.14.6.6 Warning signs for lockers shall be in accordance with applicable local, state, and federal regulations or with NFPA 704. [**30:**14.6.6]

66.15 Outdoor Storage

In some cases, flammable and combustible liquids will be stored outdoors rather than inside a building. While outdoor storage eliminates the possibility of a fire inside the building, a fire involving outdoor storage still presents a risk of damage to adjacent structures or storage. Outdoor storage does, however, allow for unrestricted dispersal of heat, smoke, and products of combustion. Additionally, because of the ease of access, a fire in an outdoor storage area can be more readily controlled by manual fire-fighting operations than one within a structure.

Outdoor storage does present security problems. While storage of liquids outdoors reduces the potential for fire damage to the main structure, the liquids are more accessible to vandals. Facility management should conduct a security vulnerability assessment in accordance with 66.6.10.

For the purposes of this chapter, outdoor storage is considered to include any storage area covered by a roof that provides weather protection for the containers, as long as the arrangement of the roof will not confine heat, smoke, and products of combustion. This same area might have one or two (but no more) walls without materially affecting natural ventilation, but the walls must not provide any confinement.

In addition to these requirements for outdoor storage, environmental requirements must also be considered, particularly in relation to groundwater pollution. Additional curbing or a drainage system might have to be provided to control any spill that might occur. Drainage or collection systems must be assessed from a fire protection standpoint to eliminate a fire hazard in areas to which the spilled liquids drain, no matter how remote from the storage.

66.15.1 Scope. This section shall apply to the storage of liquids outdoors in the following:

(1) Drums or other containers that do not exceed 119 gal (450 L) individual capacity
(2) Portable tanks that do not exceed 660 gal (2500 L) individual capacity
(3) Intermediate bulk containers that do not exceed 793 gal (3000 L) individual capacity

[**30:**15.1]

66.15.2 Reserved.

66.15.3 General Requirements. Outdoor storage of liquids in containers, intermediate bulk containers, and portable tanks shall comply with Table 66.15.3 and with all applicable requirements of this section. [**30:**15.3]

Note the eighth column, labeled "Minimum Separation Distance Between Piles or Rack Sections." This clearance must be maintained to allow emergency access for fire fighting.

66.15.3.1 Where two or more classes of liquids are stored in a single pile, the maximum quantity permitted in that pile shall be that of the most hazardous class of liquid present. [**30:**15.3.1]

The requirement in 66.15.3.1 means that the pile takes on the identity of the more hazardous class and that the total amount of liquids in the pile cannot exceed what is allowed for that class. The following three examples illustrate how Table 66.15.3 is applied.

Example 1

There are 1700 gal (6434.5 L) of a Class II liquid in drums stored outside a warehouse. How many gallons (liters) of a Class IB liquid can be stored in the same pile?

Solution:

The Class IB storage is more hazardous, so provisions governing IB pile storage are applicable. (See 66.15.3.1.) The maximum allowed per pile is 2200 gal (8327 L). Because the storage already consists of 1700 gal (6434.5 L) of a Class II liquid, only 500 gal (1892.5 L) of a Class IB liquid can be stored in the same pile.

Example 2

Consider a manufacturing plant where it has been decided that there is no protection for adjacent exposed properties. Several

TABLE 66.15.3 Storage Limitations for Outside Storage

	Containers		Portable Tanks and Metal IBCs		Rigid Plastic and Composite IBCs		Minimum Separation Distance (ft)		
Liquid Class	Maximum Quantity per Pile (gal)[a,b,c]	Maximum Storage Height (ft)	Maximum Quantity per Pile (gal)	Maximum Storage Height (ft)	Maximum Quantity per Pile (gal)[a,c]	Maximum Storage Height (ft)	Between Piles or Rack Sections	To Property Line That Is or Can Be Built Upon[b,d]	To Street, Alley, or Public Way[b]
IA	1,100	10	2,200	7	NP	NP	5	50	10
IB	2,200	12	4,400	14	NP	NP	5	50	10
IC	4,400	12	8,800	14	NP	NP	5	50	10
II	8,800	12	17,600	14	8,800	14	5	25	5
III	22,000	18	44,000	14	22,000	18	5	10	5

For SI units, 1 ft = 0.3 m; 1 gal = 3.8 L.

NP: Not permitted.

[a]See 66.15.3.1 regarding mixed-class storage.

[b]See 66.15.3.4 for smaller pile sizes.

[c]For storage in racks, the quantity limits per pile do not apply, but the rack arrangements should be limited to a maximum of 50 ft (15 m) in length and two rows or 9 ft (2.7 m) in depth.

[d]See 66.15.3.3 regarding protection for exposures. [**30:** Table 15.3]

piles of drums containing a Class IB liquid are located 125 ft (38 m) from the nearest property line that can be built upon. An industrial plant on an adjacent property is in the process of forming its own fire brigade. What will be the new distance requirement for the containers?

Solution:

Where there is no protection for exposures, the distance specified in Table 66.15.3 must be doubled in accordance with 66.15.3.3. Thus, 100 ft (30 m) is needed. The plant in question has its storage 125 ft (38 m) away, so there is no violation. Where the protection for exposures is in effect, the plant can move its storage to within 50 ft (15 m) of its neighbor. See Exhibit 66.22.

Example 3

How close to an adjacent property that can be built upon and how close to a nearby street is a manufacturing plant allowed to place 2300 gal (8706 L) of kerosene (Class II) in drums? Assume there is no protection for exposures.

Solution:

With no protection for exposures, the distance to the property line, as given in Table 66.15.3, must be doubled, to 50 ft (15 m). (See 66.15.3.3.) However, the plant is allowed to store 8800 gal (33,308 L) but has stored only 2300 gal (8706 L). This amount is substantially less than 50 percent of the allowable amount, so the plant can reduce the required distance by 50 percent, back to 25 ft (7.5 m), per 66.15.3.4. Similarly, the plant can reduce the distance to the street by 50 percent, but to no less than 3 ft (0.90 m). Therefore, the plant's storage must be at least 25 ft (7.5 m) from the property line and at least 3 ft (0.90 m) from the nearest street. See Exhibit 66.23.

66.15.3.2 No container, intermediate bulk container, or portable tank in a pile shall be more than 200 ft (60 m) from a minimum 20 ft (6 m) wide access way to permit approach of fire control apparatus under all weather conditions. [**30:**15.3.2]

66.15.3.3 The distances specified in Table 66.15.3 shall apply to properties that have protection for exposures as defined. If there are exposures and protection for exposures does not exist, the distance to the property line that is or can be built upon shall be doubled. [**30:**15.3.3]

66.15.3.4 Where total quantity stored does not exceed 50 percent of the maximum quantity per pile, as specified in Table 66.15.3, the distances to a property line that is or can be built upon and to streets, alleys, or public ways shall be permitted to be reduced by 50 percent but in no case to less than 3 ft (0.9 m). [**30:**15.3.4]

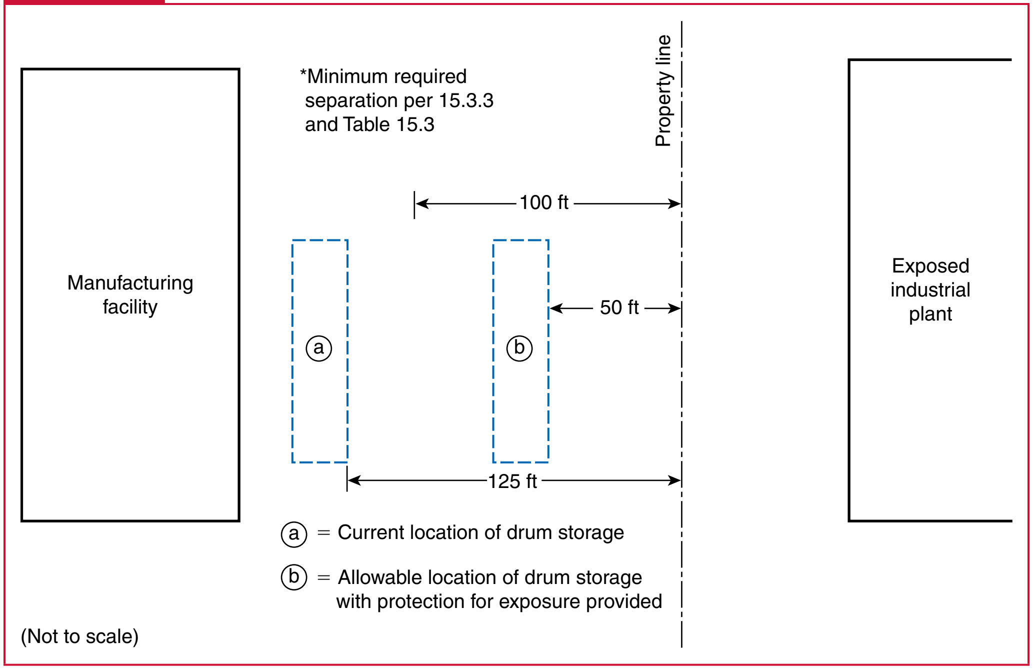
66.15.3.5 The storage area shall be graded in a manner to divert possible spills away from buildings or other exposures or shall be surrounded by a curb at least 6 in. (150 mm) high. [**30:**15.3.5]

66.15.3.5.1 Where curbs are used, provisions shall be made to drain accumulations of groundwater or rainwater or spills of liquids. Drains shall terminate at a safe location and shall flow freely under fire conditions. [**30:**15.3.5.1]

66.15.3.6 When accessible to the public, the storage area shall be protected against tampering and trespassing. [**30:**15.3.6]

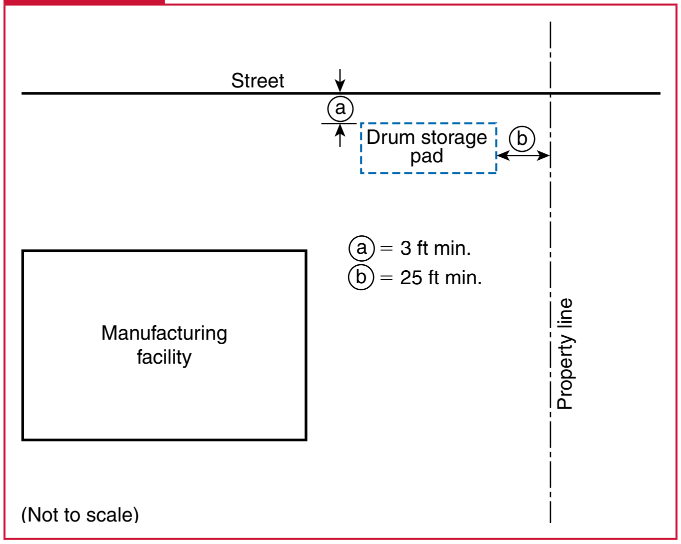
66.15.3.7 The storage area shall be kept free of weeds, debris, and other combustible materials not necessary to the storage for a distance of at least 10 ft (3 m) around the perimeter of the stored materials. [**30:**15.3.7]

Exhibit 66.22



Separation distances for Example 2.

Exhibit 66.23



Separation distances for Example 3.

66.15.3.8 The storage area shall be permitted to be protected from the weather by a canopy or roof that does not limit the dissipation of heat or dispersion of flammable vapors and does not restrict fire-fighting access and control. [**30:**15.3.8]

66.15.4 Outdoor Storage Adjacent to a Building.

66.15.4.1 A maximum of 1100 gal (4160 L) of liquids in containers, intermediate bulk containers, or portable tanks shall be permitted to be stored adjacent to a building under the same management, provided the following conditions apply:

(1) The adjacent building wall has an exterior fire resistance rating of 2 hours.
(2) The adjacent building wall has no openings at grade or above grade that are within 10 ft (3 m) horizontally of the storage.
(3) The adjacent building wall has no openings directly above the storage.
(4) The adjacent building wall has no openings below grade within 50 ft (15 m) horizontally of the storage.

[**30:**15.4.1]

66.15.4.2 The provisions of 66.15.4.1(1) through (4) shall be permitted to be waived, subject to the approval of the AHJ, if the building in question is one story, is of fire-resistive or noncombustible construction, and is devoted principally to the storage of liquids. [**30:**15.4.2]

66.15.4.3 The quantity of liquid stored adjacent to a building that meets the conditions of 66.15.4.1(1) through (4) shall be permitted to exceed that permitted in 66.15.4.1, provided the maximum quantity per pile does not exceed 1100 gal (4160 L) and each pile is separated by a 10 ft (3 m) minimum clear space along the common wall. [**30:**15.4.3]

66.15.4.4 The quantity of liquid stored shall be permitted to exceed the 1100 gal (4160 L) quantity specified by 66.15.4.1 where a minimum distance equal to that specified by Table 66.15.3 for distance to property line shall be maintained between buildings and the nearest container or portable tank. [**30:**15.4.4]

66.15.4.5 Where the provisions of 66.15.4.1 cannot be met, a minimum distance equal to that specified by Table 66.15.3 for distance to property line shall be maintained between buildings and the nearest container or portable tank. [**30:**15.4.5]

66.16 Automatic Fire Protection for Inside Liquid Storage Areas

Section 66.16 includes information on and requirements for fire protection and fire control for indoor storage of flammable and combustible liquids. These requirements are based on studies of fire incidents, research, and full-scale fire tests under various conditions.

To determine the proper fire protection system design criteria, the user must follow these steps:

1. Identify the class of liquid being stored and the type of container being used.
2. Identify the method of storage (palletized, stacked, nested, or rack).
3. Use Figures 66.16.4.1(a), 66.16.4.1(b), and 66.16.4.1(c) to identify the appropriate tables in 66.16.5.2 from which candidate fire protection designs can be selected.
4. From those candidates, choose the fire protection design that is most appropriate for the actual conditions.

Numerous factors are involved in selecting the appropriate fire protection system design criteria, including the following:

- Liquid type (liquid classification, water miscibility)
- Container size
- Container type (metal, plastic, glass)
- Packaging (cartoned, uncartoned)
- Storage arrangement (rack, palletized)
- Storage height
- Building height
- Aisle width
- Rack type (single row, double row, multiple row)

66.16.1 Scope.

66.16.1.1* This section shall apply to automatic fire protection systems for all inside storage of flammable and combustible liquids in containers, intermediate bulk containers, and portable tanks as specified in 66.9.4. [**30:**16.1.1]

A.66.16.1.1 See Annex E of NFPA 30 for limitations of the protection criteria of Table 16.5.2.1 through Table 16.5.2.12 of NFPA 30, particularly for intermediate bulk containers and portable tanks having capacities greater than 60 gal (230 L). [**30:**A.16.1.1]

Protected storage allowed under previous editions of NFPA 30 can be continued if the class of liquids stored, the quantity of liquids stored, fire protection, and building configuration remain unchanged. Table A.66.16.1.1(a) and Table A.66.16.1.1(b), reprinted here from the 1993 edition of NFPA 30, can be used as a reference for storage arrangements in previously approved, protected, inside liquid storage areas. [**30:**A.16.1.1]

For certain liquids such as ketones, esters, and alcohols, the minimum required densities established in the listing criteria for foam discharge devices are often higher than the general densities specified for protection of flammable and combustible liquids. When determining the design criteria for extinguishing systems using foam, it is important to ensure that the listing criteria, which are typically based on empirical data from fire tests, are not overlooked. Otherwise, the fire protection system design can be inadequate for proper protection. [**30:**A.16.1.1]

Early suppression fast-response (ESFR) sprinklers have been tested for protection of liquids only to the extent reflected in the tables in Section 16.5 of NFPA 30. Any other use of ESFR sprinklers for protection of liquids should be based on an engineering analysis that evaluates the potential failure of the sprinkler system based on a rapid-growth fire or a large pool fire that would operate more sprinklers than are accommodated by the design area. The use of ESFR protection, particularly without provisions for the control of spread of liquid, presents the possibility of a liquid pool fire that could exceed the limited design operating area of an ESFR system. [**30:**A.16.1.1]

The information in Table 16.5.2.1 through Table 16.5.2.12 of NFPA 30 was developed from full-scale fire tests. Where only one K-factor sprinkler is allowed, this was the only size proven to provide fire control. Where a choice of K-factors is allowed by the tables, each was able to provide fire control; however, the larger K-factor sprinklers sometimes demonstrated better fire control and further limited fire damage. Where only one response–type of sprinkler is allowed, this is the only type of sprinkler proven to provide fire control. Where a choice of response characteristics (SR or QR) is allowed by the tables, each was able to provide fire control; however, the QR sprinklers sometimes demonstrated better fire control and further limited fire damage. [**30:**A.16.1.1]

In the testing involving metal containers, only steel containers were tested. Other metal containers, such as aluminum, have not been tested. [**30:**A.16.1.1]

66.16.1.2* This section shall not apply to Class IA flammable liquids or to unstable flammable or combustible liquids. [**30:**16.1.2]

A.66.16.1.2 To date, there has been no full-scale testing to determine appropriate fire protection design criteria for Class IA liquids or unstable liquids. [**30:**A.16.1.2]

66.16.1.3 Storage of liquids that is protected in accordance with the applicable requirements of this section shall be considered protected, as defined in 66.16.2.3. All other storage shall be considered unprotected unless an alternate means of protection has been approved by the AHJ. [**30:**16.1.3]

The *Code* specifically allows the AHJ to accept an alternative protection scheme, for example, one based on full-scale fire tests. Annex E of NFPA 30 includes information on fire test protocols for situations that are not specifically addressed in Section 66.16.

Δ ***TABLE A.66.16.1.1(a)*** *Storage Arrangements for Protected Palletized or Solid Pile Storage of Liquids in Containers and Portable Tanks*

		Maximum Storage Height (ft)		Maximum Quantity per Pile (gal)		Maximum Quantity* (gal)	
Liquid Class	**Storage Level**	**Containers**	**Portable Tanks**	**Containers**	**Portable Tanks**	**Containers**	**Portable Tanks**
IA	Ground floor	5	—	3,000	—	12,000	—

III	Multirow,	Ground floor	40	55,000
	double row,	Upper floors	20	55,000
	or single row	Basement	20	25,000

For SI units, 1 ft = 0.3 m; 1 gal = 3.8 L.

NP: Not permitted.

*Maximum quantity allowed on racks in cut-off rooms and attached buildings.

†Maximum quantity allowed per rack section in liquid warehouses. [**30:** Table A.16.1.1(b)]

66.16.2 Definitions Specific to Section 66.16. For the purpose of this section, the following terms shall have the definitions given. [**30:**16.2]

Δ **66.16.2.1* Protected.** For the purposes of 66.16, this term shall apply to the storage of containers that meet the appropriate provisions of 66.16 or alternate provisions that have been approved by the authority having jurisdiction *(see 66.16.3.5 and Section 66.16.9)*. [**30:**16.2.2]

N **A.66.16.2.1** The term *protected* indicates that the fire risk is managed so as to control the fire and prevent it from spreading beyond the design area of the automatic fire protection system. [**30:**A.16.2.2]

N **66.16.2.2* Unprotected.** For the purposes of this chapter, this term shall apply to the storage of containers that do not meet the criteria to be considered protected, as defined in 66.16.2.1. [**30:**16.2.3]

N **A.66.16.2.2** The term *unprotected* indicates that the growth of a fire might exceed the capabilities of the automatic fire protection system and extend beyond the design area of the system. In such cases, the total contents of the fire area might become involved in a fire, regardless of the protection features provided. [**30:**A.16.2.3]

Experience with actual fires and with full-scale fire tests shows that even a well-designed fire protection system cannot successfully control a fire involving flammable or combustible

TABLE A.66.16.2.3 *Common Relieving- and Nonrelieving-Style Metal Containers*

Container Type	Relieving Style	Nonrelieving Style
≤1 qt[a]	All	N/A
>1 qt and ≤6 gal[a]	Metal containers with plastic cap, or flexible or rigid plastic spout with plastic cap	Metal containers with steel spout and steel screw cap
≤1 gal, friction lid	Metal containers with metal friction-fit covers (e.g., paint can lid)	N/A
1 gal and ≤6 gal (lug cover)	Metal containers with metal covers held in place with a mechanical friction-fit (e.g., lug-type) closure mechanism	N/A
>6 gal and ≤60 gal[b,c] (drums)	Metal containers, tight or open-head (drums) having at least one 2 in. plastic plug (Note: Cap seals, if used, need to be plastic and nonmetallic)	Open head metal containers with steel covers having no steel flange openings; or open head and tight head metal containers with steel flange openings where only steel plugs and/or cap seals are used
>60 gal and ≤793 gal	Metal portable tanks or metal intermediate bulk containers with at least one relief device conforming to the design, construction, and capacity of the container's section	N/A

For SI units, 1 gal = 3.8 L.

N/A: Not applicable.

[a]All containers ≤1 qt are considered relieving style because their failure is inconsequential.

[b]In full-scale fire tests, where containers were provided with both ¾ in. (19 mm) and 2 in. (50 mm) relieving vent openings and, in some cases, both vents were obstructed by pallet slats, rupture of containers did not occur. Because it is not possible to determine if all conceivable obstruction scenarios were represented, where drums are stacked more than one high, provide an additional ¾ in. (19 mm) or 2 in. (50 mm) pressure-relieving mechanism.

[c]The use of plastic plugs instead of steel plugs (bungs) in a steel drum in order to achieve a relieving-style container should contemplate the following issues in order to assure the safe storage of liquids:

(1) The compatibility of the plastic plug materials and gaskets with the liquids being stored.

(2) The stability and shelf life of the liquids being stored as the plastic plugs can admit water vapor, oxygen, and light.

(3) The difference in expansion coefficients for plastic plugs and steel drums for those drums subject to temperature variations and hot or cold conditions.

(4) The tooling issues involved with the use of plastic plugs as the torque levels are different from those levels used for steel plugs.

(5) The training of fill line operators in order to avoid cross-threading and/or the stripping of threads.

(6) The voiding of the United Nations (UN) rating on the steel drum by installing plastic plugs. If the user needs to install a plug other than the one originally provided by the container manufacturer, then the user should contact the manufacturer to ensure that the UN rating will still be valid.

[**30:** Table A.16.2.4]

liquids if rupture of containers or collapse of the storage array results in a pool of burning liquid. The burning liquid spreads faster than the fire protection system can respond. By using relieving-style containers, the chance for such a spill is minimized and the ability of the protection system to gain control of the fire is enhanced.

Examples of relieving-style metal containers include friction lid containers (such as paint cans), lug head containers, F-style (rectangular) containers that have plastic spouts, tight-head metal containers that have plastic pull-up pour spouts, and steel drums fitted with approved pressure-relieving bung closures.

66.16.2.3* Relieving-Style Container. A metal container, a metal intermediate bulk container, or a metal portable tank that is equipped with at least one pressure-relieving mechanism at its top that is designed, sized, and arranged to relieve the internal pressure generated due to exposure to fire so that violent rupture is prevented. [**30:**16.2.4]

A.66.16.2.3 Table A.66.16.2.3 provides examples of commonly used metal containers that are considered either relieving style or nonrelieving style for use in developing protected storage arrangements in accordance with Table 16.5.2.1 through Table 16.5.2.12 of NFPA 30. [**30:**A.16.2.4]

66.16.2.4* Unsaturated Polyester Resin (UPR). A resin that contains up to 50 percent by weight of Class IC, Class II, or Class III liquid, but no Class IA or Class IB liquid. [**30:**16.2.5]

A.66.16.2.4 Unsaturated polyester resins (UPRs) are high molecular weight unsaturated polymers dissolved in a reactive monomer, usually styrene, in concentrations of 50 percent or less by weight. UPRs are combined with reinforcements such as fiberglass and/or fillers to produce a wide range of products. Examples of such products include automobile parts, bathroom tubs and shower stalls, cultured marble, and many products for architectural, recreational, construction, and corrosion-resistant applications. UPRs are normally packaged in 55 gal (208 L) drums. The U.S. Department of Transportation classification for UPRs is “UN 1866, Resin Solution”; however, it should be noted that this classification includes many materials that are not unsaturated polyester resins. [**30:**A.16.2.5]

66.16.2.5 Viscous Liquid. A liquid that gels, thickens, or solidifies when heated or whose viscosity at room temperature versus weight percent content of Class I, Class II, or Class III liquid is in the shaded portion of Figure 66.16.2.5. [**30:**16.2.6]

Viscous liquids include such products as thick resins, adhesives, and coatings. Some of these liquids are mixtures that contain a small percentage of volatile flammable or combustible liquids, with the balance being noncombustible. Others are mixtures containing minor amounts of volatile flammable liquids, with the balance being high flash point combustible liquids. Although these liquids might exhibit a low flash point, their rate of evaporation (volatility) is also low and they do not produce

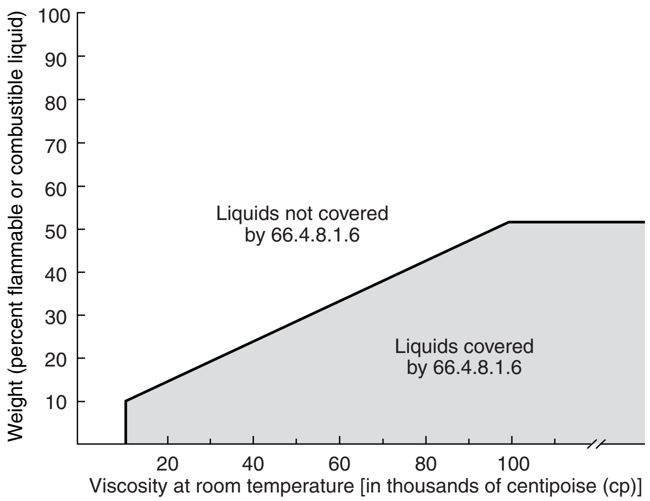

***FIGURE 66.16.2.5** Viscous Liquid: Viscosity Versus Weight Percent Flammable or Combustible Component. [**30:** Figure 16.2.6]*

large quantities of ignitible vapors. Also, spills tend to be localized and easily controlled.

66.16.2.6 Water-Miscible Liquid. A liquid that mixes in all proportions with water without the use of chemical additives, such as emulsifying agents. [**30:**16.2.7]

66.16.3 General Requirements.

66.16.3.1 Where different classes of liquids, container types, and storage configurations are stored in the same protected area, protection shall meet either of the following:

(1) Requirements of this section for the most severe storage fire hazard present
(2) Where areas are not physically separated by a barrier or partition capable of delaying heat from a fire in one hazard area from fusing sprinklers in an adjacent hazard area, the required protection for the more demanding hazard shall:
   (a) Extend 20 ft (6 m) beyond its perimeter, but not less than the required minimum sprinkler design area
   (b) Be provided with means to prevent the flow of burning liquid under emergency conditions into adjacent hazard areas
   (c) Provide containment and drainage as required by 66.16.8

[**30:**16.3.1]

66.16.3.2 Unless otherwise specified in this section, single-row racks shall not be more than 4.5 ft (1.4 m) in depth and double-row racks shall not be more than 9 ft (2.8 m) in depth. [**30:**16.3.2]

66.16.3.3 When applying the fire protection criteria of this section, a minimum aisle space of 6 ft (1.8 m) shall be provided between adjacent piles or adjacent rack sections, unless otherwise specified in the tables in 66.16.5. [**30:**16.3.3]

Δ **66.16.3.4** Viscous liquids, as defined in 66.16.2.5, shall be permitted to be protected using either of the following, as applicable:

(1) For metal containers, the criteria for a Class IIIB liquid in accordance with Figure 66.16.4.1(a)
(2) For nonmetallic containers, the criteria for Class IIIB liquids, as determined by Figure 66.16.4.1(b)
(3) For nonmetallic containers, the criteria for cartoned unexpanded Group A plastics in accordance with NFPA 13 as indicated in Figure 66.16.4.1(b).

[**30:**16.3.4]

66.16.3.5 Protection systems that are designed and developed based on full-scale fire tests performed at an approved test facility or on other engineered protection schemes shall be considered an acceptable alternative to the protection criteria set forth in this section. Such alternative protection systems shall be approved by the AHJ. [**30:**16.3.5]

66.16.3.6 For relieving-style containers of greater than 6.6 gal (25 L) and up to 119 gal (450 L) capacity, the following shall apply:

(1) The pressure-relieving mechanism shall be listed and labeled in accordance with FM Global *Approval Standard for Plastic Plugs for Steel Drums,* Class Number 6083, or equivalent.
(2) The pressure-relieving mechanism shall not be painted, and cap seals, if used, shall be made of thermoplastic material.
(3) For metal containers greater than 6.6 gal (25 L) capacity, the pressure-relieving mechanism shall be unobstructed or an additional pressure-relieving mechanism shall be provided.

[**30:**16.3.6]

66.16.3.7 To be considered protected by Table 66.16.5.2.9 and Table 66.16.5.2.10, rigid nonmetallic intermediate bulk containers shall be listed and labeled in accordance with UL 2368, *Standard for Fire Exposure Testing of Intermediate Bulk Containers for Flammable and Combustible Liquids*; FM Class 6020, *Approval Standard for Intermediate Bulk Containers*; or an equivalent test procedure. [**30:**16.3.7]

66.16.4 Automatic Sprinkler and Foam-Water Sprinkler Fire Protection Systems.

66.16.4.1 Where automatic sprinkler systems or low-expansion foam-water sprinkler systems are used to protect storage of liquids, Figure 66.16.4.1(a), Figure 66.16.4.1(b), or Figure 66.16.4.1(c), whichever is applicable, and the appropriate table in 66.16.5 shall be used to determine protection criteria. [**30:**16.4.1]

66.16.4.1.1 Figure 66.16.4.1(a) shall be used for miscible and nonmiscible flammable and combustible liquids in metal containers, metal portable tanks, and metal intermediate bulk containers. [**30:**16.4.1.1]

66.16.4.1.2 Figure 66.16.4.1(b) shall be used for miscible and nonmiscible flammable and combustible liquids in nonmetallic containers and in nonmetallic intermediate bulk containers. [**30:**16.4.1.2]

66.16.4.1.3 Figure 66.16.4.1(c) shall be used for water-miscible flammable and combustible liquids in nonmetallic containers and in nonmetallic intermediate bulk containers. [**30:**16.4.1.3]

66.16.4.2 Automatic sprinkler and foam-water fire protection systems shall be wet pipe, deluge, or preaction systems. [**30:**16.4.2]

66.16.4.2.1 If a preaction system is used, it shall be designed so that water or foam solution will immediately discharge from the sprinkler upon sprinkler actuation. [**30:**16.4.2.1]

Δ **66.16.4.2.2** A foam-water sprinkler system that meets any of the design criteria specified in the water sprinkler tables in this section shall be acceptable, provided that the system is installed in accordance with NFPA 16. [**30:**16.4.2.2]

66.16.4.3 Water-based fire protection systems shall be inspected, tested, and maintained in accordance with NFPA 25. [**30:**16.4.3]

66.16.5 Fire Protection System Design Criteria.

66.16.5.1 General. Subsections 66.16.5.2.1 through 66.16.5.2.12 and their related tables, Table 66.16.5.2.1 through Table 66.16.5.2.12, shall be used to determine the protection criteria and storage arrangement for the applicable liquid class, container type, and storage configuration, as described in 66.16.5.2.1 through 66.16.5.2.12 and subject to the provisions of 66.16.5.1. [**30:**16.5.1]

66.16.5.1.1 Table 66.16.5.2.1 through Table 66.16.5.2.12 shall apply only to stable liquids. [**30:**16.5.1.1]

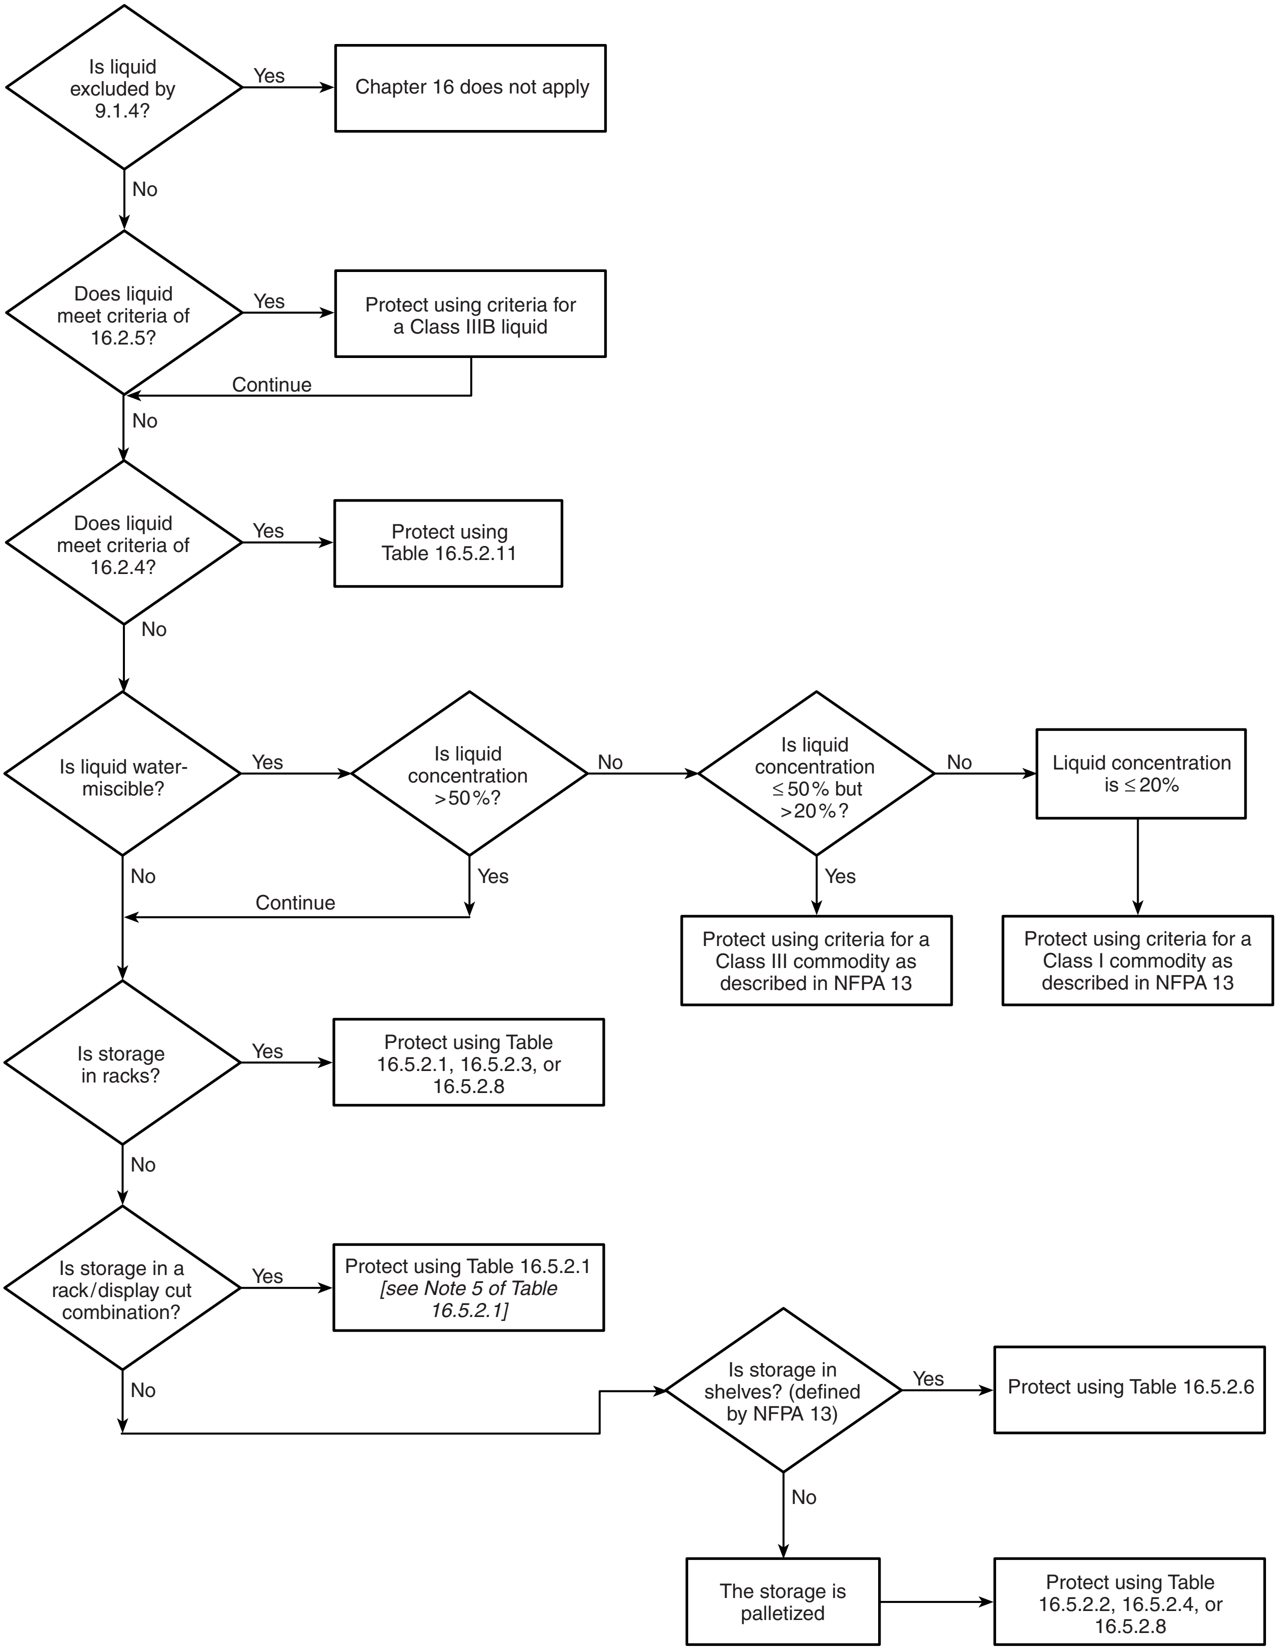
66.16.5.1.1.1 The protection criteria in Table 66.16.5.2.1 through Table 66.16.5.2.12 shall only be used with ceilings having a pitch of 2 in 12 or less. [**30:**16.5.1.1.1]

66.16.5.1.2 When foam or foam-water fire protection systems are provided, discharge densities shall be determined based on the listing criteria of the foam discharge devices selected, the foam concentrate, the specific liquids to be protected, and the criteria in the appropriate table in this section. Where the discharge densities given in the tables differ from those in the listing criteria for the discharge devices, the greater of the two shall be used. [**30:**16.5.1.2]

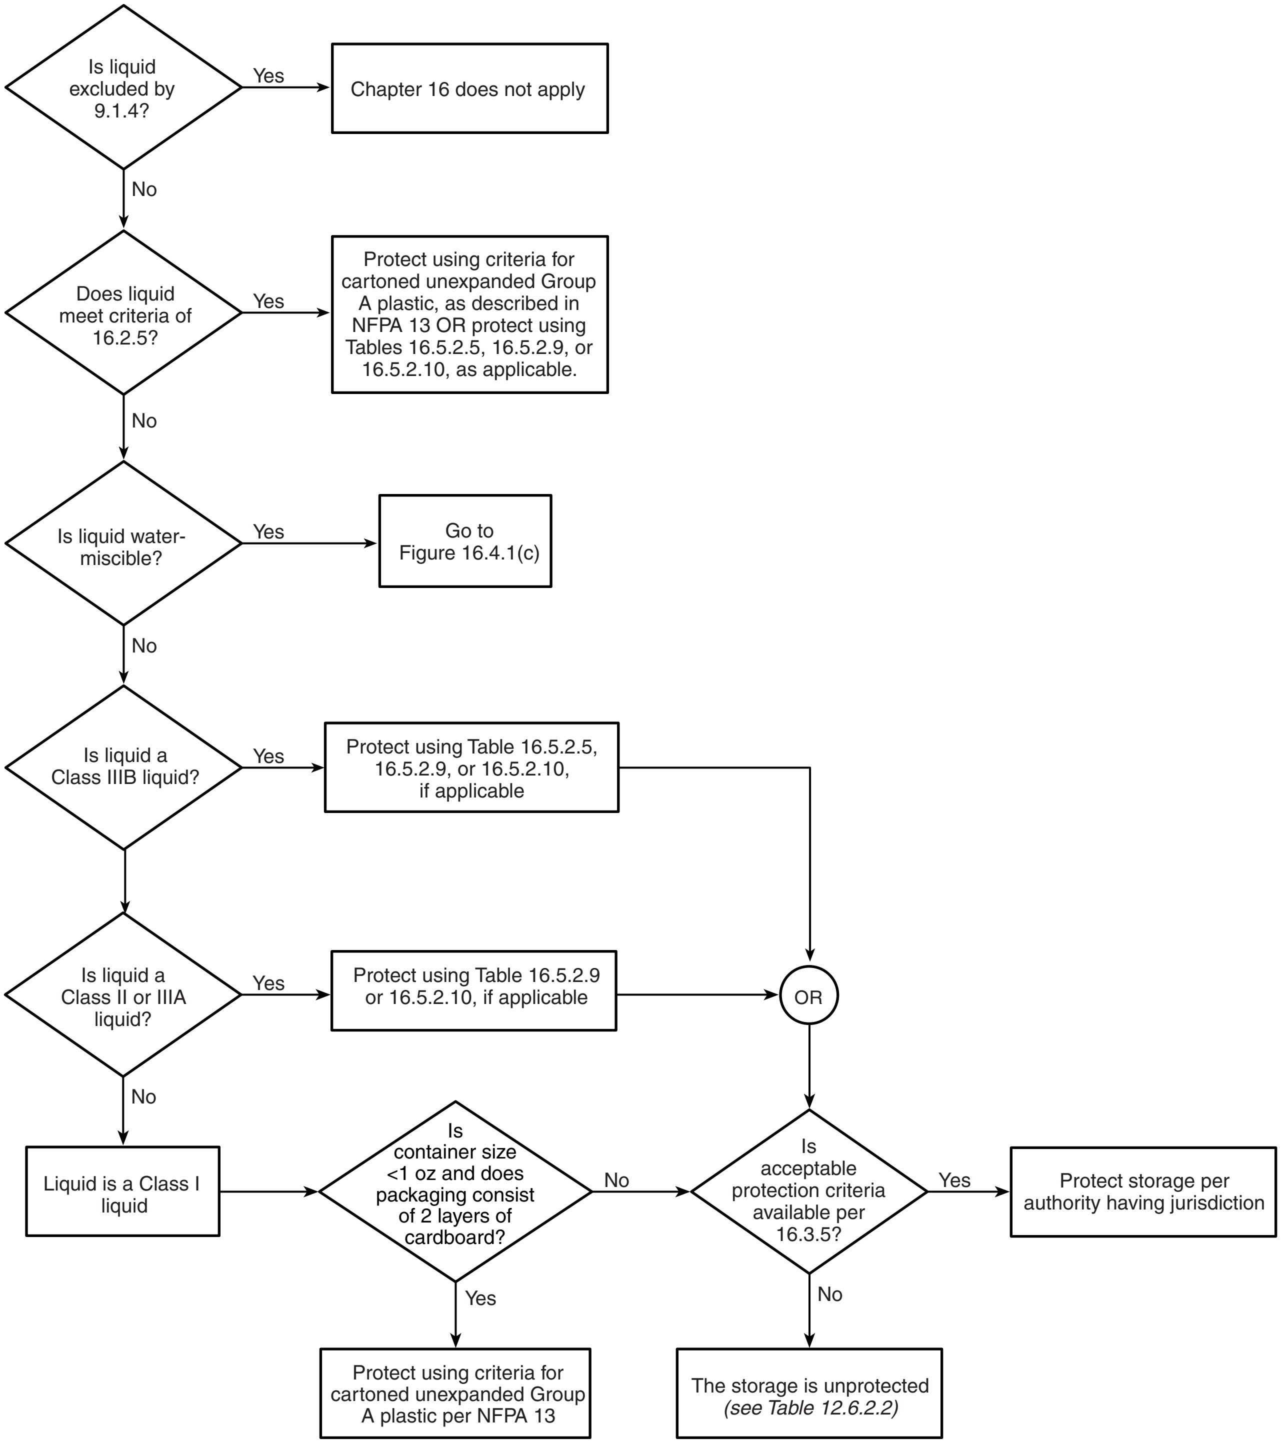
66.16.5.1.3 In-rack sprinklers shall be installed in accordance with the provisions of Section 13.3 and NFPA 13. In addition, the following modifications shall apply:

(1) In-rack sprinklers shall be laid out in accordance with 66.16.5.1.10 and 66.16.6, as applicable.
(2) Sprinklers in multiple-level in-rack sprinkler systems shall be provided with water shields unless they are separated by horizontal barriers or are specifically listed for installation without water shields.
(3) A vertical clear space of at least 6 in. (150 mm) shall be maintained between the sprinkler deflector and the top of the tier of storage.
(4) Sprinkler discharge shall not be obstructed by horizontal rack structural members.
(5) Where in-rack sprinklers are installed below horizontal barriers, the deflector shall be located a maximum of 7 in. (180 mm) below the barrier.
(6) Longitudinal and transverse flue spaces of at least 6 in. (150 mm) shall be maintained between each rack load.

[**30:**16.5.1.3]



Δ ***FIGURE 66.16.4.1(a)*** *Fire Protection Criteria Decision Tree for Miscible and Nonmiscible Flammable and Combustible Liquids in Metal Containers. [**30:** Figure 16.4.1(a)]*



Note: All cross-references refer to NFPA 30.

Δ ***FIGURE 66.16.4.1(b)*** *Fire Protection Criteria Decision Tree for Miscible and Nonmiscible Flammable and Combustible Liquids in Nonmetallic Containers. [**30:** Figure 16.4.1(b)]*

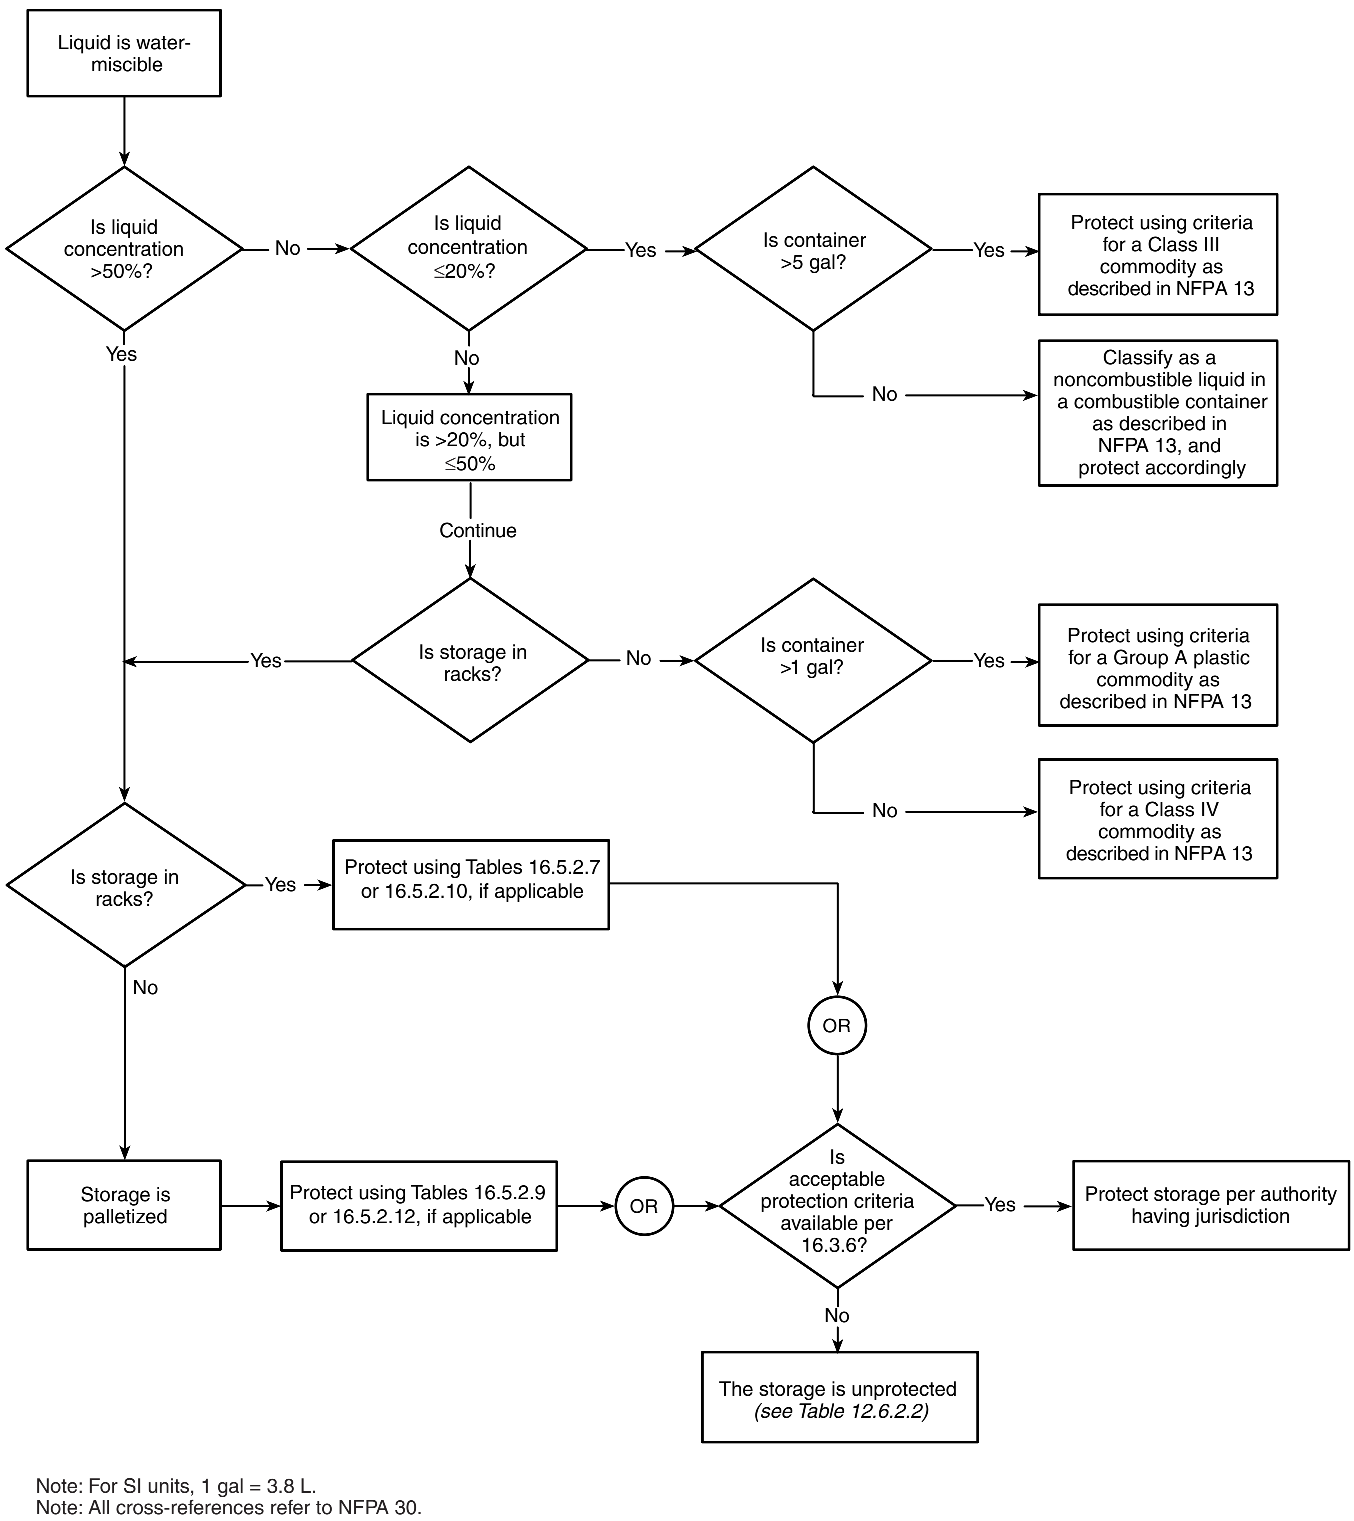


FIGURE 66.16.4.1(c) *Fire Protection Criteria Decision Tree for Miscible Flammable and Combustible Liquids in Nonmetallic Containers. [**30:** Figure 16.4.1(c)]*

66.16.5.1.4 Ceiling sprinklers shall be installed in accordance with Section 13.3 and NFPA 13 and shall be permitted to have the following maximum head spacing:

(1) Classes I, II, and IIIA liquids: 100 ft^2 (9.3 m^2) per sprinkler
(2) Class IIIB liquids: 120 ft^2 (11.1 m^2) per sprinkler

[**30:**16.5.1.4]

66.16.5.1.4.1 Ordinary or intermediate temperature–rated K-25 extended-coverage sprinklers shall be permitted to be used as standard response high temperature sprinklers at greater than 144 ft^2 (13 m^2) coverage, with 12 ft (3.7 m) minimum spacing and a maximum coverage area of 196 ft^2 (18 m^2) coverage. [**30:**16.5.1.4.1]

66.16.5.1.5 The ceiling heights given in Table 66.16.5.2.1 through Table 66.16.5.2.12, excluding Table 66.16.5.2.8, shall be permitted to be increased by a maximum of 10 percent if an equivalent percent increase in ceiling sprinkler design density is provided. [**30:**16.5.1.5]

Δ **66.16.5.1.6** Foam-water sprinkler systems shall be installed in accordance with NFPA 16. [**30:**16.5.1.6]

66.16.5.1.6.1 Foam-water sprinkler systems shall have at least 15 minutes of foam concentrate, based on the required design flow rate. [**30:**16.5.1.6.1]

66.16.5.1.6.2* Foam-water sprinkler systems shall provide foam solution at the minimum required concentration with as few as four sprinklers flowing. [**30:**16.5.1.6.2]

A.66.16.5.1.6.2 Most fire tests using foam-water protection schemes have been conducted with immediate foam solution discharge from the operating sprinklers. If an appreciable delay is encountered before properly proportioned foam is discharged, control of the fire might not be established. One method of accomplishing immediate foam solution discharge is by using an in-line balanced pressure (ILBP) proportioning system. [**30:**A.16.5.1.6.2]

66.16.5.1.7 When relieving style containers are used, both ¾ in. (20 mm) and 2 in. (50 mm) listed and labeled pressure-relieving mechanisms are required on containers greater than 6 gal (23 L) capacity. [**30:**16.5.1.7]

66.16.5.1.8 For the purposes of 66.16.5, a rigid nonmetallic intermediate bulk container is one that meets the maximum allowable capacity criteria of Table 66.9.4.3 and has been listed and labeled in accordance with UL 2368, *Standard for Fire Exposure Testing of Intermediate Bulk Containers for Flammable and Combustible Liquids*, or equivalent. [**30:**16.5.1.8]

66.16.5.1.9 For the purposes of 66.16.5, the following shall apply:

(1) 1 gal = 3.8 L; 1 ft = 0.3 m; 1 ft^2 = 0.09 m^2
(2) 1 gpm/ft^2 is equivalent to 40.7 L/min/m^2 or 40.7 mm/min
(3) A gauge pressure of 1 psi is equivalent to a gauge pressure of 6.9 kPa
(4) SR = standard response sprinkler; QR = quick response sprinkler; ESFR = early suppression fast response sprinkler; OT = ordinary temperature; HT = high temperature
(5) Where an ordinary-temperature sprinkler is indicated, an intermediate-temperature sprinkler shall be used where ambient conditions require.

[**30:**16.5.1.9]

66.16.5.1.10 For the purposes of 66.16.5, the following shall apply to the in-rack sprinkler design layouts specified in Table 66.16.5.2.1 through Table 66.16.5.2.12:

(1) Layout 1, as referenced in Table 66.16.5.2.1, shall mean one line of in-rack sprinklers 8 ft (2.4 m) above the floor in the longitudinal flue space, with sprinklers spaced not more than 10 ft (3 m) on center.
(2) Layout 2, as referenced in Table 66.16.5.2.1, shall mean one line of in-rack sprinklers 6 ft (1.8 m) above the floor and one line of in-rack sprinklers 12 ft (3.6 m) above the floor in the longitudinal flue space, with sprinklers spaced not more than 10 ft (3 m) on center. Sprinklers shall be staggered vertically.
(3) Layout 3, as referenced in Table 66.16.5.2.1 and Table 66.16.5.2.1, shall mean one line of in-rack sprinklers in the longitudinal flue space at every storage level above the floor except above the top tier, with sprinklers spaced not more than 10 ft (3 m) on center. Sprinklers shall be staggered vertically, where more than one level of in-rack sprinklers is installed.
(4) Layout 4, as referenced in Table 66.16.5.2.1 and Table 66.16.5.2.3, shall mean one line of in-rack sprinklers in the longitudinal flue space at every other storage level, except above the top tier, beginning above the first storage level, with sprinklers spaced not more than 10 ft (3 m) on center. Sprinklers shall be staggered vertically where more than one level of in-rack sprinklers is installed.
(5) Layout 5, as referenced in Table 66.16.5.2.1, shall mean one line of in-rack sprinklers in the longitudinal flue space at every storage level above the floor except above the top tier and face sprinklers at the first storage level at each rack upright. In-rack sprinklers shall be spaced not more than 9 ft (2.7 m) on center and shall be staggered vertically, where more than one level of in-rack sprinklers is installed.
(6) Layout 6, as referenced in Table 66.16.5.2.1, shall mean one line of in-rack sprinklers in the longitudinal flue space at every other storage level above the first storage level except the top tier and face sprinklers at the first storage level at each rack upright. In-rack sprinklers shall be spaced not more than 10 ft (3 m) on center and shall be staggered vertically, where more than one level of in-rack sprinklers is installed.
(7) Layout 7, as referenced in Table 66.16.5.2.8, shall be as shown in Figure 66.16.6.5(a).
(8) Layout 8, as referenced in Table 66.16.5.2.8, shall be as shown in Figure 66.16.6.5(b) or Figure 66.16.6.5(c).
(9) Layout 9, as referenced in Table 66.16.5.2.8, shall be as shown in Figure 66.16.6.5(d) or Figure 66.16.6.5(e).

[**30:**16.5.1.10]

66.16.5.1.11 The "Fire Test Ref." number given for each entry in Table 66.16.5.2.1 through Table 66.16.5.2.12 shall be used to identify in Section D.2 of NFPA 30 the information on the fire tests on which the protection criteria for that entry are based. [**30:**16.5.1.11]

66.16.5.1.12 The water supply shall be sufficient to meet the fixed fire protection demand plus a total of at least 500 gpm (1900 L/min) for inside and outside hose connections for at least 2 hours, unless otherwise specified in this chapter. [**30:**16.5.1.12]

66.16.5.2 Specific Design Criteria.

66.16.5.2.1 Table 66.16.5.2.1 shall apply to the following:

(1) Automatic sprinkler protection
(2) Single- or double-row rack storage
(3) Nonmiscible liquids and miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Metal containers, metal portable tanks, metal intermediate bulk containers
(5) Relieving- or nonrelieving-style containers

[**30:**16.5.2.1]

In the 2015 edition of the *Code*, Table 66.16.5.2.1 was amended to allow the use of in-rack sprinklers having K-factors greater than 5.6 or 8.0, because larger K-factors have been shown to provide improved performance. The column under "In-Rack Sprinkler Protection" that was previously labeled "Design Flow" was amended to "Discharge Flow" to emphasize that a minimum flow rate is necessary, in addition to the minimum discharge pressure, to ensure proper operation. Note (1) of Table 66.16.5.2.1 was expanded to provide the designer with criteria for two levels of in-rack sprinklers. In prior editions of the *Code*, guidance was provided only for one level of in-rack sprinklers and for three or more levels of in-rack sprinklers. Note (7) was added to specify a minimum discharge pressure for in-rack sprinklers to allow for larger-orifice sprinklers and to ensure a proper discharge pattern.

66.16.5.2.2 Table 66.16.5.2.2 shall apply to the following:

(1) Automatic sprinkler protection
(2) Palletized or stacked storage
(3) Nonmiscible liquids and miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Metal containers, metal portable tanks, metal intermediate bulk containers
(5) Relieving- or nonrelieving-style containers

[**30:**16.5.2.2]

66.16.5.2.3 Table 66.16.5.2.3 shall apply to the following:

(1) Foam water sprinkler protection
(2) Single- or double-row rack storage
(3) Nonmiscible liquids and miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Metal containers, metal portable tanks, metal intermediate bulk containers
(5) Relieving- or nonrelieving-style containers

[**30:**16.5.2.3]

In the 2015 edition of the *Code*, Table 66.16.5.2.3 was amended to allow the use of in-rack sprinklers having K-factors greater than 5.6 or 8.0, because larger K-factors have been shown to provide improved performance. The column under "In-Rack Sprinkler Protection" that was previously labeled "Design Flow" was amended to "Discharge Flow" to emphasize that a minimum flow rate is necessary, in addition to the minimum discharge pressure, to ensure proper operation. Note (5) was added to specify a minimum discharge pressure for in-rack sprinklers to allow for larger-orifice sprinklers and to ensure a proper discharge pattern.

66.16.5.2.4 Table 66.16.5.2.4 shall apply to the following:

(1) Foam water sprinkler protection
(2) Palletized or stacked storage
(3) Nonmiscible liquids and miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Metal containers, metal portable tanks, metal intermediate bulk containers
(5) Relieving- or nonrelieving-style containers

[**30:**16.5.2.4]

66.16.5.2.5 Table 66.16.5.2.5 shall apply to the following:

(1) Automatic sprinkler protection
(2) Single-, double-, or multiple-row rack storage
(3) Class IIIB nonmiscible liquids and Class IIIB miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Nonmetallic containers or intermediate bulk containers
(5) Cartoned or uncartoned

[**30:**16.5.2.5]

66.16.5.2.6 Table 66.16.5.2.6 shall apply to the following:

(1) Automatic sprinkler protection
(2) Shelf storage
(3) Nonmiscible liquids and miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Nonrelieving-style metal containers

[**30:**16.5.2.6]

The sprinkler K-factor in Table 66.16.5.2.6 was corrected in the 2015 edition of the *Code* to reflect what was used in the actual tests on which the table is based. Note (3) was added to reflect the actual aisle space used in those tests.

66.16.5.2.7 Table 66.16.5.2.7 shall apply to the following:

(1) Automatic sprinkler protection
(2) Single- or double-row rack storage
(3) Water-miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Glass or plastic containers
(5) Cartoned or uncartoned
(6) Minimum 8 ft (2.4 m) aisle width

[**30:**16.5.2.7]

66.16.5.2.8 Table 66.16.5.2.8 shall apply to the following:

(1) Automatic sprinkler protection
(2) Single- or double-row rack storage or palletized storage

Δ ***TABLE 66.16.5.2.1*** *Design Criteria for Sprinkler Protection of Single- and Double-Row Rack Storage of Liquids in Metal Containers, Portable Tanks, and IBCs*

Container Style and Capacity (gal)	Maximum Storage Height (ft)	Maximum Ceiling Height (ft)	Ceiling Sprinkler Protection: Sprinkler Type	Ceiling Sprinkler Protection: Sprinkler Response	Ceiling Sprinkler Protection: Design Density (gpm/ft²)	Ceiling Sprinkler Protection: Design Area (ft²)	In-Rack Sprinkler Protection: Sprinkler Type	In-Rack Sprinkler Protection: Sprinkler Response	In-Rack Sprinkler Protection: Discharge Flow (gpm)	In-Rack Sprinkler Protection: Layout (*See 66.16.5.1.10*)	Notes	Fire Test Ref. *[See NFPA 30: Table D.2(a)]*
NONRELIEVING-STYLE CONTAINERS — LIQUID CLASSES IB, IC, II, IIIA

	25	30	K ≥ 8.0	SR or QR (HT)	0.3	3000	K ≥ 5.6	QR (OT)	30	4, 7	1, 5	8
>5 and ≤60	25	30	K ≥ 11.2	SR (HT)	0.6	3000	K ≥ 5.6	QR (OT)	30	6, 7	1	10
Portable tanks and IBCs	25	30	K ≥ 11.2	SR (HT)	0.6	3000	K ≥ 5.6	QR or SR (OT)	30	5, 7	1	12
RELIEVING-STYLE CONTAINERS — LIQUID CLASS IIIB												
≤ 5 gal	40	50	K ≥ 8.0	SR or QR (HT)	0.3	2000	K ≥ 5.6	QR (OT)	30	4, 7	1	9
>5 and ≤60	40	50	K ≥ 8.0	SR (HT)	0.3	3000	K ≥ 5.6	QR (OT)	30	4, 7	1, 3	11
Portable tanks and IBCs	40	50	K ≥ 8.0	SR (HT)	0.3	3000	K ≥ 5.6	QR (OT)	30	4, 7	1, 6	13

For SI units, 1 gal = 3.8 L, 1 ft = 0.3 m, 1 ft² = 0.09 m², 1 gpm/ft² = 40.7 L/min/m² = 40.7 mm/min.

For definitions of abbreviations used in the Response column, see 66.16.5.1.9(4). See also 66.16.5.1.9(5).

(1) In-rack sprinkler design shall be based on the following:

(a) Where one level of in-rack sprinklers is installed, the design shall include the 8 most hydraulically remote sprinklers

(b) Where two levels of in-rack sprinklers are installed, the design shall include the 6 most hydraulically remote sprinklers on each level.

(c) Where three or more levels of in-rack sprinklers are installed, the design shall include the 6 most hydraulically remote sprinklers on the top three levels.

(2) Protection for uncartoned or case-cut nonsolid shelf display up to 6.5 ft. (2 m) and storage above on pallets in racking and stored on shelf materials, including open wire mesh, or 2 in. × 6 in. (50 mm × 150 mm) wooden slats, spaced a minimum of 2 in. (50 mm) apart.

(3) Increase ceiling density to 0.60 if more than one level of storage exists above the top level of in-rack sprinklers.

(4) Double-row racks limited to maximum 6 ft (1.8 m) depth.

(5) For K=8.0 and larger ceiling sprinklers, increase ceiling density to 0.60 over 2000 ft² if more than one level of storage exists above the top level of in-rack sprinklers.

(6) Reduce in-rack sprinkler spacing to maximum 9 ft (2.7 m) centers.

(7) The minimum in-rack discharge pressure shall not be less than 10 psi.

[**30:**Table 16.5.2.1]

Δ *TABLE 66.16.5.2.2 Design Criteria for Sprinkler Protection of Palletized and Stacked Storage of Liquids in Metal Containers, Portable Tanks, and IBCs*

Portable tanks and IBCs	1-high	30	K≥8.0	SR (HT)	0.25	3000	—	16
	2-high	30	K≥11.2	SR (HT)	0.50	3000	—	17

For SI units, 1 gal = 3.8 L, 1 ft = 0.3 m, 1 ft^2 = 0.09 m^2, 1 gpm/ft^2 = 40.7 L/min/m^2 = 40.7 mm/min.

For definitions of abbreviations used in the Response column, see 66.16.5.1.9(4). See also 66.16.5.1.9(5).

Notes:

(1) Minimum hose stream demand can be reduced to 250 gpm for 2 hours.

(2) Sprinklers must also be hydraulically calculated to provide a density of 0.80 gpm/ft^2 over 1000 ft^2.

(3) Drums must be placed on open slatted pallet, not nested, to allow pressure relief from drums on lower levels. [**30:** Table 16.5.2.2]

(3) Nonmiscible liquids and miscible liquids with concentration of flammable or combustible component greater than 50 percent by volume
(4) Relieving-style metal containers

[**30:**16.5.2.8]

Table 66.16.5.2.8 was amended in the 2015 edition of the *Code* by changing the required minimum discharge pressure to a minimum discharge flow to ensure proper discharge distribution. Note (7) was added to specify a minimum discharge pressure for in-rack sprinklers to allow for larger-orifice sprinklers and to ensure a proper discharge pattern.

66.16.5.2.9 Table 66.16.5.2.9 shall apply to the following:

(1) Automatic sprinkler protection
(2) Palletized storage
(3) Class II and Class III nonmiscible and Class II and Class III miscible liquids
(4) Listed and labeled rigid nonmetallic intermediate bulk containers

[**30:**16.5.2.9]

In the 2015 edition of the *Code*, a reference to FM Class 6020, *Approval Standard for Intermediate Bulk Containers,* which is an equivalent evaluation procedure for IBCs, was added to Note (2) of Table 16.5.2.9.

△ ***TABLE 66.16.5.2.3** Design Criteria for Foam-Water Sprinkler Protection of Single- or Double-Row Rack Storage of Liquids in Metal Containers, Portable Tanks, and IBCs*

For SI units, 1 gal = 3.8 L, 1 ft = 0.3 m, 1 ft^2 = 0.09 m^2, 1 gpm/ft^2 = 40.7 L/min/m^2 = 40.7 mm/min.

For definitions of abbreviations used in the Response column, see 66.16.5.1.9(4). See also 66.16.5.1.9(5).

Notes:

(1) In-rack sprinkler design based on the 6 most hydraulically remote sprinklers in each of the upper three levels.

(2) Design area can be reduced to 1500 ft^2 when using a preprimed foam-water system installed in accordance with NFPA 16, *Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems*, and maintained according to NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

(3) Design area can be reduced to 2000 ft^2 when using a preprimed foam-water system installed in accordance with NFPA 16 and maintained according to NFPA 25.

(4) In-rack sprinkler hydraulic design can be reduced to three sprinklers operating per level, with three levels operating simultaneously, when using a preprimed foam-water sprinkler system designed in accordance with NFPA 16 and maintained in accordance with NFPA 25.

(5) The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 10 psi.

[**30:** Table 16.5.2.3]

66.16.5.2.10 Table 66.16.5.2.10 shall apply to the following:

(1) Automatic sprinkler protection
(2) Single- or double-row rack storage
(3) Class II and Class III nonmiscible and Class II and Class III miscible liquids
(4) Listed and labeled rigid nonmetallic intermediate bulk containers

[**30:**16.5.2.10]

66.16.5.2.11 Table 66.16.5.2.11 shall apply to the following:

(1) Automatic sprinkler protection
(2) Palletized or stacked storage
(3) Unsaturated polyester resins (UPRs) with not more than 50 percent by weight of Class IC, II, or IIIA liquid
(4) Metal containers; nonrelieving style allowed only up to 6 gal (23 L)

[**30:**16.5.2.11]

66.16.5.2.12 Table 66.16.5.2.12 shall apply to the following:

(1) Automatic sprinkler protection
(2) Palletized or stacked storage
(3) Miscible liquids with concentration of flammable or combustible components no greater than 80 percent by volume
(4) Glass or plastic containers

[**30:**16.5.2.12]

≤5, cartoned or uncartoned	12	30	Pendent ESFR K≥14.0 (OT)	12 @ 75 psi	—	—	—	—	—	7

For SI units, 1 gal = 3.8 L, 1 ft = 0.3 m, 1 psi = 6.9 kPa.

For definitions of abbreviations used in the Response column, see 16.5.1.9(4). See also 16.5.1.9(5).

Notes:

(1) The in-rack sprinkler water demand shall be based on the simultaneous operation of the most hydraulically remote sprinklers as follows:

(a) Seven sprinklers where only one level of in-rack sprinklers is installed.

(b) Fourteen sprinklers (seven on each of the two top levels) where more than one level of in-rack sprinklers is installed.

(2) The in-rack sprinkler water demand should be balanced with the ceiling sprinkler water demand at their point of connection.

(3) One-gallon and 1-quart containers are not required to be relieving style.

(4) Provide minimum 3 in. transverse flue at rack uprights.

(5) For Class IIIB liquids, see also Table 16.5.2.5.

(6) Racks can have open-mesh wire intermediate shelving on lower levels.

(7) The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 10 psi.

△ ***TABLE 66.16.5.2.9*** *Design Criteria for Sprinkler Protection of Palletized Storage of Class II and Class III Liquids in Listed and Labeled Rigid Nonmetallic IBCs*

Maximum Capacity (gal)	Maximum Storage Height	Maximum Ceiling Height (ft)	Ceiling Sprinkler Protection: Sprinkler Type	Ceiling Sprinkler Protection: Sprinkler Response	Ceiling Sprinkler Protection: Design Density (gpm/ft²)	Ceiling Sprinkler Protection: Design Area (ft²)	Notes	Fire Test Ref. *[See Table D.2(i) of NFPA 30]*

For definitions of abbreviations used in the Response column, see 66.16.5.1.9(4). *(See also 66.16.5.1.9(5).)* [**30:** Table 16.5.2.12]

66.16.6 Fire Protection System Design Schemes.

66.16.6.1 Fire Protection System Design Scheme A.

66.16.6.1.1 Horizontal barriers of plywood having a minimum thickness of ⅜ in. (10 mm) or of sheet metal of minimum 22 gauge thickness shall be installed in accordance with Figure 66.16.6.1.1(a), Figure 66.16.6.1.1(b), or Figure 66.16.6.1.1(c), whichever is applicable. All liquid storage shall be located beneath a barrier. *[See also 66.16.6.1.9 for liquids with flash points equal to or greater than 450°F (230°C).]* [**30:**16.6.1.1]

66.16.6.1.2 In-rack sprinklers shall be installed in accordance with Figure 66.16.6.1.1(a), Figure 66.16.6.1.1(b), or Figure 66.16.6.1.1(c), whichever is applicable. [**30:**16.6.1.2]

66.16.6.1.3 Vertical barriers shall not be provided between in-rack sprinklers. [**30:**16.6.1.3]

66.16.6.1.4 In-rack sprinklers shall meet the following requirements:

(1) In-rack sprinklers shall be ordinary temperature–rated quick-response sprinklers and shall have a nominal K-factor equal to or greater than 8.0. Intermediate-temperature sprinklers shall be used where ambient conditions require.

(2) In-rack sprinklers shall be installed below each barrier level.

(3) In-rack sprinklers shall provide a minimum operating flow of 57 gpm (220 L/min) out of each of the hydraulically most remote six sprinklers (six on one line or three on two lines) if one barrier level is provided, or out of each of the hydraulically most remote eight sprinklers (eight on one line or four on two lines on the same level), if two or more barrier levels are provided. The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 10 psi (0.69 bar).

[**30:**16.6.1.4]

In the 2015 edition of the *Code*, item (1) was amended to allow intermediate-temperature sprinklers where ambient temperatures might exceed what is normally expected. Item (3) was amended to require a minimum flow rate in addition to the minimum discharge pressure, to ensure a proper discharge pattern.

For the 2018 edition of the *Code*, item (3) has been further amended to allow the use of either one or two lines of in-rack sprinklers for calculating the pressure demand for the most hydraulically remote sprinklers.

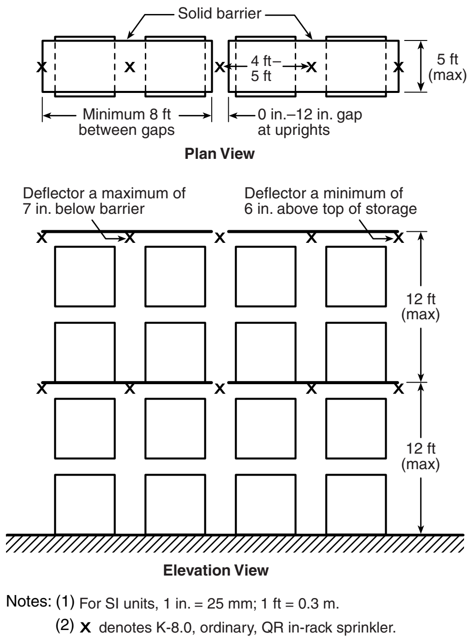

*FIGURE 66.16.6.1.1(a) Single-Row Rack Sprinkler Layout for Design Scheme "A." [**30:** Figure 16.6.1.1(a)]*

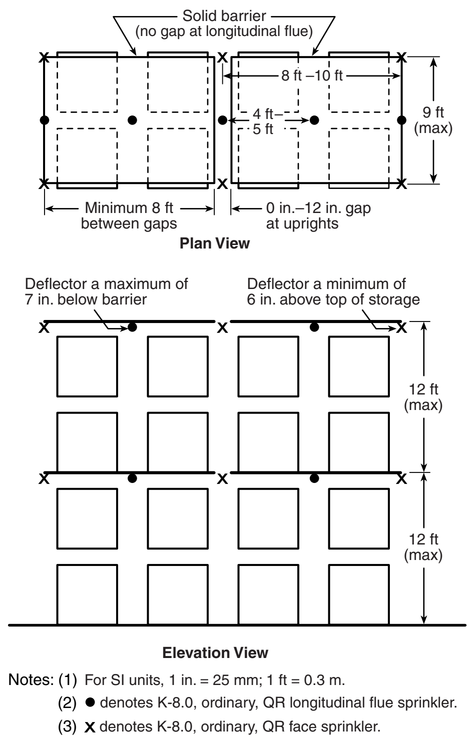

*FIGURE 66.16.6.1.1(b) Double-Row Rack Sprinkler Layout for Design Scheme "A." [**30:** Figure 16.6.1.1(b)]*

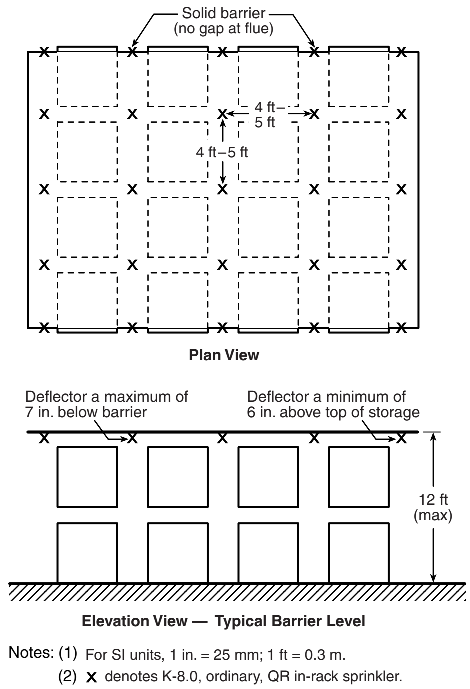

*FIGURE 66.16.6.1.1(c) Multiple-Row Rack Sprinkler Layout for Design Scheme "A." [**30:** Figure 16.6.1.1(c)]*

66.16.6.1.5* Where adjacent rack bays are not dedicated to storage of liquids, the barrier and in-rack sprinkler protection shall be extended at least 8 ft (2.4 m) beyond the area devoted to liquid storage. In addition, barrier and in-rack sprinkler protection shall be provided for any rack across the aisle within 8 ft (2.4 m) of the perimeter of the liquid storage in accordance with 66.16.6.1. [**30:**16.6.1.5]

A.66.16.6.1.5 The 8 ft (2.4 m) separation distance required in 66.16.6.1.5 is measured from the face of liquid storage in one rack to the face of liquid storage and/or other storage across the aisle in an adjacent rack. Rack designers, code officials, and plan reviewers are cautioned to the fact that many rack storage arrangements involve the storage of pallets that overhang the face of the rack. Therefore, although the structural rack members might be arranged to have an 8 ft (2.4 m) aisle between the racks, the distance between the face of the stored materials in the racks could be less than 8 ft (2.4 m) when the racks are filled with pallets. This will not be in compliance with the requirements of 66.16.6.1.5, unless the barrier and in-rack sprinkler protection is extended. [**30:**A.16.6.1.5]

66.16.6.1.6 Ceiling sprinkler demand shall not be included in the hydraulic calculations for in-rack sprinklers. [**30:**16.6.1.6]

66.16.6.1.7 Water demand at point of supply shall be calculated separately for in-rack and ceiling sprinklers and shall be based on the greater demand. [**30:**16.6.1.7]

66.16.6.1.8 Ceiling sprinklers shall meet the following requirements:

(1) Ceiling sprinkler protection shall be designed to protect the surrounding occupancy.
(2) Any sprinkler type shall be acceptable.
(3) If standard spray sprinklers are used, they shall be capable of providing not less than 0.20 gpm/ft^2 over 3000 ft^2 (8 mm/min over 270 m^2).
(4) If the liquid storage does not extend to the full height of the rack, protection for commodities stored above the top horizontal barrier shall meet the requirements of Section 13.3 and NFPA 13 for the commodities stored, based on the full height of the rack.

66.16.6.1.9 Barriers shall not be required for liquids with closed-cup flash points of 450°F (230°C) or greater. If barriers are omitted, the following shall apply:

(1) Ceiling sprinkler protection shall provide a minimum density of 0.3 gpm/ft^2 over the most hydraulically remote 2000 ft^2 (12 mm/min over 180 m^2) using ordinary temperature, standard-response sprinklers. Sprinklers shall have a nominal K-factor equal to or greater than 8.0. Intermediate-temperature sprinklers shall be used where ambient conditions require.
(2) The ceiling sprinkler water demand and the in-rack water demand shall be balanced at their point of connection.
(3) The sprinklers located at the rack face shall be staggered vertically.

[**30:**16.6.1.9]

Item (1) was amended in the 2015 edition of the *Code* to allow intermediate-temperature sprinklers where ambient temperatures might exceed what is normally expected.

66.16.6.1.10 A 500 gpm (1900 L/min) hose stream allowance shall be provided. [**30:**16.6.1.10]

66.16.6.2 Fire Protection System Design Scheme "B."

66.16.6.2.1 Horizontal barriers of plywood having a minimum thickness of ⅜ in. (10 mm) or of sheet metal of minimum 22 gauge thickness shall be installed in accordance with Figure 66.16.6.2.1(a), Figure 66.16.6.2.1(b), or Figure 66.16.6.2.1(c), whichever is applicable. All liquid storage shall be located beneath a barrier. [**30:**16.6.2.1]

66.16.6.2.2 In-rack sprinklers shall be installed in accordance with Figure 66.16.6.2.1(a), Figure 66.16.6.2.1(b), or Figure 66.16.6.2.1(c), whichever is applicable. [**30:**16.6.2.2]

66.16.6.2.3 Vertical barriers shall not be provided between in-rack sprinklers. [**30:**16.6.2.3]

Δ **66.16.6.2.4** In-rack sprinklers shall meet the following requirements:

(1) In-rack sprinklers shall be ordinary temperature–rated quick-response sprinklers and shall have a nominal K-factor equal to or greater than 8.0. Intermediate-temperature sprinklers shall be used where ambient conditions require.
(2) In-rack sprinklers shall be installed below each barrier level.

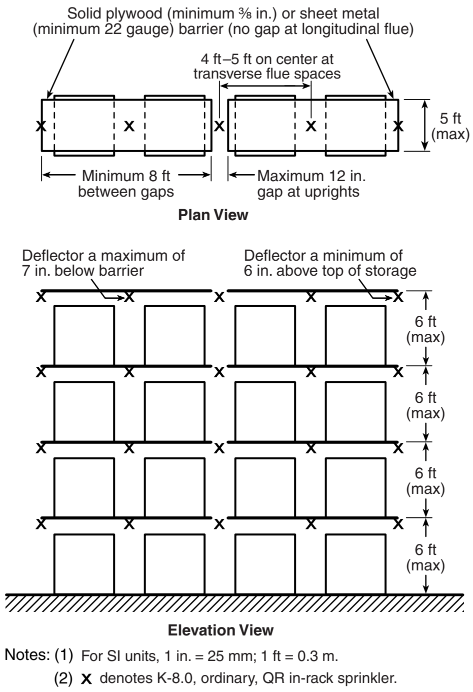

FIGURE 66.16.6.2.1(a) Single-Row Rack Sprinkler Layout for Design Scheme "B" — Sprinklers in Center of Rack. [30: Figure 16.6.2.1(a)]

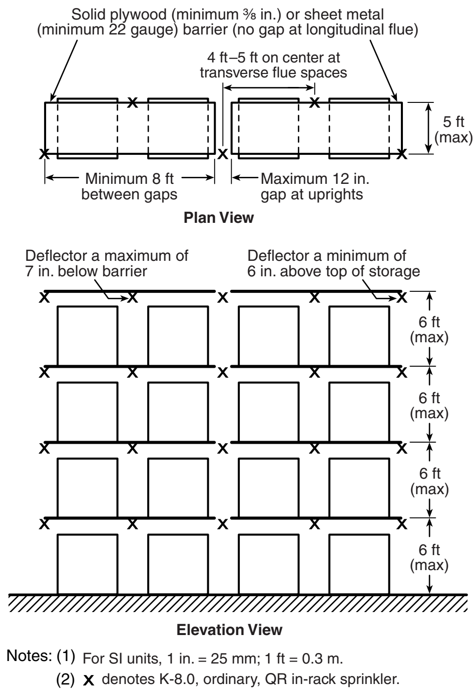

FIGURE 66.16.6.2.1(b) Single-Row Rack Sprinkler Layout for Design Scheme "B" — Sprinklers on Face of Rack. [30: Figure 16.6.2.1(b)]

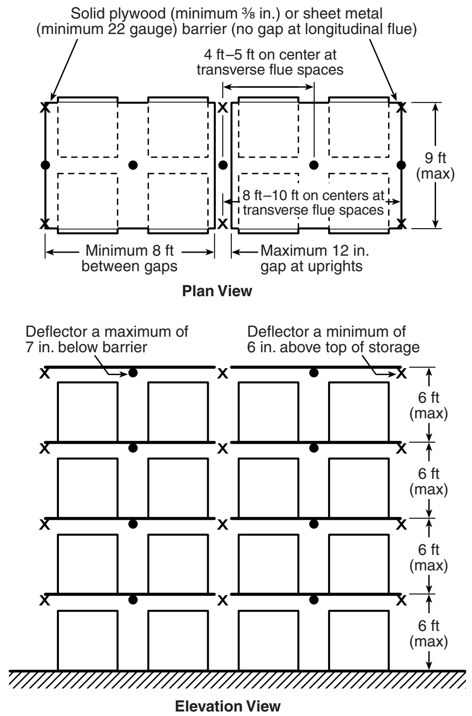

Notes: (1) For SI units, 1 in. = 25 mm; 1 ft = 0.3 m.
(2) ● denotes K-8.0, ordinary, QR longitudinal flue sprinkler.
(3) X denotes K-8.0, ordinary, QR face sprinkler.

***FIGURE 66.16.6.2.1(c)** Double-Row Rack Sprinkler Layout for Design Scheme "B." [**30:** Figure 16.6.2.1(c)]*

(3) For containers that do not exceed 60 gal (230 L) capacity, in-rack sprinklers shall provide a minimum discharge flow of 57 gpm (220 L/min) out of each of the hydraulically most remote six sprinklers (six on one line or three on two lines) if one barrier level is provided, or out of each of the hydraulically most remote eight sprinklers (eight on one line or four on two lines on the same level), if two or more barrier levels are provided. The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 10 psi (0.69 bar).
(4) For containers that exceed 60 gal (230 L) capacity, but do not exceed 793 gal (3000 L), in-rack sprinklers shall provide a minimum discharge flow of 57 gpm out of each of the hydraulically most remote 12 sprinklers (12 on one line or six on two lines on the same level). The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 10 psi (0.69 bar).

[**30:**16.6.2.4]

Item (1) was amended in the 2015 edition of the *Code* to allow the use of in-rack sprinklers with K-factors greater than 8.0, to correlate with changes made elsewhere in the chapter. Item (1) was also amended to allow the use of intermediate-temperature sprinklers where ambient temperatures might exceed what is normally expected.

For the 2018 edition of the *Code*, items (3) and (4) have been amended to allow the use of either one or two lines of in-rack sprinklers for calculating the pressure demand for the most hydraulically remote sprinklers.

66.16.6.2.5 If there are adjacent rack bays that are not dedicated to storage of liquids, the barrier and in-rack sprinkler protection shall be extended beyond the area devoted to liquid storage as follows:

(1) For containers that do not exceed 1 gal (3.8 L) capacity, protection shall be extended at least 8 ft (2.4 m) beyond the area devoted to liquid storage. In addition, adjacent racks across the aisles on each side of the liquid storage shall be protected in accordance with Section 13.3 and NFPA 13 for the commodity stored.
(2) For containers that exceed 1 gal (3.8 L) capacity, but do not exceed 793 gal (3000 L), protection shall be extended at least 8 ft (2.4 m) beyond the area devoted to liquid storage. In addition, protection shall be provided to any rack across the aisle within 8 ft (2.4 m) of the perimeter of the liquid storage in accordance with 66.16.6.2.

[**30:**16.6.2.5]

66.16.6.2.6 Ceiling sprinklers for containers that do not exceed 1 gal (3.8 L) capacity shall meet the following requirements:

(1) Ceiling sprinklers shall be designed to protect the surrounding occupancy.
(2) Ceiling sprinkler water demand shall not be included in the hydraulic calculations for the in-rack sprinkler protection.
(3) Water demand at the point of supply shall be calculated separately for in-rack and ceiling sprinklers and shall be based on the greater of the two.
(4) Any sprinkler type shall be acceptable for the ceiling sprinkler protection.
(5) If standard spray sprinklers are used, they shall be capable of providing not less than 0.20 gpm/ft^2 over 3000 ft^2 (8 L/min over 270 m^2).
(6) If the liquid storage does not extend to the full height of the rack, protection for commodities stored above the top horizontal barrier shall meet the requirements of Section 13.3 and NFPA 13 for the commodities stored, based on the full height of the rack.

[**30:**16.6.2.6]

66.16.6.2.7 Ceiling sprinklers for containers that exceed 1 gal (3.8 L) capacity, but do not exceed 60 gal (230 L), shall meet the following requirements:

(1) Ceiling sprinkler protection shall provide a minimum density of 0.45 gpm/ft^2 (18.3 mm/min) over the most hydraulically remote 3000 ft^2 (270 m^2), using high-temperature, standard-response sprinklers of nominal K-factor of 11.2 or greater. Other types of sprinklers shall not be used.
(2) Ceiling sprinkler water demand and the in-rack sprinkler demand shall be balanced at the point of connection.

[**30:**16.6.2.7]

66.16.6.2.8 Ceiling sprinklers for containers that exceed 60 gal (230 L) capacity, but do not exceed 793 gal (3000 L), shall meet the following requirements:

(1) Ceiling sprinklers shall be designed to provide a minimum density of 0.60 gpm/ft^2 over 3000 ft^2 (24 mm/min over the most remote 270 m^2), using high-temperature–rated, standard-response sprinklers of nominal K-factor of 11.2 or greater. Other types of sprinklers shall not be used.

(2) Ceiling sprinkler water demand and the in-rack sprinkler demand shall be balanced at the point of connection.

[**30:**16.6.2.8]

66.16.6.2.9 A 500 gpm (1900 L/min) hose stream allowance shall be provided. [**30:**16.6.2.9]

66.16.6.3 Fire Protection System Design Scheme "C."

66.16.6.3.1 Horizontal barriers of plywood having a minimum thickness of ⅜ in. (10 mm) or of sheet metal of minimum 22 gauge thickness shall be installed in accordance with Figure 66.16.6.3.1(a), Figure 66.16.6.3.1(b), or Figure 66.16.6.3.1(c), whichever is applicable. All liquid storage shall be located beneath a barrier. [**30:**16.6.3.1]

66.16.6.3.2 Vertical baffles shall not be installed between in-rack sprinklers. [**30:**16.6.3.2]

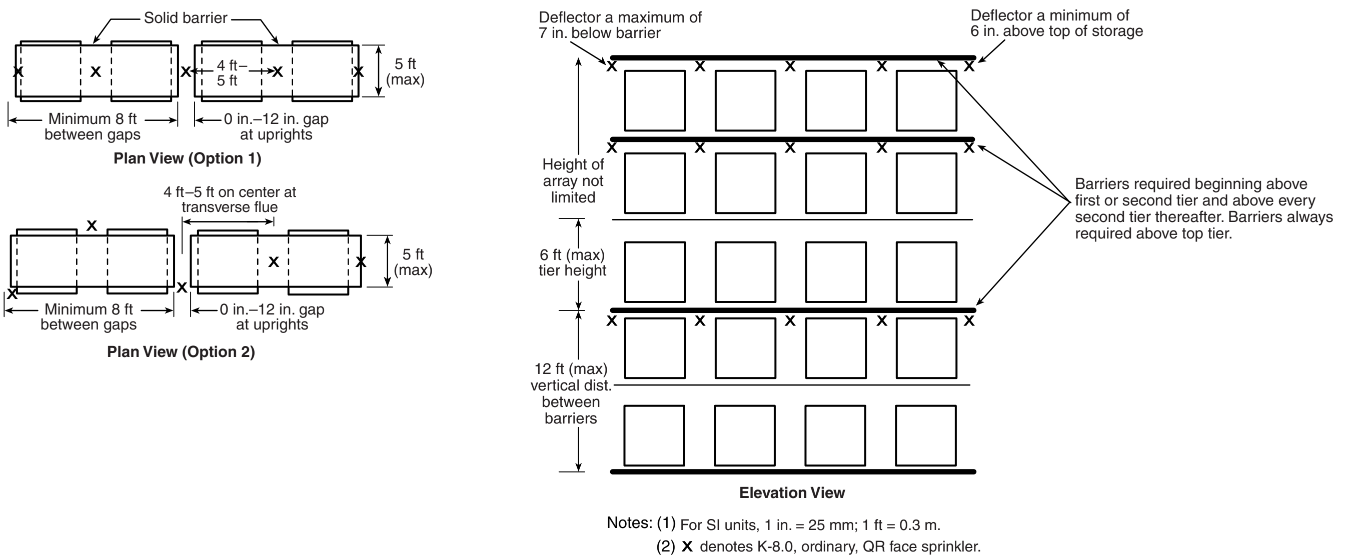

*FIGURE 66.16.6.3.1(a) Single-Row Rack Sprinkler Layout for Design Scheme "C." [**30:** Figure 16.6.3.1(a)]*

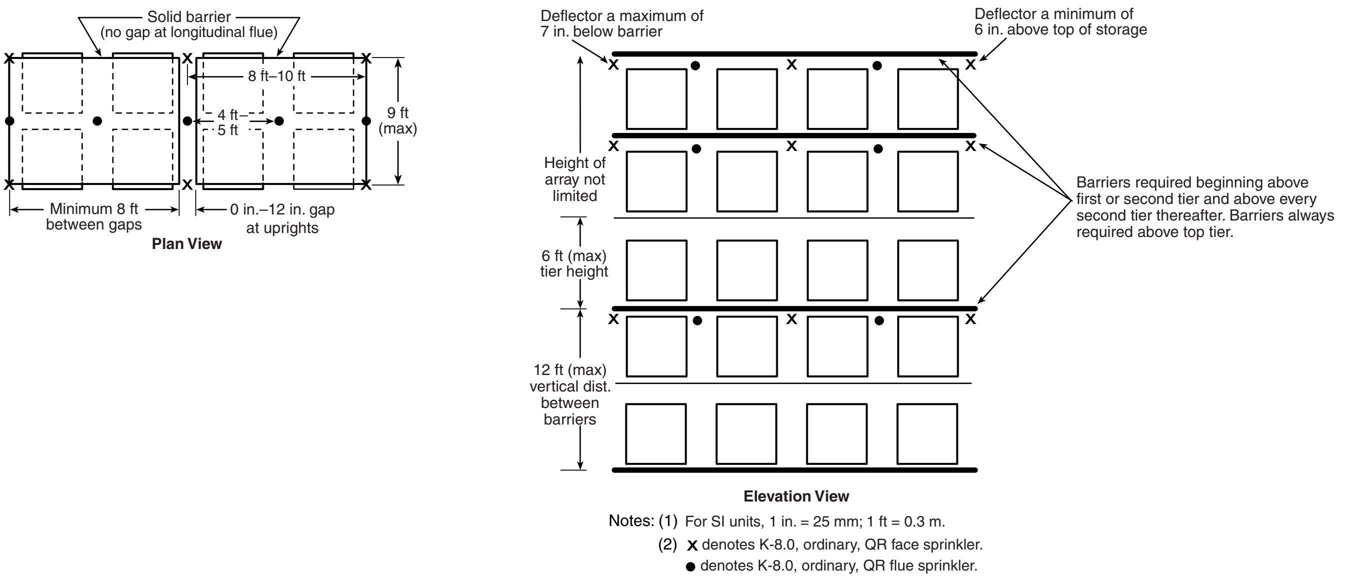

*FIGURE 66.16.6.3.1(b) Double-Row Rack Sprinkler Layout for Design Scheme "C." [**30:** Figure 16.6.3.1(b)]*

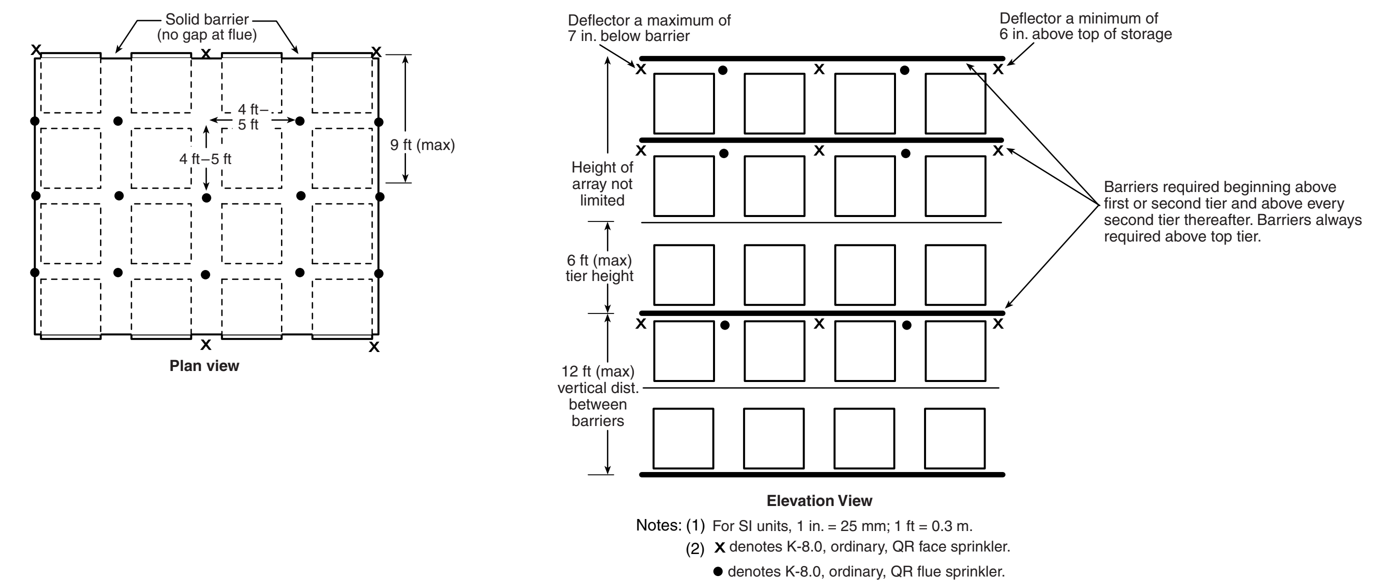

FIGURE 66.16.6.3.1(c) *Multiple-Row Rack Sprinkler Layout for Design Scheme "C." [**30:** Figure 16.6.3.1(c)]*

66.16.6.3.3 In-rack sprinklers shall meet the following requirements:

(1) In-rack sprinklers shall be ordinary temperature–rated, quick-response sprinklers. Sprinklers shall have a nominal K-factor equal to or greater than 8.0. An intermediate-temperature sprinkler shall be used where ambient conditions require.
(2) In-rack sprinklers shall be installed below each barrier level.
(3) In-rack sprinklers shall provide a minimum discharge flow of 30 gpm (110 L/min) out of each of the hydraulically most remote six sprinklers (six on one line or three on two lines), if one barrier level is provided, or out of each of the hydraulically most remote eight sprinklers (eight on one line or four on two lines on the same level), if two or more barrier levels are provided. The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 10 psi (0.69 bar).

[**30:**16.6.3.3]

Item (1) was amended in the 2015 edition of the *Code* to allow the use of in-rack sprinklers with K-factors greater than 8.0, to correlate with changes made elsewhere in the chapter. Item (1) was also amended to allow the use of intermediate-temperature sprinklers where ambient temperatures might exceed what is normally expected.

For the 2018 edition of the *Code*, item (3) has been amended to allow the use of either one or two lines of in-rack sprinklers for calculating the pressure demand for the most hydraulically remote sprinklers.

66.16.6.3.4 If there are adjacent bays of in-rack arrays that are not dedicated to storage of liquids, the barrier and in-rack sprinkler protection shall be extended at least 8 ft (2.4 m) beyond the area devoted to liquid storage. [**30:**16.6.3.4]

66.16.6.3.5 Ceiling sprinkler demand shall not be included in the hydraulic calculations for in-rack sprinklers. [**30:**16.6.3.5]

66.16.6.3.6 Water demand at point of supply shall be calculated separately for in-rack and ceiling sprinklers and shall be based on the greater demand. [**30:**16.6.3.6]

66.16.6.3.7 Ceiling sprinklers shall meet the following requirements:

(1) Ceiling sprinkler protection shall be designed to protect the surrounding occupancy.
(2) Any sprinkler type shall be acceptable.
(3) If standard spray sprinklers are used, they shall be capable of providing not less than 0.20 gpm/ft^2 over 3000 ft^2 (8 mm/min over 270 m^2).
(4) If the liquid storage does not extend to the full height of the rack, protection for commodities stored above the top horizontal barrier shall meet the requirements of Section 13.3 and NFPA 13 for the commodities stored, based on the full height of the rack.

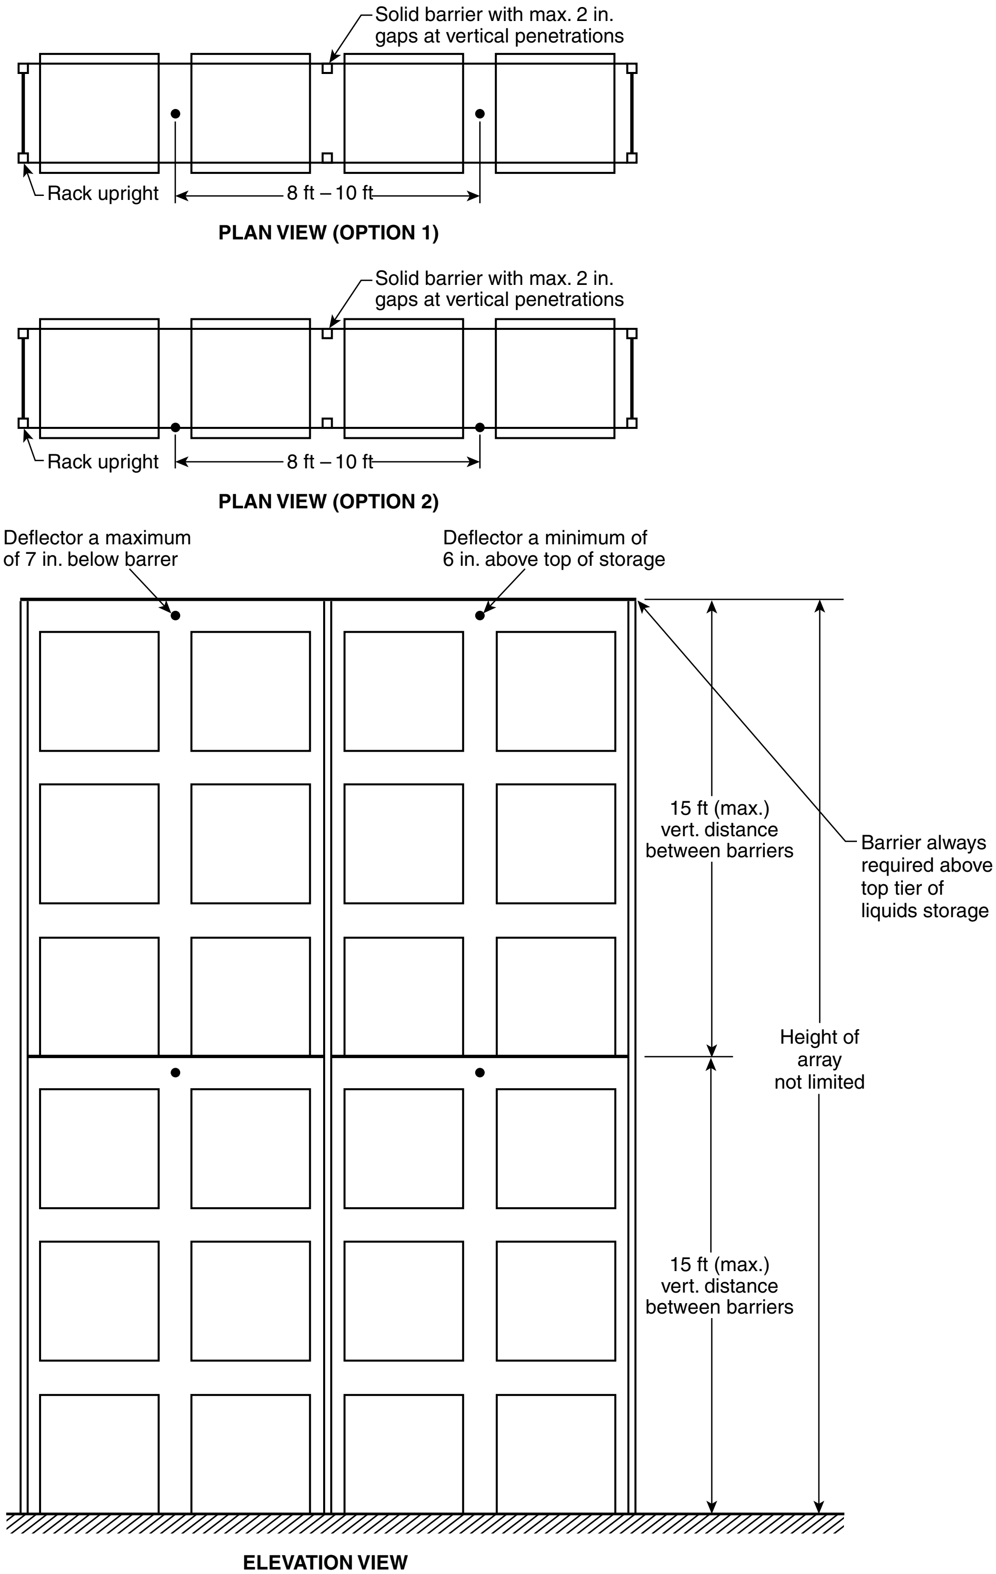
[**30:**16.6.3.7]

66.16.6.3.8 A 500 gpm (1900 L/min) hose stream allowance shall be provided. [**30:**16.6.3.8]

N **66.16.6.4 Fire Protection System Design Scheme "E."**

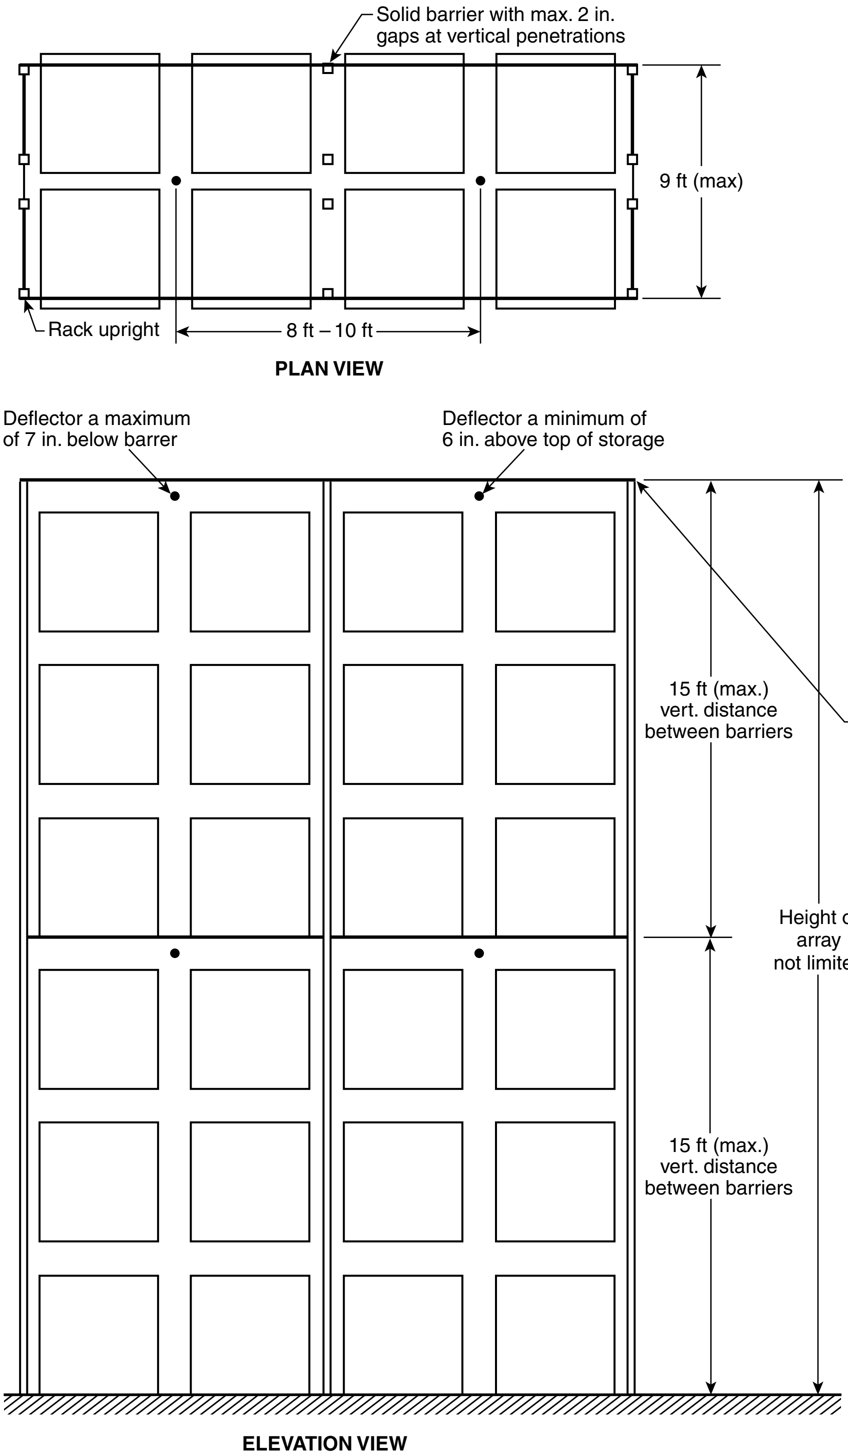
N **66.16.6.4.1** Sprinklers and horizontal barriers shall be installed in accordance with Figure 66.16.6.4.1(a) or Figure 66.16.6.4.1(b), whichever is applicable. Horizontal barriers shall be of plywood having a minimum thickness of ⅜ in. (10 mm) or of sheet metal of minimum 22 gauge thickness. All liquid storage shall be located beneath a barrier. [**30:**16.6.4.1]

N **66.16.6.4.2** Vertical baffles shall not be installed between in-rack sprinklers. [**30:**16.6.4.2]



Notes: (1) For SI units, 1 in. = 25 mm; 1 ft = 0.3 m.
(2) • Denotes K-25.2 extended coverage pendent CMDA storage sprinkler

*FIGURE 66.16.6.4.1(a) Single-Row Rack Sprinkler Layout for Design Scheme "E." [**30:**16.6.4.1(a)]*



Notes: (1) For SI units, 1 in. = 25 mm; 1 ft = 0.3 m.
(2) • Denotes K-25.2 extended coverage pendent CMDA storage sprinkler

*FIGURE 66.16.6.4.1(b) Double-Row Rack Sprinkler Layout for Design Scheme "E." [**30:**16.6.4.1(b)]*

N **66.16.6.4.3** In-rack sprinklers shall meet the following requirements:

(1) In-rack sprinklers shall be intermediate temperature–rated, pendent sprinklers with a nominal K-factor of 25.2 and shall be listed as extended coverage control mode density/area storage sprinklers.
(2) In-rack sprinklers shall be positioned in a transverse flue below each barrier level.
(3) In-rack sprinklers shall not be positioned within 3.5 ft (1 m) of a rack upright.
(4) The minimum in-rack sprinkler discharge pressure shall not be less than a gauge pressure of 30 psi (207 kPa).
(5) Where one level of in-rack sprinklers is installed, the design shall include the 3 most hydraulically remote sprinklers on a single line.
(6) Where two levels of in-rack sprinklers are installed, the design shall include the 3 most hydraulically remote sprinklers on a single line, and the 2 most hydraulically remote sprinklers on the next adjacent level.
(7) Where three or more levels of in-rack sprinklers are installed, the design shall include the 3 most hydraulically remote sprinklers on a single line, and the 2 most hydraulically remote sprinklers on the next two adjacent levels.
(8) Foam-water sprinkler protection shall be permitted to be substituted for water sprinkler protection, provided the same design criteria is used, and that the sprinkler is listed for use with foam.

[**30:**16.6.4.3]

N **66.16.6.4.4** If there are adjacent bays of in-rack arrays that are not dedicated to storage of liquids, the barrier and in-rack sprinkler protection shall be extended at least 6 ft (1.8 m) beyond the area devoted to liquid storage. [**30:**16.6.4.4]

N **66.16.6.4.5** Ceiling sprinkler demand shall not be included in the hydraulic calculations for in-rack sprinklers. [**30:**16.6.4.5]

N **66.16.6.4.6** Water demand at point of supply shall be calculated separately for in-rack and ceiling sprinklers and shall be based on the greater demand. [**30:**16.6.4.6]

N **66.16.6.4.7** Ceiling sprinklers shall meet the following requirements:

(1) Ceiling sprinkler protection shall be designed to protect the surrounding occupancy.
(2) Any sprinkler type shall be acceptable.
(3) If standard spray sprinklers are used, they shall be capable of providing not less than 0.30 gpm/ft^2 over 3000 ft^2 (8 mm/min over 270 m^2) when supplied with water. Design area can be reduced to 2000 ft^2 when using a preprimed foam-water system installed in accordance with NFPA 16 and maintained in accordance with NFPA 25.
(4) If the liquid storage does not extend to the full height of the rack, protection for commodities stored above the top horizontal barrier shall meet the requirements of NFPA 13 for the commodities stored, based on the full height of the rack.

[**30:**16.6.4.7]

N **66.16.6.4.8** A 500 gpm (1900 L/min) hose stream allowance shall be provided. [**30:**16.6.4.8]

Δ **66.16.6.5 In-Rack Sprinkler Layouts for Table 66.16.5.2.8.** Where indicated in Table 66.16.5.2.8, in-rack sprinklers shall be installed as follows:

(1) Where Layout 7 is required, in-rack sprinklers shall be installed in accordance with Figure 66.16.6.5(a),
(2) Where Layout 8 is required, in-rack sprinklers shall be installed in accordance with Figure 66.16.6.5(b) or Figure 66.16.6.5(c).
(3) Where Layout 9 is required, in-rack sprinklers shall be installed in accordance with Figure 66.16.6.5(d), or Figure 66.16.6.5(e), whichever is applicable. [**30:**16.6.5]

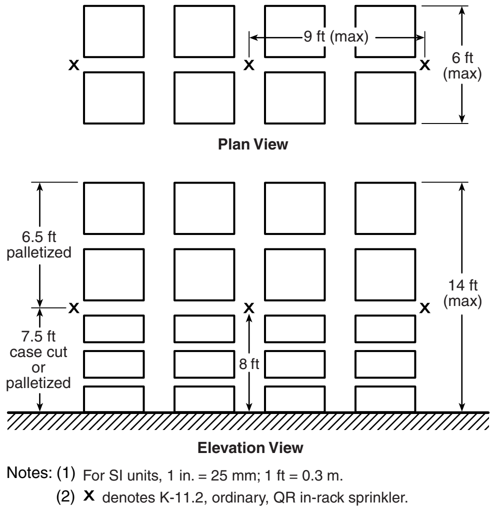


FIGURE 66.16.6.5(a) Double-Row Rack Sprinkler Layout G. [30: Figure 16.6.5(a)]

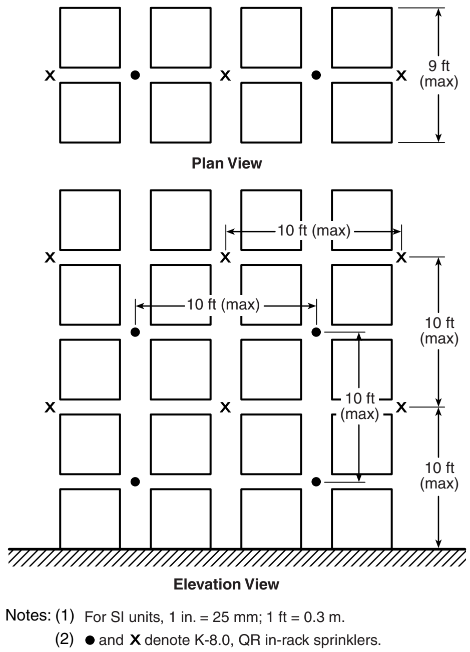

FIGURE 66.16.6.5(b) Double-Row Rack Sprinkler Layout I — Option #1. [30: Figure 16.6.5(b)]

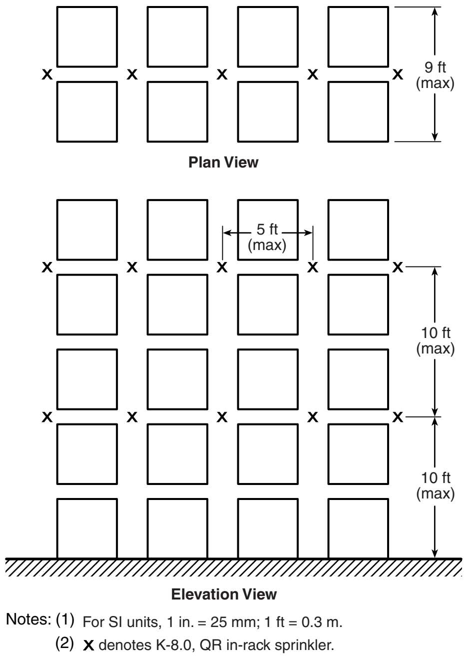

***FIGURE 66.16.6.5(c)** Double-Row Rack Sprinkler Layout I — Option #2. [**30:** Figure 16.6.5(c)]*

66.16.7 Water Supply. Water supplies for automatic sprinklers, other water-based protection systems, hose streams, and hydrants shall be capable of supplying the anticipated water flow demand for a minimum of 2 hours. [**30:**16.7]

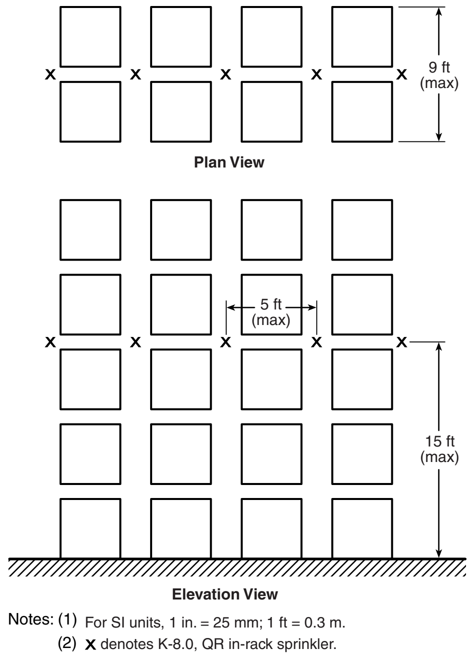

***FIGURE 66.16.6.5(e)** Double-Row Rack Sprinkler Layout H — Option #2. [**30:** Figure 16.6.5(e)]*

66.16.8 Containment, Drainage, and Spill Control.

66.16.8.1 Containment or containment and drainage shall be provided in accordance with Figure 66.16.8.1, when protection systems are installed in accordance with the provisions of this section. [**30:**16.8.1]

66.16.8.2* Where control of the spread of liquid is required, means to limit the spread of liquid to an area not greater than the design discharge area of the ceiling sprinkler system shall be provided. [**30:**16.8.2]

Δ **A.66.16.8.2** Subsection 66.16.8 requires that control of liquid spread be provided to prevent a pool fire on the floor from spreading and opening more sprinkler heads than the design of the sprinkler system anticipates. For example, if the sprinkler system is designed to provide 0.45 gpm/ft^2 over 3000 ft^2 (18 mm/min over 280 m^2), 66.16.8.2 requires that the spread of liquid also be limited to 3000 ft^2 (280 m^2). Various means are available to achieve this control. [**30:**A.16.8.2]

Typical methods use trench or spot drains that divide the floor of the storage area into rectangles having areas equal to or less than the design area of the sprinkler system. Drains are centered under racks, and the floor is sloped toward the drain trenches with a minimum slope of 1 percent. The floor is made highest at the walls. See Figure A.66.16.8.2(a) and Figure A.66.16.8.2(b). Trenches are arranged as described in NFPA 15 and as shown in Figure A.66.16.8.2(c). Note particularly the dimensions of the trenches, and note that the solid covering spans one-third of the width on either side of the open grate and the open grate spans the middle third. Spot drains can be similarly arranged. Another method, shown in

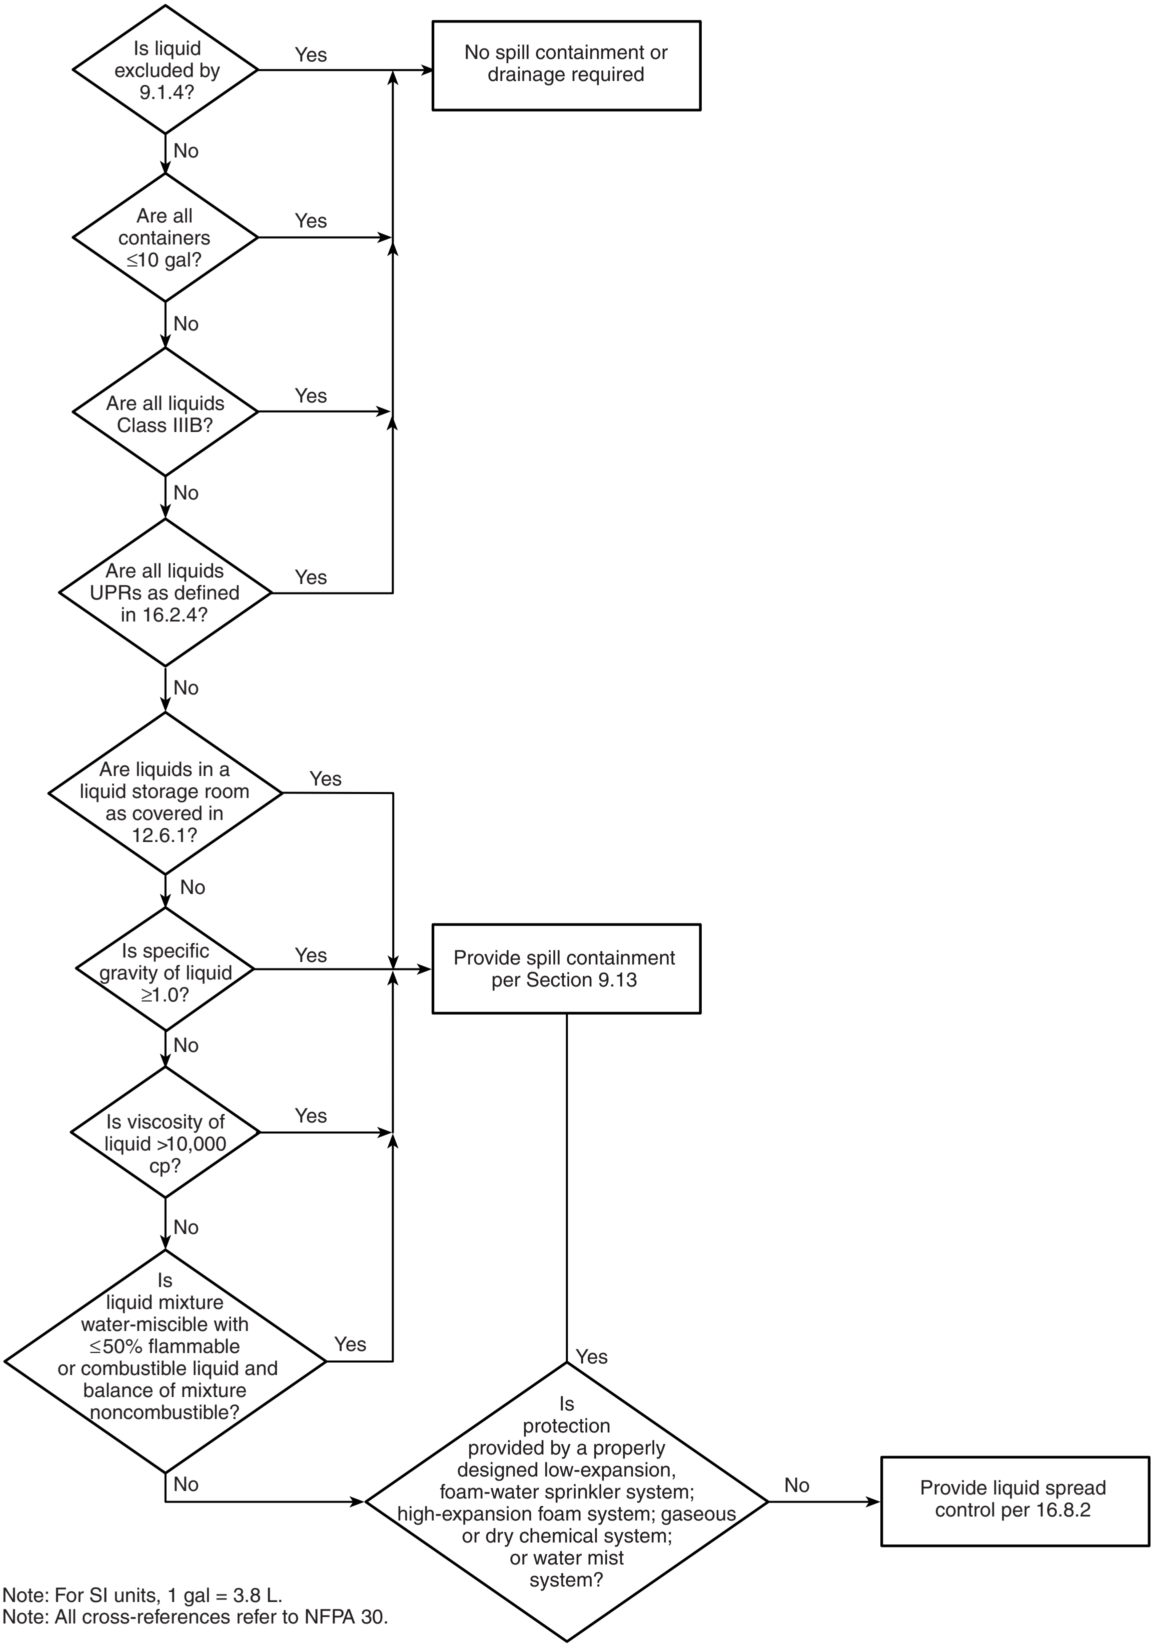

*FIGURE 66.16.8.1 Spill Containment and Liquid Spread Control for Protected Storage. [**30:**Figure 16.8.1]*

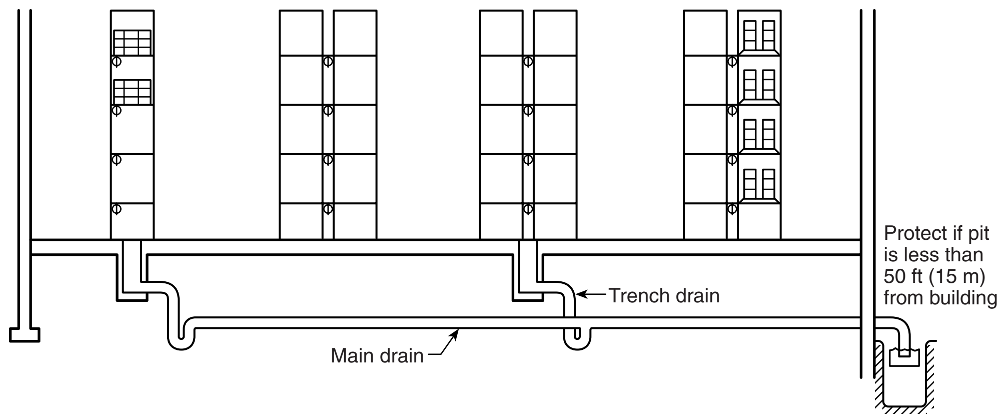

*FIGURE A.66.16.8.2(a) General Scheme for Warehouse Spill Control of Liquids. [**30:** Figure A.16.8.2(a)]*

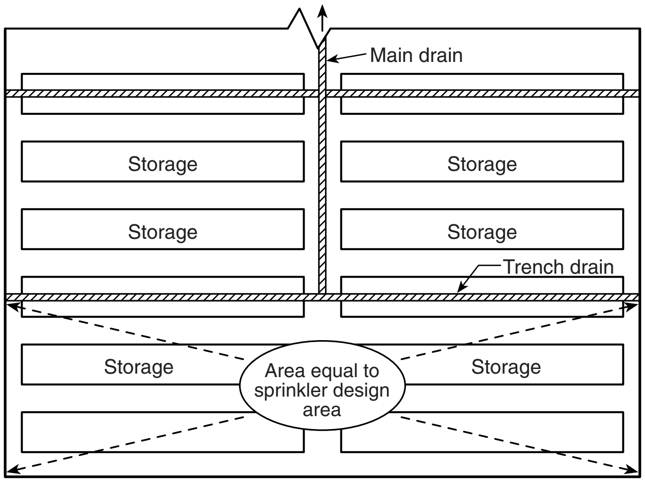

*FIGURE A.66.16.8.2(b) Plan View of Warehouse Spill Control of Liquids. [**30:** Figure A.16.8.2(b)]*

Figure A.66.16.8.2(d), uses spot drains located at building columns, where the area between any four columns does not exceed the design area of the sprinkler system. The floor is sloped to direct water flow to the drains. [**30:**A.16.8.2]

Connections to the drains are provided at trapped sumps, arranged as described in NFPA 15. See Figure A.66.16.8.2(e). To provide a safety factor, the drain pipes are sometimes sized to carry 150 percent of anticipated sprinkler discharge. The following equation can be used to calculate the flow of the drain pipe:

$$F = 1.5DA \qquad \textbf{[A.66.16.8.2]}$$

where:

F = flow (gpm or L/min)

D = sprinkler design density (gpm/ft^2 or L/min/m^2)

A = sprinkler design area (ft^2 or m^2)

[**30:**A.16.8.2]

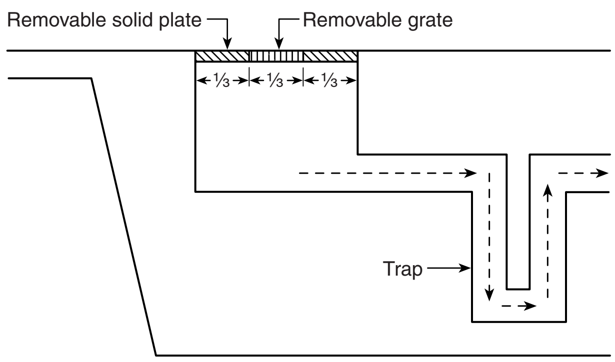

*FIGURE A.66.16.8.2(c) Details of Drainage Trench Design. [**30:** Figure A.16.8.2(c)]*

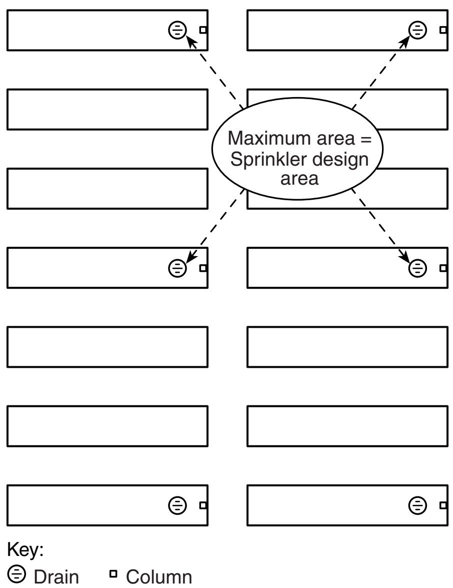

*FIGURE A.66.16.8.2(d) Typical Arrangement of Floor Drains. [**30:** Figure A.16.8.2(d)]*

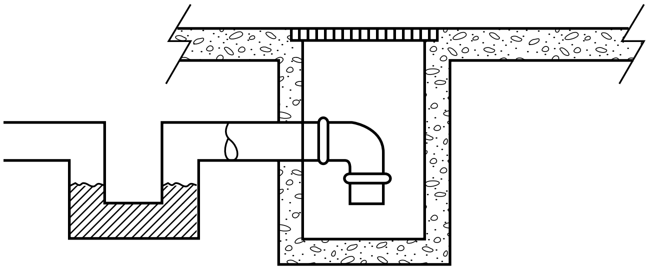

*FIGURE A.66.16.8.2(e) Details of Liquid-Seal Trap. [**30:** Figure A.16.8.2(e)]*

Additional information can be found in *Guidelines for Safe Warehousing of Chemicals*, Center for Chemical Process Safety, American Institute of Chemical Engineers. [**30:**A.16.8.2]

66.16.9 Other Automatic Fire Protection Systems. Alternate fire protection systems, such as automatic water spray systems, automatic water mist systems, high-expansion foam systems, dry chemical extinguishing systems, alternate sprinkler system configurations, or combinations of systems shall be permitted if approved by the AHJ. Such alternate systems shall be designed and installed in accordance with the appropriate NFPA standard and with manufacturer's recommendations for the system(s) selected. [**30:**16.9]

66.17 Processing Facilities

66.17.1 Scope.

66.17.1.1* This section shall apply where the processing of liquids is the principal activity, except as covered elsewhere in this *Code* or in other NFPA standards. *(See 66.1.4.)* [**30:**17.1.1]

A.66.17.1.1 Facilities designed in accordance with Chapter 17 of NFPA 30 do not use the maximum allowable quantity and control area concepts found in the building code. [**30:**A.17.1.1]

Section 66.17 is intended to cover facilities that both use and produce commodities that are flammable or combustible liquids, such as the chemical process plant shown in Exhibit 66.24. Such facilities range in scale and complexity from pharmaceutical manufacturing, whose process capacity might be not much greater than what would be considered a small pilot plant in other industries, up to 100,000 barrels (16,000 m^3) per day petroleum refineries, or large integrated chemical plants of similar size or larger.

66.17.1.2 Provisions of this chapter shall not prohibit the use of movable tanks for the dispensing of flammable or combustible liquids into fuel tanks of motorized equipment outside on premises not accessible to the public, where such use has the approval of the AHJ. [**30:**17.1.2]

There is a demonstrated need for refueling motorized equipment that is not self-propelled — for example, an air compressor, welding cart, or generator — for maintenance operations, particularly during plant shutdowns, turnarounds, and major process upgrades at larger facilities such as refineries and large petrochemical plants. Paragraph 66.17.1.2, which allows the use of a tank vehicle for such refueling, is based on a similar provision in 42.7.6 .

Exhibit 66.24

A typical chemical process plant.

66.17.2 Reserved.

66.17.3 General Requirements.

66.17.3.1 Liquid processing operations shall be located and operated so that they do not constitute a significant fire or explosion hazard to life, to property of others, or to important buildings or facilities within the same plant. [**30:**17.3.1]

66.17.3.2 Specific requirements shall depend on the inherent risk in the operations themselves, including the liquids being processed, operating temperatures and pressures, and the capability to control any liquid or vapor releases or fire incidents that could occur. [**30:**17.3.2]

66.17.3.3 The interrelationship of the many factors involved shall be based on good engineering and management practices to establish suitable physical and operating requirements. [**30:**17.3.3]

66.17.3.4 Process facilities shall comply with the applicable requirements for specific operations set forth in Sections 66.18, 66.19, 66.28, or 66.29. [**30:**17.3.4]

66.17.3.5 Process facilities shall comply with the applicable requirements for procedures and practices for fire and explosion prevention, protection, and control set forth in Section 66.6. [**30:**17.3.5]

66.17.3.6 Processing and handling of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. *(See 66.4.1.2 and A.66.6.4.1.2.)* [**30:**17.3.6]

66.17.3.7 When a process heats a liquid to a temperature at or above its flashpoint, the following shall apply:

(1) The process vessel shall be closed to the room in which it is located and vented to the outside of the building.
(2) If the vessel needs to be opened to add ingredients, the room ventilation shall meet the requirements of 66.17.11 and the process heating controls will be interlocked with the ventilation such that the process heat will shut down if the ventilation fails or is turned off.
(3) The process vessel shall be equipped with an excess temperature control set to limit excessive heating of the liquid and the subsequent release of vapors.
(4) If a heat transfer medium is used to heat the liquid and the heat transfer fluid can heat the liquid to its boiling point on failure of the process and excess temperature heat controls, a redundant excess temperature control shall be provided.

[**30:**17.3.7]

66.17.4 Location of Process Vessels and Equipment.

66.17.4.1 Liquid-processing vessels and equipment shall be located in accordance with the requirements of this section. [**30:**17.4.1]

66.17.4.2 Processing vessels and buildings containing such processing vessels shall be located so that a fire involving the vessels does not constitute an exposure hazard to other occupancies. [**30:**17.4.2]

66.17.4.3 The minimum distance of a processing vessel to a property line that is or can be built upon, including the opposite side of a public way; to the nearest side of a public way; or to the nearest important building on the same property shall be determined by one of the following:

(1) In accordance with Table 66.17.4.3
(2) In accordance with an engineering evaluation of the process, followed by application of sound fire protection and process engineering principles

[**30:**17.4.3]

The primary performance objective required by 66.17.4.2 and 66.17.4.3 is that the processing vessel or the building housing will not constitute a fire exposure to adjacent buildings or structures. To that end, Table 66.17.4.3 specifies minimum separation distances based on vessel capacity, process operating pressure, and whether the liquid is stable or unstable. However, it must be understood that the separation distances in Table 66.17.4.3 are minimums: If the separation distances based on an engineering evaluation indicate that the minimum separation distances given in the table are not appropriate for the hazard, then greater separation distances as determined by the engineering evaluation are to be used. The engineering evaluation is not optional; it is specifically required by 66.6.4 and 66.17.15.

The maximum operating liquid capacity of a processing vessel is analogous to the maximum capacity of a storage tank. However, some processing vessels are designed to operate only partially filled with liquid, with the remainder of the vessel containing a gas or a vapor. The liquid capacity of the vessel is what is of importance here. One major difference is that the "nearest important building on the same property" is qualified to mean a building that is not directly related to the process. The vessel might or might not be housed in a building, so the distances are measured from the vessel itself.

The greater spacing required by Table 66.17.4.3 for unstable liquids recognizes the possibility that a runaway chemical reaction might produce pressures and flow rates that exceed the capacity of the vent system. The distances specified in the table are doubled if protection for exposures is not provided.

As an example of the application of Table 66.17.4.3, consider two 12,000 gal (45,400 L) batch processing vessels that might or might not be located in a building. The vessels operate at atmospheric pressure and are vented to atmosphere through a reflux condenser. The process involves an exothermic (heat releasing) reaction, and at least one of the reactants can be considered unstable.

The appropriate separation distances, taken from the third row and the fourth and eighth columns of the table, are as follows: 50 ft (15 m) from the nearest property line; 50 ft (15 m) from the opposite side of any public way; 50 ft (15 m) from the nearest important building on the same property that is not directly related to the process; and 50 ft (15 m) from the nearest side of any public way.

Exhibit 66.25 illustrates the separation distances. Note that the presence or absence of the building wall, as indicated by the double-dashed line in the diagram, has no influence on the separation distances.

66.17.4.3.1 Processing vessels used solely to process stable Class IIIB liquids shall be located in accordance with Table 22.4.1.6 of NFPA 30. [**30:**17.4.3.1]

66.17.4.4 Where process vessels are located in a building and the exterior wall facing the exposure (line of adjoining property that is or can be built upon or nearest important building on the same property) is greater than 25 ft (7.6 m) from the exposure and is a blank wall having a fire resistance rating of not less than 2 hours, any greater distances required by Table 66.17.4.3 shall be permitted to be waived. If the exterior wall is a blank wall having a fire resistance rating of not less than 4 hours, all distances required by Table 66.17.4.3 shall be permitted to be waived. [**30:**17.4.4]

66.17.4.5 All the distances given in Table 66.17.4.3 shall be doubled where protection for exposures is not provided. [**30:**17.4.5]

66.17.4.6* Liquid-processing equipment, such as pumps, heaters, filters, and exchangers, shall not be located closer than 25 ft (7.6 m) to property lines where the adjoining property is or can be built upon or to the nearest important building on the same property that is not an integral part of the process. This spacing requirement shall be permitted to be waived where exposures are protected in accordance with 66.17.4.3. [**30:**17.4.6]

A.66.17.4.6 Equipment operated at gauge pressures that exceed 1000 psi (6900 kPa) might require greater spacing. [**30:**A.17.4.6]

The 25 ft (7.6 m) minimum separation distance required by 66.17.4.6 reflects the philosophy that such equipment is

TABLE 66.17.4.3 *Location of Process Vessels with Respect to Property Lines, Public Ways, and the Nearest Important Building on the Same Property — Protection for Exposures Is Provided*

	Minimum Distance (ft)							
	From Property Line that Is or Can Be Built upon, Including Opposite Side of Public Way				From Nearest Side of Any Public Way or from Nearest Important Building on Same Property that Is Not an Integral Part of the Process

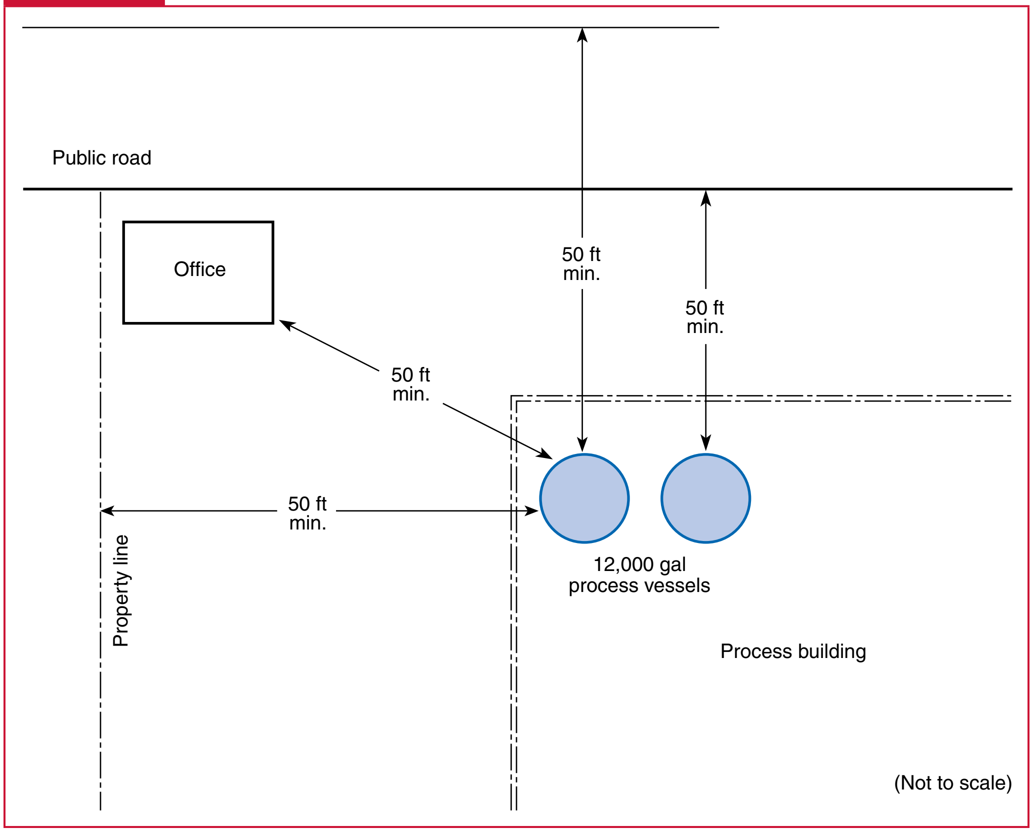
275 or less	5	25	50	100	5	25	50	100
276 to 750	10	25	50	100	5	25	50	100
751 to 12,000	15	25	50	100	5	25	50	100
12,001 to 30,000	20	30	50	100	5	25	50	100
30,001 to 50,000	30	45	75	120	10	25	50	100
50,001 to 100,000	50	75	125	200	15	25	50	100
Over 100,000	80	120	200	300	25	40	50	100

For SI units, 1 gal = 3.8 L; 1 ft = 0.3 m; 1 psi = a gauge pressure of 6.9 kPa.

Note: Double all of above distances where protection for exposures is not provided.

*Gauge pressure. [**30:** Table 17.4.3]

Exhibit 66.25



Example of the application of Table 66.17.4.3.

inherently more prone to leakage and periodic repair than process vessels. The Annex A note is an important reminder that process equipment operating at high pressures requires special consideration. Leaks in equipment operating at high pressures can result in sizable releases of vapor or atomized liquid, sometimes culminating in explosions.

66.17.4.7 Processing equipment in which unstable liquids are handled shall be separated from unrelated plant facilities by either of the following:

(1) 25 ft (7.6 m) clear spacing
(2) A wall having a fire resistance rating of not less than 2 hours and explosion resistance consistent with the expected hazard

[**30:**17.4.7]

66.17.5 Accessibility. Each process unit or building containing liquid-processing equipment shall be accessible from at least one side for fire fighting and fire control. [**30:**17.5]

66.17.6 Construction Requirements.

66.17.6.1 Process buildings or structures used for liquid operations shall be constructed consistent with the operations being conducted and with the classes of liquids handled. They shall be constructed to minimum Type II (000) construction, as defined in *NFPA 5000*, and shall be constructed in accordance with Table 66.17.6.1. [**30:**17.6.1]

***TABLE 66.17.6.1** Minimum Separation Distances for Buildings or Structures Used for Liquid Handling and Operations*

Liquid Class	Minimum Type of Construction*	Minimum Separation Distance (ft): To Street, Alley, or Public Way	Minimum Separation Distance (ft): To Adjacent Property Line that Is or Can Be Built Upon
Class I liquids; unstable liquids of any class; liquids of any class heated above their flash points†	II (222)	5	10
	II (111)	5	25
	II (000)	10	50
Class II	II (111)	5	10
	II (000)	5	25
Class III	II (000)	5	10

For SI units, 1 ft = 0.3 m.

Note: Distances apply to properties that have protection for exposures, as defined in this code. If there are exposures for which protection does not exist, the distances should be doubled, in accordance with 66.17.6.3.

*Construction types are defined in NFPA 220, *Standard on Types of Building Construction*. [**30:** Table 17.6.1]

†For stable liquids of any class heated above their flash points, see 66.6.4.1.2 and A.66.6.4.1.2.

66.17.6.2 Construction types shall be as defined in *NFPA 5000*. [**30:**17.6.2]

66.17.6.3 Where protection for exposures is not provided, the applicable distances given in Table 66.17.6.1 shall be doubled. [**30:**17.6.3]

66.17.6.4 For buildings or structures that are not provided with approved automatic sprinkler protection, the separation distances otherwise required by Table 66.17.6.1 shall be determined by an engineering evaluation of the process, but shall not be less than the separation distances required by Table 66.17.4.3. [**30:**17.6.4]

66.17.6.5 Buildings or structures used solely for blending, mixing, or dispensing of Class IIIB liquids at temperatures below their flash points shall be permitted to be constructed of combustible construction, subject to the approval of the AHJ. [**30:**17.6.5]

66.17.6.6 Buildings or structures used for processing or handling of liquids where the quantities of liquids do not exceed 360 gal (1360 L) of Class I and Class II liquids and 720 gal (2725 L) of Class IIIA liquids shall be permitted to be constructed of combustible construction, subject to the approval of the AHJ. [**30:**17.6.6]

66.17.6.7 Buildings or structures used for processing or handling of liquids protected with automatic sprinklers or equivalent fire protection systems shall be permitted to be constructed of combustible construction, subject to the approval of the AHJ. [**30:**17.6.7]

Δ **66.17.6.8*** Load-bearing building supports and load-bearing supports of vessels and equipment capable of releasing quantities of liquids that could result in a fire capable of causing substantial property damage shall be protected by one or more of the following:

(1) Drainage to a safe location to prevent liquids from accumulating under vessels or equipment or around load-bearing supports
(2) Fire-resistive construction
(3) Fire-resistant protective coatings or systems
(4) Water spray systems designed and installed in accordance with NFPA 15
(5) Other alternate means acceptable to the AHJ

[**30:**17.6.8]

A.66.17.6.8 API 2218, *Fireproofing Practices in Petroleum and Petrochemical Processing Plants*, contains guidance on selecting and installing fire-resistant coatings to protect exposed steel supports from a high-challenge fire exposure. It also contains a general discussion on determining need for such protection and estimating the extent of the area exposed. [**30:**A.17.6.8]

66.17.6.9 Class I liquids shall not be handled or used in basements. [**30:**17.6.9]

This requirement is based on several incidents in which spilled liquid or vapors from a spill migrated to belowgrade levels and were ignited. Fighting the ensuing fires proved challenging, because of the difficulties in accessing the belowgrade areas.

66.17.6.9.1 Where Class I liquids are handled or used above grade within buildings with basements or closed pits into which flammable vapors can travel, such belowgrade areas shall be provided with mechanical ventilation designed to prevent the accumulation of flammable vapors. [**30:**17.6.9.1]

66.17.6.9.2 Means shall be provided to prevent liquid spills from running into basements. [**30:**17.6.9.2]

66.17.6.10* Smoke and heat venting shall be permitted to be used where it assists access for fire fighting. [**30:**17.6.10]

Δ **A.66.17.6.10** NFPA 204 provides information on this subject. [**30:**A.17.6.10]

66.17.6.11* Areas shall have exit facilities arranged to prevent occupants from being trapped in the event of fire. [**30:**17.6.11]

When the provisions of NFPA *101*®, *Life Safety Code*®, are to be applied, the requirements for high-hazard industrial occupancies should be followed.

Δ **A.66.17.6.11** NFPA *101* provides information on this subject. [**30:**A.17.6.11]

66.17.6.11.1 Exits shall not be exposed by the drainage facilities described in 66.17.10. [**30:**17.6.11.1]

66.17.6.12 Aisles shall be maintained for unobstructed movement of personnel and fire protection equipment. [**30:**17.6.12]

Δ **66.17.6.13** Indoor areas where Class IA or unstable liquids are in use shall be designed to direct flame, combustion gases, and pressures resulting from a deflagration away from important buildings or occupied areas through the use of damage-limiting construction in accordance with NFPA 68. [**30:**17.6.13]

Paragraph 66.17.6.13 is a minimum requirement. Explosion venting (more correctly, deflagration venting) might also be desirable where stable liquids or other classes of liquids are heated and their vapors released. Hot vapors will cool and condense and might form an ignitible cloud of mist.

66.17.6.13.1 The damage-limiting construction design shall be in accordance with recognized standards and shall be acceptable to the AHJ. *(See A.66.9.16.1.)* [**30:**17.6.13.1]

66.17.6.13.2 Where unstable liquids are in use, an approved engineered construction method that is designed to limit damage from an explosion (deflagration or detonation, depending on the characteristics of the liquid) shall be used. [**30:**17.6.13.2]

66.17.7 Reserved.

66.17.8 Reserved.

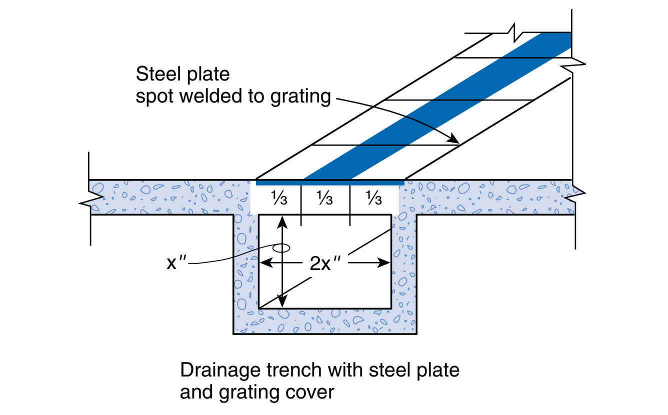
66.17.9 Electrical Systems. Electrical wiring and electrical utilization equipment shall comply with Section 66.7. [**30:**17.9]

66.17.10 Containment, Drainage, and Spill Control.

66.17.10.1* A facility shall be designed and operated to prevent the discharge of liquids to public waterways, public sewers, or adjoining property. [**30:**17.10.1]

Δ **A.66.17.10.1** This might require curbs, scuppers, or special drainage systems to control the spread of fire. Annex A of NFPA 15 provides information on this subject. [**30:**A.17.10.2]

Exhibit 66.26



Details of a well-designed drainage trench.

If scuppers are used to direct liquid leakage, they must not be located in a wall that is immediately adjacent to a diked area; otherwise, a spill drained from within a process building could endanger the storage tanks within the dike. The reference to Annex A of NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, is to a description of a vented trench (see Exhibit 66.26). A vented trench is designed so that any flame propagation through it is "lazy" due to lack of air, which minimizes damage. In all cases, the system must discharge to a location acceptable to local, state, and federal environmental authorities.

66.17.10.2 Emergency drainage systems shall be provided to direct liquid leakage and fire protection water to a safe location. [**30:**17.10.2]

66.17.10.3 Emergency drainage systems, if connected to public sewers or discharged into public waterways, shall be equipped with traps or separators. [**30:**17.10.3]

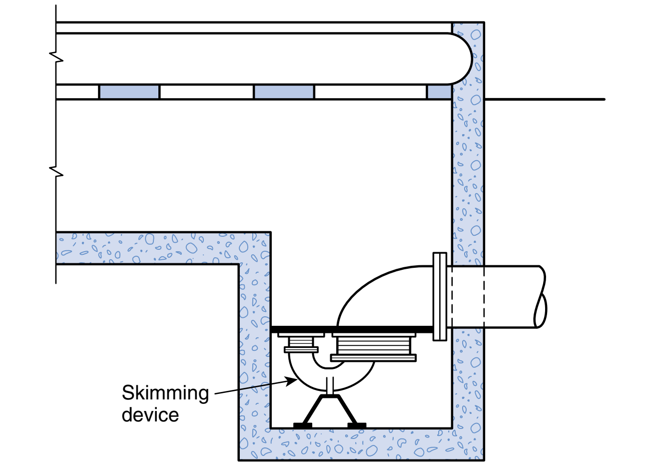
A trap ensures that a liquid seal is maintained as material flows through it, thus preventing flame propagation beyond the trap. Separators are most useful where a two-phase system — oil and water, for example — is discharged and only one phase requires control. See Exhibit 66.27 for an illustration of a suitable trap.

66.17.11 Ventilation.

NFPA 30 requires that the estimated ventilation rate be confirmed either by calculation or by actual test. Once again, environmental legislation is driving the technology of fire protection. Recent regulations that seek to limit discharge of volatile organic gases and vapors have spurred the development of rigorous modeling methods and calculation procedures for estimating the quantity of vapors emitted to a reasonable degree of accuracy (see 66.17.11.2). Annex F of NFPA 30 provides details on the calculation procedure recommended. Undoubtedly, other methods are available and more will be developed.

66.17.11.1 Enclosed processing areas handling or using Class I liquids, or Class II or Class III liquids heated to temperatures at

Exhibit 66.27



Details of a drainage system trap.

or above their flash points, shall be ventilated at a rate sufficient to maintain the concentration of vapors within the area at or below 25 percent of the lower flammable limit (LFL). Compliance with 66.17.11.2 through 66.17.11.10 shall be deemed as meeting the requirements of this section. [**30:**17.11.1]

66.17.11.2* Ventilation requirements shall be confirmed by one of the following:

(1) Calculations based on the anticipated fugitive emissions *(see Annex F of NFPA 30 for calculation method)*.
(2) Sampling of the actual vapor concentration under normal operating conditions. Sampling shall be conducted at a 5 ft (1.5 m) radius from each potential vapor source extending to or toward the bottom and the top of the enclosed processing area. The vapor concentration used to determine the required ventilation rate shall be the highest measured concentration during the sampling procedure.

[**30:**17.11.2]

A.66.17.11.2 Equipment in enclosed processing areas can deteriorate over time, and periodic evaluation should be conducted to ensure that leakage rates have not increased or that the ventilation rate is adequate for any increase in leakage rates. [**30:**A.17.11.2]

66.17.11.3 A ventilation rate of not less than 1 $ft^3/min/ft^2$ (0.3 $m^3/min/m^2$) of solid floor area shall be considered as meeting the requirements of 66.17.11.1. [**30:**17.11.3]

66.17.11.4 Ventilation shall be accomplished by mechanical or natural means. [**30:**17.11.4]

66.17.11.5 Exhaust ventilation discharge shall be to a safe location outside the building. [**30:**17.11.5]

66.17.11.6 Recirculation of the exhaust air shall be permitted only when it is monitored continuously using a fail-safe system that is designed to automatically sound an alarm, stop recirculation, and provide full exhaust to the outside in the event that vapor–air mixtures in concentrations over one-fourth of the lower flammable limit are detected. [**30:**17.11.6]

66.17.11.7* Provision shall be made for introduction of make-up air in such a manner as to avoid short-circuiting the ventilation. [**30:**17.11.7]

Δ **A.66.17.11.7** NFPA 91 and NFPA 90A provide information on this subject. [**30:**A.17.11.7]

66.17.11.8 Ventilation shall be arranged to include all floor areas or pits where flammable vapors can collect. [**30:**17.11.8]

66.17.11.9 Local or spot ventilation to control special fire or health hazards, if provided, shall be permitted to be utilized for up to 75 percent of the required ventilation. [**30:**17.11.9]

66.17.11.10 Where equipment such as dispensing stations, open centrifuges, plate and frame filters, and open vacuum filters is used in a building, the equipment and ventilation of the building shall be designed to limit flammable vapor–air mixtures under normal operating conditions to the interior of equipment and to not more than 5 ft (1.5 m) from equipment that exposes Class I liquids to the air. [**30:**17.11.10]

66.17.12 Reserved.

66.17.13 Reserved.

66.17.14* Process Equipment and Vessels. Equipment shall be designed and arranged to prevent the unintentional escape of liquids and vapors and to minimize the quantity escaping in the event of accidental release. [**30:**17.14]

Δ **A.66.17.14** Where the vapor space of equipment is usually within the flammable range, the probability of explosion damage to the equipment can be limited by inerting, by providing an explosion suppression system, or by designing the equipment to contain the peak explosion pressure that can be modified by explosion relief. Where the special hazards of operation, sources of ignition, or exposures indicate a need, consideration should be given to providing protection by one or more of the above means. [**30:**A.17.14]

See NFPA 68 and NFPA 69 for additional information on various methods of mitigating losses from explosions. [**30:**A.17.14]

66.17.15 Management of Operations Hazards.

66.17.15.1 This section shall apply to the management methodology used to identify, evaluate, and control the hazards involved in processing and handling of flammable and combustible liquids. These hazards include, but are not limited to, preparation; separation; purification; and change of state, energy content, or composition. [**30:**17.15.1]

66.17.15.2 Operations involving flammable and combustible liquids shall be reviewed to ensure that fire and explosion hazards resulting from loss of containment of liquids are provided with corresponding fire prevention and emergency action plans.

Exception No. 1: Operations where liquids are used solely for on-site consumption as fuels.

Exception No. 2: Operations where Class II or Class III liquids are stored in atmospheric tanks or transferred at temperatures below their flash points.

Exception No. 3: Mercantile occupancies, crude petroleum exploration, drillings, and well servicing operations, and normally unoccupied facilities in remote locations.
*[**30:**17.15.2]*

66.17.15.3 The extent of fire prevention and control that is provided shall be determined by means of an engineering evaluation of the operation and application of sound fire protection and process engineering principles. This evaluation shall include, but not be limited to, the following:

(1) Analysis of the fire and explosion hazards of the operation
(2) Analysis of emergency relief from process vessels, taking into consideration the properties of the materials used and the fire-protection and control measures taken
(3) Analysis of applicable facility design requirements in 66.17.3 through 66.17.4
(4) Analysis of applicable requirements in Sections 66.18, 66.19, 66.28, and 66.29 for liquid handling, transfer, and use
(5) Analysis of local conditions, such as exposure to and from adjacent properties and exposure to floods, earthquakes, and windstorms
(6) Analysis of the emergency response capabilities of the local emergency services

[**30:**17.15.3]

66.17.15.4 A written emergency action plan that is consistent with available equipment and personnel shall be established to respond to fires and related emergencies. This plan shall include the following:

(1) Procedures to be followed in case of fire or release of liquids or vapors, such as sounding the alarm, notifying the fire department, evacuating personnel, and controlling and extinguishing the fire
(2) Procedures and schedules for conducting drills of these procedures
(3) Appointment and training of personnel to carry out assigned duties, which shall be reviewed at the time of initial assignment, as responsibilities or response actions change, and whenever anticipated duties change
(4) Procedures for maintenance of the following:
    (a) Fire protection equipment and systems
    (b) Drainage and containment systems
    (c) Ventilation equipment and systems
(5) Procedures for shutting down or isolating equipment to reduce, control, or stop the release of liquid or vapors, including assigning personnel responsible for maintaining critical plant functions or shutdown of plant processes and safe startup following isolation or shutdown
(6) Alternate measures for the safety of occupants

[**30:**17.15.4]

66.17.15.5 The fire hazards management review conducted in accordance with 66.17.15.2 shall be repeated whenever the hazards leading to a fire or explosion change significantly. Conditions that might require repeating a review shall include, but are not limited to, the following:

(1) When changes occur in the materials in process
(2) When changes occur in process equipment
(3) When changes occur in process control
(4) When changes occur in operating procedures or assignments

[**30:**17.15.5]

66.18 Dispensing, Handling, Transfer, and Use of Liquids

66.18.1 Scope. This section applies where liquids are handled, dispensed, transferred, or used, including in process areas. [**30:**18.1]

66.18.2 Reserved.

66.18.3 General Requirements. Processing and handling of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. *(See 66.4.1.2 and A.66.6.4.1.2.)* [**30:**18.3]

66.18.4 Dispensing, Handling, Transfer, and Use.

66.18.4.1 Class I liquids shall be kept in closed tanks or containers when not actually in use. Class II and Class III liquids shall be kept in closed tanks or containers when not actually in use when the ambient or process temperature is at or above their flash points. [**30:**18.4.1]

Note that Class II and Class III liquids are required to be kept in closed containers only if they are exposed to ambient temperatures or process temperatures that exceed their flash points. Good practice dictates that all containers be kept tightly capped or sealed when not in use.

66.18.4.2 Where liquids are used or handled, provisions shall be made to promptly and safely mitigate and dispose of leakage or spills. [**30:**18.4.2]

66.18.4.3 Class I liquids shall not be used outside closed systems where there are open flames or other ignition sources within the classified areas set forth in Section 66.7. [**30:**18.4.3]

66.18.4.4 Transfer of liquids among vessels, containers, tanks, and piping systems by means of air or inert gas pressure shall be permitted only under all of the following conditions:

(1) The vessels, containers, tanks, and piping systems shall be designed for such pressurized transfer and shall be capable of withstanding the anticipated operating pressure.
(2) Safety and operating controls, including pressure-relief devices, shall be provided to prevent overpressure of any part of the system.
(3) Only inert gas shall be used to transfer Class I liquids. Only inert gas shall be used to transfer Class II and Class III liquids that are heated above their flash points.

[**30:**18.4.4]

The provisions of 66.18.4.4 provide a reasonable balance between safety and flexibility, based on current industry practices. Inert gas must still be used for any Class I liquid or any other liquid being handled at or above its flash point except as provided for in 66.18.4.4.1.

66.18.4.4.1 Dispensing of Class I liquids from a container by means of air shall be permitted under the following conditions:

(1) The pressure shall be generated by means of a listed hand-operated device.
(2) Pressure shall not exceed a gauge pressure of 6 psi (41 kPa) and pressure relief shall be provided.
(3) The container shall not exceed 119 gal (450 L) and shall be capable of withstanding the maximum pressure generated by the device.
(4) The device shall be bonded and grounded or shall be demonstrated as not being capable of generating a static charge under any operating condition.
(5) The material of construction of the device shall be compatible with the liquid dispensed.

[**30:**18.4.4.1]

Paragraph 66.18.4.4.1 was added to the 2015 edition of the *Code*. It addresses manually operated pumps, such as the one shown in Exhibit 66.28. Such pumps are already allowed for transferring Class II and Class III liquids by inference in 66.18.4.4. This provision of the *Code* extends the use of compressed air to transfer Class I liquids, albeit with considerable restrictions. First, only a manual pump can be used; a compressed air system is still prohibited. A maximum pressure is imposed, and use is restricted to containers as they are defined in this *Code*. Because 66.18.4.4.1 addresses liquids that are ignitible at ambient conditions, control of static electric charges is mandated.

66.18.4.5 Positive displacement pumps shall be provided with pressure relief that discharges back to the tank, pump suction, or other suitable location or shall be provided with interlocks to prevent overpressure. [**30:**18.4.5]

Exhibit 66.28

Example of a hand pump for liquids. (Courtesy of GoatThroat® Pumps)

The intent of 66.18.4.5 is to prevent failure of the piping system due to overpressure caused by a line blockage, shut valve, and so on. Unlike a centrifugal pump, in such cases a positive displacement pump will continue to pressurize the discharge piping until it fails.

66.18.4.6 Piping, valves, and fittings shall meet the requirements of Section 66.27. [**30:**18.4.6]

Δ **66.18.4.7** Approved hose shall be permitted to be used at transfer stations. [**30:**18.4.7]

Prior to the 2018 edition of the *Code*, 66.18.4.7 also referred to flexible connectors. This reference was deleted because flexible connectors are addressed in 66.27.5.2.

66.18.4.8* The staging of liquids in containers, intermediate bulk containers, and portable tanks shall be limited to the following:

(1) Containers, intermediate bulk containers, and portable tanks that are in use
(2) Containers, intermediate bulk containers, and portable tanks that were filled during a single shift
(3) Containers, intermediate bulk containers, and portable tanks needed to supply the process for one continuous 24-hour period
(4) Containers, intermediate bulk containers, and portable tanks that are stored in accordance with Section 66.9

[**30:**18.4.8]

A.66.18.4.8 The process area is not intended to be a storage area for liquid containers. However, it is recognized that containers will be brought into the process area either for transfer of liquids to the process or for dispensing liquids from the process to the containers. [**30:**A.18.4.8]

The amount of liquid in containers in the process area should be limited as much as possible. Full containers should not be stored in the process area but can be staged there. Only the amount of liquid needed for one continuous 24-hour period should be brought into the process area in full containers. Partial containers can remain in the process area as long as they do not increase the hazard present. Containers that were filled in the process area can remain there during the shift that they were filled but should be relocated to the appropriate storage area before the end of the workday or shift in the case of 24-hour-a-day operations. [**30:**A.18.4.8]

66.18.4.9 Class I, Class II, or Class IIIA liquids used in a process and staged in the process area shall not be filled in the process area.

Exception No. 1: Intermediate bulk containers and portable tanks that meet the requirements of Section 66.9.

*Exception No. 2: Intermediate products that are manufactured in the process area. [**30:**18.4.9]*

66.18.5 Incidental Operations.

66.18.5.1* This section shall apply to areas where the use, handling, and storage of liquids is only a limited activity to the established occupancy classification. [**30:**18.5.1]

A.66.18.5.1 Incidental operations are operations that utilize liquids only as a limited activity to that which establishes the occupancy classification. Examples include automobile assembly, assembly of electronic equipment, furniture manufacturing, and areas within refineries, distilleries, and chemical plants where the use of liquids is incidental, such as in maintenance shops, offices, or vehicle repair shops. Some more detailed descriptions follow:

(1) *Vehicle Assembly.* Vehicle assembly operations usually involve both process and incidental use of liquids. An example of a process operation would be paint storage and mixing utilized for application of the vehicle primer, color coats, and clear coats. For these operations, the requirements of Chapter 17 of NFPA 30 apply. Examples of incidental use would be sealer deck wipedown operations, windshield washer solvent dispensing, brake fluid filling, and final line paint repair operations. These operations might be continuous. However, the quantities of liquids used and the vapor exposures are significantly reduced from larger volume usage found within vehicle body component paint mixing and storage operations.
(2) *Assembly of Electrical Equipment.* Examples of incidental use of liquids in these types of occupancies might include "photoresist" coating operations, "softbaking" operations, wave solder operations, and wipedown operations.
(3) *Chemical Plant Maintenance Shop.* Incidental use of liquids is commonplace in maintenance shops located within a chemical plant. Examples are cutting oils used in a machine shop, Class II solvents for degreasing, and Class I and II paint solvents and fuels associated with automotive and industrial truck repair.
(4) *Cleaning and Sanitation.* Under provisions established by the U.S. Food and Drug Administration (FDA) in 21 CFR, "GMP for Medical Devices," Class I and Class II liquids can be used for cleaning and sanitation purposes. Limited quantities are used to remove manufacturing materials, mold release compounds, and other contaminants not intended to be on the final product. An example would be the use of isopropyl alcohol (IPA), transferred to a cleaning wipe via a plunger-type liquid-dispensing container. The cleaning wipe is then used to remove manufacturing materials not intended to be on the final product. The key point here is not that the liquid is not part of the final product, but that limited quantities of liquid are used and the use is incidental to the manufacturing operation that produces the product.

[**30:**A.18.5.1]

66.18.5.2 Class I liquids or Class II and Class III liquids that are heated up to or above their flash points shall be drawn from or transferred into vessels, containers, or portable tanks as follows:

(1) From original shipping containers with a capacity of 5.3 gal (20 L) or less
(2) From safety cans
(3) Through a closed piping system
(4) From portable tanks or containers by means of a device that has antisiphoning protection and that draws through an opening in the top of the tank or container
(5) By gravity through a listed self-closing valve or self-closing faucet

[**30:**18.5.2]

66.18.5.2.1 If hose is used in the transfer operation, it shall be equipped with a self-closing valve without a hold-open latch in addition to the outlet valve. Only listed or approved hose shall be used. [**30:**18.5.2.1]

66.18.5.2.2 Means shall be provided to minimize generation of static electricity. Such means shall meet the requirements of 66.6.5.4. [**30:**18.5.2.2]

66.18.5.2.3 Where pumps are used for liquid transfer, means shall be provided to deactivate liquid transfer in the event of a liquid spill or fire. [**30:**18.5.2.3]

66.18.5.3 Storage of liquids other than those governed by 66.18.5.4 and 66.18.5.5 shall comply with Section 66.9. [**30:**18.5.3]

66.18.5.4 The maximum allowable quantities (MAQs) of liquids in containers in use in incidental operations in a control area shall not exceed the greater of the following:

(1)* The amount required to supply incidental operations for one continuous 24-hour period, provided the hazard analysis required in Section 66.6 accounts for these quantities

A.66.18.5.4(1) The intent of this requirement is to allow the quantities of flammable and combustible liquids needed to safely and efficiently operate for the actual operating hours in any 24-hour period. As an example, if the facility operates only 8 hours out of 24 (i.e., a single shift) and uses 50 gal (190 L) of liquid during that time, then 50 gal (190 L) is the allowable quantity for the continuous 24-hour period. If the facility increases operations to two shifts, then the allowable quantity doubles to 100 gal (380 L). [**30:**A.18.5.4(1)]

(2) The aggregate sum of the quantities provided in Table 66.18.5.4

N ***TABLE 66.18.5.4*** *MAQ of Flammable and Combustible Liquids Per Control Area for Incidental Operations*

	Open Use		Use — Closed Containers	
Liquid Class(es)	**gal**	**L**	**gal**	**L**
IA	10	38	30	115
IB and IC	30	115	120	460
II	30	115	120	460
IIIA	80	300	330	1,265
IIIB	3,300	12,650	13,200	50,600

Notes:

Quantities are permitted to be increased 100 percent where stored in approved flammable liquids storage cabinets or in safety cans. Where note (2) also applies, the increase for both notes is permitted to be applied accumulatively.

Quantities are permitted to be increased 100 percent in buildings equipped throughout with an approved automatic sprinkler system installed in accordance with NFPA 13. Where Note (1) also applies, the increase for both notes is permitted to be applied accumulatively.

[**30:**18.5.4]

N **66.18.5.4.1** Where the quantities of liquids in incidental operations are governed by 66.18.5.4(2), the aggregate quantity of liquids in storage and in use shall not exceed the maximum allowable quantity per control area in Section 66.9. [**30:**18.5.4.1]

N **66.18.5.4.2** Control areas shall be in accordance with Section 66.9. [**30:**18.5.4.2]

• **66.18.5.5** Where quantities of liquids in excess of the limits in 66.18.5.4.1 are necessary, storage shall be in tanks that meet all applicable requirements of Section 66.17, Sections 66.21 through 66.25, and Section 66.27. [**30:**18.5.5]

The use of tanks, pumps, and piping systems eliminates the need for frequent opening and handling of small containers, greatly reducing the likelihood of spills.

66.18.5.6 Areas in which liquids are transferred from one tank or container to another container shall be provided with the following:

(1) Separation from other operations where potential ignition sources are present by distance or by fire-resistant construction

With respect to the separation distance or fire-resistive construction required by 66.17.6, no specific distance and no specific hourly fire resistance rating are cited to address the intent of 66.18.5.6(1). The appropriate determination requires considerable judgment on the part of the user. For example, a 1 gpm (3.8 L/min) leak will feed an 8 ft^2 (0.75 m^2) pool of burning liquid. While no one would want to stand close to such a fire, a simple metal partition would effectively stop the radiant heat.

(2) Drainage or other means to control spills
(3) Natural or mechanical ventilation that meets the requirements of 66.17.11

[**30:**18.5.6]

66.18.6 Ventilation for Dispensing Areas. Liquid storage areas where dispensing is conducted shall be provided with either a gravity system or a continuous mechanical exhaust ventilation system. Mechanical ventilation shall be used if Class I liquids are dispensed within the room. [**30:**18.6]

66.18.6.1 Exhaust air shall be taken from a point near a wall on one side of the room and within 12 in. (300 mm) of the floor, with one or more make-up inlets located on the opposite side of the room within 12 in. (300 mm) of the floor. [**30:**18.6.1]

66.18.6.2 The location of both the exhaust and inlet air openings shall be arranged to provide air movement across all portions of the floor to prevent accumulation of flammable vapors. [**30:**18.6.2]

66.18.6.3* Exhaust ventilation discharge shall be to a safe location outside the building. [**30:**18.6.3]

A.66.18.6.3 A "safe location" should be selected as the location of a vent discharge to minimize the potential for ignitible vapors to travel to a source of ignition after discharge from the vent. Electrical equipment that does not meet the requirements for hazardous locations can serve as an ignition source. The Technical Committee advises that vent discharge locations should consider such factors as the following:

(1) Characteristics of the exhausted material (vapor density, toxicity, velocity of discharge, etc.)
(2) Proximity to potential ignition sources
(3) Building openings such as doors, windows, air intakes, and so forth.
(4) Dispersion characteristics (distance to discharge within the flammable range, direction of discharge, atmospheric conditions, and the influence of building and neighboring buildings on discharged vapors)
(5) Likelihood of vapor accumulation following discharge, such as accumulation under building eaves
(6) Likelihood of sufficient discharge volume to allow an ignitible concentration to reach an ignition source

[**30:**A.18.6.3]

Historically, NFPA 30 has provided prescriptive guidance, often based on area classification requirements, and results have been acceptable. Closer distances should be accepted only if an engineering study by a qualified engineer justifies closer distances. Similarly, the specified distances might not be acceptable for all installations, thus the guidance provided above. [**30:**A.18.6.3]

66.18.6.3.1 Recirculation of the exhaust air shall be permitted only when it is monitored continuously using a fail-safe system that is designed to automatically sound an alarm, stop recirculation, and provide full exhaust to the outside in the event that vapor-air mixtures in concentrations over one-fourth of the lower flammable limit are detected. [**30:**18.6.3.1]

Δ **66.18.6.4** If ducts are used, they shall not be used for any other purpose and shall comply with NFPA 91. [**30:**18.6.4]

Δ **66.18.6.4.1** If make-up air to a mechanical system is taken from within the building, the opening shall be equipped with a fire door or damper, as required in NFPA 91. [**30:**18.6.4.1]

66.18.6.4.2 For gravity systems, the make-up air shall be supplied from outside the building. [**30:**18.6.4.2]

66.18.6.5 Mechanical ventilation systems shall provide at least 1 cfm of exhaust air for each square foot of floor area (0.3 $m^3/min/m^2$), but not less than 150 cfm (4 m^3/min). [**30:**18.6.5]

66.18.6.5.1 The mechanical ventilation system for dispensing areas shall be equipped with an airflow switch or other equally reliable method that is interlocked to sound an audible alarm upon failure of the ventilation system. [**30:**18.6.5.1]

66.19 Specific Operations

66.19.1 Scope. This section shall apply to the handling and use of flammable and combustible liquids in specific operations as herein described. [**30:**19.1]

66.19.2 Definitions Specific to Section 66.19.

66.19.2.1* Cooking Oil. Where used in this chapter, cooking oil shall be defined as a Class IIIB combustible liquid. This definition shall apply to both fresh, or new, cooking oil and waste, or used, cooking oil. [**30:**19.2.1]

A.66.19.2.1 Cooking oil is a Class IIIB liquid with a high flash point typically above 500°F (260°C). Because of its high flash point, cooking oil presents a lower fire hazard than Class IIIB liquids having flash points lower than 500°F (260°C). Fresh, or new, cooking oil is supplied to the user for cooking operations. As the oil becomes degraded through repeated use, it must be replaced with fresh oil. This waste, or used, cooking oil is recovered from the cooking appliance and temporarily stored for offsite removal. To maintain fluidity in the transfer process, the waste oil is heated to approximately 100°F (38°C), well below the flash point temperature. [**30:**A.19.2.1]

This definition of *cooking oil* was added to support 66.19.7, which was added to the 2015 edition of the *Code*. The definition explicitly recognizes that cooking oil is a Class IIIB liquid.

66.19.3 Reserved.

66.19.4 Recirculating Heat Transfer Systems.

Recirculating heat transfer systems are considered to be — and indeed are — much safer than systems involving direct-fired units. However, if the fluid used in the system is combustible and is heated up to or above its flash point, the potential for a fire is present. Even if the fluid is not heated to its flash point, a release under pressure, which does happen, can result in a cloud of very fine mist that can quite easily be ignited.

66.19.4.1 Scope.

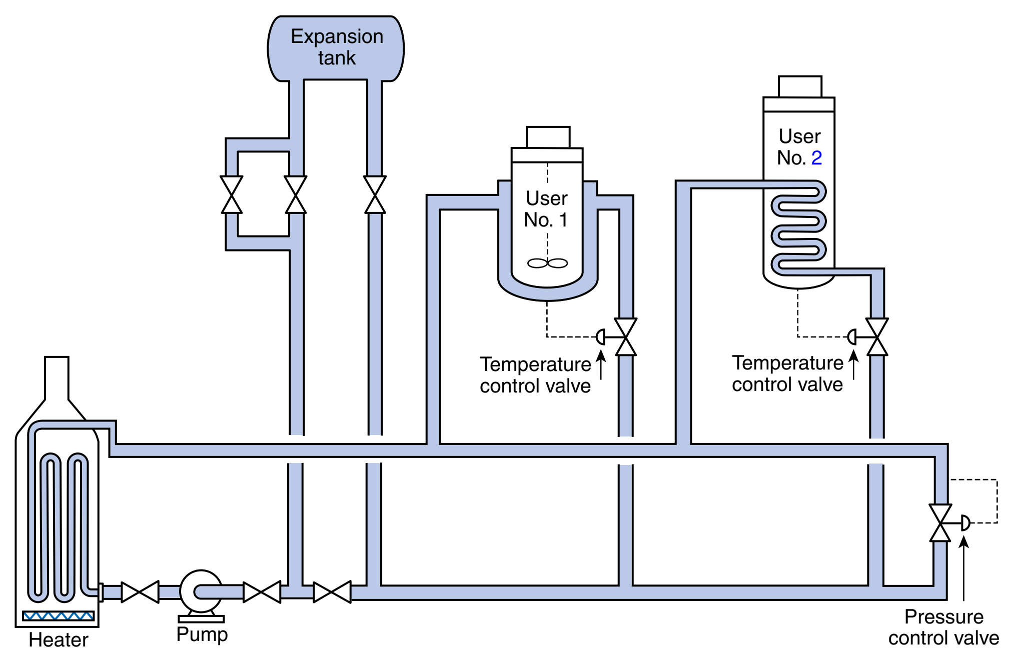
The types of heating systems covered in 66.19.4 use a fluid to transfer heat from the point at which it is generated, usually a boiler, to the process where the heat is used. The liquid circulates back and forth between its starting point and the point at which the heat is expended. The heat transfer fluid does not take part in any kind of reaction, and it is not otherwise used in any kind of a process. See Exhibit 66.29.

66.19.4.1.1 This section shall apply only to recirculating heat transfer systems that use a heat transfer fluid that is heated up to or above its flash point under normal operation. [**30:**19.4.1.1]

66.19.4.1.2 This section shall not apply to process streams used as a means of heat transfer or to any heat transfer system of 60 gal (230 L) capacity or less. [**30:**19.4.1.2]

It is common in chemical and refining processes to use heated process streams to transfer thermal energy from an outgoing process stream to an incoming one. This strategy saves enormous amounts of fuel by utilizing heat that otherwise might be wasted.

Exhibit 66.29



Schematic of a recirculating heat transfer system.

66.19.4.2* General Requirements. A heater or vaporizer for heat transfer fluid that is located inside a building shall meet all applicable requirements of Section 66.17. [**30:**19.4.2]

A.66.19.4.2 Mist explosions have occurred when heat transfer fluid that is above its boiling point has been released in an enclosed area. Consideration should be given to locating heaters or vaporizers either in a detached building or in a room with damage-limiting construction. [**30:**A.19.4.2]

66.19.4.3* System Design.

A.66.19.4.3 The system should be interlocked to stop circulation of the heat transfer fluid through the system and to shut off the system heater or vaporizer in the event of a fire, abnormally low pressure in the system, or operation of an approved heat detection system. Where the refractory inside the heater or vaporizer can retain enough heat to cause either breakdown of the heat transfer fluid or tube fouling if fluid circulation through the unit is stopped, circulation could have to be continued. In the event of a confirmed fire, it is desirable to subdivide the piping system by means of interlocked safety shutoff valves. A practical way of accomplishing this is to isolate all secondary circulating loops from the primary loop that runs into and out of the vaporizer or heater. [**30:**A.19.4.3]

A well-marked remote emergency shutoff switch or electrical disconnect should be provided to shut down the entire system in the event of an emergency. This should be located either in a constantly attended location or at a location that would be accessible in the event of a leak or a fire. [**30:**A.19.4.3]

If there are any process or utility lines running in or through rooms or areas containing parts of the heat transfer system, consideration should be given to providing emergency shutoff valves. They should be located so they are readily accessible in the event of a fire. [**30:**A.19.4.3]

Where the liquid level in the system expansion tank is maintained by an automatically actuated supply pump taking suction from the heat transfer fluid storage tank, an interlock should be provided to shut down the supply pump when a high level indicator is actuated, regardless of whether the pump is in automatic or manual mode. [**30:**A.19.4.3]

66.19.4.3.1* Drainage shall be provided at strategic low points in the heat transfer system. Drains shall be piped to a safe location that is capable of accommodating the total capacity of the system or the capacity of that part of the system that is isolated. [**30:**19.4.3.1]

A.66.19.4.3.1 Heat transfer fluid systems have the potential for releasing large quantities of heated flammable or combustible liquid. Low point drains piped to a safe location provide the ability to remove heat transfer fluid from a breached piping system in order to minimize the total quantity of fluid released. An engineering analysis should be used to determine the location and design of low-point drains. The engineering analysis should consider system inventory, the amount of heat transfer fluid that can be released in a specific fire area, the exposure created by a release, and the fire protection provided. [**30:**A.19.4.3.1]

66.19.4.3.2* Where the heat transfer system expansion tank is located above floor level and has a capacity of more than 250 gal (950 L), it shall be provided with a low-point drain line that can allow the expansion tank to drain to a drain tank on a lower level. The drain line valve shall be operable from a safe location. [**30:**19.4.3.2]

A.66.19.4.3.2 Where possible, the drain tank(s) should be located below the lowest system drain opening to permit gravity flow. Breather vents should be provided based on the maximum emptying or filling rates. [**30:**A.19.4.3.2]

66.19.4.3.3 A heat transfer fluid system shall not be used to provide direct building heat. [**30:**19.4.3.3]

66.19.4.3.4 All pressure-relief device outlets shall be piped to a safe location. [**30:**19.4.3.4]

Δ **66.19.4.4* Fuel Burner Controls and Interlocks.** Oil- or gas-fired heaters or vaporizers shall be designed and installed in accordance with the applicable requirements of NFPA 31 or NFPA 85 whichever is applicable. Wood dust suspension-fired heaters or vaporizers shall be designed and installed in accordance with the applicable requirements of NFPA 85. [**30:**19.4.4]

A.66.19.4.4 If stack gas from a heater or vaporizer is recovered to provide auxiliary heat for other equipment (e.g., rotary dryers), suitable dampers, isolation gates, burner control logic, or other means should be provided to ensure that all equipment is properly purged and will operate in a safe manner. The control logic should anticipate all possible operating modes of the individual pieces of equipment, whether operating singly or together, to ensure safe startup and shutdown under normal or upset conditions. [**30:**A.19.4.4]

Instrumentation and interlocks should be provided to sound an alarm and to automatically shut down the fuel source to the heater or vaporizer when any of the following conditions are detected:

(1) Low flow of heat transfer fluid through the heat exchange tubes of the heater, as measured at the discharge.
(2) High temperature or pressure of the fluid at the heater or vaporizer outlet. The high-temperature interlock should be set at or below the manufacturer's maximum recommended bulk fluid temperature.
(3) Low pressure at the heater or vaporizer outlet or elsewhere in the system. This interlock could require a bypass to allow for startup.
(4) Low fluid level in the expansion tank.
(5) Low liquid level in the vaporizer.
(6) Sprinkler system flow in any area containing the heat transfer equipment or piping.

[**30:**A.19.4.4]

Alarm set points should be provided at levels below or above the automatic shutoff setpoints to monitor the above-mentioned variables and provide an opportunity for operators to correct the problem before conditions reach an unsafe level. [**30:**A.19.4.4]

66.19.4.5 Piping.

66.19.4.5.1* Piping shall meet all applicable requirements of Section 66.27. [**30:**19.4.5.1]

A.66.19.4.5.1 Where possible, piping should be run underground, outside, or in floor trenches. Overhead routing of heat transfer fluid piping should be minimized. [**30:**A.19.4.5.1]

66.19.4.5.2 All pipe connections shall be welded. [**30:**19.4.5.2]

66.19.4.5.2.1 Welded, threaded connections shall be permitted to be used for piping 2 in. (50 mm) and smaller. [**30:**19.4.5.2.1]

66.19.4.5.2.2 Mechanical joints shall be permitted to be used at pump, valve, and equipment connections. [**30:**19.4.5.2.2]

66.19.4.5.3 New piping that is to be insulated with permanent insulation and existing piping that has been disturbed and is to be reinsulated with permanent insulation shall be covered with a closed-cell, nonabsorbent insulation material. [**30:**19.4.5.3]

The reason for requiring closed-cell, nonabsorbent insulation is to prevent a minor piping leak from soaking into the insulation without being noticed, which creates a fire hazard. First, detection of the leak is delayed. Second, the heat transfer fluid is kept in contact with the heated pipe and can thermally degrade; the longer the leak goes undetected, the greater the fluid degrades. Finally, if the leak goes undetected for too long, degradation might lead to spontaneous heating and subsequent ignition of the leaked fluid.

66.19.4.5.3.1 Where all pipe joints are welded and where there are no other points in the system subject to leakage, such as at valves or pumps, other types of insulation shall be permitted. [**30:**19.4.5.3.1]

66.19.4.5.3.2 Where dams are formed around possible leak-producing areas, using metal "donut" flanges that are welded to the pipe or using a "donut" segment of nonabsorbent insulation sealed to the pipe to prevent migration of leakage into adjacent insulation, the piping from dam to dam shall be considered to be a closed system and other types of insulation shall be permitted. The area subject to leakage where the dam has been constructed shall be insulated with nonabsorbent insulation or a nonabsorbent insulation system. [**30:**19.4.5.3.2]

66.19.4.5.3.3 Where removable, reusable insulated covers are required for access, the covers shall be fabricated of flexible or rigid insulation that is encapsulated in a manner to provide a nonabsorbent insulation system to prevent absorption of leakage into the insulation. [**30:**19.4.5.3.3]

66.19.4.6 Fire Protection.

Δ **66.19.4.6.1*** Automatic sprinkler protection meeting the requirements of Section 13.3 and NFPA 13 for Extra Hazard (Group I) Occupancies shall be provided for building areas containing a heat transfer system heater or vaporizer. [**30:**19.4.6.1]

A.66.19.4.6.1 Historical records show that fires involving heat transfer fluids can be very severe and long lasting. It is recommended that automatic sprinkler or deluge protection be provided throughout all building areas potentially exposed to a heat transfer fluid spill fire. [**30:**A.19.4.6.1]

66.19.4.6.2 An alternate fire protection system shall be permitted to be used, if approved by the AHJ. Such alternate system shall be designed and installed in accordance with the appropriate NFPA standard and with manufacturer's recommendations for the system selected. [**30:**19.4.6.2]

66.19.4.7 Operation.

66.19.4.7.1* Operations involving heat transfer fluid systems and equipment shall be reviewed to ensure that the fire and explosion hazards resulting from loss of containment of the fluid or failure of the system are provided with corresponding fire prevention and emergency action plans. [**30:**19.4.7.1]

A.66.19.4.7.1 Some factors that should be considered as part of such a review include the following:

(1) Infiltration of material being heated into the heat transfer system. In this case, the system should be shut down and the internal leak point found and repaired as soon as possible.
(2) Leaks in the system. Any leak should be corrected promptly regardless of how small. Corrections should be permanent, such as repacking valve stems and replacing leaky gaskets. Any heat transfer fluid released as a result of a leak or operation of a safety valve should be cleaned up immediately if it is or can come in contact with a hot surface. Other spills can be cleaned up at the first available opportunity.
(3) Pipe or equipment insulation that is soaked with heat transfer fluid. In this case, the cause of the leak should be corrected promptly and the insulation replaced with clean, dry insulation.
(4) High temperature anywhere in the system. In this case, operating procedures should specify shutdown of the heater or vaporizer fuel supply as soon as the temperature of the heat transfer fluid exceeds the manufacturer's recommended maximum bulk fluid temperature. Any corrective actions taken to correct a high temperature condition should only be done with the heat source shut off.

[**30:**A.19.4.7.1]

66.19.4.7.2 Operators of heat transfer systems shall be trained in the hazards of improper operation of the system and leakage and shall be trained to recognize upset conditions that can lead to dangerous situations. [**30:**19.4.7.2]

66.19.4.7.3 Safety interlocks shall be inspected, calibrated, and tested annually or at other intervals established in accordance with other applicable standards to determine that they are in proper operating condition. [**30:**19.4.7.3]

66.19.5 Vapor Recovery and Vapor Processing Systems.

Vapor recovery and vapor processing systems (referred to in the commentary that follows as "vapor-handling systems") can present a significant risk of fire and explosion because, under normal operating conditions, they handle vapor-air mixtures that are in the flammable range. Of necessity, they interconnect all the tanks and process equipment that they serve with long runs of fairly large-diameter piping. The piping collects the vapors that would otherwise be discharged to the atmosphere and directs them to a central collection point, where they are either condensed to liquid and recovered or processed in some fashion. Unfortunately, the piping also provides a means for fire or explosion to travel between storage tanks and equipment. In addition, a flame front that travels through a pipe that is long enough will "pressure pile" and accelerate. If the flame front reaches its detonation velocity, it will rupture the piping. For that reason, the U.S. Coast Guard requires the use of approved detonation arresters in vapor recovery and collection piping installed at marine terminals. These detonation arresters are much more robustly built than simple flame arresters in order to accommodate the much higher pressures that can result from occurrences of ignition.

66.19.5.1 Scope.

66.19.5.1.1 This section shall apply to vapor recovery and vapor processing systems where the vapor source operates at pressures from vacuum up to and including a gauge pressure of 1.0 psi (6.9 kPa), or where there is a potential for vapor mixtures in the flammable range. [**30:**19.5.1.1]

Δ **66.19.5.1.2** This section shall not apply to the following:

(1) Marine systems that comply with U.S. Department of Transportation Regulations in Title 33, Code of Federal Regulations, Parts 154, 155, and 156, and U.S. Coast Guard Regulations in Title 46, Code of Federal Regulations, Parts 30, 32, 35, and 39
(2) Marine and automotive service station systems that comply with Chapter 30 and NFPA 30A

[**30:**19.5.1.2]

The DOT and the U.S. Coast Guard have jurisdiction over and have promulgated standards for pipeline terminals and marine terminals, respectively. Hence, those facilities are not covered by NFPA 30 or by this *Code*. NFPA 30A addresses the small vapor recovery systems used at automotive and marine service stations (see Section 42.9).

66.19.5.2 Overpressure Protection and Vacuum Protection. Tanks and equipment shall have independent venting for overpressure or vacuum conditions that could occur from malfunction of the vapor recovery or vapor processing system.

Exception: For tanks, venting shall comply with 66.21.4.3. [30:19.5.2]

66.19.5.3 Vent Location.

66.19.5.3.1 Vents on vapor processing systems shall be not less than 12 ft (3.7 m) from adjacent ground level, with outlets located and directed so that ignitible vapors will disperse to a concentration below the lower flammable limit before reaching any location that contains an ignition source. [**30:**19.5.3.1]

66.19.5.3.2 Vent outlets shall be located so that vapors will not be trapped by eaves or other obstructions and shall be at least 5 ft (1.5 m) from building openings and at least 15 ft (4.5 m) from powered ventilation air intake devices. [**30:**19.5.3.2]

66.19.5.3.3 Vapor processing equipment and their vents shall be located in accordance with 66.17.3. [**30:**19.5.3.3]

66.19.5.4 Vapor Collection Systems.

66.19.5.4.1 Vapor collection piping shall be designed to prevent trapping liquid. [**30:**19.5.4.1]

The vapor handled by the collection piping can be expected to condense to some degree, depending on environmental factors and ambient conditions. The condensate collects in low points in the piping, potentially isolating some parts of the system. The condensate acts like the water seal in a reverse trap in a plumbing system. If condensate collects and isolates a storage tank from the rest of the collection system, vapors from the tank can no longer be directed to the vapor-handling system. A worst-case condition might lead to damaging back pressure on the tank the next time it is filled. Therefore, it is imperative that the piping system be designed and installed to eliminate any low points and to ensure that condensate can drain to a receiver at the vapor collection point. Alternatively, points in the system where condensate can collect can be fitted with collection pots and drains.

66.19.5.4.2 Vapor recovery and vapor processing systems that are not designed to handle liquid shall be provided with a means to eliminate any liquid that carries over to or condenses in the vapor collection system. [**30:**19.5.4.2]

66.19.5.5 Liquid Level Monitoring.

66.19.5.5.1* A liquid knock-out vessel used in the vapor collection system shall have means to verify the liquid level and a high liquid level sensor that activates an alarm. [**30:**19.5.5.1]

A.66.19.5.5.1 If the liquid knock-out vessel utilizes a pump for automatic liquid removal, consideration should be given to a low-level alarm and shutdown to avoid running the pump dry, resulting in a potential source of ignition. [**30:**A.19.5.5.1]

66.19.5.5.2 For unattended facilities, the high liquid level sensor shall initiate shutdown of liquid transfer into the vessel and shutdown of vapor recovery or vapor processing systems. [**30:**19.5.5.2]

66.19.5.6 Overfill Protection.

66.19.5.6.1 Storage tanks served by vapor processing or vapor recovery systems shall be equipped with overfill protection in accordance with 66.21.7.1. [**30:**19.5.6.1]

66.19.5.6.2 Overfill protection of tank vehicles shall be in accordance with applicable provisions of 66.28.11.1. [**30:**19.5.6.2]

66.19.5.7 Sources of Ignition.

66.19.5.7.1 Vapor Release. Tank or equipment openings provided for purposes of vapor recovery shall be protected against possible vapor release in accordance with 66.23.13.7 and 66.28.11.1.8.1. [**30:**19.5.7.1]

66.19.5.7.2* Electrical Area Classification. Electrical area classification shall be in accordance with Section 66.7. [**30:**19.5.7.2]

A.66.19.5.7.2 Electrical enclosures that need to be opened frequently for maintenance (i.e., enclosures housing vapor processing system controls) have a higher potential for mechanical damage that could render the enclosures unable to contain an explosion. Additional inspection could be needed to ensure the integrity of the enclosure. [**30:**A.19.5.7.2]

66.19.5.7.3* Static Electricity. Vapor collection and vapor processing equipment shall be protected against static electricity in accordance with 66.6.5.4. [**30:**19.5.7.3]

Δ **A.66.19.5.7.3** NFPA 77 and API RP 2003, *Protection Against Ignition Arising Out of Static, Lightning, and Stray Currents*, can be used as a reference for protections against static ignition. [**30:**A.19.5.7.3]

66.19.5.7.4* Spontaneous Ignition. Equipment shall be designed or written procedures established and implemented to prevent ignition where the potential exists for spontaneous ignition. [**30:**19.5.7.4]

A.66.19.5.7.4 Spontaneous ignition can be a problem in the following:

(1) Facilities where pyrophoric deposits can accumulate from the handling of oxygen-deficient vapors containing sulfur compounds or asphaltic materials. When air is introduced into the system, the pyrophoric materials can react, resulting in potential ignition and fire.
(2) Facilities that handle fluids in such a way that mixing of hypergolic or otherwise incompatible materials can occur. Such mixing could occur with fluids remaining in the vapor recovery system from prior loading activities.
(3) Facilities handling oxygenated hydrocarbons in carbon absorption units. Higher heats of absorption for these types of vapors can potentially lead to overheated carbon beds and increase the chance that an oxidation reaction can be initiated. (For further information, refer to API Report, "An Engineering Analysis of the Effects of Oxygenated Fuels on Marketing Vapor Recovery Equipment.")

[**30:**A.19.5.7.4]

66.19.5.7.5* Friction Heat or Sparks from Mechanical Equipment. Mechanical equipment used to move vapors that are in the flammable range shall be designed to prevent sparks or other ignition sources under both normal and equipment malfunction conditions. [**30:**19.5.7.5]

A.66.19.5.7.5 U.S. Coast Guard Regulations in Title 33, Code of Federal Regulations, Part 154, Section 154.826(b), (c), and (d), can be used as a reference for vapor mover designs that minimize the potential for ignition. [**30:**A.19.5.7.5]

66.19.5.7.6* Flame Propagation. Where there is reasonable potential for ignition of a vapor mixture in the flammable range, means shall be provided to stop the propagation of flame through the vapor collection system. The means chosen shall prevent flame propagation under the conditions with which they will be used. [**30:**19.5.7.6]

Δ **A.66.19.5.7.6** The potential for ignition in the vapor collection system needs to be evaluated on a case-by-case basis. If ignition occurs, flame propagation in piping systems containing vapor mixtures in the flammable range normally starts with low-speed burning (deflagration). As the flame moves through the piping, it accelerates and, within a short distance, can reach supersonic speeds (detonation). Initial low-speed flame propagation can be stopped by flame arresters, liquid seals, or automatic fast-acting valve systems where designed, operated, and tested within the requirements of NFPA 69. Flame propagation can also be stopped for both deflagrations and detonations by use of detonation arresters tested in accordance with U.S. Department of Transportation Coast Guard Regulations of the 33 CFR 154, Appendix A, or other procedures acceptable to the AHJ, or automatic fast-acting valve systems tested under the appropriate conditions. [**30:**A.19.5.7.6]

66.19.5.7.7 Explosion Protection. Where used, explosion protection systems shall comply with NFPA 69. [**30:**19.5.7.7]

66.19.5.8 Emergency Shutdown Systems. Emergency shutdown systems shall be designed to fail to a safe position in the event of loss of normal system power (i.e., air or electric) or equipment malfunction. [**30:**19.5.8]

66.19.6 Solvent Distillation Units.

66.19.6.1 Scope.

66.19.6.1.1 This section shall apply to solvent distillation units having distillation chambers or still pots that do not exceed 60 gal (227 L) nominal capacity and are used to recycle Class I, Class II, or Class IIIA liquids. [**30:**19.6.1.1]

The capacity of the typical solvent distillation unit is of such size that the recovered solvent can be collected in a common 55 gal (208 L) drum. The intent of 66.19.6 is that units with a capacity greater than 60 gal (227 L) should be treated as a process under the scope of Section 66.17.

66.19.6.1.2 This section shall not apply to research, testing, or experimental processes; to distillation processes carried out in petroleum refineries, chemical plants, or distilleries; or to distillation equipment used in dry cleaning operations. [**30:**19.6.1.2]

66.19.6.2 Equipment. Solvent distillation units shall be approved or shall be listed in accordance with ANSI/UL 2208, *Standard for Solvent Distillation Units.* [**30:**19.6.2]

66.19.6.3 Solvents. Solvent distillation units shall only be used to distill liquids for which they have been investigated and that are listed on the unit's marking or contained within the manufacturers' literature. [**30:**19.6.3]

66.19.6.3.1 Unstable or reactive liquids or materials shall not be processed unless they have been specifically listed on the system's markings or contained within the manufacturer's literature. [**30:**19.6.3.1]

Handling an unstable or reactive material in a solvent distillation unit can lead to an uncontrolled chemical reaction, with the possibility of fire or rupture of the unit due to overpressure.

66.19.6.4 Location.

66.19.6.4.1 Solvent distillation units shall be located and operated in locations in accordance with their approval or listing. [**30:**19.6.4.1]

66.19.6.4.2 Solvent distillation units shall not be used in basements. [**30:**19.6.4.2]

66.19.6.4.3 Solvent distillation units shall be located away from potential sources of ignition, as indicated on the unit's marking. [**30:**19.6.4.3]

66.19.6.5 Liquid Storage. Distilled liquids and liquids awaiting distillation shall be stored in accordance with this *Code*. [**30:**19.6.5]

66.19.7 Cooking Oil Storage Tank Systems in Commercial Kitchens.

66.19.7.1 Scope.

66.19.7.1.1 This section shall apply to storage tank systems for cooking oil, as defined in 66.19.2.1, located in commercial kitchens where tank capacities are greater than 60 gal (227 L). [**30:**19.7.1.1]

Prior design criteria in NFPA 30 were more relevant to industrial usage of storage tanks for flammable and combustible liquids, and the requirements reflected that bias. High flash point cooking oils in a restaurant back-of-house setting represent a different, and generally lower, hazard than commonly anticipated by Subsection 66.19.7 unifies all pertinent fire safety requirements for such storage and handling, providing ease of use for operators of commercial kitchens and fire officials, and establishes a level of safety commensurate with the hazard.

66.19.7.1.2 This section shall apply to both fresh and waste cooking oil storage tank systems. [**30:**19.7.1.2]

Previously, *Code* requirements focused on used, spent, and inedible cooking oil. For systems that hold fresh cooking oil, tanks and components must be certified as food grade. The steel oil burner and industrial aboveground storage tank standards previously referenced in the codes and associated tank standards did not anticipate food grade processes. This requirement emphasizes that both fresh and waste oil tank storage systems are in use. An example of a combined system is shown in Exhibit 66.30.

66.19.7.1.3* Where there are conflicts between the requirements of this section and requirements of other sections of this code, the requirements of this section shall take precedence. [**30:**19.7.1.3]

A.66.19.7.1.3 The goal of 66.19.7 is to consolidate in one location all requirements for commercial kitchen cooking oil storage and operations. There are a number of chapters in NFPA 30 that apply to these systems, including chapters on storage tanks and piping systems, transferring and dispensing of liquids, and so forth. Many of these requirements are more applicable to industrial or process situations and commercial kitchen cooking oil storage and use was not anticipated. All applicable chapters have been assessed in detail. Those specific requirements in this section that are in potential conflict with other sections of this code have been identified, and alternate methods or exceptions have been developed where

Exhibit 66.30

Example of a combined cooking oil storage system that handles fresh and used cooking oil. (Courtesy of Restaurant Technologies, Inc.)

appropriate. This approach eliminates the need to add exceptions throughout the existing code, improving ease of use particularly for fire officials. [**30:**A.19.7.1.3]

66.19.7.2 Design and Construction of Cooking Oil Storage Tanks.

66.19.7.2.1 Materials of Construction. Tanks shall be constructed of materials of metallic or nonmetallic construction. [**30:**19.7.2.1]

There are limitations on the use of currently listed metallic tanks for food grade processes, including requirements for welds and fillets for metallic tanks that conflict with food grade use. The new requirements address those limitations by adding provisions for food grade–approved nonmetallic tanks, as well as traditional listed flammable or combustible liquid steel tanks.

66.19.7.2.1.1 Tanks and their appurtenances shall be constructed of materials compatible with cooking oil. [**30:**19.7.2.1.1]

66.19.7.2.1.2* For tanks storing waste cooking oil, the materials of construction of the tanks and their appurtenances shall be compatible with cooking oil at minimum temperatures of 140°F (60°C) continuous and 235°F (113°C) intermittent. [**30:**19.7.2.1.2]

A.66.19.7.2.1.2 Waste oil is drained from commercial cooking equipment via a transfer pump and transfer lines to a waste oil storage tank. The oil might be as hot as 375°F (190°C), still well below the oil's flash point. Experience shows that the oil loses significant heat in the transfer process. The maximum temperature of waste cooking oil entering the storage tank is typically below 235°F (113°C). The storage tank should be constructed of materials compatible with cooking oil in that temperature range. [**30:**A.19.7.2.1.2]

Waste cooking oil is normally disposed of at elevated temperatures to ensure fluidity. Filter boxes, transfer pumps, shuttles, and other devices are used to transfer the oil to minimize the risk of burns to personnel. Because the devices are at room temperature when employed, the cooking oil loses temperature immediately upon exposure. Empirical data suggest that the temperature of the cooking oil as it enters the waste oil tank is typically below 235°F (113°C). Also, any residual oil in the waste oil tank acts as a heat sink to immediately cool hot incoming oil.

66.19.7.2.2 Design Standards.

66.19.7.2.2.1* Metallic cooking oil storage tanks shall be listed in accordance with ANSI/UL 142, *Standard for Steel Aboveground Tanks for Flammable and Combustible Liquids*, or ANSI/UL 80, *Standard for Steel Tanks for Oil-Burner Fuels and Other Combustible Liquids*. [**30:**19.7.2.2.1]

A.66.19.7.2.2.1 Existing steel tanks listed for flammable and combustible liquids are considered acceptable for waste oil use. These tank standards contain design and construction requirements that would not meet food code requirements, making the tanks unacceptable for storage of liquid food products (i.e., fresh cooking oil). [**30:**A.19.7.2.2.1]

Δ **66.19.7.2.2.2** Nonmetallic cooking oil storage tanks shall be listed in accordance with UL 2152, *Outline of Investigation for Special Purpose Nonmetallic Containers and Tanks for Specific Combustible or Noncombustible Liquids,* and shall not exceed 200 gal (757 L) per tank. [**30:**19.7.2.2.2]

An important aspect of a metallic or nonmetallic storage tank is its listing by a recognized third-party approval agency. When 66.19.7 was added to the 2015 edition of the *Code*, no listing requirements existed for nonmetallic cooking oil storage tanks. This situation has been remedied with the development of UL 2152, *Outline of Investigation for Special Purpose Nonmetallic Containers and Tanks for Specific Combustible or Noncombustible Liquids*, and it is therefore appropriate to reference it here. The 200 gal (760 L) maximum tank capacity for nonmetallic tanks was qualitatively established after discussions with AHJs to limit the overall size of a single tank. This capacity is also well below the maximum allowed for portable tanks, as established elsewhere in the *Code*. Note that there is no limit to the number of tanks that are permitted to be installed. However, local or state building and fire codes might restrict the total aggregate amount of Class IIIB liquidq, based on specific protection features and specific situations. It is not intended that any special containment or drainage be provided with this installation. An example of a nonmetallic combined fresh and waste oil tank system is shown in Exhibit 66.31.

Exhibit 66.31

Example of a nonmetallic combined cooking oil storage system that handles fresh and waste cooking oil. (Courtesy of Restaurant Technologies, Inc.)

66.19.7.2.3 Normal Venting.

66.19.7.2.3.1 The normal vent(s) shall be located above the maximum normal liquid level. [**30:**19.7.2.3.1]

66.19.7.2.3.2 The normal vent shall be at least as large as the largest filling or withdrawal connection. [**30:**19.7.2.3.2]

66.19.7.2.3.3 Where used, normal vents, including vent piping, that are smaller than 1.25 in. (32 mm) nominal inside diameter shall be tested to verify that internal tank pressures will remain below a gauge pressure of 0.5 psi (3.5 kPa) under maximum expected flow rates for tank filling and withdrawal. These tests shall be permitted to be conducted by a qualified outside agency or by the manufacturer, if certified by a qualified observer. [**30:**19.7.2.3.3]

The size of the normal vent must be engineered to prevent excessive back pressure during filling and withdrawal. Vents for cooking oil tanks usually contain a screen or similar device to prevent entry by insects or rodents, which must be taken into consideration.

66.19.7.2.3.4* Normal vents shall be permitted to discharge inside the building. [**30:**19.7.2.3.4]

A.66.19.7.2.3.4 High flash point cooking oils do not create ignitable vapors when stored under the conditions specified in 66.19.7. [**30:**A.19.7.2.3.4]

66.19.7.2.4 Emergency Venting.

66.19.7.2.4.1 Cooking oil storage tanks shall be provided with emergency relief venting in accordance with Section 66.22. [**30:**19.7.2.4.1]

66.19.7.2.4.2* For nonmetallic cooking oil storage tanks, emergency relief venting by form of construction shall be permitted. This shall include the low melting point of the material of construction of the tank. [**30:**19.7.2.4.2]

This concept of emergency relief venting is applicable only to cooking oil tanks. Normally, tanks storing Class IIIB liquids are exempt from the emergency venting requirements of 66.22.7 only if they exceed 12,000 gal (45,400 L) capacity (see 66.22.7.1.1.3). FM Global, in Data Sheet 7-88, *Storage Tanks for Flammable Liquids*, notes that emergency venting for plastic tanks, such as glass fiber reinforced plastic, is not required since the plastic is expected to melt.

A.66.19.7.2.4.2 Nonmetallic tanks will melt above the liquid level as an external exposure fire progresses, venting the vapor space of the tank. [**30:**A.19.7.2.4.2]

66.19.7.2.4.3 For metallic cooking oil storage tanks, emergency relief venting by form of construction shall be prohibited. [**30:**19.7.2.4.3]

Industry and authorities having jurisdiction have agreed that current emergency vent designs should apply, with the exception of venting by form of construction (i.e., weak roof-to-shell seam). A weak roof-to-shell seam is not a reliable means of providing for emergency venting for such small tanks.

66.19.7.2.4.4 Emergency vents shall be permitted to discharge inside the building. [**30:**19.7.2.4.4]

It is reasonable to allow emergency vents from these tanks to vent into the building. The emergency vent would operate only if an exposure fire were boiling the contents of the tank. Cooking oils have boiling points well above 500°F (260°C), so it would take considerable time for the tank contents to boil. By the time the emergency vent opened, the surrounding fire would have progressed to the point where release of vapors would be inconsequential.

66.19.7.2.5* Prevention of Overfilling of Cooking Oil Storage Tanks. Every cooking oil storage tank shall be provided with means to prevent an accidental overfill. Such means shall be automatic and fail-safe in nature. [**30:**19.7.2.5]

A.66.19.7.2.5 Although generally not required for tanks storing Class IIIB liquids, overfill protection is considered necessary for cooking oil storage tanks to prevent inadvertent spillage. [**30:**A.19.7.2.5]

An example of overfill protection for a fresh oil tank would be a high level switch that automatically shuts off the delivery pump. The system can be designed as a fail-safe system, with the communication circuit normally being closed. Any disconnected wire, break in the wire, or other compromise to the communication circuit would result in the shutdown of the delivery pump.

Tank fill pipes are not required to terminate within 6 in. (150 mm) of the bottom of the tank unless required by the tank listing. Flammable vapors and static charges are not anticipated.

66.19.7.2.6 Tank Heating.

Δ **66.19.7.2.6.1*** Electrical equipment used for heating cooking oil shall be listed to ANSI/UL 499, *Standard for Electrical Heating Appliances*, and shall comply with *NFPA 70*. [**30:**19.7.2.6.1]

A.66.19.7.2.6.1 The prohibition of electrical immersion heaters in nonmetallic tanks eliminates a primary ignition source for the oil stored in the tank. [**30:**A.19.7.2.6.1]

Δ **66.19.7.2.6.2*** Electrical equipment used for heating cooking oil shall comply with *NFPA 70* and shall be equipped with automatic means to limit the temperature of the oil to less than 140°F (60°C). [**30:**19.7.2.6.2]

A.66.19.7.2.6.2 The temperature limitation of 140°F (60°C) corresponds to ASTM C1055 (ISO 13732-1) restrictions for maximum allowable temperatures of nonmetallic industrial surfaces for human contact. [**30:**A.19.7.2.6.2]

Due to the low fire hazard associated with high flash point cooking oils, NFPA 30 permits nonclassified electrical equipment for Class IIIB storage installations inside buildings.

66.19.7.2.6.3 Use of electrical immersion heaters in nonmetallic tanks shall be prohibited. [**30:**19.7.2.6.3]

66.19.7.3 Tank Installation and Testing.

66.19.7.3.1 Location of Cooking Oil Storage Tanks. Tanks shall be installed in locations appropriate for storage of foodstuffs or inventory and shall not be installed in areas designated as cooking areas. [**30:**19.7.3.1]

66.19.7.3.1.1* Tanks shall be spaced at least 3 ft (0.9 m) away from any cooking appliance or any surface heated to a temperature above 140°F (60°C) continuous and at least 6 ft (1.8 m) away from any open flame. [**30:**19.7.3.1.1]

A.66.19.7.3.1.1 The kitchen cooking area has historically been an area where fires occur. Tanks should, therefore, be located away from the kitchen cooking area. [**30:**A.19.7.3.1.1]

66.19.7.3.1.2* Tanks shall not be installed under commercial kitchen ventilation hoods. [**30:**19.7.3.1.2]

A.66.19.7.3.1.2 The area beneath the ventilation hood is another area of potential accidental ignition. [**30:**A.19.7.3.1.2]

Ventilation hoods in kitchens usually have their own listed fire protection systems. The installation of cooking oil tanks under ventilation hoods might void their listing.

66.19.7.3.1.3 Tanks shall not be required to be separated from one another. [**30:**19.7.3.1.3]

The tank spacing requirements in Section 66.22 are not intended to be applied to cooking oil systems. They were developed based on the needs of much larger tanks. Even the minimal 3 ft (0.9 m) separation allowed by 66.22.4.2.1.2 might be problematic in a food preparation area.

66.19.7.3.2 Foundations for and Anchoring of Cooking Oil Storage Tanks.

Δ **66.19.7.3.2.1*** Tanks shall be secured to prevent the tank from tipping over. [**30:**19.7.3.2.1]

N **A.66.19.7.3.2.1** Guidance on securing tanks from tipping over is provided by the manufacturer's instructions in accordance with the tank listing. [**30:**A.19.7.3.2.1]

66.19.7.3.2.2 In areas subject to earthquakes, tank supports, the foundation, and anchoring shall meet the requirements of the applicable building code for the specific seismic zone. Engineering evaluation by a qualified, impartial outside agency shall be an acceptable method of meeting this requirement. [**30:**19.7.3.2.2]

66.19.7.3.2.3 Where a tank is located in areas subject to flooding, the method for anchoring the tank to the floor shall be capable of preventing the tank, either full or empty, from floating during a rise in water level up to the established maximum flood stage. Engineering evaluation by a qualified, impartial outside agency shall be an acceptable method of meeting this requirement. [**30:**19.7.3.2.3]

66.19.7.3.3 Tank Openings Other than Vents.

66.19.7.3.3.1 Each connection to the tank below the normal liquid level through which liquid can normally flow shall be provided with an internal or external valve located as close as possible to the shell of the tank, in accordance with Section 66.22. [**30:**19.7.3.3.1]

66.19.7.3.3.2* Connections to the tank above the normal liquid level through which liquid can normally flow shall not be required to have a valve, provided there exists a liquid-tight closure at the opposite end of the line. The liquidtight closure shall be in the form of a valve, a plug, or a coupling or fitting with positive shutoff. [**30:**19.7.3.3.2]

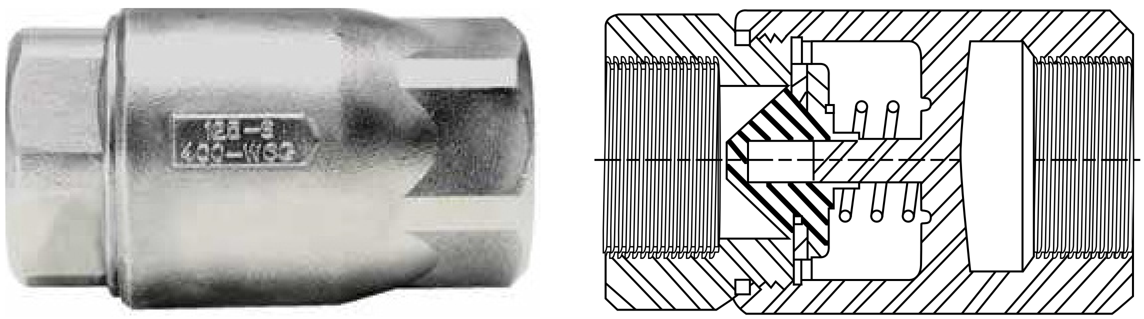
A.66.19.7.3.3.2 An example of a fitting with a positive shutoff is a spring-loaded check valve or a hydraulic quick-coupling with a spring-loaded poppet. [**30:**A.19.7.3.3.2]

An example of a suitable check valve is shown in Exhibit 66.32. Exhibit 66.33 shows an example of a suitable hydraulic quick-coupling.

66.19.7.3.4 Field Testing.

66.19.7.3.4.1* As an alternate method to the testing requirements in Section 66.21, cooking oil storage tanks shall be tested for leaks at the time of installation by filling the tank with cooking oil to a liquid level above the highest tank seam or connection within the normal liquid level. Before the tank is placed in service, all leaks shall be corrected in an approved manner or the tank shall be replaced. [**30:**19.7.3.4.1]

Exhibit 66.32



Example of a suitable check valve for use in a cooking oil storage system. (Courtesy of Conbraco Industries)

Exhibit 66.33

Example of suitable hydraulic quick-couplings for use in a cooking oil storage system. (Courtesy of Parker-Hannifin)

A.66.19.7.3.4.1 Cooking oil storage tanks are atmospheric tanks with open vents. The requirement in Section 66.21 to pressurize the tank for leak testing would be difficult to achieve in the field, due to tank construction and configuration. It is also desirable to prevent water contamination of the cooking oil. A more appropriate test would be to fill the tank with cooking oil to cover all connections and seams below the normal liquid level. [**30:**A.19.7.3.4.1]

66.19.7.3.4.2 An approved listing mark on a cooking oil storage tank shall be considered to be evidence of compliance with tank testing requirements. [**30:**19.7.3.4.2]

66.19.7.4 Fire Protection for Cooking Oil Storage Tanks.

Δ **66.19.7.4.1 Identification for Emergency Responders.** A sign or marking that meets the requirements of NFPA 704 or another approved system, shall be applied to each cooking oil storage tank in accordance with Section 66.21. Additional signage shall be applied to each tank identifying the contents of the tank as cooking oil, either fresh or waste. [**30:**19.7.4.1]

Δ **66.19.7.4.2*** In areas where tanks are located, no additional ventilation shall be required beyond that required for comfort ventilation and provided that all cooking equipment is provided with exhaust systems in accordance with NFPA 96. [**30:**19.7.4.2]

A.66.19.7.4.2 Supplemental ventilation, as is required for cooking operations, is not needed for cooking oil storage tanks. [**30:**A.19.7.4.2]

66.19.7.4.3 If ventilation is not provided as specified in 66.19.7.4.2, then the tank shall be vented to another room inside the building that meets these requirements, or the tank shall be vented to the outside of the building. [**30:**19.7.4.3]

The installation of these cooking oil systems does not require a dedicated ventilation system, assuming that sufficient comfort ventilation is provided in the area and all the cooking equipment is provided with exhaust systems as required and in accordance with NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*.

66.19.7.5 Transfer Lines.

66.19.7.5.1* Design and Construction of Fresh Cooking Oil Transfer Lines. Transfer lines for fresh cooking oil shall be permitted to be constructed of metallic or nonmetallic materials that are compatible with cooking oil and food products. Nonmetallic transfer lines shall also meet the following requirements:

(1) Transfer lines in pressure applications shall be rated for a working gauge pressure of 100 psi (689 kPa) at 70°F (21°C), or the maximum output pressure of the transfer pump, whichever is higher.
(2) Transfer lines in suction applications shall be rated for full vacuum at 70°F (21°C).
(3) Transfer lines shall be rated for temperatures up to 120°F (49°C) continuous.
(4) The maximum nominal inside diameter shall be no larger than 1.25 in. (32 mm).
(5) Leakage shall be controlled through the use of check valves or antisiphon valves at points where the lines connect to the fresh oil tank.

[**30:**19.7.5.1]

Δ **A.66.19.7.5.1** Waste oil lines are generally pumped until there is little residual oil remaining in the lines. Fresh cooking oil lines are likely to contain residual oil after fill and removal operations. Restricting the fresh oil line size to 1.25 in. (32 mm) maximum inside diameter limits the amount of oil in the line. Additionally, the requirement for check valves or antisiphon valves on the lines at points where the lines connect to the tank eliminates the possibility of a compromised line siphoning the contents of the tank. To the extent possible, transfer lines should avoid being routed over seating areas. These requirements are designed to minimize fire risk by limiting cooking oil quantities in transfer lines that could become involved in a fire. In buildings protected by automatic fire sprinklers, the need to add sprinklers in previously unprotected spaces (assuming the transfer lines are located in these spaces) should be considered in accordance with the requirements of NFPA 13. [**30:**A.19.7.5.1]

The transfer process in waste oil systems requires that the oil be above ambient temperature to ensure fluidity. Materials used in the transfer process must be able to withstand those temperatures. As an example of listed equipment that might be used, pumps used for fresh and waste oil use might be listed in accordance with ANSI/NSF 4, *Commercial Cooking, Rethermalization and Powered Hot Food Holding and Transport Equipment*. Filters might be listed in accordance with UL 1889, *Standard for Commercial Filters for Cooking Oil*.

66.19.7.5.2* Design and Construction of Waste Cooking Oil Transfer Lines. Waste cooking oil transfer lines shall be permitted to be constructed of metallic or nonmetallic materials that are compatible with cooking oil. [**30:**19.7.5.2]

The transfer process in waste oil systems requires that the oil be above ambient temperature to ensure fluidity. Materials used in the transfer process must be able to withstand those temperatures. As an example of listed equipment that might be used, pumps used for fresh and waste oil use might be listed in accordance with ANSI/NSF-4. Filters might be listed in accordance with ANSI/UL 1889.

A.66.19.7.5.2 The temperature and pressure ratings for the waste oil lines are consistent with the maximum expected conditions. [**30:**A.19.7.5.2]

It was determined that the requirements for piping and transfer in Section 66.27 were more applicable to industrial applications. Hose or pipe material must be rated for cooking oil at working pressures and temperatures. The requirements in 66.19.7.5.2.1 through 66.19.7.5.5 are based on hose manufacturers' ratings for hoses specifically designed and currently in use for hot cooking oil transfer in commercial deep fat fryers and filtration systems.

66.19.7.5.2.1 Transfer lines shall be rated for use with cooking oil at elevated temperatures of 275°F (135°C) continuous and 350°F (177°C) intermittent. [**30:**19.7.5.2.1]

66.19.7.5.2.2 Nonmetallic transfer lines shall be rated for working pressures up to 250 psi (1724 kPa) at 275°F (135°C). [**30:**19.7.5.2.2]

66.19.7.5.3 Flow Control. Cooking oil transfer lines shall be equipped with means to prevent unintended transfer or dispensing of cooking oil. These means shall be permitted to be in the form of momentary control switches, valves, check valves, antisiphon valves, plugs, couplings, fittings, or any combination thereof that are fail-safe in nature. [**30:**19.7.5.3]

66.19.7.5.4 Pressure Control. Pumping systems used to transfer cooking oil shall have means to prevent overpressurization of transfer lines. These means shall be in the form of relief valves, bypass valves, pressure sensor devices, or the pressure limitation of the pump itself. [**30:**19.7.5.4]

66.19.7.5.5 Installation of Cooking Oil Transfer Lines in Plenum-Rated Spaces. Cooking oil transfer lines installed in plenum-rated spaces shall be enclosed in noncombustible raceways or enclosures, or shall be covered with a material listed and labeled for installation within a plenum. [**30:**19.7.5.5]

Although the installation of cooking oil lines in a return air plenum is not encouraged, sometimes it cannot be avoided. This requirement is intended to ensure that the lines do not contribute to combustible loading within the plenum space.

66.19.7.5.6 Testing of Cooking Oil Transfer Lines. Cooking oil transfer lines shall be tested after installation and prior to use. Testing shall be with cooking oil at the normal operating pressures. Any leaks discovered in transfer lines as a result of testing shall be repaired or the transfer lines replaced prior to placing the transfer lines into service. [**30:**19.7.5.6]

66.20 Reserved

66.21 Storage of Liquids in Tanks — Requirements for All Storage Tanks

66.21.1 Scope. This section shall apply to the following:

(1) The storage of flammable and combustible liquids, as defined in 3.3.169.1 and 3.3.169.2 and Section 66.4, in fixed tanks that exceed 60 gal (230 L) capacity
(2) The storage of flammable and combustible liquids in portable tanks that exceed 660 gal (2500 L) capacity
(3) The storage of flammable and combustible liquids in intermediate bulk containers that exceed 793 gal (3000 L) capacity
(4) The design, installation, testing, operation, and maintenance of such tanks, portable tanks, and bulk containers

[**30:**21.1]

Section 66.21 applies to any fixed tank, as long as the capacity is greater than 60 gal (230 L). The "793 gal" originally specified in 66.21.1 referred only to portable tanks and intermodal containers used in transportation. Recall that Section 66.9 covers portable tanks up to 660 gal (2500 L) and IBCs up to 793 gal (3000 L). Also, Section 66.9 applies only to the storage of portable tanks. If a portable tank or an IBC is connected to a fixed piping system, it takes on the characteristics of a fixed tank, and the appropriate requirements of Section 66.21 and subsequent chapters apply.

66.21.2 Definitions Specific to Section 66.21. For the purpose of this section, the following definitions shall apply. [**30:**21.2]

66.21.2.1 Compartmented Tank. A tank that is divided into two or more compartments intended to contain the same or different liquids. [**30:**21.2.1]

66.21.3 General Requirements.

66.21.3.1 Storage of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 and 66.21.6 justifies following the requirements for some other liquid class. [**30:**21.3.1]

66.21.3.2 Tanks shall be permitted to be of any shape, size, or type consistent with recognized engineering standards. Metal tanks shall be welded, riveted, and caulked, or bolted or constructed using a combination of these methods. [**30:**21.3.2]

A structurally acceptable tank of any shape can be designed using sound engineering practices. However, as a practical matter, factors such as economy in fabrication, the material of construction used, and the operating pressure combine to limit the shape of a tank to one of the following:

1. Vertical cylindrical tank with a flat or nearly flat bottom and a flat, coned, or domed fixed roof or open top with floating roof
2. Horizontal cylindrical tank with flat or dished ends
3. Spherical or toroidal tank

In all cases, the foundation and supporting structure must be considered integral parts of the design.

66.21.3.3 Tanks designed and intended for aboveground use shall not be used as underground tanks. [**30:**21.3.3]

66.21.3.4 Tanks designed and intended for underground use shall not be used as aboveground tanks. [**30:**21.3.4]

Paragraph 66.21.3.4 is intended primarily to prevent an underground tank from being excavated and reused aboveground. The design of an underground tank is based on the support of the surrounding backfill. It does not anticipate the saddle-type supports normally provided for horizontal aboveground tanks. Also, an underground tank is not provided with emergency relief venting, as is required for aboveground tanks by 66.22.7.

Paragraph 66.21.3.3 is justified by the fact that typical aboveground tanks are not manufactured to resist the corrosion of the underground environment.

66.21.3.5 Tanks shall be designed and built in accordance with recognized engineering standards for the material of construction being used. [**30:**21.3.5]

66.21.4 Design and Construction of Storage Tanks.

Δ **66.21.4.1 Materials of Construction.** Tanks shall be of steel or other approved noncombustible material in accordance with 66.21.4.1.1 through 66.21.4.1.4, or of combustible materials in accordance with 66.21.4.1.1 and 66.21.4.1.3 through 66.21.4.1.5. [**30:**21.4.1]

66.21.4.1.1 The materials of construction for tanks and their appurtenances shall be compatible with the liquid to be stored. In case of doubt about the properties of the liquid to be stored, the supplier, producer of the liquid, or other competent authority shall be consulted. [**30:**21.4.1.1]

• **66.21.4.1.2** Unlined concrete tanks shall be permitted to be used for storing liquids that have a gravity of 40°API or heavier. Concrete tanks with special linings shall be permitted to be used for other liquids, provided they are designed and constructed in accordance with recognized engineering standards. [**30:**21.4.1.2]

API gravity is a measure of a liquid's density. The API gravities for petroleum products range from about 10° for heavy lubricating oils up to 80° or more for natural gas condensates. A low number indicates a denser, more viscous, less volatile fluid. Normal motor grade gasoline has an API gravity in the range of 55° to 65°. The "40° API" specified in 66.21.4.1.2 corresponds roughly to kerosene or light distillate oil. Such materials have flash points of about 130°F (54.4°C). Thus, a minor leak of a 40° API liquid from an unlined concrete tank would not create an unusual ignition hazard, and such tanks are therefore permitted.

66.21.4.1.3 Tanks shall be permitted to have combustible or noncombustible linings. The selection, specification, and type of lining material and its required thickness shall be based on the properties of the liquid to be stored. When there is a change in the characteristics of the liquid to be stored, the compatibility of the lining and the liquid shall be verified. [**30:**21.4.1.3]

Tanks are occasionally lined with a plastic or elastomeric material, such as spray-on epoxy resins and rubber liners, to provide corrosion protection, provide protection against minor leaks, or maintain product quality. (Some liquids are adversely affected by contact with metals.) Whether the lining material is combustible or noncombustible does not matter because the quantity is small and will not contribute to fire loss. Even though such a lining is electrically insulating, it will not increase the risk of ignition from static electricity. (See NFPA 77, *Recommended Practice on Static Electricity*.)

Paragraph 66.21.4.1.3 is the basis for allowing tanks that have developed minor leaks to be repaired using a spray-on application of an epoxy resin liner to the inside wall of the tank. The decision to allow such a repair has historically been left to the AHJ. However, environmental regulations for underground storage systems might disallow such repairs on underground tanks in any given case or might exert more stringent control. At the least, it is expected that such a repair will be allowed only once in the lifetime of a tank.

As noted in the second sentence of 66.21.4.1.3, care must be exercised in the selection of a lining material. The lining is required to be compatible with and resistant to degradation from any liquid that is likely to be stored in the tank.

The purpose of the third sentence is to warn the *Code* user that any change in service initiates a re-evaluation of the suitability of the lining to the liquid to be stored.

66.21.4.1.4 An engineering evaluation shall be made if the specific gravity of the liquid to be stored exceeds that of water or if the tank is designed to contain liquids at a liquid temperature below 0°F (–18°C). [**30:**21.4.1.4]

N **66.21.4.1.5** Tanks shall be permitted to be constructed of combustible materials when approved. Tanks constructed of combustible materials shall be limited to any of the following:

(1) Underground installation
(2) Use where required by the properties of the liquid stored
(3) Aboveground storage of Class IIIB liquids in areas not exposed to a spill or leak of Class I or Class II liquid
(4) Storage of Class IIIB liquids inside a building protected by an approved automatic fire-extinguishing system

[**30:**21.4.1.5]

There simply is no fire hazard to worry about with underground tanks. Indeed, a significant portion of underground tanks are of glass fiber–reinforced plastic construction. Items (3) and (4) are justified by the very low risk of ignition of Class IIIB liquids. Again, the potential for a fire is very low. Item (2) does leave the door open for use of an aboveground tank constructed of combustible materials for lower classes of liquids if warranted by the chemical characteristics of the liquid, such as when the liquid is severely corrosive to metal. However, in such a case, it would be preferable to use a metal tank with an appropriate lining. The AHJ should be consulted in such situations.

66.21.4.2 Design Standards for Storage Tanks.

66.21.4.2.1 Design Standards for Atmospheric Tanks.

Δ **66.21.4.2.1.1*** Atmospheric tanks shall be designed and constructed in accordance with recognized engineering standards. Atmospheric tanks that meet any of the following standards shall be deemed as meeting the requirements of 66.21.4.2.1:

(1) API Specification 12B, *Bolted Tanks for Storage of Production Liquids*
(2) API Specification 12D, *Field Welded Tanks for Storage of Production Liquids*
(3) API Specification 12F, *Shop Welded Tanks for Storage of Production Liquids*
(4) API Standard 650, *Welded Tanks for Oil Storage*

(11) ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids*

[**30:**21.4.2.1.1]

The wording of 66.21.4.2.1.1 is broad enough to allow flexibility in tank design and installation methods. The AHJ might allow departures from recognized standards where special needs or unusual situations warrant, as long as equivalent performance is ensured. This enhanced flexibility has proven to be beneficial for aboveground tanks as well as underground tanks, as environmental protection receives more attention. Note the many factory-built "new technology" tanks being produced today, such as concrete-encased tanks, recognized by addition of the reference to ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids*, and the several types of secondary containment-type tanks now included under the listing criteria of UL 58, *Standard for Steel Underground Tanks for Flammable and Combustible Liquids*, and ANSI/UL 142, *Standard for Steel Aboveground Tanks for Flammable and Combustible Liquids*.

The allowance for bolted tanks for storage of oil in producing areas, as given in 66.21.4.2.1.1(1), recognizes that the tanks are usually small, they can be easily relocated, and their use at a particular site might be temporary. A bolted tank is easily dismantled and moved to a new location. Although such tanks are vulnerable to fire damage from a ground fire because of damage to the gaskets, the advantages outweigh the shortcomings. At main gathering stations and pipeline terminals, more substantial tanks would be required.

Δ **A.66.21.4.2.1.1** Atmospheric tanks include tanks of compartmented design and tanks that incorporate secondary containment.

For shop-fabricated steel generator base, work bench, lube oil, used oil, and day tanks, see UL 142A, *Outline of Investigation for Special Purpose Aboveground Tanks for Specific Flammable or Combustible Liquids.* [**30:**A.21.4.2.1.1]

Δ **66.21.4.2.1.2** Atmospheric tanks designed and constructed in accordance with Appendix F of API Standard 650, *Welded Tanks for Oil Storage*, shall be permitted to operate at pressures from atmospheric to a gauge pressure of 1.0 psi (6.9 kPa). All other tanks shall be limited to operation from atmospheric to a gauge pressure of 0.5 psi (3.5 kPa) except as permitted in 66.21.4.2.1.3 and 66.21.4.2.1.4. [**30:**21.4.2.1.2]

Δ **66.21.4.2.1.3** Atmospheric tanks that are not designed and constructed in accordance with Appendix F of API Standard 650, *Welded Tanks for Oil Storage*, shall be permitted to operate at pressures from atmospheric to a gauge pressure of 1.0 psi (6.9 kPa) only if an engineering analysis is performed to determine that the tank can withstand the elevated pressure. [**30:**21.4.2.1.3]

66.21.4.2.1.4 Horizontal cylindrical and rectangular tanks built according to any of the standards specified in 66.21.4.2.1.1 shall be permitted to operate at pressures from atmospheric to a gauge pressure of 1.0 psi (6.9 kPa) and shall be limited to a gauge pressure of 2.5 psi (17 kPa) under emergency venting conditions. [**30:**21.4.2.1.4]

Tanks constructed to the specifications of ANSI/UL 142 are shop-built and leak-tested prior to shipment as completely assembled units. Although horizontal tanks are pressure-tested to a gauge pressure of 5 psi to 7 psi (34.4 kPa to 48.2 kPa), they are limited to service at a gauge pressure of 1 psi (6.9 kPa) maximum internal operating pressure and to a gauge pressure of 2.5 psi (17 kPa) under emergency venting conditions. These restrictions recognize that failure of a horizontal tank is invariably accompanied by release of the tank contents. Vertical tanks are required to be tested only to a pressure that exceeds a gauge pressure of 1.5 psi (10.3 kPa); however, they are also subject to liquid release upon failure, so the same service restrictions apply. There is an exception: Vertical tanks built to prior editions of ANSI/UL 142 and labeled "built to weak shell-to-roof joint design" are not expected to fail in such a manner as to release the contents. It is assumed that the weak seam will fail upon overpressure and only vapors will be released. The current edition of ANSI/UL 142 does not recognize weak shell-to-roof joint design

The term *emergency venting conditions* is not defined in Chapter 3. It is meant to describe a situation in which a tank is fully exposed to flame, resulting in heating and boiling of its contents. Normal venting is based solely on liquid addition or withdrawal and atmospheric temperature and pressure changes. (See 66.21.4.3.) Because consequences of fire exposure can have a substantial effect on the allowable spacing and location of tanks as set forth in 66.22.4, this subject must be dealt with before comment is made on specific requirements. Subsection 66.22.7 addresses the venting capabilities necessary if the tank is exposed to a fire.

Flames contacting aboveground tanks can heat the contained liquid, causing it to boil, and can also damage tank supports and the unwet portion of the tank shell. Boiling effects can be mitigated by design (see 66.22.7.2) or by additional relief valves (see 66.22.7.3). Supports for elevated tanks can be constructed of fire-resistive materials, as covered in 66.22.5.2, or insulated to delay failure. Flame contact on the unwet portion of the shell of a tank can heat that portion of the shell to the point that it loses much of its structural strength. For a vertical tank, this heating can result in distortion at the top of the shell, but tank collapse and spill of contents are not likely. Heating the top of the shell of a horizontal tank, however, is likely to result in structural failure with release of contents.

For a pressure tank, the result of heating the unwet portion of the shell can be serious. Such tanks usually store liquids having boiling points below atmospheric temperature, and therefore their relief valves are set to maintain the resulting higher pressure. When heated sufficiently, the shell loses strength and the resulting tear is likely to spread below the liquid level. The tear can extend completely around a horizontal tank so as to sever the head, release the contents, and cause the pieces to rocket. The possibility of this type of failure is accounted for in Table 66.22.4.1.3. This phenomenon is known as a "BLEVE" (boiling liquid expanding vapor explosion) and is defined as catastrophic failure of a container into two or more major pieces when the contained liquid is at a temperature well above its boiling point at normal atmospheric pressure. The classic cases of BLEVEs have involved tank cars of liquefied petroleum gases, but the phenomenon is applicable to liquids as well.

66.21.4.2.1.5 Low-pressure tanks and pressure vessels shall be permitted to be used as atmospheric tanks. [**30:**21.4.2.1.5]

Section 66.21.4.2.1.5 simply means that a tank designed for pressure will be acceptable for a less demanding service. However, the more stringent spacing requirements for pressure tanks that are specified in 66.22.4.1 are not to be waived unless the emergency venting system has the required capacity at atmospheric pressure.

66.21.4.2.1.6 Atmospheric tanks shall not be used to store a liquid at a temperature at or above its boiling point. [**30:**21.4.2.1.6]

A liquid having a boiling point below the prevailing atmospheric temperature would be expected to boil continuously if stored in an atmospheric tank, which would result in considerable product loss and greatly increase the risk of ignition. (The boiling rate would depend on the rate at which the tank received heat from the surrounding atmosphere and from solar radiation.) Interpretation of 66.21.4.2.1.6 should take the liquid's atmospheric boiling point as that at the location of the tank, not at sea level. The boiling point of a liquid at an altitude of 10,000 ft (3050 m) can be as much as 20°F (11°C) lower than it would be at sea level. As a practical matter, this usually dictates that liquids at temperatures close to their boiling points be stored in pressure tanks, simply to avoid product loss.

66.21.4.2.2 Design Standards for Low-Pressure Tanks.

Δ **66.21.4.2.2.1** Low-pressure tanks shall be designed and constructed in accordance with recognized engineering standards. Low-pressure tanks that meet either of the following standards shall be deemed as meeting the requirements of 66.21.4.2.2:

(1) API 620, *Design and Construction of Large, Welded, Low-Pressure Storage Tanks*
(2) ASME *Code for Unfired Pressure Vessels*, Section VIII, Division 1

[**30:**21.4.2.2.1]

66.21.4.2.2.2 Low-pressure tanks shall not be operated above their design pressures. [**30:**21.4.2.2.2]

66.21.4.2.2.3 Pressure vessels shall be permitted to be used as low-pressure tanks. [**30:**21.4.2.2.3]

66.21.4.2.3 Design Standards for Pressure Vessels.

66.21.4.2.3.1 Tanks with storage pressures above a gauge pressure of 15 psi (100 kPa) shall be designed and constructed in accordance with recognized engineering standards. Pressure vessels that meet any of the following standards shall be deemed as meeting the requirements of 66.21.4.2.3:

(1) Fired pressure vessels shall be designed and constructed in accordance with Section I (Power Boilers), or Section VIII, Division 1 or Division 2 (Pressure Vessels), as applicable, of the ASME *Boiler and Pressure Vessel Code*.
(2) Unfired pressure vessels shall be designed and constructed in accordance with Section VIII, Division 1 or Division 2, of the ASME *Boiler and Pressure Vessel Code*. [**30:**21.4.2.3.1]

Δ **66.21.4.2.3.2*** Pressure vessels that do not meet the requirements of 66.21.4.2.3.1(1) or 66.21.4.2.3.1(2) shall be permitted to be used, provided they are approved by the AHJ. [**30:**21.4.2.3.2]

A.66.21.4.2.3.2 Such pressure vessels are generally referred to as "state special." [**30:**A.21.4.2.3.2]

66.21.4.2.3.3 Pressure vessels shall not be operated above their design pressures. The normal operating pressure of the vessel shall not exceed the design pressure of the vessel. [**30:**21.4.2.3.3]

66.21.4.3 Normal Venting for Storage Tanks.

Paragraphs 66.21.4.3.1 through 66.21.4.3.12 consider venting only from the fire protection standpoint. Stricter requirements might be imposed by the EPA or by local regulations to control and capture evaporative emissions. As stated previously, environmental regulations might require the use of vapor collection systems, which could involve lengthy runs of piping to handle the vapor-air mixtures expelled from a tank during filling. Because

Exhibit 66.34

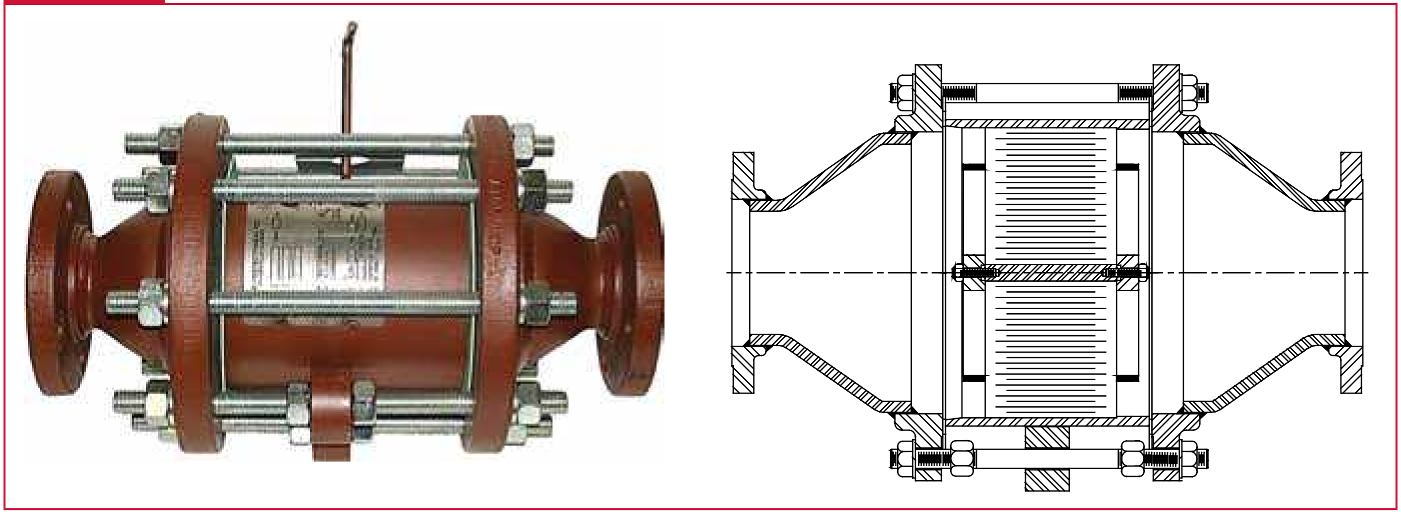

Photo (left) and diagram (right) of a pipeline detonation arrester. (Courtesy of Protectoseal Company)

flame arresters are not effective in long vent lines, special detonation arresters must be used. These arresters are designed and tested to withstand the pressures imposed by compression ignition ("dieseling") and "pressure piling." (See Exhibit 66.34 for an example.) Inerting of the manifold system or other means might be necessary to avoid hazardous situations. (See NFPA 69, *Standard on Explosion Prevention Systems*.)

66.21.4.3.1 Storage tanks shall be vented to prevent the development of vacuum or pressure that can distort the tank or exceed the rated design pressure of the tank when the tank is filled or emptied or because of atmospheric temperature changes. Normal vents shall be located above the maximum normal liquid level. [**30:**21.4.3.1]

The prohibition against distorting the roof of a cone roof tank applies specifically to tanks built in accordance with API 650, *Welded Tanks for Oil Storage*. Roof distortion should, by design, cause failure of the weak roof-to-shell type of construction typically used with API 650 tanks. Failure should occur only under emergency conditions. For all other tanks, the design is proven by pressure test.

In order for a tank to be filled, air and vapor must get out, or the tank will become pressurized. Pushing out the air and vapor requires that the pressure in the tank be slightly above atmospheric pressure. For that reason, tanks are designed to withstand an internal gauge pressure of at least 8 in. (20 cm) of water [$1/3$ psi (2.3 kPa)]. Similarly, in order for a tank to be emptied, air must get in, or the tank will become underpressurized. To allow air to get in, the pressure in the tank must be slightly below atmospheric pressure. For that reason, tanks are designed to withstand a vacuum of 2.5 in. (6.35 cm) of water [$1/10$ psi (0.689 kPa)].

Consideration of the low pressure for which a tank is designed might lead one to question why more tanks do not fail, even given safety factors of 2 to 1 or higher. Adequate normal venting is the answer. If an atmospheric storage tank is equipped with a normal vent of sufficient size — to prevent the development of an internal vacuum or pressure sufficient to distort the roof or to exceed the design pressure — *and* the vent is kept clear at all times, the tank will neither implode nor explode.

Exhibit 66.35 illustrates the deformation that can be expected if the normal vent's outflow capacity is not great enough for the rate of flow of liquid into the tank. Likewise, Exhibit 66.36 shows what can happen if the flow rate out of the tank is too great for the normal vent to accommodate it.

Exhibit 66.35

Damage to tanks caused by inadequate normal outflow venting capacity.

Exhibit 66.36

Damage to tanks caused by inadequate normal inflow venting capacity.

66.21.4.3.2* Normal venting shall be provided for primary tanks and each primary compartment of a compartmented tank. [**30:**21.4.3.2]

A.66.21.4.3.2 Normal venting is not required for the interstitial space of a secondary containment tank. [**30:**A.21.4.3.2]

This requirement addresses those rare occasions when a single compartment tank is retrofitted with one or more internal bulkheads to create two or more compartments. Each compartment will need its own normal vent and its own emergency vent if necessary.

66.21.4.3.3 Normal vents shall be sized in accordance with either API Standard 2000, *Venting Atmospheric and Low-Pressure Storage Tanks*, or another approved standard. Alternatively, the normal vent shall be at least as large as the largest filling or withdrawal connection, but in no case shall it be less than 1.25 in. (32 mm) nominal inside diameter. [**30:**21.4.3.3]

66.21.4.3.4* Atmospheric storage tanks shall be vented so as not to exceed the tank's design operating pressure or a gauge pressure of 1.0 psi (6.9 kPa), whichever is less, and shall be vented to prevent the development of vacuum. [**30:**21.4.3.4]

N **A.66.21.4.3.4** Tanks intended for normal operation at pressures greater than a gauge pressure of 1.0 psi (6.9 kPa) are designed in accordance with 66.21.4.2.3. It is recognized that a slight vacuum is necessary to operate a vacuum vent. [**30:**A.21.4.3.4]

This paragraph has been revised for the 2018 edition of the *Code* to eliminate any potential conflict with 66.21.4.2.1.2. This paragraph now specifically states that the means of venting must also prevent development of excessive vacuum that might distort the tank. The Annex A item references the section that applies to low-pressure tanks.

66.21.4.3.5 Low-pressure tanks and pressure vessels shall be vented to prevent the development of pressure or vacuum that exceeds the rated design pressure of the tank or vessel. Means shall also be provided to prevent overpressure from any pump discharging into the tank or vessel when the pump discharge pressure can exceed the design pressure of the tank or vessel. [**30:**21.4.3.5]

In flammable and combustible liquids service, a low-pressure tank or a pressure vessel would be used only for storing liquids with unusually high vapor pressures, such as Class IA liquids. For pressures of up to 1 psi (6.89 kPa) or so, pallet-type (weighted) check valves can be used to prevent overpressure. Many of these valves also incorporate vacuum breakers. For tanks built to the specifications of API 620, a conventional relief valve can be used. In that case, a separate vacuum-breaking device might be needed unless the vapor pressure of the stored product, under all conditions of storage, is high enough to prevent the development of a dangerous vacuum under conditions of maximum possible withdrawal rate. Tanks built to the ASME *Code for Unfired Pressure Vessels* are often built to withstand full vacuum, so they might not need a vacuum breaker. Although an open vent might be adequate to protect the tank from pressure rupture or vacuum collapse, an open vent must not be used if the tank contains a Class I liquid and should not be used for any liquid heated above its flash point, except as permitted in 66.21.4.3.8.

66.21.4.3.6 If any tank or pressure vessel has more than one fill or withdrawal connection and simultaneous filling or withdrawal can be made, the vent size shall be based on the maximum anticipated simultaneous flow. [**30:**21.4.3.6]

66.21.4.3.7 For tanks equipped with vents that permit pressures to exceed a gauge pressure of 2.5 psi (17 kPa) and for low-pressure tanks and for pressure vessels, the outlet of all vents and vent drains shall be arranged to discharge in a manner that prevents localized overheating of or flame impingement on any part of the tank, if vapors from the vents are ignited. [**30:**21.4.3.7]

66.21.4.3.8 Tanks and pressure vessels that store Class IA liquids shall be equipped with venting devices that are closed, except when venting under pressure or vacuum conditions. [**30:**21.4.3.8]

This requirement is intended to limit the escape of hazardous quantities of vapors from Class IA liquids, which boil at temperatures below 100°F (37.8°C). If a Class IA liquid were stored in a tank that is open to the atmosphere, it would always be at a temperature below ambient because it would be continuously cooled by the loss of heat of vaporization required to produce the vapors that fill the vapor space of the tank. Vaporization would continue because the tank would always be absorbing heat from its surroundings. This continuous generation of vapors is significant and would constitute unacceptable loss of product and generation of dangerous quantities of vapor. With a normally closed vent, however, vaporization can be controlled to a great degree. See also the commentary to 66.21.4.3.9.

66.21.4.3.9 Tanks and pressure vessels that store Class IB and Class IC liquids shall be equipped with venting devices or with listed flame arresters. When used, vent devices shall be closed, except when venting under pressure or vacuum conditions. [**30:**21.4.3.9]

With Class IB and Class IC liquids, less vaporization takes place than with Class IA liquids, so an open vent can be used, except where the vapor space might be in the flammable range.

Therefore, a vent fitted with a flame arrester is permitted as an alternative to a normally closed vent device. Because of the higher boiling points and accompanying lower vapor pressures of Class IB and Class IC liquids, the degree of liquid supercooling caused by vaporization, and hence the rate of vaporization, is insignificant from a fire protection standpoint. See also the commentary to 66.21.4.3.8. Note that tanks storing Class II and Class III liquids are not required to have any sort of venting device.

66.21.4.3.10 Tanks of 3000 barrels (bbl) [126,000 gal or (475 m^3)] capacity or less that store crude petroleum in crude-producing areas and outside aboveground atmospheric tanks of less than 1000 gal (3785 L) capacity that contain other than Class IA liquids shall be permitted to have open vents. [**30:**21.4.3.10]

The exemption for relatively small crude gathering tanks is allowed because such tanks are generally in sparsely populated areas and usually have vapor spaces too rich to burn as a result of release of dissolved gases. The exemption for tanks under 1000 gal (3785 L) capacity containing other than Class IA liquids is due to the relatively insignificant rate of vapor release. In addition, the vent location requirements of 66.27.8.1 make it highly improbable that a continuous vapor trail in the flammable range would exist between the vapor space of the tank and any exterior source of ignition.

66.21.4.3.11* Flame arresters or venting devices required in 66.21.4.3.8 and 66.21.4.3.9 shall be permitted to be omitted on tanks that store Class IB or Class IC liquids where conditions are such that their use can, in case of obstruction, result in damage to the tank. [**30:**21.4.3.11]

Δ **A.66.21.4.3.11** Liquid properties that justify omitting such devices include, but are not limited to, condensation, corrosiveness, crystallization, polymerization, freezing, or plugging. When any of these conditions exist, consideration should be given to heating, use of devices that employ special materials of construction, use of liquid seals, or inerting. See NFPA 69. [**30:**A.21.4.3.11]

66.21.4.3.12 Piping for normal vents shall be designed in accordance with Section 66.27. [**30:**21.4.3.12]

66.21.4.4* Tank Fill Pipes. Fill pipes that enter the top of a tank shall terminate within 6 in. (150 mm) of the bottom of the tank. Fill pipes shall be installed or arranged so that vibration is minimized.

Exception No. 1: Fill pipes in tanks whose vapor space under the expected range of operating conditions is not in the flammable range or is inerted need not meet this requirement.

*Exception No. 2: Fill pipes in tanks handling liquids with minimal potential for accumulation of static charge need not meet this requirement, provided that the fill line is designed and the system is operated to avoid mist generation and to provide residence time downstream of filters or screens to allow dissipation of the generated static charge. [**30:**21.4.4]*

Δ **A.66.21.4.4** In Exception No. 2, examples of liquids with minimal potential for accumulation of static charge include crude oil, asphalt, and water-miscible liquids. For additional information, see NFPA 77. [**30:**A.21.4.4]

The manner in which liquid enters a tank can cause turbulence and splashing, particularly if the inlet pipe terminates above the liquid surface. The intent of 66.21.4.4 is to require that the fill pipe terminate close to the bottom of the tank to minimize the generation of a static electrical charge from the free-fall and splashing of liquid entering the tank. The second sentence, regarding vibration, is a warning that a pipe supported only at the top might vibrate and break off, without anyone becoming aware of it. The resulting falling stream would defeat the purpose of having the fill pipe extend to within 6 in. (150 mm) of the bottom.

Several incidents involving Class II liquids have prompted the general application of this requirement to all liquids. Note that fine droplets of a combustible liquid are easily ignited at temperatures below the liquid's flash point, as demonstrated by the ease of ignition of No. 2 fuel oil when pumped through the atomizer of an oil burner.

Exception No. 2 recognizes that (1) crude oils, residual oils, and asphalts have such a low electrical resistivity that static generation has not proved to be a problem; and (2) water-miscible liquids allow free movement of the static charge so that the charge easily bleeds off to the grounded tank shell.

Static charge can accumulate in a liquid in many ways. Charged mists can develop when a falling stream of liquid breaks up into fine droplets. Flow of liquid through a pipe generates a charge in the liquid; the effect is more pronounced at high flow velocities and is greatly enhanced if the flow involves two or more phases. In the specific case of filling a tank, the quantity of static charge accumulates as the volume of liquid increases in the tank. In some cases, the charge reaches such high levels that it spontaneously leaks off to grounded objects by nonincendive corona discharge instead of gradual dissipation. (This phenomenon does not occur in liquids with resistivity of less than 10^{10} ohm-centimeters; the charges are able to migrate too easily through the liquid and recombine.) *Nonincendive* means that although the voltage is high enough to cause discharge, insufficient energy is released to cause ignition.

The risk of producing an incendive (i.e., ignition-capable) spark is dramatically increased when a charged, high-resistivity fluid flows either over or adjacent to an isolated (i.e., ungrounded) conductor. The conductor accumulates a static charge. If the isolated conductor is then brought near a grounded conductor, an immediate discharge occurs in the form of a spark of relatively high energy, usually well above that required for ignition of a flammable atmosphere. No isolated conductors should be introduced into a system that is prone to static generation. Such parts include metal floats on liquid level gauges, metal sampling cups on wooden rods or nylon cords, metal parts in plastic dip tubes, and isolated metal parts on intrinsically safe electrical equipment.

For further information, see NFPA 77; API RP 2003, *Protection Against Ignition Arising Out of Static, Lightning and Stray*

Currents; and *Electrostatic Hazards: Their Evaluation and Control*, by H. Haase. See also Supplement 5, Electrostatics, of the NFPA 30 Handbook.

66.21.4.5* Corrosion Protection.

A.66.21.4.5 Other means of internal corrosion protection include protective coatings and linings and cathodic protection. [**30:**A.21.4.5]

66.21.4.5.1 Corrosion protection shall meet the requirements of 66.21.4.5.2 or 66.21.4.5.3, whichever is applicable. [**30:**21.4.5.1]

66.21.4.5.2 Internal Corrosion Protection for Metal Storage Tanks. Where tanks are not designed in accordance with standards of the American Petroleum Institute, the American Society of Mechanical Engineers, or Underwriters Laboratories Inc., or if corrosion is anticipated beyond that provided for in the design formulas or standards used, additional metal thickness or approved protective coatings or linings shall be provided to compensate for the corrosion loss expected during the design life of the tank. [**30:**21.4.5.2]

66.21.4.5.3 Internal Corrosion Protection for Nonmetallic Tanks. Where tanks are not designed in accordance with standards of the American Petroleum Institute, the American Society of Mechanical Engineers, ASTM International, or Underwriters Laboratories Inc., or if degradation is anticipated beyond that provided for in the design formulas or standards used, degradation shall be compensated for by providing additional tank material thickness or by application of protective coatings or linings, as determined by an engineering analysis. [**30:**21.4.5.3]

66.21.5 Testing Requirements for Tanks.

66.21.5.1 General. All tanks, whether shop-built or field-erected, shall be tested before they are placed in service in accordance with the requirements of the code under which they were built. [**30:**21.5.1]

66.21.5.1.1 An approved listing mark on a tank shall be considered to be evidence of compliance with 66.21.5.1. Tanks not so marked shall be tested before they are placed in service in accordance with the applicable requirements for testing in the codes listed in 66.21.4.2.1.1, 66.21.4.2.2.1, or 66.21.4.2.3.1 or in accordance with recognized engineering standards. Upon satisfactory completion of testing, a permanent record of the test results shall be maintained by the owner. [**30:**21.5.1.1]

This provision of the *Code* requires the owner to maintain a permanent record of the test results, to avoid future questions about the tank's original listing.

66.21.5.1.2 Where the vertical length of the fill and vent pipes is such that, when filled with liquid, the static head imposed on the bottom of the tank exceeds a gauge pressure of 10 psi (70 kPa), the tank and its related piping shall be tested hydrostatically to a pressure equal to the static head thus imposed by using recognized engineering standards. [**30:**21.5.1.2]

The intent of 66.21.5.1.2 is that the tank be tested to the pressure that would be developed if the tank were accidentally overfilled, causing liquid to rise into the vent pipe. However, under no circumstances should the pressure exceed the design pressure of the tank.

66.21.5.1.3 Before the tank is initially placed in service, all leaks or deformations shall be corrected in an approved manner. Mechanical caulking shall not be permitted for correcting leaks in welded tanks except for pinhole leaks in the roof. [**30:**21.5.1.3]

66.21.5.1.4 Tanks to be operated at pressures below their design pressure shall be tested by the applicable provisions of 66.21.5.1.1 or 66.21.5.1.2 based upon the pressure developed under full emergency venting of the tank. [**30:**21.5.1.4]

66.21.5.2* Tightness Testing. In addition to the tests called for in 66.21.5.1, all tanks and connections shall be tested for tightness after installation and before being placed in service in accordance with 66.21.5.2.2 and 66.21.5.2.3, as applicable. Except for underground tanks, this test shall be made at operating pressure with air, inert gas, or water. [**30:**21.5.2]

A.66.21.5.2 See PEI RP200, *Recommended Practices for Installation of Aboveground Storage Systems for Motor Vehicle Fueling*, and STI R 931, *Double Wall AST Installation and Testing Instructions*, for additional requirements to test secondary containment tanks. [**30:**A.21.5.2]

When testing with air or inert gas is done, positive means such as a relief valve or regulator should be incorporated into the air or inert gas supply to ensure that the test pressure does not exceed that specified. Tests using air should not be made on top of stored product, which means that the test must be made prior to putting any liquid into the tank. Nor should air tests be made on tanks that have been emptied of liquid but not purged of vapors. These safety precautions prevent formation of an ignitible atmosphere in the tank.

66.21.5.2.1 Testing required by 66.21.5.2 shall not be required for a primary tank or an interstitial space that continues to maintain a factory-applied vacuum in accordance with the manufacturer's instructions. Such components shall be considered to be tight until such time that the vacuum is broken. Final tightness testing of an interstitial space shall not be required if the factory-applied vacuum is maintained until one of the following conditions is met:

(1) For aboveground tanks, the tank is set on the site at the location where it is intended to be installed.
(2) For underground tanks, backfill has been completed to the top of the tank.

[**30:**21.5.2.1]

Nearly all factory-built aboveground and underground storage tanks that incorporate secondary containment are shipped from the factory with the interstitial space under vacuum. As long as the vacuum stays intact and meets manufacturers' specifications, both the primary vessel and the secondary containment are demonstrated as being tight and there is no need to test.

66.21.5.2.2 Air pressure shall not be used to test tanks that contain flammable or combustible liquids or vapors. *(See 66.27.7 for testing pressure piping.)* [**30:**21.5.2.2]

66.21.5.2.3 For field-erected tanks, the tests required by 66.21.5.1.1 or 66.21.5.1.2 shall be permitted to be considered the test for tank tightness. [**30:**21.5.2.3]

66.21.5.2.4 Horizontal shop-fabricated aboveground tanks shall be tested for tightness either hydrostatically or with air pressure at not less than a gauge pressure of 3 psi (20 kPa) and not more than a gauge pressure of 5 psi (35 kPa). [**30:**21.5.2.4]

66.21.5.2.5 Vertical shop-fabricated aboveground tanks shall be tested for tightness either hydrostatically or with air pressure at not less than a gauge pressure of 1.5 psi (10 kPa) and not more than a gauge pressure of 2.5 psi (17 kPa). [**30:**21.5.2.5]

66.21.5.2.6 Single-wall underground tanks and piping, before being covered, enclosed, or placed in use, shall be tested for tightness either hydrostatically or with air pressure at not less than a gauge pressure of 3 psi (20 kPa) and not more than a gauge pressure of 5 psi (35 kPa). [**30:**21.5.2.6]

66.21.5.2.7* Underground secondary containment tanks and horizontal aboveground secondary containment tanks shall have the primary (inner) tank tested for tightness either hydrostatically or with air pressure at not less than a gauge pressure of 3 psi (20 kPa) and not more than a gauge pressure of 5 psi (35 kPa). [**30:**21.5.2.7]

A.66.21.5.2.7 Underground double-wall tanks can be considered to be a type of secondary containment. The terms "double-wall tank" and "jacketed tank" are sometimes used to describe underground secondary containment tanks. [**30:**A.21.5.2.7]

66.21.5.2.7.1 The interstitial space of such tanks shall be tested either hydrostatically or with air pressure at a gauge pressure of 3 to 5 psi (20 to 35 kPa), by vacuum at 5.3 in. Hg (18 kPa), or in accordance with the tank's listing or the manufacturer's instructions. These limits shall not be exceeded. [**30:**21.5.2.7.1]

66.21.5.2.7.2 The pressure or vacuum shall be held for not less than 1 hour or for the duration specified in the listing procedures for the tank. [**30:**21.5.2.7.2]

The 1-hour test duration ensures sufficient time for pressure to bleed down to a detectable level should there be a pinhole leak. The test procedures required by 66.21.5.2.7.1 and 66.21.5.2.8.1 do not apply if the tank is shipped with a factory-applied vacuum in the interstitial space and the vacuum complies with 66.21.5.2.1.

66.21.5.2.8 Vertical aboveground secondary containment–type tanks shall have their primary (inner) tank tested for tightness either hydrostatically or with air pressure at not less than a gauge pressure of 1.5 psi (10 kPa) and not more than a gauge pressure of 2.5 psi (17 kPa). [**30:**21.5.2.8]

66.21.5.2.8.1 The interstitial space of such tanks shall be tested either hydrostatically or with air pressure at a gauge pressure of 1.5 to 2.5 psi (10 to 17 kPa), by vacuum at 5.3 in. Hg (18 kPa), or in accordance with the tank's listing or manufacturer's instructions. These limits shall not be exceeded. [**30:**21.5.2.8.1]

66.21.5.2.8.2 The pressure or vacuum shall be held for not less than 1 hour or for the duration specified in the listing procedures for the tank. [**30:**21.5.2.8.2]

66.21.5.3* Periodic Testing. Each tank shall be tested when required by the manufacturer's instructions and applicable standards to ensure the integrity of the tank. [**30:**21.5.3]

Δ **A.66.21.5.3** For information on testing of underground tanks, see NFPA 329. For information on testing aboveground tanks, see API 653, *Tank Inspection, Repair, Alteration, and Reconstruction*. [**30:**A.21.5.3]

66.21.6 Fire Prevention and Control.

66.21.6.1 General Requirements.

66.21.6.1.1 This section shall apply to the commonly recognized management techniques and fire control methods used to prevent or minimize the loss from fire or explosion in tank storage facilities. The wide range in size, design, and location of tank storage facilities shall preclude the inclusion of detailed fire prevention and control methods applicable to all such facilities. [**30:**21.6.1.1]

66.21.6.1.2 Tank storage facilities shall establish and implement fire prevention and control methods for life safety, for minimizing property loss, and for reducing fire exposure to adjoining facilities resulting from fire and explosion. Compliance with 66.21.6.2 through 66.21.6.6 shall be deemed as meeting the requirements of 66.21.6.1. [**30:**21.6.1.2]

66.21.6.2 Control of Ignition Sources. In order to prevent the ignition of flammable vapors in tank storage facilities, ignition sources shall be controlled in accordance with Section 66.6. [**30:**21.6.2]

66.21.6.3 Management of Fire Hazards. The extent of fire and explosion prevention and control procedures and measures provided for tank storage facilities shall be determined by an engineering evaluation of the installation and operation, followed by the application of recognized fire and explosion protection and process engineering principles. The evaluation shall include, but not be limited to, the following:

(1) Analysis of fire and explosion hazards of the facility
(2) Analysis of local conditions, such as exposure to and from adjacent properties, flood potential, or earthquake potential
(3) Facility, fire department or mutual aid response

[**30:**21.6.3]

66.21.6.4 Fire Control. Tank storage facilities for flammable and combustible liquids shall be reviewed to ensure that fire and explosion hazards resulting from loss of containment of liquids are provided with corresponding fire prevention and emergency action plans. *(See also 66.6.3.)* [**30:**21.6.4]

66.21.6.5 Emergency Planning and Training.

As is the case for fire control, emergency planning and training must be tailored for each individual facility, which will require considerable judgment and consultation among the facility operator, the AHJ, and local emergency response services. Much of what follows in this subsection is mandated in more detail by OSHA in 29 CFR 1910.

66.21.6.5.1* An emergency plan, consistent with the available equipment, resources, and personnel, shall be established and implemented to respond to fires and explosions, and other emergencies. This plan shall address the following:

(1) Procedures to be used in case of fire, explosion, or accidental release of liquid or vapor including, but not limited to, sounding the alarm, notifying the fire department, evacuating personnel, controlling and mitigating the explosion, and controlling and extinguishing the fire
(2) Appointing and training of personnel to carry out emergency response duties
(3) Maintenance of fire protection, spill control and containment, and other emergency response equipment
(4) Conducting emergency response drills
(5) Shutdown or isolation of equipment to control unintentional releases
(6) Alternative measures for the safety of personnel while any fire protection or other emergency response equipment is shut down or inoperative

[**30:**21.6.5.1]

A.66.21.6.5.1 Resources include, but are not limited to, the following:

(1) Mutual aid
(2) Water supply
(3) Extinguishing agent supply

[**30:**A.21.6.5.1]

66.21.6.5.2 Personnel responsible for the use and operation of fire protection equipment shall be trained in the use of and be able to demonstrate knowledge of the use or operation of that equipment. Refresher training shall be conducted at least annually. [**30:**21.6.5.2]

66.21.6.5.3 Planning of effective fire control measures shall be coordinated with local emergency response agencies and shall include, but not be limited to, the identification of all tanks by location, contents, size, and hazard identification as required in 66.21.7.2.1. [**30:**21.6.5.3]

66.21.6.5.4 Procedures shall be established to provide for safe shutdown of tank storage facilities under emergency conditions and for safe return to service. These procedures shall provide requirements for periodic training of personnel and inspection and testing of associated alarms, interlocks, and controls. [**30:**21.6.5.4]

66.21.6.5.5 Emergency procedures shall be kept available in an operating area. The procedures shall be reviewed and updated in accordance with 66.6.4.2. [**30:**21.6.5.5]

66.21.6.5.6 Where tank storage facilities are unattended, a summary of the emergency plan shall be posted or located in a strategic location that is accessible to emergency responders. [**30:**21.6.5.6]

66.21.6.6 Inspection and Maintenance of Fire Protection and Emergency Response Equipment.

66.21.6.6.1* All fire protection and emergency response equipment shall be maintained, inspected, and tested in accordance with regulatory requirements, standard practices, and equipment manufacturers' recommendations. [**30:**21.6.6.1]

Δ **A.66.21.6.6.1** See NFPA 25 or other specific fire protection system standards. [**30:**A.21.6.6.1]

66.21.6.6.2 Maintenance and operating procedures and practices at tank storage facilities shall be established and implemented to control leakage and prevent spillage and release of liquids. [**30:**21.6.6.2]

Cleanup operations should be conducted in a manner that minimizes vapor loss. Many commercially available absorbents and adsorbents have been developed, primarily to mitigate environmental damage, but are still of great benefit. Also, some fire-suppression foams and recently developed vapor-suppression foams are helpful in controlling vapors from large-scale spills.

66.21.6.6.3 Ground areas around tank storage facilities shall be kept free of weeds, trash, or other unnecessary combustible materials. [**30:**21.6.6.3]

66.21.6.6.4 Accessways established for movement of personnel shall be maintained clear of obstructions to permit evacuation and access for manual fire fighting and emergency response in accordance with regulatory requirements and the emergency plan. [**30:**21.6.6.4]

66.21.6.6.5 Combustible waste material and residues in operating areas shall be kept to a minimum, stored in covered metal containers, and disposed of daily. [**30:**21.6.6.5]

66.21.6.6.6 Personnel responsible for the inspection and maintenance of fire protection and emergency response equipment shall be trained and shall be able to demonstrate knowledge of the inspection and maintenance of that equipment. Refresher training shall be conducted as needed to maintain proficiency. [**30:**21.6.6.6]

66.21.7 Operation of Storage Tanks.

66.21.7.1* Prevention of Overfilling of Storage Tanks. Facilities with aboveground tanks larger than 1320 gal (5000 L) storing Class I or Class II liquids shall establish procedures or shall provide equipment, or both, to prevent overfilling of tanks. [**30:**21.7.1]

A.66.21.7.1 Further guidance is given in API 2350, *Overfill Protection for Storage Tanks in Petroleum Facilities*. [**30:**A.21.7.1]

66.21.7.1.1 Facilities with aboveground tanks that receive and transfer Class I liquids from mainline pipelines or marine vessels shall establish and follow formal written procedures to prevent overfilling of tanks utilizing one of the following methods of protection:

(1) Tanks shall be gauged at intervals in accordance with established procedures by personnel continuously on the premises during product receipt. Acknowledged communication shall be

maintained with the supplier so flow can be shut down or diverted in accordance with established procedures.

(2) Tanks shall be equipped with a high-level detection device that is either independent of any gauging equipment or incorporates a gauging and alarm system that provides electronic self-checking to indicate when the gauging and alarm system has failed. Alarms shall be located where personnel who are on duty throughout product transfer can arrange for flow stoppage or diversion in accordance with established procedures.

(3) Tanks shall be equipped with an independent high-level detection system that will automatically shut down or divert flow in accordance with established procedures.

[**30:**21.7.1.1]

Δ **66.21.7.1.2** Alternatives to instrumentation described in 66.21.7.1.1(2) and 66.21.7.1.1(3) shall be allowed where approved as affording equivalent protection. [**30:**21.7.1.2]

Δ **66.21.7.1.3** Instrumentation systems covered in 66.21.7.1.1(2) and 66.21.7.1.1(3) shall be wired fail-safe, such that valid alarm conditions or system failures create an alarm condition that will notify personnel or automatically shut down or divert flow. [**30:**21.7.1.3]

66.21.7.1.3.1 Written instrumentation performance procedures shall be established to define valid alarm conditions and system failures in accordance with API 2350, *Overfill Protection for Storage Tanks in Petroleum Facilities*. [**30:**21.7.1.3.1]

66.21.7.1.3.2 System failure shall include but not be limited to the following:

(1) Loss of main electrical power
(2) Electrical break, short circuit, or ground fault in the level detection system circuit or the alarm and signal circuit
(3) Failure or malfunction of the level detection system control equipment or signaling devices

[**30:**21.7.1.3.2]

66.21.7.1.4 Formal written procedures required by 66.21.7.1.1 shall include the following:

(1) Instructions covering methods to check for lineup and receipt of initial delivery to tank designated to receive shipment.
(2) Provision for training and monitoring the performance of operating personnel by supervisors.
(3) Schedules and procedures for inspection and testing of gauging equipment and high-level instrumentation and related systems. Inspection and testing intervals shall be approved but shall not exceed 1 year.

[**30:**21.7.1.4]

66.21.7.1.5 An underground tank shall be equipped with overfill prevention equipment that will operate as follows either alert the transfer operator when the tank is no more than 90 percent full by triggering an audible and visual high-level alarm or automatically shut off the flow of liquid into the tank when the tank is no more than 95 percent full. [**30:**21.7.1.5]

66.21.7.1.5.1 Other methods of overfill protection shall be permitted as approved by the AHJ. [**30:**21.7.1.5.1]

The requirements in 66.21.7.1.5 apply specifically to underground storage tanks and are intended to coordinate with the rules established by the EPA.

66.21.7.1.6 Shop-fabricated aboveground atmospheric storage tanks, constructed to the recognized standards of 66.21.4.2.1.1, shall meet the requirements of 66.21.7.1.6.1 through 66.21.7.1.6.4 whenever the vertical length from the tank bottom to the top of the fill, normal vent, or emergency vent exceeds 12 ft (3.7 m). [**30:**21.7.1.6]

66.21.7.1.6.1 An approved means shall be provided to notify the tank filling operator of the pending completion of the tank fill operation at the fill connection. [**30:**21.7.1.6.1]

66.21.7.1.6.2 An approved means shall be provided to stop delivery of liquid to the tank prior to the complete filling of the tank. [**30:**21.7.1.6.2]

66.21.7.1.6.3 In no case shall these provisions restrict or interfere with the functioning of the normal vent or emergency vent. [**30:**21.7.1.6.3]

Any interference with the proper functioning of the normal vent or the emergency vent could, in an extreme event, cause catastrophic failure of the tank.

66.21.7.1.6.4 The manufacturer of the tank shall be consulted to determine if reinforcement of the tank is required. If reinforcement is deemed necessary, it shall be done. [**30:**21.7.1.6.4]

66.21.7.2 Identification and Security.

Δ **66.21.7.2.1 Identification for Emergency Responders.** A sign or marking that meets the requirements of NFPA 704 or another approved system, shall be applied to storage tanks containing liquids. The marking shall be located where it can be seen, such as on the side of the tank, the shoulder of an accessway or walkway to the tank or tanks, or on the piping outside of the diked area. If more than one tank is involved, the markings shall be so located that each tank can be identified. [**30:**21.7.2.1]

See Exhibit 66.37.

Exhibit 66.37

NFPA 704, Standard System for the Identification of the Hazards of Materials for Emergency Response, placards on small storage tanks.

66.21.7.2.2* Security for Unsupervised Storage Tanks. Unsupervised, isolated aboveground storage tanks shall be secured and shall be marked to identify the fire hazards of the tank and the tank's contents to the general public. Where necessary to protect the tank from tampering or trespassing, the area where the tank is located shall be secured. [**30:**21.7.2.2]

A.66.21.7.2.2 Protection from tampering or trespassing might include one or more of the following: appropriate fencing around isolated tanks in remote areas; "No Trespassing" signs; warning signs indicating the fire hazard of the tank or its contents; locked or secured access to stairways and ladders; locked or secured hatches, valves, and so forth. [**30:**A.21.7.2.2]

66.21.7.3 Storage Tanks in Areas Subject to Flooding.

In several instances, high water levels have floated full or partially full tanks from their foundations, resulting in release of tank contents and damage to piping systems and to other tanks. The provisions of 66.21.7.3 are intended to prevent such incidents from occurring. See Exhibit 66.38.

Exhibit 66.38

Storage tanks dislodged from their foundations due to Hurricane Katrina floodwaters.

66.21.7.3.1 Water Loading.

66.21.7.3.1.1 The filling of a tank to be protected by water loading shall be started as soon as floodwaters are predicted to reach a dangerous flood stage. [**30:**21.7.3.1.1]

66.21.7.3.1.2 Where independently fueled water pumps are relied on, sufficient fuel shall be available at all times to permit continuing operations until all tanks are filled. [**30:**21.7.3.1.2]

66.21.7.3.1.3 Tank valves shall be locked in a closed position when water loading has been completed. [**30:**21.7.3.1.3]

66.21.7.3.2 Operating Instructions. Operating instructions or procedures to be followed in a flood emergency shall be established and implemented by personnel identified in 66.21.7.3.3. [**30:**21.7.3.2]

66.21.7.3.3 Personnel Training. Personnel responsible for activating and performing flood emergency procedures shall be trained in their implementation and shall be informed of the location and operation of valves and other controls and equipment necessary to effect the intent of these procedures. Personnel shall also be trained in the procedures required to place the facility back into service following a flood emergency. [**30:**21.7.3.3]

66.21.7.4 Removal from Service of Storage Tanks.

66.21.7.4.1* Closure of Aboveground Storage Tanks. Aboveground tanks taken out of service or abandoned shall be emptied of liquid, rendered vapor-free, and safeguarded against trespassing in accordance with NFPA 326, or in accordance with the requirements of the AHJ. [**30:**21.7.4.1]

These requirements are basic precautions that must be taken for any tank, whether aboveground or underground, that is taken out of service on a temporary or permanent basis. Many jurisdictions require these precautions for a tank that has been empty for more than 60 days and require that the tank be completely removed if permanently abandoned. See Annex C of NFPA 30 for further information.

A.66.21.7.4.1 For further information, see API 2015, *Safe Entry and Cleaning of Petroleum Storage Tanks*; and API 2016, *Guidelines and Procedures for Entering and Cleaning Petroleum Storage Tanks*. [**30:**A.21.7.4.1]

66.21.7.4.2 Reuse of Aboveground Storage Tanks. Aboveground tanks shall be permitted to be reused for flammable or combustible liquids service provided they comply with applicable sections of this *Code* and are approved. [**30:**21.7.4.2]

66.21.7.4.3 Removal from Service of Underground Storage Tanks.

Δ **66.21.7.4.3.1 General.** Underground tanks taken out of service or abandoned shall be emptied of liquid, rendered vapor-free, and safeguarded against trespassing in accordance with this section and in accordance with NFPA 326 or the requirements of the AHJ. The procedures outlined in this section shall be followed when taking underground tanks temporarily out of service, closing them in place permanently, or removing them. [**30:**21.7.4.3.1]

66.21.7.4.3.2 Temporary Closure. Underground tanks shall be rendered temporarily out of service only when it is planned that they will be returned to active service, closed in place permanently, or removed within an approved period not exceeding 1 year. The following requirements shall be met:

(1) Corrosion protection and release detection systems shall be maintained in operation.
(2) The vent line shall be left open and functioning.
(3) The tank shall be secured against tampering.
(4) All other lines shall be capped or plugged.

[**30:**21.7.4.3.2]

66.21.7.4.3.2.1 Tanks remaining temporarily out of service for more than 1 year shall be permanently closed in place or removed in accordance with 66.21.7.4.3.3 or 66.21.7.4.3.4, as applicable. [**30:**21.7.4.3.2.1]

Prior to a tank being taken temporarily out of service, federal, state, and local fire and environmental authorities must be notified to determine the maximum duration a tank is allowed to be temporarily closed. Some jurisdictions do not allow temporary closure at all.

66.21.7.4.3.3 Permanent Closure in Place. Underground tanks shall be permitted to be permanently closed in place if approved by the AHJ. All of the following requirements shall be met:

(1) All applicable AHJs shall be notified.
(2)* A safe workplace shall be maintained throughout the prescribed activities.

A.66.21.7.4.3.3(2) Special training might be required. [**30:**A.21.7.4.3.3(2)]

(3) All flammable and combustible liquids and residues shall be removed from the tank, appurtenances, and piping and shall be disposed of in accordance with regulatory requirements and industry practices, using a written procedure.
(4) The tank, appurtenances, and piping shall be made safe by either purging them of flammable vapors or inerting the potential explosive atmosphere. Confirmation that the atmosphere in the tank is safe shall be by testing of the atmosphere using a combustible gas indicator if purging, or an oxygen meter if inerting, at intervals in accordance with written procedures.
(5) Access to the tank shall be made by careful excavation to the top of the tank.
(6) All exposed piping, gauging and tank fixtures, and other appurtenances, except the vent, shall be disconnected and removed.
(7) The tank shall be completely filled with an inert solid material.
(8) The tank vent and remaining underground piping shall be capped or removed.
(9) The tank excavation shall be backfilled.

[**30:**21.7.4.3.3]

Δ **66.21.7.4.3.4 Removal and Disposal.** Underground tanks and piping shall be removed in accordance with the following requirements:

(1) The steps described in 66.21.7.4.3.3(1) through 66.21.7.4.3.3(5) shall be followed.
(2) All exposed piping, gauging and tank fixtures, and other appurtenances, including the vent, shall be disconnected and removed.
(3) All openings shall be plugged, leaving a ¼ in. (6 mm) opening to avoid buildup of pressure in the tank.
(4) The tank shall be removed from the excavated site and shall be secured against movement.
(5) Any corrosion holes shall be plugged.
(6) The tank shall be labeled with its former contents, present vapor state, vapor-freeing method, and a warning against reuse.
(7) The tank shall be removed from the site as authorized by the AHJ, preferably the same day.

[**30:**21.7.4.3.4]

66.21.7.4.3.5 Temporary Storage of Removed Tanks. If it is necessary to temporarily store an underground tank that has been removed, it shall be placed in a secure area where public access is restricted. A ¼ in. (6 mm) opening shall be maintained to avoid buildup of pressure in the tank. [**30:**21.7.4.3.5]

Δ **66.21.7.4.3.6 Disposal of Tanks.** Disposal of underground tanks shall meet the following requirements:

(1) Before a tank is cut up for scrap or landfill, the atmosphere in the tank shall be tested in accordance with 66.21.7.4.3.3(4) to ensure that it is safe.
(2) The tank shall be made unfit for further use by cutting holes in the tank heads and shell.

[**30:**21.7.4.3.6]

66.21.7.4.3.7 Documentation. All necessary documentation shall be prepared and maintained in accordance with all federal, state, and local rules and regulations. [**30:**21.7.4.3.7]

66.21.7.4.3.8 Reuse of Underground Storage Tanks. Underground tanks shall be permitted to be reused for underground storage of flammable or combustible liquids provided they comply with applicable sections of this *Code* and are approved. [**30:**21.7.4.3.8]

This provision requires that approval for reuse of tanks be received to confirm that the tanks meet all appropriate sections of this *Code* and NFPA 30.

66.21.7.5* Leak Detection and Inventory Records for Underground Storage Tanks. Accurate inventory records or a leak detection program shall be maintained on all Class I liquid storage tanks for indication of leakage from the tanks or associated piping. [**30:**21.7.5]

A.66.21.7.5 See NFPA 329 for information on testing methods. [**30:**A.21.7.5]

66.21.8 Inspection and Maintenance of Storage Tanks and Storage Tank Appurtenances.

66.21.8.1* Each storage tank constructed of steel shall be inspected and maintained in accordance with API Standard 653, *Tank Inspection, Repair, Alteration, and Reconstruction*, or STI SP001, *Standard for the Inspection of Aboveground Storage Tanks*, whichever is applicable. [**30:**21.8.1]

A.66.21.8.1 Regular inspections of aboveground storage tanks, including shop fabricated aboveground storage tanks, performed in accordance with national standards, provide a means to ensure system maintenance. Acceptable standards include, but are not limited to, the following:

(1) API 653, *Tank Inspection, Repair, Alteration, and Reconstruction*
(2) STI SP001, *Standard for Inspection of Aboveground Storage Tanks*
(3) API 12R1, *Setting, Maintenance, Inspection, Operation, and Repair of Tanks in Production Service*
(4) API 2350, *Overfill Protection for Storage Tanks in Petroleum Facilities*

[**30:**A.21.8.1]

66.21.8.2 Each storage tank constructed of other materials shall be inspected and maintained in accordance with the manufacturer's instructions and applicable standards to ensure compliance with the requirements of this *Code*. [**30:**21.8.2]

66.21.8.3 Testing of storage tanks shall meet the requirements of 66.21.5. [**30:**21.8.3]

66.21.8.4 Each storage tank shall be maintained liquidtight. Each storage tank that is leaking shall be emptied of liquid or repaired in a manner acceptable to the AHJ. [**30:**21.8.4]

This requirement ensures that any tank that shows evidence of leaking will be repaired or taken out of service reasonably quickly, before environmental damage occurs or a dangerous fire hazard develops.

66.21.8.5 Each storage tank that has been structurally damaged, repaired, reconstructed, relocated, jacked, or damaged by impact, flood, or other trauma, or is suspected of leaking shall be inspected and tested in accordance with 66.21.5 or in a manner acceptable to the AHJ. [**30:**21.8.5]

66.21.8.6* Storage tanks and their appurtenances, including normal vents, emergency vents, overfill prevention devices, and related devices, shall be inspected and maintained to ensure that they function as intended in accordance with written procedures. [**30:**21.8.6]

A.66.21.8.6 For additional information, see API 653, *Tank Inspection, Repair, Alteration, and Reconstruction*, API RP 2350, *Overfill Protection for Storage Tanks in Petroleum Facilities*, and PEI RP600, *Recommended Practices for Overfill Prevention for Shop-Fabricated Aboveground Tanks*. [**30:**A.21.8.6]

66.21.8.7 Openings for gauging on storage tanks storing Class I liquids shall be provided with a vaportight cap or cover. Such covers shall be closed when not gauging. [**30:**21.8.7]

66.21.8.8* Facilities with aboveground storage tanks shall establish and implement a procedure to check for and remove water from the bottom of storage tanks that contain nonmiscible liquids. [**30:**21.8.8]

A.66.21.8.8 The accumulation of water in the bottom of a tank encourages microbial activity that hampers operations and increases the risk of product release. It is imperative that tank owners and operators routinely monitor the tank bottom for accumulation of water and establish a procedure for when and how the water is to be removed. Additional information can be found in API 1501, *Filtration and Dehydration of Aviation Fuels*, API RP 1621, *Bulk Liquid Stock Control at Retail Outlets*, and API Standard 2610, *Design, Construction, Operation, Maintenance, and Inspection of Terminal and Tank Facilities*. Other sources of information are ASTM D6469, *Standard Guide for Microbial Contamination in Fuels and Fuel Systems*, the National Oilheat Research Alliance *Oilheat Technician's Manual*, and the STI publication *Keeping Water Out of Your Storage System*. [**30:**A.21.8.8]

66.21.9 Change of Stored Liquid. Storage tanks that undergo any change of stored liquid shall be re-evaluated for compliance with Sections 66.21 through 66.25, as applicable. [**30:**21.9]

66.22 Storage of Liquids in Tanks — Aboveground Storage Tanks

66.22.1 Scope. This chapter shall apply to the following:

(1) The storage of flammable and combustible liquids, as defined in 3.3.169.1 and 3.3.169.2 and Section 66.4, in fixed tanks that exceed 60 gal (230 L) capacity
(2) The storage of flammable and combustible liquids in portable tanks that exceed 660 gal (2500 L) capacity
(3) The storage of flammable and combustible liquids in intermediate bulk containers that exceed 793 gal (3000 L)
(4) The design, installation, testing, operation, and maintenance of such tanks, portable tanks, and bulk containers

[**30:**22.1]

66.22.2 Definitions Specific to Section 66.22. For the purpose of this section, the terms in this section shall have the definition given. [**30:**22.2]

66.22.2.1 Fire-Resistant Tank. An atmospheric aboveground storage tank with thermal insulation that has been evaluated for resistance to physical damage and for limiting the heat transferred to the primary tank when exposed to a hydrocarbon fuel fire and is listed in accordance with UL 2080, *Standard for Fire Resistant Tanks for Flammable and Combustible Liquids*, or an equivalent test procedure. [**30:**22.2.1]

66.22.2.2 Floating Roof Tank. An aboveground storage tank that incorporates one of the following designs:

(1) A closed-top pontoon or double-deck metal floating roof in an open-top tank constructed in accordance with API Standard 650, *Welded Steel Tanks for Oil Storage*
(2) A fixed metal roof with ventilation at the top and roof eaves constructed in accordance with API Standard 650 and containing a closed-top pontoon or double-deck metal floating roof meeting the requirements of API Standard 650
(3) A fixed metal roof with ventilation at the top and roof eaves constructed in accordance with API Standard 650 and containing a metal floating cover supported by liquidtight metal floating devices that provide buoyancy to prevent the liquid surface from being exposed when half of the flotation is lost

[**30:**22.2.2]

A floating roof tank is a tank in which a pan or cover actually floats on the surface of the liquid. The floating roof rides up and down as the liquid level in the tank changes and moves within the tank shell, much like a piston in a cylinder. A floating roof tank can be of the open-top type, where there is no fixed roof at the top of the shell (see Exhibit 66.39), or it can be of the internal type, where the tank has a fixed roof (see Exhibit 66.40). The latter is recognized by its "eyebrow" vents, located just below the tank eave.

Experience has shown that tanks with floating roofs that meet the criteria of 66.22.2.1 are not likely to be involved in serious fires. Most fires in such tanks have involved burning only at the resilient seal between the floating roof and the shell and are

Exhibit 66.39

Open-top floating roof tanks.

Exhibit 66.40

Closed-top floating roof tank.

usually easily extinguished. If the tank is of the open-top type, handheld extinguishing equipment might prove adequate. If the tank is of the internal type, with a fixed cone or geodesic dome roof, fire fighting is obviously more complex.

In fires involving open-top floating roof tanks where a floating roof has sunk, resulting in a full-surface fire, there is only one reported incident of boil-over, which occurred at the Trieste, Italy, pipeline terminal in the early 1970s. In that incident, two 500 ft (153 m) diameter crude oil tanks were set afire by explosive charges set by a terrorist group. The floating roofs sank, and boil-over occurred about 12 hours later. However, in most cases, it is thought that the sunken roof presents a barrier to the downward progress of the hot oil layer, thus preventing a boil-over. For those reasons, floating roof tanks are given preferred treatment in 66.22.4.1.

Item (3) of 66.22.2.2 recognizes flotation devices other than pontoons or floats — honeycomb panels, for example — but the requirement is somewhat stricter in that the cover cannot tip in any manner that results in exposure of the liquid surface. Previously, NFPA 30 required only that the pan or cover not sink completely. It is now recognized that a cover that tips and exposes any liquid presents as great a degree of fire risk as one that sinks and exposes the entire surface of the liquid.

66.22.2.2.1 For the purposes of this section, an aboveground storage tank with an internal metal floating pan, roof, or cover that does not meet 66.22.2.2 or one that uses plastic foam (except for seals) for flotation, even if encapsulated in metal or fiberglass, shall meet the requirements for a fixed roof tank. [**30:**22.2.2.1]

Cone roof tanks with internal floating pans, such as those described here, are considered to be the equivalent of a fixed roof tank because the internal floating pans are prone to sinking and because foamed plastic and similar flotation devices will not withstand the conditions imposed by a fire.

66.22.2.3 Protected Aboveground Tank. An atmospheric aboveground storage tank with integral secondary containment and thermal insulation that has been evaluated for resistance to physical damage and for limiting the heat transferred to the primary tank when exposed to a hydrocarbon pool fire and is listed in accordance with ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids*, or an equivalent test procedure. [**30:**22.2.3]

66.22.3 General Requirements. Storage of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. [**30:**22.3]

66.22.4* Location of Aboveground Storage Tanks.

The provisions of this subsection are intended to ensure that tanks are located such that they will not jeopardize structures on the property of others. In the days when tanks had wood-supported combustible roofs, it was not uncommon for fire to spread from one tank to another. Therefore, regulations provided that tanks be widely spaced from each other and from all other facilities. With the advent of roofs made completely of steel, this risk greatly decreased. Experience indicated that, given no ground-spill fire, one tank could burn without damaging neighboring tanks or adjoining property. However, distance between adjacent tanks and distance between tanks and property lines or adjacent structures remain principal planning criteria. Instead of basing the spacing on an arbitrarily selected distance, it is now considered more practical and realistic to base it on a fraction of the tank diameter, except for those tanks that use emergency relief devices, which are based on capacity, to limit internal pressures. The tables in 66.22.4 use both tank diameter and tank capacity, as appropriate.

A.66.22.4 See PEI RP200, *Recommended Practices for Installation of Aboveground Storage Systems for Motor Vehicle Fueling*, for additional information. [**30:**A.22.4]

66.22.4.1 Location with Respect to Property Lines, Public Ways, and Important Buildings.

Sections 66.22.4.1.1 through 66.22.4.1.8 and Tables 66.22.4.1.1(a) through 66.22.4.1.6 govern the siting of tanks in relation to surrounding buildings, public roads and highways, and property lines. Table 66.22.4.1.1(a), Table 66.22.4.1.3, Table 66.22.4.1.4, and Table 66.22.4.1.5, used in conjunction with Table 66.22.4.1.1(b), apply to Class I, II, and IIIA liquids and base their spacing requirements on the characteristics of the liquid, the manner in which it is stored, the type of tank used, the protection provided for the tank, and the protection provided for exposures. Class IIIB liquids are covered in 66.22.4.1.6.

The tables recognize that it can be difficult, sometimes impossible, to extinguish a tank fire. Therefore, efforts are directed at protecting adjacent buildings and adjoining properties. Fire protection for exposures should not be confused with fire suppression systems and equipment used to fight a tank fire. The tables also recognize that there is little possibility of extinguishing a fire in a tank that exceeds 150 ft (45 m) in diameter without specialized equipment and tactics. Even with fixed fire-suppression equipment installed, set-up time is often required, during which exposed tanks or structures need to be protected from radiant heat to prevent fire spread.

Detailed commentary that outlines the terminology in these tables as well as the use and application of 66.22.4.1 is provided in *NFPA 30 and NFPA 30A: Flammable and Combustible Liquids Code Handbook*. Where applicable, users of this *Code* should reference the *NFPA 30 Handbook* for additional information. It is not copied here as it is generally outside the scope of this *Code*, but it may be useful to users seeking additional information on this topic. See 22.4.1 of *NFPA 30 Handbook*.

Δ **66.22.4.1.1** Tanks storing Class I, Class II, or Class IIIA stable liquids whose internal pressure is not permitted to exceed a gauge pressure of 2.5 psi (17 kPa) shall be located in accordance with Table 66.22.4.1.1(a) and Table 66.22.4.1.1(b). Where tank spacing is based on a weak roof-to-shell seam design, the user shall present evidence certifying such construction to the AHJ upon request. [**30:**22.4.1.1]

Δ ***TABLE 66.22.4.1.1(a)*** *Location of Aboveground Storage Tanks Storing Stable Liquids — Internal Pressure Not to Exceed a Gauge Pressure of 2.5 psi (17 kPa)*

Type of Tank	Protection	Minimum Distance (ft): From Property Line That Is or Can Be Built Upon, Including the Opposite Side of a Public Way[a]	Minimum Distance (ft): From Nearest Side of Any Public Way or from Nearest Important Building on the Same Property[a]
Floating roof	Protection for exposures[c]	½ × diameter of tank	⅙ × diameter of tank
	None	Diameter of tank but need not exceed 175 ft	⅙ × diameter of tank
Vertical with weak roof-to-shell seam	Approved foam or inerting system[c] on tanks not exceeding 150 ft in diameter[d]	½ × diameter of tank	⅙ × diameter of tank
	Protection for exposures[c]	Diameter of tank	⅓ × diameter of tank
	None	2 × diameter of tank but need not exceed 350 ft	⅓ × diameter of tank
Horizontal and vertical tanks with emergency relief venting to limit pressures to 2.5 psi (gauge pressure of 17 kPa)	Approved inerting system[b] on the tank or approved foam system on vertical tanks	½ × value in Table 66.22.4.1.1(b)	½ × value in Table 66.22.4.1.1(b)
	Protection for exposures[b]	Value in Table 66.22.4.1.1(b)	Value in Table 66.22.4.1.1(b)
	None	2 × value in Table 66.22.4.1.1(b)	Value in Table 66.22.4.1.1(b)
Protected aboveground tank	None	½ × value in Table 66.22.4.1.1(b)	½ × value in Table 66.22.4.1.1(b)

For SI units, 1 ft = 0.3 m.

[a]The minimum distance cannot be less than 5 ft (1.5 m).

[b]See definition 3.3.46 of NFPA 30, Protection for Exposures.

[c]See NFPA 69.

[d]For tanks over 150 ft (45 m) in diameter, use “Protection for Exposures” or “None,” as applicable. [**30:** Table 22.4.1.1(a)]

TABLE 66.22.4.1.1(b) *Reference Table for Use with Tables 66.22.4.1.1(a), 66.22.4.1.3, and 66.22.4.1.5*

Tank Capacity (gal)	Minimum Distance (ft) From Property Line that Is or Can Be Built Upon, Including the Opposite Side of a Public Way	Minimum Distance (ft) From Nearest Side of Any Public Way or from Nearest Important Building on the Same Property
275 or less	5	5
276 to 750	10	5
751 to 12,000	15	5
12,001 to 30,000	20	5
30,001 to 50,000	30	10
50,001 to 100,000	50	15
100,001 to 500,000	80	25
500,001 to 1,000,000	100	35
1,000,001 to 2,000,000	135	45
2,000,001 to 3,000,000	165	55
3,000,001 or more	175	60

For SI units, 1 ft = 0.3 m; 1 gal = 3.8 L. [**30:** Table 22.4.1.1(b)]

Δ ***TABLE 66.22.4.1.3*** *Location of Aboveground Storage Tanks Storing Stable Liquids — Internal Pressure Permitted to Exceed a Gauge Pressure of 2.5 psi (17 kPa)*

Any type	Protection for exposures*	1½ × value in Table 66.22.4.1.1(b) but not less than 25 ft	1½ × value in Table 66.22.4.1.1(b) but not less than 25 ft
	None	3 × value in Table 66.22.4.1.1(b) but not less than 50 ft	1½ × value in Table 66.22.4.1.1(b) but not less than 25 ft

For SI units, 1 ft = 0.3 m.

*See definition 3.3.46 of NFPA 30, Protection for Exposures.
[**30:** Table 22.4.1.3]

66.22.4.1.2 Vertical tanks with weak roof-to-shell seams *(see 66.22.7.2)* that store Class IIIA liquids shall be permitted to be located at one-half the distances specified in Table 66.22.4.1.1(a), provided the tanks are not within the same diked area as, or within the drainage path of, a tank storing a Class I or Class II liquid. [**30:**22.4.1.2]

66.22.4.1.3 Tanks storing Class I, Class II, or Class IIIA stable liquids and operating at pressures that exceed a gauge pressure of 2.5 psi (17 kPa), or are equipped with emergency venting that will permit pressures to exceed a gauge pressure of 2.5 psi (17 kPa), shall be located in accordance with Table 66.22.4.1.3 and Table 66.22.4.1.1(b). [**30:**22.4.1.3]

66.22.4.1.4 Tanks storing liquids with boil-over characteristics shall be located in accordance with Table 66.22.4.1.4. Liquids with boil-over characteristics shall not be stored in fixed roof tanks larger than 150 ft (45 m) in diameter, unless an approved inerting system is provided on the tank. [**30:**22.4.1.4]

Δ ***TABLE 66.22.4.1.4*** *Location of Aboveground Storage Tanks Storing Boil-Over Liquids*

Type of Tank	Protection	Minimum Distance (ft) From Property Line that Is or Can Be Built Upon, Including the Opposite Side of a Public Way[a]	Minimum Distance (ft) From Nearest Side of Any Public Way or from Nearest Important Building on the Same Property[a]
Floating roof	Protection for exposures[b]	½ × diameter of tank	⅙ × diameter of tank
	None	Diameter of tank	⅙ × diameter of tank
Fixed roof	Approved foam or inerting system[c]	Diameter of tank	⅓ × diameter of tank
	Protection for exposures[b]	2 × diameter of tank	⅔ × diameter of tank
	None	4 × diameter of tank but need not exceed 350 ft	⅔ × diameter of tank

For SI units, 1 ft = 0.3 m.

[a]The minimum distance cannot be less than 5 ft.

[b]See definition 3.3.46 of NFPA 30, Protection for Exposures.

[c]See NFPA 69, *Standard on Explosion Prevention Systems*.
[**30:** Table 22.4.1.4]

TABLE 66.22.4.1.5 Location of Aboveground Storage Tanks Storing Unstable Liquids

Type of Tank	Protection	Minimum Distance (ft): From Property Line that Is or Can Be Built Upon, Including the Opposite Side of a Public Way	Minimum Distance (ft): From Nearest Side of Any Public Way or from Nearest Important Building on the Same Property[a]
Horizontal and vertical tanks with emergency relief venting to permit pressure not in excess of a gauge pressure of 2.5 psi (17 kPa)	Tank protected with any one of the following: approved water spray, approved inerting,[a] approved insulation and refrigeration, approved barricade	Value in Table 66.22.4.1.1(b) but not less than 25 ft	Not less than 25 ft
	Protection for exposures[b]	2½ × value in Table 66.22.4.1.1(b) but not less than 50 ft	Not less than 50 ft
	None	5 × value in Table 66.22.4.1.1(b) but not less than 100 ft	Not less than 100 ft
Horizontal and vertical tanks with emergency relief venting to permit pressure over a gauge pressure of 2.5 psi (17 kPa)	Tank protected with any one of the following: approved water spray, approved inerting,[a] approved insulation and refrigeration, approved barricade	2 × value in Table 66.22.4.1.1(b) but not less than 50 ft	Not less than 50 ft
	Protection for exposures[b]	4 × value in Table 66.22.4.1.1(b) but not less than 100 ft	Not less than 100 ft
	None	8 × value in Table 66.22.4.1.1(b) but not less than 150 ft	Not less than 150 ft

For SI units, 1 ft = 0.3 m.

[a]See NFPA 69, *Standard on Explosion Prevention Systems*.

[b]See definition 3.3.46 of NFPA 30, Protection for Exposures. [**30:** Table 22.4.1.5]

66.22.4.1.5 Tanks storing unstable liquids shall be located in accordance with Table 66.22.4.1.5 and Table 66.22.4.1.1(b). [**30:**22.4.1.5]

To contain the possibly violent reaction caused by heating under fire conditions, greater spacing for these tanks than for tanks storing stable liquids is mandated. Tanks storing unstable liquids have the most stringent spacing requirements.

66.22.4.1.6 Tanks storing Class IIIB stable liquids shall be located in accordance with Table 66.22.4.1.6.

*Exception: If located within the same diked area as, or within the drainage path of, a tank storing a Class I or Class II liquid, the tank storing Class IIIB liquid shall be located in accordance with 66.22.4.1.1. [**30:**22.4.1.6]*

Class IIIB liquids are considered to be almost immune from accidental fire because of their high flash points and extremely low

TABLE 66.22.4.1.6 Location of Aboveground Storage Tanks Storing Class IIIB Liquids

Tank Capacity (gal)	Minimum Distance (ft): From Property Line that Is or Can Be Built Upon, Including the Opposite Side of a Public Way	Minimum Distance (ft): From Nearest Side of Any Public Way or from Nearest Important Building on the Same Property
12,000 or less	5	5
12,001 to 30,000	10	5
30,001 to 50,000	10	10
50,001 to 100,000	15	10
100,001 or more	15	15

For SI units, 1 ft = 0.3 m; 1 gal = 3.8 L. [**30:** Table 22.4.1.6] vapor pressures. Thus, required distances from tanks to property lines are minimal. However, if a tank containing a Class IIIB liquid is situated in the drainage path of a Class I or Class II liquid (e.g., in the same diked area), the tank could be exposed by a spill fire.

66.22.4.1.7 Where two tank properties of diverse ownership have a common boundary, the AHJ shall be permitted, with the written consent of the owners of the two properties, to substitute the distances provided in 66.22.4.2 for the minimum distances set forth in 66.22.4.1.1. [**30:**22.4.1.7]

Simply put, when two owners sharing a common boundary agree, each may accept the risk from any of the tanks on the other's property to the same extent that risk is accepted from one's own. The separation distance tables are applied as if the tanks were on the same property.

66.22.4.1.8 Where end failure of a horizontal pressure tank or vessel can expose property, the tank or vessel shall be placed with its longitudinal axis parallel to the nearest important exposure. [**30:**22.4.1.8]

Paragraph 66.22.4.1.8 is based on the fact that a horizontal pressure tank exposed to fire is likely to travel (rocket) axially upon failure. Application of this rule involves the difficult decision as to which structure constitutes the nearest important risk. An office building on the same property or any occupied building on adjoining property would be considered an "important exposure." A tank containing flammable liquids might also be considered an important exposure; a normally unoccupied storage shed likely would not. See Exhibit 66.41.

66.22.4.2 Shell-to-Shell Spacing of Adjacent Aboveground Storage Tanks.

66.22.4.2.1* Tanks storing Class I, Class II, or Class IIIA stable liquids shall be separated by the distances given in Table 66.22.4.2.1. [**30:**22.4.2.1]

Exhibit 66.41

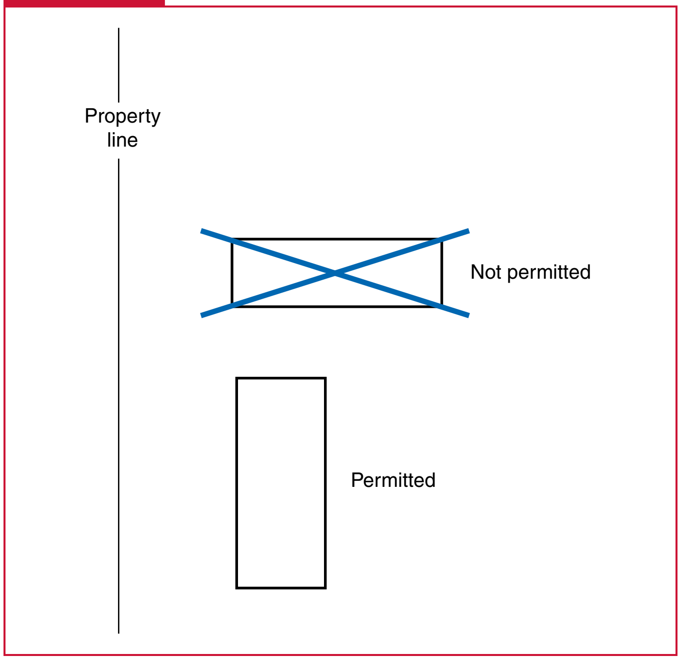

Illustration of proper orientation of pressure vessel to nearest exposure.

The minimum spacing between tanks storing stable liquids is given in Table 66.22.4.2.1. The 3 ft (0.9 m) minimum is based on the need for access for maintenance and painting and for application of hose streams to cool a fire-exposed tank. Spacing for larger tanks is an arbitrary fraction of tank diameter, sufficient to permit an orderly and safe arrangement for pipelines and to prevent spread of fire from one tank to another. Spacing alone is not a safeguard against fire spread from spilled liquid. The control of spills is covered in 66.22.11. Exceptions to the

***TABLE 66.22.4.2.1** Minimum Shell-to-Shell Spacing of Aboveground Storage Tanks*

		Fixed or Horizontal Tanks	
Tank Diameter	**Floating Roof Tanks**	**Class I or II Liquids**	**Class IIIA Liquids**
All tanks not over 150 ft (45 m) in diameter	⅙ × sum of adjacent tank diameters but not less than 3 ft (0.9 m)	⅙ × sum of adjacent tank diameters but not less than 3 ft (0.9 m)	⅙ × sum of adjacent tank diameters but not less than 3 ft (0.9 m)
Tanks larger than 150 ft (45 m) in diameter:			
If remote impounding is provided in accordance with 66.22.11.1	⅙ × sum of adjacent tank diameters	¼ × sum of adjacent tank diameters	⅙ × sum of adjacent tank diameters
If open diking is provided in accordance with 66.22.11.2	¼ × sum of adjacent tank diameters	⅓ × sum of adjacent tank diameters	¼ × sum of adjacent tank diameters

Note: The "sum of adjacent tank diameters" means the sum of the diameters of each pair of tanks that are adjacent to each other. See also A.66.22.4.2.1. [**30:** Table 22.4.2.1] spacing requirements in 66.22.4.2.1 are found in 66.22.4.2.1.1 and 66.22.4.2.1.2.

A.66.22.4.2.1 Where more than two tanks are involved, the sum of the diameters of each possible pair of tanks is calculated. For example, assume four tanks in a common diked area, numbered 1 through 4 clockwise from tank #1. The diameter of each pair of tanks is summed, as follows: 1 and 2, 1 and 3, 1 and 4, 2 and 3, 2 and 4, and 3 and 4. [**30:**A.22.4.2.1]

As an example of the application of "sum of adjacent tank diameters," assume a diked area containing three fixed roof cylindrical tanks set in a row, all three tanks of differing diameters: from left to right, 65 ft (20 m), 30 ft (9 m), and 20 ft (6 m). From left to right, designate the tanks A, B, and C. The tanks store Class I liquids.

Consider tank A first. According to Table 66.22.4.2.1, the required separation between it and adjacent tank B is one-quarter the sum of the adjacent tank diameters:

$$\tfrac{1}{4}(65 + 30) = \tfrac{1}{4}(95) = 23.75 \text{ ft, or } 23 \text{ ft } 9 \text{ in.}$$

The required separation between tank A and tank C is:

$$\tfrac{1}{4}(65 + 20) = \tfrac{1}{4}(85) = 21.25 \text{ ft, or } 21 \text{ ft } 3 \text{ in.}$$

Obviously, if the required separation between tanks A and B is satisfied, then the required separation between tanks A and C is also satisfied.

Consider, then, tank B. The required separation between tanks A and B has already been calculated. Only the required separation between tanks B and C needs to be found:

$$\tfrac{1}{4}(30 + 20) = \tfrac{1}{4}(50) = 12.5 \text{ ft, or } 12 \text{ ft } 6 \text{ in.}$$

Thus, the installation described is compliant with the *Code*'s provisions for shell-to-shell spacing.

66.22.4.2.1.1 Tanks that store crude petroleum, have individual capacities not exceeding 3000 bbl (126,000 gal or 480 m^3), and are located at production facilities in isolated locations shall not be required to be separated by more than 3 ft (0.9 m). [**30:**22.4.2.1.1]

66.22.4.2.1.2 Tanks used only for storing Class IIIB liquids shall not be required to be separated by more than 3 ft (0.9 m) provided they are not within the same diked area as, or within the drainage path of, a tank storing a Class I or Class II liquid. If located within the same diked area as, or within the drainage path of, a tank storing a Class I or Class II liquid, the tank storing Class IIIB liquid shall be spaced in accordance with the requirements for Class IIIA liquids in Table 66.22.4.2.1. [**30:**22.4.2.1.2]

66.22.4.2.2 A tank storing unstable liquid shall be separated from any other tank containing either an unstable liquid or a Class I, II, or III liquid by a distance not less than one-half the sum of their diameters. [**30:**22.4.2.2]

66.22.4.2.3 Where tanks are in a diked area containing Class I or Class II liquids or in the drainage path of Class I or Class II liquids and are compacted in three or more rows or in an irregular pattern, greater spacing or other means shall be permitted to be required by the AHJ to make tanks in the interior of the pattern accessible for fire-fighting purposes. [**30:**22.4.2.3]

66.22.4.2.4 The minimum horizontal separation between an LP-Gas container and a Class I, Class II, or Class IIIA liquid storage tank shall be 20 ft (6 m). [**30:**22.4.2.4]

66.22.4.2.4.1 Means shall be provided to prevent Class I, Class II, or Class IIIA liquids from accumulating under adjacent LP-Gas containers by means of dikes, diversion curbs, or grading. [**30:**22.4.2.4.1]

66.22.4.2.4.2 Where flammable or combustible liquid storage tanks are within a diked area, the LP-Gas containers shall be outside the diked area and at least 10 ft (3 m) away from the centerline of the wall of the diked area. [**30:**22.4.2.4.2]

66.22.4.2.5 If a tank storing a Class I, Class II, or Class IIIA liquid operates at pressures exceeding a gauge pressure of 2.5 psi (17 kPa) or is equipped with emergency relief venting that will permit pressures to exceed a gauge pressure of 2.5 psi (17 kPa), it shall be separated from an LP-Gas container by the appropriate distance given in Table 66.22.4.2.1. [**30:**22.4.2.5]

66.22.4.2.6 The requirements of 66.22.4.2.4 shall not apply where LP-Gas containers of 125 gal (475 L) or less capacity are installed adjacent to fuel oil supply tanks of 660 gal (2500 L) or less capacity. [**30:**22.4.2.6]

66.22.5 Installation of Aboveground Storage Tanks.

66.22.5.1 Tank Supports.

66.22.5.1.1 Tank supports shall be designed and constructed in accordance with recognized engineering standards. [**30:**22.5.1.1]

66.22.5.1.2 Tanks shall be supported in a manner that prevents excessive concentration of loads on the supported portion of the shell. [**30:**22.5.1.2]

66.22.5.1.3 In areas subject to earthquakes, tank supports and connections shall be designed to resist damage as a result of such shocks. [**30:**22.5.1.3]

66.22.5.2 Foundations for and Anchoring of Aboveground Storage Tanks.

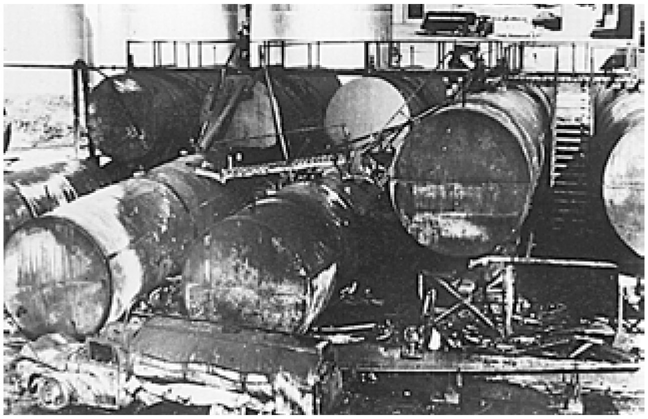
66.22.5.2.1* Tanks shall rest on the ground or on foundations made of concrete, masonry, piling, or steel. [**30:**22.5.2.1]

A.66.22.5.2.1 Appendix E of API Standard 650, *Welded Steel Tanks for Oil Storage*, and Appendix B of API 620, *Recommended Rules for the Design and Construction of Large, Welded, Low-Pressure Storage Tanks*, provide information on tank foundations. [**30:**A.22.5.2.1]

66.22.5.2.2 Tank foundations shall be designed to minimize the possibility of uneven settling of the tank and to minimize corrosion in any part of the tank resting on the foundation. [**30:**22.5.2.2]

66.22.5.2.3 Where tanks storing Class I, Class II, or Class IIIA liquids are supported above their foundations, tank supports shall be of concrete, masonry, or protected steel.

Exhibit 66.42



Aboveground tanks on unprotected steel supports (left). Aftermath of a fire where tanks were supported on unprotected steel supports (right).

*Exception: Single wood timber supports (not cribbing), laid horizontally, shall be permitted to be used for outside aboveground tanks if not more than 12 in. (300 mm) high at their lowest point. [**30:**22.5.2.3]*

Unprotected steel supports are prohibited. Experience has shown that they soften and buckle after only brief exposure to fire, allowing the tank to tip or fall to the ground and breaking piping connections, resulting in release of tank contents. Exhibit 66.42 dramatically illustrates this danger. One can still find storage tanks installed on unprotected steel supports, even though the practice has been prohibited since the first edition of NFPA 30, in 1913.

The exception for solid timber supports less than 12 in. (300 mm) high is based on the slow burning characteristic of heavy timber construction. The premise is fire suppression will have taken place before an exposure fire degrades the timber supports to the point where stability of the tanks is compromised. Note that this requirement is intended to apply only to fixed tanks. Portable tanks would not be expected to comply, especially if located in areas where loss of the tank contents would not significantly add to consequences of the fire, such as at an isolated construction site.

Δ **66.22.5.2.4*** Steel support structures or exposed piling for tanks storing Class I, Class II, or Class IIIA liquids shall be protected by materials having a fire resistance rating of not less than 2 hours.

Exception No. 1: Steel saddles do not need to be protected if less than 12 in. (300 mm) high at their lowest point.

*Exception No. 2: At the discretion of the AHJ, water spray protection in accordance with NFPA 15 or NFPA 13, is permitted to be used. [**30:**22.5.2.4]*

A.66.22.5.2.4 For further information, see ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, and ANSI/UL 1709, *Standard for Rapid Rise Fire Tests of Protection Materials for Structural Steel*. [**30:**A.22.5.2.4]

Experience has shown that unprotected steel saddles of the size specified in Exception No. 1 to 66.22.5.2.4 can be mounted directly on the tank foundation or can be supported above the foundation on fire-resistant steel piers or masonry piers without presenting a risk to the stability of the tanks.

66.22.5.2.5 Where a tank is located in an area subject to flooding, provisions shall be taken to prevent tanks, either full or empty, from floating during a rise in water level up to the established maximum flood stage. *(See 66.21.7.3.)* [**30:**22.5.2.5]

66.22.6 Vent Piping for Aboveground Tanks. Piping for normal and emergency relief venting shall be constructed in accordance with Section 66.27. [**30:**22.6]

66.22.7 Emergency Relief Venting for Fire Exposure for Aboveground Storage Tanks.

When exposed to fire, the liquid contents of a tank are heated and can be expected to boil, evolving vapor at a rate greater than can be handled by the normal vent, as described in 66.21.4.3 for normal operating conditions. Provisions for safely releasing the additional vapor are described in 66.22.7. Failure to provide adequate emergency relief venting can cause tanks to explode violently or rocket great distances, as shown in Exhibit 66.43.

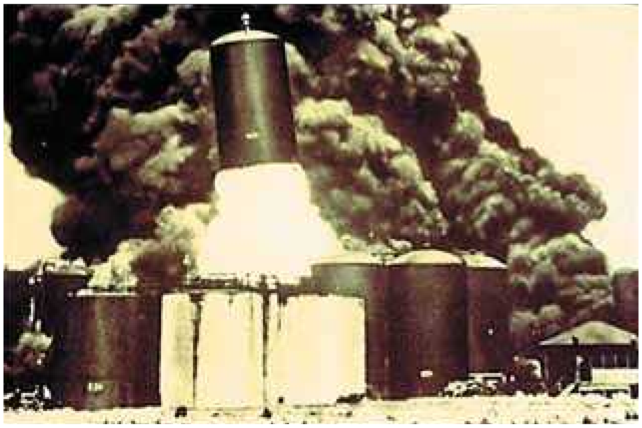
66.22.7.1 General.

66.22.7.1.1 Every aboveground storage tank shall have emergency relief venting in the form of construction or a device or devices that will relieve excessive internal pressure caused by an exposure fire. [**30:**22.7.1.1]

66.22.7.1.1.1 This requirement shall apply to each compartment of a compartmented tank, the interstitial space (annulus) of a secondary containment–type tank, and the enclosed space of tanks of closed-top dike construction. [**30:**22.7.1.1.1]

66.22.7.1.1.2 This requirement shall also apply to spaces or enclosed volumes, such as those intended for insulation,

Exhibit 66.43



Catastrophic failure and rocketing of a tank due to inadequate emergency relief venting.

membranes, or weather shields, that are capable of containing liquid because of a leak from the primary vessel. The insulation, membrane, or weather shield shall not interfere with emergency venting. [**30:**22.7.1.1.2]

66.22.7.1.1.3 Tanks storing Class IIIB liquids that are larger than 12,000 gal (45,400 L) capacity and are not within the diked area or the drainage path of tanks storing Class I or Class II liquids shall not be required to meet the requirements of 66.22.7.1.1. [**30:**22.7.1.1.3]

Class IIIB liquids have such low vapor pressures and high boiling points that, in the time required to reach boiling and thus cause excessive internal pressure, the metal shell above the internal liquid level of tanks of this size will have softened and failed. In effect, the tank will have self-vented. The additional provision that such tanks not be in a diked area with or in the drainage path of Class I and II liquids is to minimize the chance of these tanks being exposed to an external fire.

66.22.7.1.2 For vertical tanks, the emergency relief venting construction referred to in 66.22.7.1.1 shall be permitted to be a floating roof, a lifter roof, a weak roof-to-shell seam, or another approved pressure-relieving construction. [**30:**22.7.1.2]

66.22.7.1.3 If unstable liquids are stored, the effects of heat or gas resulting from polymerization, decomposition, condensation, or self-reactivity shall be taken into account. [**30:**22.7.1.3]

66.22.7.1.4 If two-phase flow is anticipated during emergency venting, an engineering evaluation shall be conducted in order to size the pressure-relieving devices. [**30:**22.7.1.4]

66.22.7.2 Weak Roof-to-Shell Seam Construction. If used, a weak roof-to-shell seam shall be constructed to fail preferential to any other seam and shall be designed in accordance with API Standard 650, *Welded Steel Tanks for Oil Storage*. [**30:**22.7.2]

66.22.7.3 Pressure-Relieving Devices.

66.22.7.3.1* Where entire dependence for emergency relief venting is placed upon pressure-relieving devices, the total venting capacity of both normal and emergency vents shall be sufficient to prevent rupture of the shell or bottom of a vertical tank or of the shell or heads of a horizontal tank. [**30:**22.7.3.1]

A.66.22.7.3.1 An engineering evaluation should be performed whenever two-phase flow is anticipated. The objective of the engineering evaluation determining emergency vent requirements and design of the relief system is to protect against catastrophic failure resulting in unacceptable risk to persons or to the facility. Factors that should be included in the evaluation are as follows:

(1) Properties of the materials including evaluated influence of two-phase flow and thermally induced instability. See the following references from the Design Institute for Emergency Relief Systems of the Center for Chemical Process Safety/American Institute of Chemical Engineers:
   (a) Fisher, H. G. and Forrest, H. S., "Protection of Storage Tanks from Two-Phase Flow Due to Fire Exposure"
   (b) Houser, J., et al., "Vent Sizing for Fire Considerations: External Fire Duration, Jacketed Vessels, and Heat Flux Variations Owing to Fuel Consumption"
   (c) *Guidelines for Pressure Relief and Effluent Handling Systems*
(2) Rate of heat input to the tank and contents. Computer models such as PLGS (supported by the UK Health and Safety Executive) can be useful in making the analysis.
(3) Fire duration. For pool fires this analysis can be based on burning rate and pool depth. Computer programs can be useful in making this analysis.

[**30:**A.22.7.3.1]

66.22.7.3.2 Emergency relief vent devices shall be vaportight and shall be permitted to be any one of the following:

(1) Self-closing manway cover
(2) Manway cover provided with long bolts that permit the cover to lift under internal pressure
(3) Additional or larger relief valve or valves

[**30:**22.7.3.2.1]

66.22.7.3.3 The outlets of all vents and vent drains on tanks equipped with emergency relief venting that permits pressures to exceed a gauge pressure of 2.5 psi (17.2 kPa) shall be arranged to discharge so that localized overheating of or flame impingement on any part of the tank will not occur if vapors from the vents are ignited. [**30:**22.7.3.9]

66.22.7.3.4 Each commercial tank venting device shall have the following information either stamped or cast into the metal body of the device or included on a metal nameplate permanently affixed to it.

(1) Start-to-open pressure
(2) Pressure at which the valve reaches the full open position
(3) Flow capacity at the pressure indicated by 66.22.7.3.4(2)

[**30:**22.7.3.10]

66.22.7.4* Extension of Emergency Vent Piping. Piping to or from approved emergency vent devices for atmospheric and low-pressure tanks shall be sized to provide emergency vent flows that limit the back pressure to less than the maximum pressure permitted by the design of the tank. Piping to or from approved emergency vent devices for pressure vessels shall be sized in accordance with the ASME *Boiler and Pressure Vessel Code*. [**30:**22.7.4]

A.66.22.7.4 Vent sizing formulae and prescriptive vent sizes, such as those established by ANSI/UL 142, *Standard for Steel Aboveground Tanks for Flammable and Combustible Liquids*, are typically based on the direct installation of a venting device on to a tank with a nipple not exceeding 12 in. (300 mm). When the outlet of a vent must be extended to a remote location, such as for tanks located in buildings, which require vent discharges to be located outside, a significant reduction in vent flow can occur unless the size of the vent and connecting piping is increased. In such cases, the size of vents and vent pipe extensions should be calculated to ensure that a tank will not be over-pressurized during a fire exposure. [**30:**A.22.7.4]

66.22.8 Fire Control.

66.22.8.1* A fire-extinguishing system in accordance with an applicable NFPA standard shall be provided or shall be available for vertical atmospheric fixed-roof storage tanks larger than 50,000 gal (190 m^3) capacity, storing Class I liquids, if located in a congested area where there is an unusual exposure hazard to the tank from adjacent property or to adjacent property from the tank. [**30:**22.8.1]

Δ **A.66.22.8.1** Protection against fire or explosion required for large flammable liquid storage tanks should consider the use of fixed, semi-fixed, or portable protection system designed in conformance with good engineering practice such as those described in NFPA 11, NFPA 15 and NFPA 69. Ordinary combustibles (such as wood) would be subject to radiant heat unpiloted ignition from a burning tank, when such exposures are located a distance of less than about 150 percent of the tank diameter (assuming no wind effects). Exposure from adjacent property to the tanks would depend on the specific products and storage arrangement and may require some engineering analysis based on the occupancy and its exposure potential. [**30:**A.22.8.1]

The criteria set forth in 66.22.8.1 are the only conditions in which NFPA 30 mandates fire protection for a storage tank, and even here there is an element of subjectivity because the AHJ will have to determine if an unusual exposure hazard truly exists. In all other cases, the determination of whether to provide fixed fire protection and, if so, the type of protection to be provided, is based strictly on engineering and fire hazard evaluations of the facility.

Fire-extinguishing systems are not required for small fixed roof tanks because such tanks are seldom involved in a fire. If these tanks should become involved, there is little risk that the fire will spread. Spill fires cannot be extinguished by equipment designed for tank fires and are usually controlled by public fire departments.

The separation distances in Table 66.22.4.2.1 are based on the considerations contained in 66.22.8.1.

66.22.8.2 Fixed-roof tanks storing Class II or Class III liquids at temperatures below their flash points and floating-roof tanks storing any liquid shall not require protection when installed in accordance with this section. [**30:**22.8.2]

66.22.9 Additional Requirements for Fire-Resistant Aboveground Storage Tanks.

66.22.9.1 Fire-resistant tanks shall be tested and listed in accordance with UL 2080, *Standard for Fire Resistant Tanks for Flammable and Combustible Liquids*. [**30:**22.9.1]

66.22.10 Additional Requirements for Protected Aboveground Storage Tanks.

66.22.10.1 Protected aboveground tanks shall be tested and listed in accordance with ANSI/UL 2085, *Standard for Protected Aboveground Tanks for Flammable and Combustible Liquids*. [**30:**22.10.1]

66.22.11* Control of Spills from Aboveground Storage Tanks. Every tank that contains a Class I, Class II, or Class IIIA liquid shall be provided with means to prevent an accidental release of liquid from endangering important facilities and adjoining property or from reaching waterways. Such means shall meet the requirements of 66.22.11.1, 66.22.11.2, 66.22.11.3, or 66.22.11.4, whichever is applicable. [**30:**22.11]

A.66.22.11 "Accidental release" includes but is not limited to the following:

(1) Leakage from the tank shell
(2) Overfill
(3) Leakage from piping connected to the tank

[**30:**A.22.11]

The requirements of 66.22.11 are based on the rationale that release of product from a tank, whatever the cause, must not be permitted to endanger important facilities and adjoining property or to reach any waterways. The principal fear is that such a spill might be ignited and cause extensive spread of fire. Another major concern is environmental pollution that might be difficult to control.

These spill control requirements are primarily directed at releases due to overfilling the tank or to a major leak from piping connected to the tank. Releases due to a leaking shell are also covered, but they are minor and tend to be much smaller. The spill control provisions of NFPA 30 do not, however, anticipate catastrophic failure of the entire tank shell, such as occurred in Floreffe, Pennsylvania, in January 1988. See Exhibit 66.44.

Tanks storing Class IIIB liquids do not require spill control for fire protection purposes alone because it is highly unlikely that ignition of a spill will occur, although environmental contamination will likely result regardless of whether a fire occurs.

Exhibit 66.44

Destroyed oil storage tank, Floreffe, Pennsylvania, January 2, 1988.

66.22.11.1 Remote Impounding. Where control of spills is provided by drainage to a remote impounding area so that spilled liquid does not collect around tanks, the requirements of 66.22.11.1.1 through 66.22.11.1.4 shall apply. [**30:**22.11.1]

66.22.11.1.1 The drainage route shall have a slope of not less than 1 percent away from the tank for at least 50 ft (15 m) toward the impounding area. [**30:**22.11.1.1]

The concept of remote impounding is that any spilled liquid will be led, by grading, swales, ditches, or other channels, to an impounding area large enough to contain all the liquid from the largest tank that can drain into it. The impounding area must be located so that, if a spill ignites, the fire will not seriously expose other tanks or adjoining property. A reasonable slope away from the tank is required so that liquid will not come to rest closer than 50 ft (15 m) from the tank or 50 ft (15 m) from any property line that can be built upon.

In early tank installations where tanks were often placed on hills to achieve gravity flow, sloping the surrounding terrain away from the tank was easily attained. Installations on relatively flat terrain present a much more difficult problem. Nonetheless, significant drainage control with a minimum of grading is possible. This method is much preferred to the shortcut practice of placing each tank in the center of a flat diked area, where even a minor spill would likely make piping and control valves inaccessible and subject to fire damage. The remote impounding area must be large enough to contain all the liquid from the largest tank that can drain into it. A 1 percent slope away from the tank generally ensures adequate drainage control. Exhibit 66.45 illustrates the concept of remote impounding.

66.22.11.1.2 The impounding area shall have a capacity not less than that of the largest tank that drains into it.

*Exception: Where compliance with 66.22.11.1.2 is not possible because there is not enough open area around the tanks, "partial" remote impounding for a percentage of the required capacity is permitted. The remainder of the volume required for spill control can be provided by open diking meeting the requirements of 66.22.11.2. [**30:**22.11.1.2]*

Most liquid releases are small, involving only a small percentage of the total capacity of the spill control system. Combined spill control systems allow the facility to take advantage of remote impounding to reduce the risk of small releases while still providing 100 percent containment for the largest tank should a major incident occur. Note that there is no specific percentage of the largest tank's capacity that the remote impounding basin needs to contain.

66.22.11.1.3 The drainage route shall be located so that, if the liquid in the drainage system is ignited, the fire will not seriously expose tanks or adjoining property. [**30:**22.11.1.3]

66.22.11.1.4 The impounding area shall be located so that, when filled to capacity, the liquid will not be closer than 50 ft (15 m) from any property line that is or can be built upon or from any tank.

*Exception: Where partial remote impounding as provided for in 66.22.11.1.2 is used, the liquid in the partial remote impounding area shall meet the requirements of 66.22.11.1.4. Tank spacing shall be determined based on the diked tank provisions of Table 66.22.4.2.1. [**30:**22.11.1.4]*

66.22.11.2 Impounding Around Tanks by Open Diking. Where control of spills is provided by means of impounding by open diking around the tanks, such systems shall meet the requirements of 66.22.11.2.1 through 66.22.11.2.8. [**30:**22.11.2]

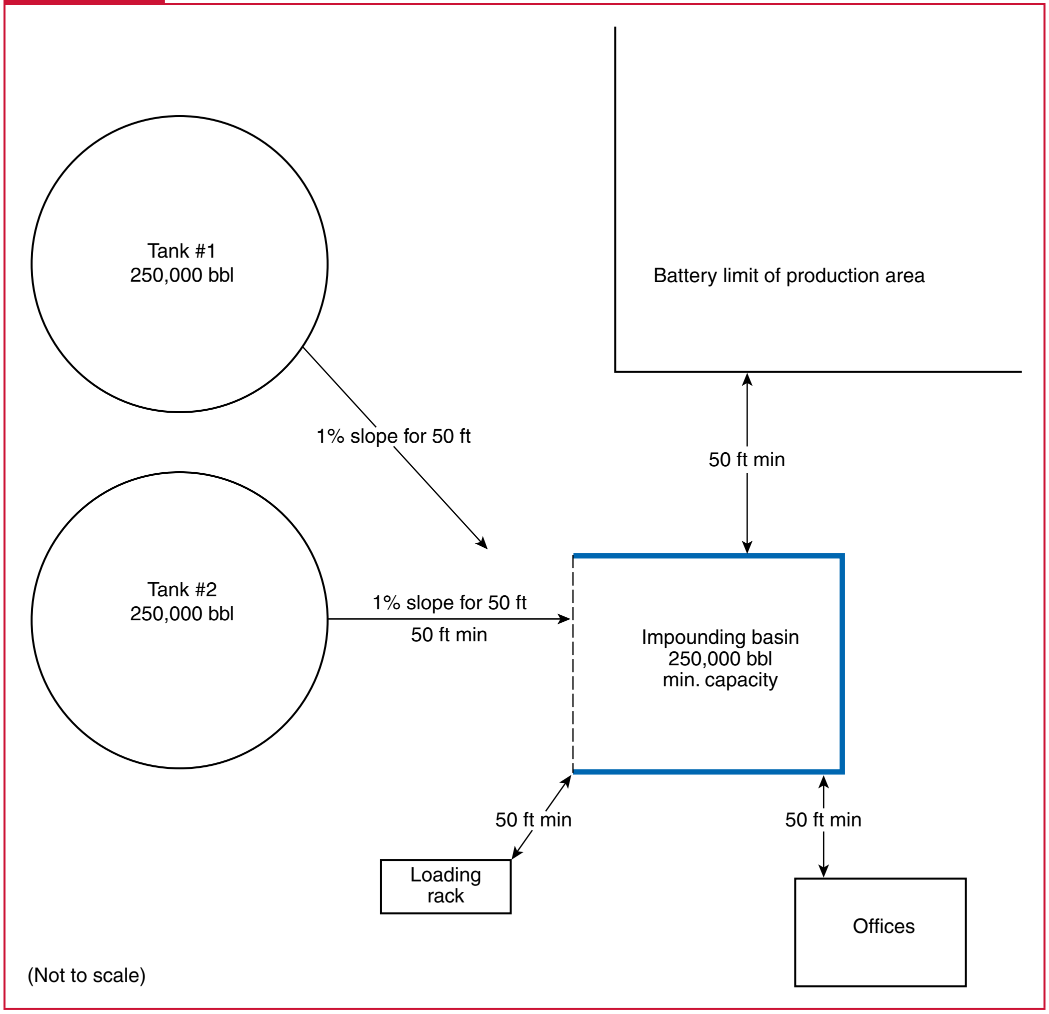
Diking is less desirable than remote impounding because it allows a ground fire to expose tanks within the diked area. However, it is often difficult to provide remote impounding, either because there is not enough open area around the tanks or because environmental regulations prohibit the use of an open impounding basin. Thus, diking becomes an important alternative. The exception to 66.22.11.1.2, which allows a combined spill control system consisting of both remote impounding and diking, provides obvious benefits: A facility that cannot meet the requirements for remote impounding completely might be able to provide partial impounding, with diking providing protection from a major incident.

66.22.11.2.1 A slope of not less than 1 percent away from the tank shall be provided for at least 50 ft (15 m) or to the dike base, whichever is less. [**30:**22.11.2.1]

66.22.11.2.2* The volumetric capacity of the diked area shall not be less than the greatest amount of liquid that can be released from the largest tank within the diked area, assuming a full tank. [**30:**22.11.2.2]

A.66.22.11.2.2 An aboveground storage tank dike is normally sized to contain the entire contents of the largest single tank within it. Some designs incorporate sufficient freeboard (additional capacity) to accommodate precipitation or fire-fighting water. The

Exhibit 66.45



Concept of a remote impounding area.

amount of this freeboard is usually governed by local conditions. [**30:**A.22.11.2.2]

NFPA 30 does not provide a specific definition of *full tank*. However, the intent is for "the greatest amount of liquid that can be released" to be some reasonable quantity. Normally, this is considered to be that quantity represented by the maximum fill height or the overfill point. Also, note that a few jurisdictions require the dike to be able to hold 110 percent of the largest tank's capacity to provide some "freeboard" for foam application and some additional containment to hold runoff from fire-fighting operations.

66.22.11.2.2.1 To allow for volume occupied by tanks, the capacity of the diked area enclosing more than one tank shall be calculated after deducting the volume of the tanks, other than the largest tank, below the height of the dike. [**30:**22.11.2.2.1]

66.22.11.2.3 To permit access, the outside base of the dike at ground level shall be no closer than 10 ft (3 m) to any property line that is or can be built upon. [**30:**22.11.2.3]

Paragraph 66.22.11.2.3 is intended to permit access for fire fighting and to provide additional protection for buildings on adjoining property in the event of a fire in the diked area.

66.22.11.2.4 Walls of the diked area shall be of earth, steel, concrete, or solid masonry designed to be liquidtight and to withstand a full hydrostatic head. [**30:**22.11.2.4]

An understanding of the meaning of *liquidtight* is important, because several jurisdictions require that the floor and walls of a dike meet a maximum permeability standard. (Permeability measures how easily a liquid can penetrate, or "soak" into, a barrier material.) For the purposes of 66.22.11.2.4, *liquidtight* means that the liquid will not breach or soak through the dike wall, at least for some reasonable length of time. Of course, because the dike is expected to hold liquid only in an emergency condition that results in a spill, the spilled liquid will presumably be removed as soon as the emergency has been stabilized. Well-compacted clays can resist the permeation of liquid for a reasonable period and are allowed for dike walls, at least for purposes of fire protection. However, environmental protection regulations might require more substantial treatment, such as an impervious lining.

66.22.11.2.4.1* Earthen walls 3 ft (0.9 m) or more in height shall have a flat section at the top not less than 2 ft (0.6 m) wide and shall have a slope that is consistent with the angle of repose of the material of which the wall is constructed. [**30:**22.11.2.4.1]

A.66.22.11.2.4.1 Diked areas for tanks containing Class I liquids located in extremely porous soils might require special treatment to prevent seepage of hazardous quantities of liquids to low-lying areas or waterways in case of spills. [**30:**A.22.11.2.4.1]

66.22.11.2.5 Where the average interior height of the walls of the diked area exceeds 6 ft (1.8 m), provisions shall be made for normal access; necessary emergency access to tanks, valves, and other equipment; and egress from the diked enclosure. The following requirements shall apply:

(1) Where the average height of a dike containing Class I liquids is over 12 ft (3.6 m) high, measured from interior grade, or where the distance between any tank and the top inside edge of the dike wall is less than the height of the dike wall, provisions shall be made for operation of valves and for access to tank roof(s) without entering below the top of the dike. These provisions shall be permitted to be met through the use of remote-operated valves, elevated walkways, or other arrangements.
(2) Piping passing through dike walls shall be designed to withstand imposed stresses as a result of settlement or fire exposure.
(3) The distance between the shell of any tank and the toe of the interior of the dike wall shall be not less than 5 ft (1.5 m).

[**30:**22.11.2.5]

The premise behind 66.22.11.2.5 is that the height of the dike should be limited to 6 ft (1.8 m) to provide relatively easy escape from the diked area for fire fighters engaged in combating small fires within the dike. The dike might need to exceed 6 ft (1.8 m), however, where the area available for the dike is limited or where a particular jurisdiction requires all tanks to be individually diked. A dike height exceeding 6 ft (1.8 m) requires further precautions, as specified in 66.22.11.2.5(1) through (3). For example, where the dike exceeds this height, the minimum distance between tanks and the toe of the interior of the dike wall must be 5 ft (1.5 m), as shown in Exhibit 66.46. Where a dike wall is unusually high, as described in 66.22.11.2.5(1) and as shown in Exhibit 66.47, special considerations apply. These provisions also reflect a concern for Class I vapors reaching unsafe concentrations when confined in the small space between the dike wall and the tank. Remotely operated valves or elevated walkways eliminate the need for personnel to enter the bottom of the diked area to operate a valve. Also, the space between the tank shell and the dike wall in Exhibit 66.47 is very likely a permit-required confined space under OSHA regulations.

Note that the provisions of 66.22.11.2.5(1), (2), and (3) are required only where the height of the dike wall exceeds 6 ft (1.8 m), as permitted in 66.22.11.2.5.

Exhibit 66.46

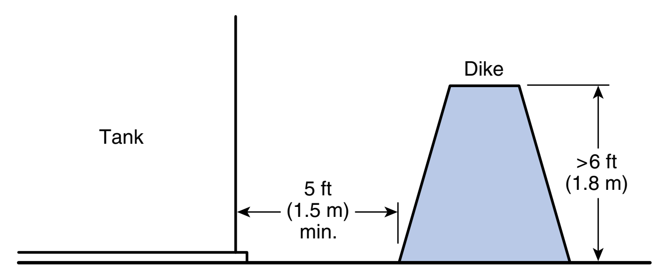


Illustration of dike wall exceeding 6 ft (1.8 m) high and application of 66.22.11.2.5(3).

Exhibit 66.47

Diked tank to which 66.22.11.2.5(1) applies.

66.22.11.2.6 Each diked area containing two or more tanks shall be subdivided, preferably by drainage channels or at least by intermediate dikes, in order to prevent minor spills from a tank from endangering adjacent tanks within the diked area. [**30:**22.11.2.6]

66.22.11.2.6.1 The drainage channels or intermediate dikes shall be located between tanks so as to take full advantage of the space with due regard for the individual tank capacities. [**30:**22.11.2.6.1]

66.22.11.2.6.2 Intermediate dikes shall be not less than 18 in. (450 mm) in height. [**30:**22.11.2.6.2]

66.22.11.2.6.3 Subdivision shall be provided according to the requirements of 66.22.11.2.6.3.1, 66.22.11.2.6.3.2, 66.22.11.2.6.3.3, 66.22.11.2.6.3.4, or 66.22.11.2.6.3.5, whichever is applicable. [**30:**22.11.2.6.3]

66.22.11.2.6.3.1 Where stable liquids are stored in vertical cone roof tanks of weak roof-to-shell seam design or in floating roof tanks, one subdivision shall be provided for each tank greater than 10,000 bbl (420,000 gal or 1590 m^3) capacity. In addition, one subdivision shall be provided for each group of tanks [with no individual tank exceeding 10,000 bbl (420,000 gal or 1590 m^3) capacity] having an aggregate capacity not greater than 15,000 bbl (630,000 gal or 2385 m^3). [**30:**22.11.2.6.3.1]

66.22.11.2.6.3.2 Where crude petroleum is stored in producing areas in any type of tank, one subdivision shall be provided for each tank greater than 10,000 bbl (420,000 gal or 1590 m^3) capacity. In addition, one subdivision shall be provided for each group of tanks [with no individual tank exceeding 10,000 bbl (420,000 gal or 1590 m^3) capacity] having an aggregate capacity not greater than 15,000 bbl (630,000 gal or 2385 m^3). [**30:**22.11.2.6.3.2]

66.22.11.2.6.3.3 Where stable liquids are stored in tanks not covered in 66.22.11.2.6.3.1, one subdivision shall be provided for each tank greater than 2380 bbl (100,000 gal or 380 m^3) capacity. In addition, one subdivision shall be provided for each group of tanks [with no individual tank exceeding 2380 bbl (100,000 gal or 380 m^3) capacity] having an aggregate capacity not greater than 3750 bbl (150,000 gal or 570 m^3). [**30:**22.11.2.6.3.3]

66.22.11.2.6.3.4* Where unstable liquids are stored in any type of tank, one subdivision shall be provided for each tank.

*Exception: Tanks that store unstable liquids and that are installed with drainage meeting the requirements of NFPA 15 need not meet this requirement. [**30:**22.11.2.6.3.4]*

A.66.22.11.2.6.3.4 Because unstable liquids will react more rapidly when heated than when at ambient temperatures, subdivision by drainage channels is the preferred method. [**30:**A.22.11.2.6.3.4]

66.22.11.2.6.3.5 Whenever two or more tanks storing Class I liquids, any one of which is over 150 ft (45 m) in diameter, are located in a common diked area, intermediate dikes shall be provided between adjacent tanks to hold at least 10 percent of the capacity of the tank so enclosed, not including the volume displaced by the tank. [**30:**22.11.2.6.3.5]

Intermediate dikes, such as those shown in Exhibit 66.48, are required to hold at least 10 percent of the capacity of the tank, not including the volume displaced by the tank, if any tank within the diked area exceeds 150 ft (45 m) in diameter. This requirement is designed to control those relatively small spills that, in the past, have resulted in major fires and destruction of all tanks within a dike enclosure.

Exhibit 66.48

Intermediate dikes around tanks.

66.22.11.2.7 Where provision is made for draining water from diked areas, such drains shall be controlled to prevent liquids from entering natural water courses, public sewers, or public drains. [**30:**22.11.2.7]

66.22.11.2.7.1 Control of drainage shall be accessible under fire conditions from outside the dike. [**30:**22.11.2.7.1]

66.22.11.2.8 Storage of combustible materials, empty drums, full drums, or barrels shall not be permitted within the diked area. [**30:**22.11.2.8]

66.22.11.3 Impounding Around Tanks by Closed-Top Diking. Where control of spills is provided by means of impounding by closed-top diking around the tanks, such systems shall meet all of the requirements of 66.22.11.4 or shall meet the requirements of 66.22.11.3.1 through 66.22.11.3.4. [**30:**22.11.3]

66.22.11.3.1* The volumetric capacity of the diked area shall not be less than the greatest amount of liquid that can be released from the largest tank within the diked area, assuming a full tank. [**30:**22.11.3.1]

A.66.22.11.3.1 See 66.22.11.2.2. [**30:**A.22.11.3.1]

66.22.11.3.2 To allow for volume occupied by tanks, the capacity of the diked area enclosing more than one tank shall be calculated after deducting the volume of the tanks, other than the largest tank, below the height of the dike. [**30:**22.11.3.2]

66.22.11.3.3 To permit access, the outside base of the dike at ground level shall be no closer than 10 ft (3 m) to any property line that is or can be built upon. [**30:**22.11.3.3]

66.22.11.3.4 Walls of the diked area shall be of steel, concrete, or solid masonry designed to be liquidtight and to withstand a full hydrostatic head. [**30:**22.11.3.4]

66.22.11.3.5 Where provision is made for draining water from diked areas, such drains shall be controlled to prevent liquids from entering natural water courses, public sewers, or public drains. [**30:**22.11.3.5]

66.22.11.3.5.1 Control of drainage shall be accessible under fire conditions from outside the dike. [**30:**22.11.3.5.1]

66.22.11.3.6 Storage of combustible materials, empty drums, full drums, or barrels shall not be permitted within the diked area. [**30:**22.11.3.6]

66.22.11.3.7 The capacity of the primary tank shall not exceed that given in 66.22.11.4.1. [**30:**22.11.3.7]

66.22.11.3.8 All piping connections to the tank shall be made above the normal maximum liquid level. [**30:**22.11.3.8]

66.22.11.3.9 The tank shall be capable of resisting the damage from the impact of a motor vehicle, or collision barriers shall be provided. [**30:**22.11.3.9]

66.22.11.3.10 Where the means of secondary containment is enclosed, it shall be provided with emergency venting in accordance with 66.22.7. [**30:**22.11.3.10]

66.22.11.3.11 Means shall be provided to establish the integrity of the secondary containment, in accordance with Section 66.21. [**30:**22.11.3.11]

66.22.11.3.12 Where the normal vent or the emergency vent device or both discharge outside the enclosure created by the closed-top diking, the tank within the enclosure shall comply with 66.22.11.4.4 and 66.22.11.4.5. [**30:**22.11.3.12]

66.22.11.3.13 Where the fill connection for the tank within the enclosure created by the closed-top diking is not located within the enclosure, the tank shall meet the requirements of 66.22.11.4.4 and 66.22.11.4.5. [**30:**22.11.3.13]

66.22.11.4 Secondary Containment–Type Aboveground Storage Tanks. Where a secondary containment–type tank is used to provide spill control, the tank shall meet all of the requirements of 66.22.11.4.1 through 66.22.11.4.10. [**30:**22.11.4]

66.22.11.4.1 The capacity of the listed primary tank for Classes I, II, and IIIA liquids shall not exceed 50,000 gal (189,000 L). [**30:**22.11.4.1]

66.22.11.4.2 All piping connections to the tank shall be made above the maximum liquid level. [**30:**22.11.4.2]

66.22.11.4.3 Means shall be provided to prevent the release of liquid from the tank by siphon flow. [**30:**22.11.4.3]

66.22.11.4.4 Means shall be provided for determining the level of liquid in the tank. This means shall be accessible to the delivery operator. [**30:**22.11.4.4]

66.22.11.4.5 Means shall be provided to prevent overfilling by sounding an alarm when the liquid level in the tank reaches 90 percent of capacity and by automatically stopping delivery of liquid to the tank when the liquid level in the tank reaches 95 percent of capacity. [**30:**22.11.4.5]

66.22.11.4.5.1 In no case shall these provisions restrict or interfere with the functioning of the normal vent or the emergency vent. [**30:**22.11.4.5.1]

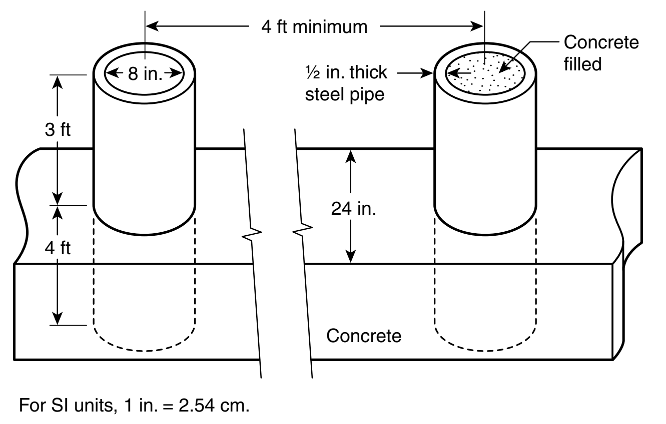
The provisions of 66.22.11.4.4 and 66.22.11.4.5 are intended to prevent spills due to overfilling the tank. It is important to understand that the overfill prevention features must not interfere with proper operation of the normal (breather) vent or the emergency vent. This rules out the use of any float-type device that can block the normal vent, resulting in overpressure of the tank.

66.22.11.4.6 Spacing between adjacent tanks shall comply with Table 66.22.4.2.1. [**30:**22.11.4.6]

66.22.11.4.7 The tank shall be capable of resisting the damage from the impact of a motor vehicle, or collision barriers shall be provided. [**30:**22.11.4.7]

Some types of secondary containment tanks are concrete-encased and, therefore, are inherently capable of absorbing a vehicle impact. Others will have to be provided with collision barriers or bollards. See Exhibit 66.49 for a typical design of a collision barrier. For additional information, see Annex E of NFPA 730, *Guide for Premises Security*.

Exhibit 66.49



Bollard-type security barrier. (Source: U.S. Army Corps of Engineers, Field Manual 19-30.)

66.22.11.4.8 Where the means of secondary containment is enclosed, it shall be provided with emergency venting in accordance with 66.22.7. [**30:**22.11.4.8]

66.22.11.4.9 Means shall be provided to establish the integrity of the secondary containment, in accordance with Section 66.21. [**30:**22.11.4.9]

66.22.11.4.10 The secondary containment shall be designed to withstand the hydrostatic head resulting from a leak from the primary tank of the maximum amount of liquid that can be stored in the primary tank. [**30:**22.11.4.10]

66.22.12 Equipment, Piping, and Fire Protection Systems in Remote Impoundment Areas and Diked Areas.

66.22.12.1* Location of Piping. Only piping for product, utility, or fire protection purposes directly connected to a tank or tanks within a single diked area shall be routed through a diked area, a remote impoundment area, a spillway draining to a remote impoundment area, or above a storage tank drainage area where the piping can be exposed to a fire.

*Exception: Piping for other product lines and from adjacent tanks is permitted to be routed through such areas if engineering designs are provided to incorporate features to prevent the piping from creating an exposure hazard. [**30:**22.12.1]*

A.66.22.12.1 As noted in the exception, engineering designs that can reduce exposure hazards include use of sealed sleeve piping and secondary containment piping to prevent leakage and the use of remotely controlled isolation valves on product lines to stop the flow of liquids when the piping is subjected to fire exposure. [**30:**A.22.12.1]

66.22.12.2 Drainage.

66.22.12.2.1 Drainage shall be provided to prevent accumulation of any liquid under the piping by providing a slope of not less than 1 percent away from the piping for at least 50 ft (15 m). [**30:**22.12.2.1]

66.22.12.2.2 Corrosion-resistant piping and piping that is protected against corrosion shall be permitted to be buried where such drainage is not provided. [**30:**22.12.2.2]

66.22.12.3* Location of Equipment. If located in a remote impoundment area, a diked area, or a spillway draining to a remote impoundment area, process equipment, pumps, instrumentation, and electrical utilization equipment shall be located or protected so that a fire involving such equipment does not constitute an exposure hazard to the tank or tanks in the same area for a period of time consistent with emergency response capabilities. [**30:**22.12.3]

A.66.22.12.3 Methods of preventing an exposure hazard include intermediate diking, drainage, or fire protection features such as water spray systems, monitors, or fire-resistive coatings. High integrity pumps or equipment also constitute a method of limiting exposure hazards. [**30:**A.22.12.3]

66.22.12.4 Fire Protection Systems. Hose connections, controls, and control valves for application of fire protection foam or water to tanks shall be located outside remote impoundment areas, diked areas, or spillways draining to a remote impoundment area. [**30:**22.12.4]

66.22.12.5 Combustible Materials. Structures such as stairways, walkways, instrumentation shelters, and supports for piping and equipment that are located in a remote impoundment area, diked area, or spillway draining to a remote impoundment area shall be constructed of noncombustible materials. [**30:**22.12.5]

66.22.13 Tank Openings Other Than Vents.

66.22.13.1 Each connection to an aboveground tank through which liquid can normally flow shall be provided with an internal or an external valve located as close as practical to the shell of the tank. [**30:**22.13.1]

Paragraph 66.22.13.1 requires a manual or remotely operated valve that can be used to isolate the tank from its piping during an emergency. A check valve alone cannot be used to meet this requirement, although one can be used in conjunction with the operating valve. A word of caution: A check valve in the inlet pipeline prevents that pipeline from being used as an emergency outlet. In a fire emergency, pumping liquid from a fire-involved tank to another tank outside the fire area can be practical.

Because repair or maintenance of internal valves usually requires that tanks be emptied, they are seldom used on larger tanks.

66.22.13.2 Each connection below the liquid level through which liquid does not normally flow shall be provided with a liquidtight closure such as a valve, plug, or blind, or a combination of these. [**30:**22.13.2]

Because a valve can be opened by mistake, resulting in a spill of tank contents, it is advisable to plug or blank the outlet of any valve not intended for operating purposes immediately after it is installed.

66.22.13.3 Openings for gauging on tanks storing Class I liquids shall be provided with a vaportight cap or cover. [**30:**22.13.3]

Gauge openings can also be used for taking samples. Metallic cups, floats, and so on, should have electrical continuity with the tank shell to avoid the possibility of ignition by static discharge, and a 30-minute static "relaxation" period should be allowed before manual gauging or sampling after a tank is filled unless the tank is fitted with a gauging tube or well. Although the atmosphere in a tank containing a Class I liquid is normally too rich to burn, vapors escaping from the gauging opening will form a hazardous zone in the immediate vicinity. If the tank is being emptied or has recently had liquid withdrawn from it, much of the vapor space in the tank might be in the flammable range and ignition might propagate into the tank, causing an explosion.

66.22.13.4 Filling and emptying connections for Class I, Class II, and Class IIIA liquids that are connected and disconnected shall be located outside of buildings at a location free from any source of ignition. [**30:**22.13.4]

66.22.13.4.1 Such connections shall be located not less than 5 ft (1.5 m) away from any building opening. [**30:**22.13.4.1]

66.22.13.4.2 Such connections for any liquid shall be closed and liquidtight when not in use and shall be properly identified. [**30:**22.13.4.2]

66.22.14 Aboveground Storage Tanks Located in Areas Subject to Flooding.

A tank located according to the requirements of this subsection will not float if filled with gasoline (specific gravity 0.7). It might, however, float if only partially full. To contend with the possibility that a tank might not be full at the time of a flood, the availability of a water supply to fill the tank in case of a flood emergency is required by 66.22.14.4.

66.22.14.1 Vertical tanks shall be located so that the tops of the tanks extend above the maximum flood stage by at least 30 percent of their allowable storage capacity. [**30:**22.14.1]

66.22.14.2 Horizontal tanks that are located where more than 70 percent of the tank's storage capacity will be submerged at the established flood stage shall be secured by one of the following methods:

(1) Anchored to resist movement
(2) Attached to a foundation of steel and concrete or of concrete having sufficient weight to provide load for the tank when filled with liquid and submerged by flood water to the established flood stage
(3) Secured from floating by other means

[**30:**22.14.2]

66.22.14.3 Tank vents or other openings that are not liquid-tight shall extend above the maximum flood stage water level. [**30:**22.14.3]

66.22.14.4 A dependable water supply shall be used for filling an empty or partially filled tank.

*Exception: Where filling the tank with water is impractical or hazardous because of the contents of the tank, the tank should be protected by other means against movement or collapse. [**30:**22.14.4]*

66.22.14.5 Spherical or spheroid tanks shall be protected by any of the methods specified in 66.22.14. [**30:**22.14.5]

66.22.15 Collision Protection for Aboveground Storage Tanks. Where a tank is exposed to vehicular impact, protection shall be provided to prevent damage to the tank. [**30:**22.15]

66.22.16 Installation Instructions for Aboveground Storage Tanks. Factory-built aboveground tanks shall be provided with instructions for testing the tanks and for installation of the normal and emergency vents. [**30:**22.16]

66.22.17 Inspection and Maintenance of Aboveground Storage Tanks.

66.22.17.1 Inspection and maintenance of aboveground tanks shall meet the requirements of 66.21.8. [**30:**22.17.1]

66.22.17.2 Each aboveground steel tank shall be inspected and maintained in accordance with API 653, *Tank Inspection, Repair, Alteration, and Reconstruction*, or STI SP001, *Standard for Inspection of Aboveground Storage Tanks*, whichever is applicable. [**30:**22.17.2]

66.22.17.3 Each tank constructed of materials other than steel shall be inspected and maintained in accordance with manufacturers' instructions and applicable standards. [**30:**22.17.3]

66.22.17.4* Pontoons in external floating roof tanks shall be inspected, at intervals not exceeding 5 years, by visual and atmospheric testing methods to ensure that the pontoon covers are mechanically secured to the floating roof deck and to ensure the pontoons do not contain liquids or vapors resulting from leaks or corrosion holes in the pontoons. If liquids, or flammable vapor concentrations at or above 25 percent of the LFL are found, the liquids or vapors shall be safely removed and the source of the leak shall be repaired. The finding of vapors at levels below 25 percent of the LFL shall result either in the implementation of monitoring of the tank pontoons at least annually to assure that vapors in the flammable range are not achieved before corrective action is taken or removal of the tank from service. Rim vents, if any, shall also be inspected to ensure that they are not frozen open. [**30:**22.17.4]

A.66.22.17.4 An explosion hazard can exist due to flammable liquids or vapors within the pontoon. Ignition can be caused by lightning strikes or general maintenance activities. Lightning protection systems and other means of tank grounding cannot prevent sparking caused by lightning across gaps such as those between pontoon covers and the tank roof, between the tank wall and the roof, or at shunts. Such sparks can serve as a source of ignition causing a fire or explosion that can result in sufficient overpressure to throw portions of the pontoon assembly completely away from the tank with subsequent, partial, or complete loss of the tank due to fire. Caution is particularly advisable where tanks with vapor-containing pontoons are located within lightning-prone areas. [**30:**A.22.17.4]

66.23 Storage of Liquids in Tanks — Underground Tanks

66.23.1 Scope. This section shall apply to the following:

(1) The storage of flammable and combustible liquids, as defined in 3.3.169.1 and 3.3.169.2, in fixed underground tanks
(2) The installation and operation of underground tanks

[**30:**23.1]

66.23.2 Definitions Specific to Chapter 23. (Reserved)

66.23.3 General Requirements.

66.23.3.1 Class II and Class III Liquids at Elevated Temperatures. Storage of Class II and Class III liquids heated at or above their flash point shall follow the requirements for Class I liquids, unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. [**30:**23.3.1]

66.23.3.2 Installation. All underground tanks shall be installed in accordance with the manufacturer's instructions. [**30:**23.3.2]

66.23.3.3 Excavation. Excavation for underground tanks shall not undermine foundations of existing structures. [**30:**23.3.3]

66.23.3.4* Care in Handling of Tank. The tank shall not be damaged during delivery, unloading, and placement into the tank excavation. [**30:**23.3.4]

A.66.23.3.4 Dropping or rolling the tank into the hole can break a weld, puncture or damage the tank, or scrape off the protective coating of coated tanks. See PEI RP100, *Recommended Practices for Installation of Underground Liquid Storage Systems*. [**30:**A.23.3.4]

Backfilling with gravel or sand containing large stones can damage a tank's coating or even cause dents or gouges. Gravel should be in accordance with its dictionary definition, "consisting of rounded pebbles." Sea sand should not be used because it might contain corrosive salt.

66.23.3.5* External Corrosion Protection for Underground Storage Tank. Underground tanks and their piping shall be protected by either of the following:

(1) A properly engineered, installed, and maintained cathodic protection system in accordance with recognized engineering standards of design
(2) Approved or listed corrosion-resistant materials or systems

[**30:**23.3.5]

A.66.23.3.5 See UL 1316, *Standard for Glass-Fiber-Reinforced Plastic Underground Storage Tanks for Petroleum Products, Alcohols, and Alcohol-Gasoline Mixtures*; UL 1746, *Standard for External Corrosion Protection Systems for Steel Underground Storage Tanks;* and STI ACT-100, *Specification for External Corrosion Protection of FRP Composite Steel Underground Tanks*, F894. [**30:**A.23.3.5]

66.23.3.5.1* Selection of the type of protection to be employed shall be based upon the corrosion history of the area and the judgment of a qualified engineer. [**30:**23.3.5.1]

A.66.23.3.5.1 See API RP 1615, *Installation of Underground Petroleum Storage Systems*, for further information. [**30:**A.23.3.5.1]

66.23.3.5.2* The AHJ shall be permitted to waive the requirements for corrosion protection where an engineering evaluation demonstrates that such protection is not necessary. [**30:**23.3.5.2]

A.66.23.3.5.2 Acceptable design standards for cathodic protection systems include the following:

(1) API RP 1632, *Cathodic Protection of Underground Petroleum Storage Tanks and Piping Systems*
(2) CAN/ULC-S603.1, *Standard for External Corrosion Protection Systems for Steel Underground Tanks for Flammable and Combustible Liquids*
(3) STI-P3, *Specification and Manual for External Corrosion Protection of Underground Steel Storage Tanks*
(4) NACE RP-0169, *Recommended Practice, Control of External Corrosion on Underground or Submerged Metallic Piping Systems*
(5) NACE RP-0285, *Recommended Practice, Corrosion Control of Underground Storage Tank Systems by Cathodic Protection*
(6) ANSI/UL 1746, *Standard for External Corrosion Protection Systems for Steel Underground Storage Tanks*, Part 1
(7) STI RP 892, *Recommended Practice for Corrosion of Underground Piping Networks Associated with Liquid Storage and Dispensing Systems*

[**30:**23.3.5.2]

Buried tanks must remain leaktight for the extent of their service life. Requiring maximum corrosion protection for tanks in all locations is unrealistic. In favorable soils, tanks have lasted leak-free for 20 years and longer; in other locations, tanks have leaked from corrosion within a few years of installation.

The current requirement directs the user to appropriate standards for guidance in designing corrosion protection for the underground tank installation. Local code officials need assistance in determining what a properly engineered cathodic protection system is, and the list of references can provide guidance. Paragraph 66.23.3.5.2 allows the AHJ to waive the requirement for corrosion protection, based on previous experience and consultation with an expert. However, environmental regulations might mandate corrosion protection in all cases, thus preempting local control.

STI RP 892, *Recommended Practice for Corrosion Protection of Underground Piping Networks Associated with Liquid Storage and Dispensing Systems*, is referenced because it is a standard on corrosion protection, not on tank design.

66.23.4 Location of Underground Storage Tanks.

66.23.4.1 Underground tanks or tanks under buildings shall be located with respect to existing building foundations and supports so that the loads carried by the foundation are not transmitted to the tank. [**30:**23.4.1]

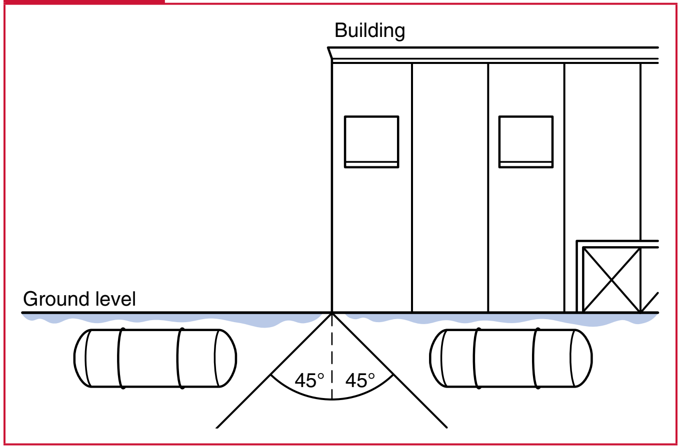
66.23.4.2 The distance from any part of a tank storing Class I liquids to the nearest wall of any basement or pit shall be not less than 1 ft (0.3 m) and to any property line that is or can be built upon shall not be less than 3 ft (0.9 m). [**30:**23.4.2]

66.23.4.3 The distance from any part of a tank storing Class II or Class III liquids to the nearest wall of any basement, pit, or property line shall be not less than 1 ft (0.3 m). [**30:**23.4.3]

The first requirement in restricting the location of underground tanks is that the excavation not jeopardize the foundation of any structure or be so placed that settlement of the structure can damage the tank. The minimum spacing of 1 ft (0.3 m) from the tank to the wall of a basement or pit provides space for protective measures, such as excavation and well points. If a leak should develop in the case of Class I liquids, it could result in the presence of flammable vapors in the adjacent underground space.

The distance requirements provide the minimum necessary for installation purposes. With Class I liquids, the 3 ft (0.9 m) distance to a property line that can be built upon is required to minimize the possibility of damage to a tank or to its protective sand or gravel envelope by construction activities on adjacent property. A common rule of thumb used by many engineers when locating a tank below the bottom foundation of a building is to place the tank outside a 45 degree angle, measured from the extension of the foundation. This rule of thumb applies to tanks located under a building or just outside a building. See Exhibit 66.50.

Exhibit 66.50



Siting of underground tanks with respect to building footings and foundations.

66.23.5 Reserved.

66.23.6 Normal Venting for Underground Storage Tanks.

66.23.6.1* Tank venting systems shall be provided with sufficient capacity to prevent blowback of vapor or liquid at the fill opening while the tank is being filled. [**30:**23.6.1]

A.66.23.6.1 The required venting capacity depends upon the filling or withdrawal rate, whichever is greater, and the vent line length. Unrestricted vent piping sized in accordance with Table 66.23.6.2 will prevent back pressure development in tanks from exceeding a gauge pressure of 2.5 psi (17.2 kPa). [**30:**A.23.6.1]

Paragraph 66.23.6.1 recognizes that vent lines might run a considerable distance, usually below ground, before rising up to the termination point. Piping larger than that shown in Table 66.23.6.2 is usually needed if a flame arrester or pressure-vacuum vent is installed, as would be the case with many Class IB and IC liquids, because of the reduced flow rate through the vent device.

66.23.6.2 Vent piping shall be sized in accordance with Table 66.23.6.2, but shall not be less than 1.25 in. (32 mm) nominal inside diameter. [**30:**23.6.2]

66.23.6.3 Where tank venting devices are installed in vent lines, their flow capacities shall be determined in accordance with 66.22.7.3.4. [**30:**23.6.3]

66.23.6.4 Piping for normal venting shall be designed in accordance with Section 66.27. [**30:**23.6.4]

66.23.7 Reserved.

66.23.8 Reserved.

66.23.9 Reserved.

66.23.10 Reserved.

TABLE 66.23.6.2 *Nominal Vent Line Diameter in Inches*

Maximum Flow (gpm)	Pipe Length*		
	50 ft	100 ft	200 ft
100	1.25	1.25	1.25
200	1.25	1.25	1.25
300	1.25	1.25	1.5
400	1.25	1.5	2
500	1.5	1.5	2
600	1.5	2	2
700	2	2	2
800	2	2	3
900	2	2	3
1000	2	2	3

For SI units, 1 in. = 25 mm; 1 ft = 0.3 m; 1 gal = 3.8 L.

*Assumes stated length of piping, plus 7 ells. [**30:** Table 23.6.2]

66.23.11 Reserved.

66.23.12 Reserved.

66.23.13 Tank Openings Other than Vents.

66.23.13.1 Connections for all tank openings shall be liquidtight and vaportight. [**30:**23.13.1]

66.23.13.2 Openings for manual gauging, if independent of the fill pipe, shall be provided with a liquidtight and vaportight cap or cover. Covers shall be kept closed when not gauging. [**30:**23.13.2]

66.23.13.2.1 If inside a building, each such opening shall be protected against liquid overflow and possible vapor release by means of a spring-loaded check valve or other approved device. [**30:**23.13.2.1]

Note that Section 66.23.4 does not prohibit having a tank under a building on the same premises, provided that the restrictions with respect to walls, foundations, and supports are met. However, the only access permitted to the tank from within the building is the specially equipped gauging opening.

66.23.13.3 Fill and discharge lines shall enter tanks only through the top. [**30:**23.13.3]

66.23.13.4 Fill lines shall be sloped toward the tank. [**30:**23.13.4]

66.23.13.5 Underground tanks for Class I liquids having a capacity of more than 1000 gal (3800 L) shall be equipped with a tight fill device for connecting the fill hose to the tank. [**30:**23.13.5]

66.23.13.6 Filling, emptying, and vapor recovery connections for Class I, Class II, or Class IIIA liquids that are connected and disconnected shall be located outside of buildings at a location free from any source of ignition and not less than 5 ft (1.5 m) from any building opening or air intake. [**30:**23.13.6]

By omission, just as vents from tanks containing Class IIIB liquids are permitted to terminate indoors, filling connections for such tanks are also permitted indoors.

66.23.13.6.1 Such connections shall be closed and liquidtight and vaportight when not in use. [**30:**23.13.6.1]

66.23.13.6.2 Such connections shall be identified. [**30:**23.13.6.2]

66.23.13.7 Tank openings provided for purposes of vapor recovery shall be protected against possible vapor release by means of a spring-loaded check valve or dry-break connection, or other approved device, unless the opening is pipe-connected to a vapor processing system. [**30:**23.13.7]

Subsection 66.23.13.7 is intended to regulate two types of systems. In one type, a vapor recovery system, vapor that is displaced when a storage tank is being filled is piped back to the vapor space of the unit from which the liquid is discharged. The opening must not permit vapor to escape from the buried tank, except when it is flowing back to the unit from which the tank is being filled. In the second type, the vapor is connected to a special unit where it is incinerated, absorbed into oil or other liquid, or adsorbed on activated carbon or similar material for later recovery or disposal by other environmentally acceptable means.

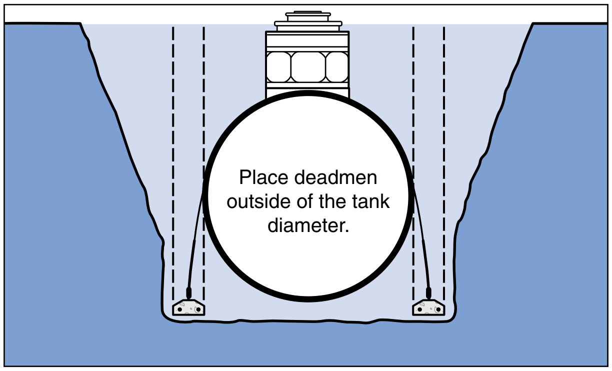
66.23.13.7.1 Openings designed for combined fill and vapor recovery shall also be protected against vapor release unless connection of the liquid delivery line to the fill pipe simultaneously connects the vapor recovery line. [**30:**23.13.7.1]

66.23.13.7.2 All connections shall be vaportight. [**30:**23.13.7.2]

66.23.14 Underground Storage Tanks Located in Areas Subject to Flooding.

Buried tanks have been known to float up out of the ground because of a high water table or floodwaters. Means for preventing tanks from becoming unsecured are prescribed in 66.23.14. One method is to place 6 in. (150 mm) of reinforced concrete over the tank, extending 12 in. (300 mm) horizontally beyond the tank in all directions. A second method uses a 6 in. (150 mm) reinforced concrete base at the bottom of the hole, with hold-down straps securing the tank to the base. A third (and the most often used) method uses deadman anchors on either side of the tank, with hold-down straps securing the tank to the anchors, as shown in Exhibit 66.51. With each of these methods, the weight of the concrete offsets the buoyancy of the tank.

Exhibit 66.51



An underground tank secured to deadman anchors with hold-down straps. (Adapted with permission from PEI/RP 100-11, Recommended Practices for Installation of Underground Liquid Storage Systems, Petroleum Equipment Institute, Figure 6-2)

66.23.14.1* Tanks shall be anchored or shall be secured by approved means to resist movement when subjected to hydrostatic forces associated with high groundwater or floodwater. [**30:**23.14.1]

A.66.23.14.1 Anchoring can be accomplished using nonmetallic straps or metallic straps that are separated from the tank shell by inert insulating dielectric material. The straps should be connected to a bottom hold-down pad or deadman anchors. For additional information, see reference to API RP 1615, *Installation of Underground Petroleum Storage Systems*; PEI RP100, *Recommended Practices for Installation of Underground Liquid Storage Systems*; and STI RP R011, *Recommended Practice for Anchoring of Steel Underground Storage Tanks*. [**30:**A.23.14.1]

Previous editions of NFPA 30 included provisions for the use of water ballast as a means to weight a tank to prevent movement during a flood. In anticipation of a flood event, water could be used to fill the tank to reduce buoyancy. While this approach remains technically viable for existing tanks that are not properly secured to prevent movement, the use of water as a means of providing ballast is no longer considered an acceptable basis of design for new tank installations. [**30:**A.23.14.1]

It is not the intent of this section to prohibit the use of water as ballast in underground tanks during system installation and prior to the initial introduction of the stored liquid. [**30:**A.23.14.1]

66.23.14.1.1 The design of the anchoring or securing method shall be based on the buoyancy of an empty tank that is fully submerged. [**30:**23.14.1.1]

66.23.14.1.2 Tank vents and other openings that are not liquid-tight shall be extended above maximum flood stage water level. [**30:**23.14.1.2]

66.23.14.1.3 Each tank shall be so constructed and installed that it will safely resist external pressures if submerged. [**30:**23.14.1.3]

66.23.15 Reserved.

66.23.16 Installation Instructions for Underground Storage Tanks. Factory-built underground tanks shall be provided with instructions for testing and for installation of the normal vents. [**30:**23.16]

66.23.17 Inspection and Maintenance of Underground Storage Tanks.

66.23.17.1 Inspection and maintenance for underground tanks shall meet the requirements of 66.21.8. [**30:**23.17.1]

66.23.17.2 Overfill protection devices or systems shall be inspected and tested annually to ensure proper operation. [**30:**23.17.2]

66.24 Storage Tank Buildings

66.24.1* Scope.

A.66.24.1 Section 66.24 provides an approach that allows considerable flexibility for compliance without compromising fire safety, while fostering ingenuity in application of fire safety principles to achieve the intended objectives, outlined in the performance criteria set out at the beginning of each subsection. Each subsection has been written with the first sentence outlining the performance criteria that, if implemented, would achieve compliance with that subsection. In order to clarify the intent of each performance criterion, the subsequent paragraphs constitute one method of achieving compliance with the intent envisioned in the performance requirements. It is recognized that other combinations of requirements can also be used to meet the intent of the performance criteria, provided such requirements are acceptable to the AHJ. [**30:**A.24.1]

66.24.1.1 This section shall apply to installations of tanks storing Class I, Class II, and Class IIIA liquids in storage tank buildings. [**30:**24.1.1]

66.24.1.2 This section shall also apply to installations of aboveground storage tanks storing Class II, Class IIIA, or Class IIIB liquids in storage tank buildings where the liquids are heated at or above their flash points. In such cases, the liquids shall be regulated as Class I liquids unless an engineering evaluation conducted in accordance with Section 66.6 justifies following the requirements for some other liquid class. [**30:**24.1.2]

66.24.1.3 This section shall not apply to the following:

(1) Tanks covered by Sections 66.17, 66.18, and 66.19.
(2) A tank that has a canopy or roof that does not limit the dissipation of heat or dispersion of flammable vapors and does not restrict fire-fighting access and control. Such tanks shall comply with the provisions of this *Code*.

[**30:**24.1.3]

66.24.2 Definitions Specific to Chapter 24. (Reserved)

66.24.3 Reserved.

66.24.4 Location of Storage Tank Buildings.

66.24.4.1 Tanks and associated equipment within the storage tank building shall be so located that a fire in the area shall not constitute an exposure hazard to adjoining buildings or tanks for a period of time consistent with the response and suppression capabilities of the fire-fighting operations available to the location. Compliance with 66.24.4.2 through 66.24.4.8 shall be deemed as meeting the requirements of 66.24.4.1. [**30:**24.4.1]

66.24.4.2 The minimum distance from exposed property lines and buildings for tank installations within structures having walls with a fire resistance rating of less than 2 hours shall be in accordance with Table 66.24.4.2. [**30:**24.4.2]

The separation distances given in Table 66.24.4.2, as well as the adjustments allowed by 66.24.4.5 and the requirements of 66.24.4.6 and 66.24.4.7, are similar to those found in Section 66.17.4 for process vessels and can be considered to provide a greater degree of safety for this application because process vessels can be expected to present a greater risk than storage tanks. Note, however, that the table does not allow storage tanks greater than 100,000 gal (380 m^3) without the approval of the AHJ.

Exhibit 66.52 illustrates application of the separation distances required by Table 66.24.4.2. In the exhibit, a small storage tank building houses four 15,000 gal (56,800 L) storage tanks, two of which store unstable resins at atmospheric pressure. The liquid resins can polymerize if exposed to fire, so the separation distances to be used are those for "Unstable Liquid — Emergency Relief — Not over 2.5 psi." Protection for exposures is provided; therefore, the provision of 66.24.4.4 does not apply. However, because of the unstable liquids, 66.24.4.5(3) does apply.

66.24.4.3 The capacity of any individual tank shall not exceed 100,000 gal (380 m^3) without the approval of the AHJ. [**30:**24.4.3]

66.24.4.4 Where protection for exposures is not provided, the distances given in Table 66.24.4.2 shall be doubled. The distances shall not be required to exceed 300 ft (90 m). [**30:**24.4.4]

66.24.4.5 Where a storage tank building has an exterior wall facing an exposure, the distances in Table 66.24.4.2 shall be permitted to be modified as follows:

(1) Where the wall is a blank wall having a fire resistance rating of not less than 2 hours, separation distance between the storage tank building and its exposure shall not be required to be greater than 25 ft (7.6 m).
(2) Where a blank wall having a fire resistance rating of not less than 4 hours is provided, the distance requirements of Table 66.24.4.2 shall not apply.
(3)* Where Class IA liquids or unstable liquids are stored, the exposing wall shall have explosion resistance in accordance with recognized engineering standards, and deflagration venting designed in accordance with NFPA 68 shall be provided in the nonexposing walls and roof.

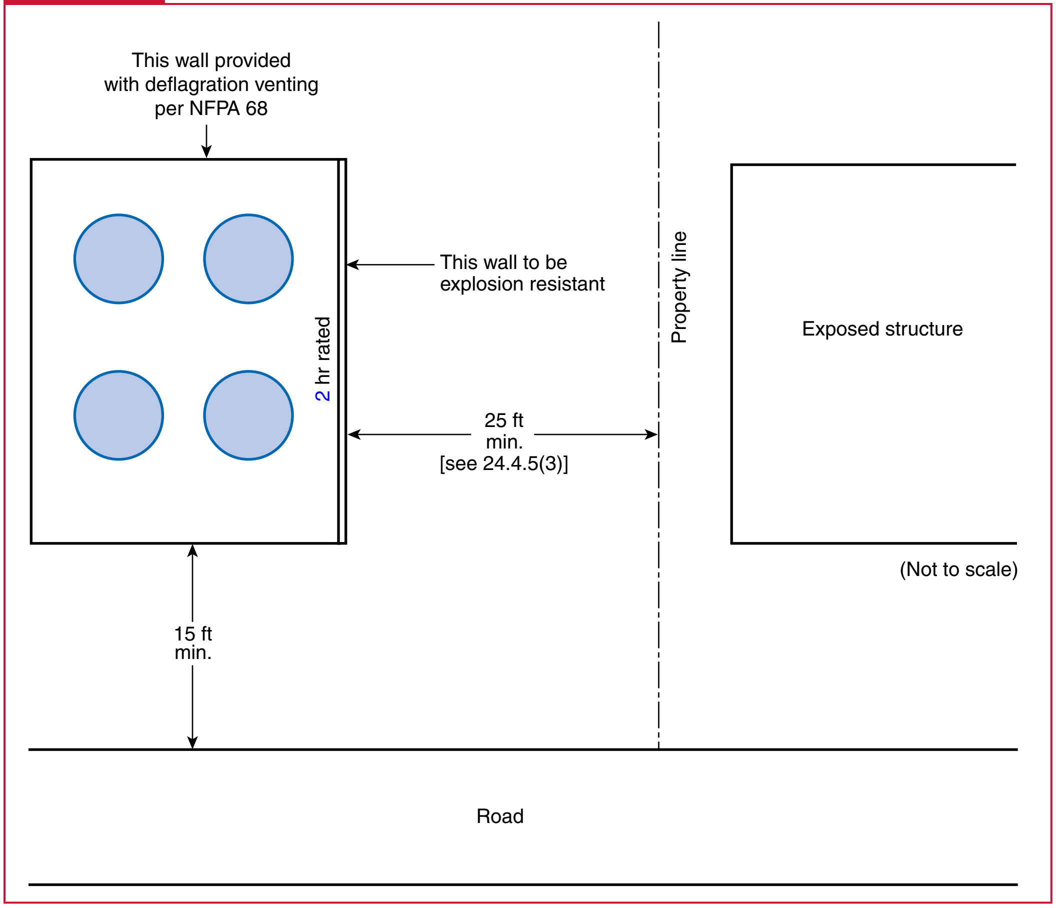
[**30:**24.4.5]

***TABLE 66.24.4.2** Location of Storage Tank Buildings with Respect to Property Lines, Public Ways, and the Nearest Important Building on the Same Property*

Largest Tank — Operating Liquid Capacity (gal)	Minimum Distance from Property Line that Is or Can Be Built Upon, Including Opposite Side of Public Way (ft)				Minimum Distance from Nearest Side of Any Public Way or from Nearest Important Building on Same Property (ft)			
	Stable Liquid Emergency Relief		Unstable Liquid Emergency Relief		Stable Liquid Emergency Relief		Unstable Liquid Emergency Relief	
	Not over 2.5 psi	Over 2.5 psi	Not over 2.5 psi	Over 2.5 psi	Not over 2.5 psi	Over 2.5 psi	Not over 2.5 psi	Over 2.5 psi
Up to 12,000	15	25	40	60	5	10	15	20
12,001 to 30,000	20	30	50	80	5	10	15	20
30,001 to 50,000	30	45	75	120	10	15	25	40
50,001 to 100,000	50	75	125	200	15	25	40	60

For SI units, 1 gal = 3.8 L; 1 ft = 0.3 m; 1 psi = 6.9 kPa. [**30:**Table 24.4.2]

Exhibit 66.52



Application of Table 24.4.2 to a storage tank building with tanks storing unstable liquids.

Δ **A.66.24.4.5(3)** See NFPA 68 for information on deflagration venting. [**30:**A.24.4.5(3)]

66.24.4.6 Other equipment associated with tanks, such as pumps, heaters, filters, and exchangers, shall not be located closer than 25 ft (7.6 m) to property lines where the adjoining property is or can be built upon or to the nearest important building on the same property that is not an integral part of the storage tank building. This spacing requirement shall not apply where exposures are protected as outlined in 66.24.4.2. [**30:**24.4.6]

66.24.4.7 Tanks in which unstable liquids are stored shall be separated from potential fire exposures by a clear space of at least 25 ft (7.6 m) or by a wall having a fire resistance rating of not less than 2 hours. [**30:**24.4.7]

66.24.4.8 Each storage tank building and each tank within the building shall be accessible from at least two sides for fire fighting and fire control. [**30:**24.4.8]

66.24.4.9 Class I liquids and Class II or Class IIIA liquids heated above their flash points shall not be stored in basements. [**30:**24.4.9]

66.24.5 Construction of Storage Tank Buildings.

66.24.5.1 Storage tank buildings shall be constructed so as to maintain structural integrity for 2 hours under fire exposure conditions and to provide access and egress for unobstructed movement of all personnel and fire protection equipment. Compliance with 66.24.5.2 through 66.24.5.7 shall be deemed as meeting the requirements of 66.24.5.1. [**30:**24.5.1]

66.24.5.2* Buildings or structures shall be of at least 2-hour fire resistance rating. [**30:**24.5.2]

Δ **A.66.24.5.2** See NFPA 220. [**30:**A.24.5.2]

66.24.5.2.1 Noncombustible or combustible construction shall be permitted when protected by automatic sprinklers or equivalent protection subject to the approval of the AHJ. [**30:**24.5.2.1]

66.24.5.3 Where Class I liquids are stored above grade within buildings with basements or other belowgrade areas into which flammable vapors can travel, such belowgrade areas shall be provided with mechanical ventilation designed to prevent the accumulation of flammable vapors. Enclosed storage tank pits shall not be considered basements. [**30:**24.5.3]

The requirements in 66.24.5.3 are intended to prevent the entrapment of vapors in an area where there might be an ignition source. The second sentence applies to those situations where the tanks are installed in a spill containment area similar to a dike, that is, below the level of the surrounding floor.

66.24.5.4* Storage tank buildings where Class IA liquids are stored shall be designed to direct flame, combustion gases, and pressure resulting from a deflagration away from important buildings or occupied areas through the use of damage-limiting construction. The damage-limiting construction design shall be designed in accordance with NFPA 68 and shall be acceptable to the AHJ. [**30:**24.5.4]

Δ **A.66.24.5.4** See NFPA 68 for information on deflagration venting. [**30:**A.24.5.4]

This provision of the *Code* recognizes that a spill involving Class IA liquids can immediately fill the area with vapors and result in an explosion. Any walls separating the storage tanks from other parts of the building or from other buildings must be capable of withstanding the anticipated overpressure. This requirement entails careful engineering.

66.24.5.5 Storage tank buildings where unstable liquids are stored shall be designed using an approved engineered construction method that is intended to limit damage from an explosion (deflagration or detonation, depending on the liquid). [**30:**24.5.5]

66.24.5.6* Access aisles not less than 3 ft (0.9 m) in width shall be provided and maintained from the exterior of the storage tank building into the building and around all storage tanks. [**30:**24.5.6]

A.66.24.5.6 The purpose of the access aisles is to provide for ease of maintenance and emergency operations. [**30:**A.24.5.6]

66.24.5.7 A clear space of at least 3 ft (0.9 m) shall be maintained between the top of each tank and the building structure for buildings protected in accordance with 66.24.6.2.3. For buildings without fixed fire suppression systems, sufficient clear space shall be provided to allow for the application of hose streams to the top of the tank(s) for cooling purposes. [**30:**24.5.7]

66.24.6 Fire Protection for Storage Tank Buildings.

66.24.6.1 Manual Fire Control Equipment for Storage Tank Buildings.

66.24.6.1.1* Listed portable fire extinguishers shall be provided for facilities in such quantities, sizes, and types as could be needed for special storage hazards as determined in accordance with 66.21.6.1.2. [**30:**24.6.1.1]

Δ **A.66.24.6.1.1** NFPA 10 provides information on the suitability of various types of extinguishers. [**30:**A.24.6.1.1]

66.24.6.1.2* Where the need is indicated in accordance with 66.21.6.3, water shall be utilized through standpipe and hose systems, or through hose connections from sprinkler systems using combination spray and straight stream nozzles to permit effective fire control. [**30:**24.6.1.2]

Δ **A.66.24.6.1.2** See NFPA 13 and NFPA 14. [**30:**A.24.6.1.2]

66.24.6.1.3 Where the need is indicated in accordance with 66.21.6.3, mobile foam apparatus shall be provided. [**30:**24.6.1.3]

66.24.6.2 Fixed Fire Control Equipment for Tank Buildings.

66.24.6.2.1 A reliable water supply or other suitable fire control agent shall be available in pressure and quantity to meet the fire demands indicated by special storage hazards or exposure as determined by 66.21.6.3. [**30:**24.6.2.1]

66.24.6.2.2* Hydrants, with or without fixed monitor nozzles, shall be provided in accordance with accepted practice. The number and placement shall depend on the hazard of the storage, or exposure, as determined by 66.21.6.3. [**30:**24.6.2.2]

A.66.24.6.2.2 See NFPA 24 for information on this subject. [**30:**A.24.6.2.2]

66.24.6.2.3* Where the need is indicated by the hazards of storage or exposure as determined by 66.21.6.3, fixed protection shall be required utilizing approved foam, foam-water sprinkler systems, sprinkler systems, water spray systems, deluge systems, gaseous extinguishing systems, dry chemical extinguishing systems, fire-resistive materials, or a combination of these. [**30:**24.6.2.3]

Δ **A.66.24.6.2.3** See NFPA 13, NFPA 15, and NFPA 16 for information on these subjects. [**30:**A.24.6.2.3]

For certain fuel types, such as ketones, esters, and alcohols, the minimum required densities established in the listing criteria for foam discharge devices are often higher than the general densities specified for protection of flammable and combustible liquids. When determining the design criteria for extinguishing systems using foam, it is important to ensure that the listing criteria, which are typically based on empirical data from fire tests, are not overlooked. Otherwise, the fire protection system design can be inadequate for proper protection. [**30:**A.24.6.2.3]

66.24.6.2.3.1 When foam or foam-water fire protection systems are provided, discharge densities shall be determined based on the listing criteria for selected foam discharge devices, the foam concentrate, and the specific flammable or combustible liquids to be protected. [**30:**24.6.2.3.1]

66.24.6.2.4 If provided, fire control systems shall be designed, installed, and maintained in accordance with the following NFPA standards:

(1) NFPA 11, *Standard for Low-, Medium-, and High-Expansion Foam*
(2) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*
(3) NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*
(4) NFPA 13, *Standard for the Installation of Sprinkler Systems*
(5) NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*
(6) NFPA 16, *Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems*
(7) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*
(8) NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*

[**30:**24.6.2.4]

66.24.7 Reserved.

66.24.8 Electrical Systems for Storage Tank Buildings.

66.24.8.1 Installation of electrical utilization equipment and wiring shall meet the requirements of Section 66.7. [**30:**24.8.1]

66.24.8.2 Section 66.7 shall be used to determine the extent of classified locations for the purpose of installation of electrical equipment. [**30:**24.8.2]

66.24.8.2.1 In establishing the extent of a classified location, it shall not extend beyond a floor, wall, roof, or other solid partition that has no openings within the classified area. [**30:**24.8.2.1]

66.24.9 Containment, Drainage, and Spill Control from Storage Tank Buildings.

66.24.9.1 Drainage systems shall be designed to minimize fire exposure to other tanks and adjacent properties or waterways. Compliance with 66.24.9.2 through 66.24.9.6 shall be deemed as meeting the requirements of 66.24.9.1. [**30:**24.9.1]

66.24.9.2 The facility shall be designed and operated to prevent the discharge of flammable or combustible liquids to public waterways, public sewers, or adjoining property under normal operating conditions. [**30:**24.9.2]

66.24.9.3 Except for drains, solid floors shall be liquidtight and walls shall be liquidtight where they join the floor and for at least 4 in. (100 mm) above the floor. [**30:**24.9.3]

66.24.9.4 Openings to adjacent rooms or buildings shall be provided with noncombustible, liquidtight raised sills or ramps at least 4 in. (100 mm) in height or shall be otherwise designed to prevent the flow of liquids to the adjoining areas. [**30:**24.9.4]

The intent of this requirement is to limit the spread of any spilled liquid, especially if it is already burning, to the area in which the spill originates. Note that this is a "two-way" provision: It protects the rest of the building from a spill that originates at the tanks and protects the tanks from a spill that might originate in an adjacent process area.

66.24.9.4.1 An open-grated trench across the width of the opening inside of the room that drains to a safe location shall be permitted to be used as an alternative to a sill or ramp. [**30:**24.9.4.1]

66.24.9.5 Means shall be provided to prevent liquid spills from running into basements. [**30:**24.9.5]

66.24.9.6* The containment shall have a capacity not less than that of the largest tank that can drain into it. [**30:**24.9.6]

Δ **A.66.24.9.6** Annex A of NFPA 15 provides information on this subject. [**30:**A.24.9.6]

A spill containment area inside a building is sized exactly as if it were an outside diked area — large enough to hold the contents of the largest tank. However, for inside tanks, an additional provision requires that spilled liquid and the water from fire-fighting operations be drained to a safe location, in recognition that the tanks are not outside but in an enclosed area. To protect the rest of the facility and to minimize hindrance to fire-fighting operations, spilled liquid and fire-fighting water must be removed. Note that an outside diked area would likely have means of drainage as well. For an inside tank installation, such provisions are critical.

66.24.9.7 Emergency drainage systems shall be provided to direct flammable or combustible liquid leakage and fire-protection water to a safe location. [**30:**24.9.7]

Any liquid that is drained from the building must be retained in a safe location. It must not be allowed to enter waterways or a municipal sewer system or storm drain, where it can present the threat of fire or explosion.

66.24.9.8 Curbs, scuppers, or special drainage systems shall be permitted to be used. [**30:**24.9.8]

66.24.9.9 Emergency drainage systems, if connected to public sewers or discharged into public waterways, shall be equipped with traps or separators. [**30:**24.9.9]

66.24.10 Ventilation for Storage Tank Buildings.

66.24.10.1 Storage tank buildings storing Class I liquids or Class II or Class III liquids at temperatures at or above their flash points shall be ventilated at a rate sufficient to maintain the concentration of vapors within the building at or below 25 percent of the lower flammable limit. Compliance with 66.24.10.2 through 66.24.10.7 shall be deemed as meeting the requirements of 66.24.10.1. [**30:**24.10.1]

Δ **66.24.10.2*** Ventilation shall be designed based on one of the following:

(1) Calculations based on the anticipated fugitive emissions *(See Annex E of NFPA 30 for calculation methods.)*
(2) Sampling of the actual vapor concentration under normal operating conditions
(3) Ventilation at a rate of not less than 1 cfm of exhaust air for each square foot of solid floor area (0.3 $m^3/min/m^2$)

[**30:**24.10.2]

Recognizing that some storage tank buildings might be quite large, A.66.24.10.2 offers two alternatives to the traditional ventilation rate specified in 66.24.10.2(3). A more detailed discussion is included in the commentary to Section 66.17.11.

A.66.24.10.2 Equipment in enclosed storage areas can deteriorate over time and periodic evaluation should be conducted to assure that leakage rates have not increased or that the ventilation rate is adequate for any increase in leakage rates. [**30:**A.24.10.2]

66.24.10.2.1 If vapor concentrations are confirmed by sampling, the sampling shall be conducted at a distance of a 5 ft (1.5 m) radius from each potential vapor source extending to or toward the bottom and the top of the enclosed storage area. The vapor concentration used to determine the required ventilation rate shall be the highest measured concentration during the sampling procedure. [**30:**24.10.2.1]

66.24.10.3 Ventilation shall be accomplished by natural or mechanical ventilation, with discharge or exhaust to a safe location outside the building. [**30:**24.10.3]

66.24.10.3.1 Recirculation of exhaust air shall be permitted only when it is monitored continuously using a fail-safe system that is designed to automatically sound an alarm, stop recirculation, and provide full exhaust to the outside in the event that vapor–air mixtures having concentrations over 25 percent of the lower flammable limit are detected. [**30:**24.10.3.1]

66.24.10.4* Provision shall be made for introduction of make-up air in such a manner as to avoid short-circuiting the ventilation. [**30:**24.10.4]

Δ **A.66.24.10.4** Local or spot ventilation might be needed for the control of special fire or health hazards. NFPA 91 and NFPA 90A provide information on this subject. [**30:**A.24.10.4]

The ventilation system intake ducts must be located in an area where they are unlikely to pick up any vapors from the discharge side of the system.

66.24.10.5 Ventilation shall be arranged to include all floor areas or pits where flammable vapors can collect. [**30:**24.10.5]

66.24.10.6 Where natural ventilation is inadequate, mechanical ventilation shall be provided and shall be kept in operation while flammable liquids are being handled. [**30:**24.10.6]

66.24.10.6.1 Local or spot ventilation, if provided, shall be permitted to be used for up to 75 percent of the required ventilation. [**30:**24.10.6.1]

Δ **66.24.10.7** Storage tank buildings with the interior grade more than 12 in. (300 mm) below the average exterior grade shall be provided with one of the following:

(1) Continuous mechanical ventilation in accordance with 66.24.10.2(3)
(2) A vapor detection system set to sound a warning alarm at a constantly attended location at 25 percent of the lower flammable limit, and to start the mechanical ventilation system

[**30:**24.10.7]

Vapors tend to accumulate in belowgrade spaces. Because some installations include spill containment basins, vapor detection is mandated. This requirement applies equally to separate storage tank buildings and to tanks located in a building in an area that is lower than the surrounding floor area.

66.24.11 Reserved.

66.24.12 Reserved.

66.24.13 Vents for Tanks Inside Storage Tank Buildings.

66.24.13.1 Vents for tanks inside tank buildings shall be designed to ensure that vapors are not released inside the building. Compliance with 66.24.13.2 through 66.24.13.6 shall be deemed as meeting the requirements of 66.24.13.1. [**30:**24.13.1]

66.24.13.2 Vents for tanks inside tank buildings shall be as required in 66.21.4.3 and 66.22.7. [**30:**24.13.2]

66.24.13.3 Emergency venting by the use of a weak roof-to-shell seam shall not be permitted. [**30:**24.13.3]

Rupture of a weak roof-to-shell seam would likely damage the building structure and any automatic sprinkler or water spray systems protecting the tank and would needlessly expose uninvolved tanks.

66.24.13.4 Automatic sprinkler systems designed in accordance with the requirements of Section 13.3 and NFPA 13 shall be accepted by the AHJ as equivalent to water spray systems for purposes of calculating the required airflow rates for emergency vents in 22.7.3.5 of NFPA 30, provided the density and coverage requirements of NFPA 15 are met. [**30:**24.13.4]

66.24.13.5 Vents shall terminate outside the building in accordance with 66.27.8.1. [**30:**24.13.5]

66.24.13.5.1 Emergency relief vents on protected aboveground tanks complying with UL 2085 containing Class II and Class III liquids shall be allowed to discharge inside the building. [**30:** 24.13.5.1]

This requirement was added to the *Code* in 2015. Protected aboveground tanks complying with ANSI/UL 2085 are designed and constructed to withstand a 2-hour fire test of 2000°F (1093°C) during which no single point on the inside wall of the primary vessel can exceed 400°F (204°C), and the average temperature rise on the inside wall cannot exceed 260°F (127°C). Given this stringent requirement, activation of the emergency vent is likely only under extreme fire conditions over an extended period of time. Further, NFPA 30 states that the required capacity of an emergency vent placed on a vent pipe that extends beyond 12 in. (300 mm) from the tank be recalculated to account for the potential back pressure and ensure activation at the appropriate pressure. It is not unusual to see vent lines extending 30 ft (9 m) or more through a building in order to achieve the exterior discharge. Allowing the emergency vent to discharge inside eliminates the need for recalculating the vent capacity and ensures proper sizing and activation of the emergency vent.

66.24.13.6 Piping for normal and emergency relief venting shall meet the requirements of Section 66.27. [**30:**24.13.6]

66.24.14 Tank Openings Other than Vents for Tanks Inside Storage Tank Buildings.

66.24.14.1 Tank openings other than vents for tanks inside tank buildings shall be designed to ensure that flammable liquids or vapors are not released inside the building. Compliance with 66.24.14.2 through 66.24.14.9 shall be deemed as meeting the requirements of 66.24.14.1. [**30:**24.14.1]

66.24.14.2 All tank openings that are located at or below the maximum liquid level shall be liquidtight. Those that are located above the maximum liquid level shall be normally closed and shall be mechanically secured to prevent release of vapors. [**30:**24.14.2]

Tank openings that are below the normal maximum liquid level must, obviously, be liquidtight and must be maintained that way. Tank openings above this level do not have to be liquidtight, but they must be secured so that no vapors escape to the inside of the building.

66.24.14.3 Each liquid transfer connection on any tank storing Class I or Class II liquids inside buildings shall be provided with one of the following:

(1) A normally closed, remotely activated valve
(2) An automatic-closing, heat-activated valve
(3) Another approved device
[**30:**24.14.3]

66.24.14.4 Connections used for emergency disposal or to provide for quick cutoff of flow in the event of fire in the vicinity of the tank shall not be required to meet the requirement of 66.24.14.3. [**30:**24.14.4]

66.24.14.5 Each connection through which liquid can gravity flow from a tank inside a building shall be provided with an internal or an external valve located as close as practical to the shell of the tank. This valve shall be considered to be in compliance with 66.24.14.3. If a separate valve is used, both valves shall be located adjacent to each other. [**30:**24.14.5]

66.24.14.6* Openings for manual gauging of Class I or Class II liquids, if independent of the fill pipe, shall be provided with a vaportight cap or cover that shall be kept closed when not in use. [**30:**24.14.6]

A.66.24.14.6 Substitutes for manual gauging include, but are not limited to, heavy-duty flat gauge glasses; magnetic, hydraulic, or hydrostatic remote reading devices; and sealed float gauges. [**30:**A.24.14.6]

66.24.14.6.1 Each such opening for any liquid shall be protected against liquid overflow and possible vapor release by means of a spring-loaded check valve or other approved device. [**30:**24.14.6.1]

66.24.14.7 The inlet of the fill pipe and the outlet of a vapor recovery line for which connections to tank vehicles and tank cars are made and broken shall be as follows:

(1) Located outside of buildings at a location free from any source of ignition
(2) Located not less than 5 ft (1.5 m) away from any building opening
(3) Closed tight and protected against tampering when not in use
(4) Identified
[**30:**24.14.7]

66.24.14.8* Tanks storing Class I, Class II, or Class IIIA liquids inside buildings shall be equipped with a device, or other means shall be provided, to prevent overflow into the building. [**30:**24.14.8]

A.66.24.14.8 Suitable devices include, but are not limited to, a float valve; a pre-set meter on the fill line; a low head pump incapable of producing overflow; or a liquidtight overflow pipe, sized at least one pipe size larger than the fill pipe, that discharges by gravity back to the outside source of liquid or to an approved location. [**30:**A.24.14.8]

An overfill cannot be allowed to simply collect in the containment area, as would be allowed with an outside aboveground tank. Paragraph 66.24.14.8 allows considerable flexibility in complying with the requirements.

66.24.14.9 Tank openings provided for purposes of vapor recovery shall be protected against possible vapor release by means of a spring-loaded check valve or dry-break connection or other approved device, unless the opening is pipe-connected to a vapor processing system. [**30:**24.14.9]

66.24.14.9.1 Openings designed for combined fill and vapor recovery shall also be protected against vapor release unless connection of the liquid delivery line to the fill pipe simultaneously connects the vapor recovery line. [**30:**24.14.9.1]

66.24.14.9.2 All connections shall be vaportight. [**30:**24.14.9.2]

66.24.15 Detection and Alarm Systems for Storage Tank Buildings.

66.24.15.1 An approved means shall be provided to promptly notify those within the plant and the available public or mutual aid fire department of any fire or other emergency. [**30:**24.15.1]

66.24.15.2 Those areas, including buildings, where the potential exists for a flammable liquid spill shall be monitored as appropriate. Such methods shall include both of the following:

(1) Personnel observation or patrol
(2) Monitoring equipment that indicates a spill or leak has occurred in an unattended area
[**30:**24.15.2]

66.24.16 Inspection and Maintenance for Storage Tank Buildings.

66.24.16.1 Combustible waste material and residues in operating areas shall be kept to a minimum, stored in covered metal containers, and disposed of daily. [**30:**24.16.1]

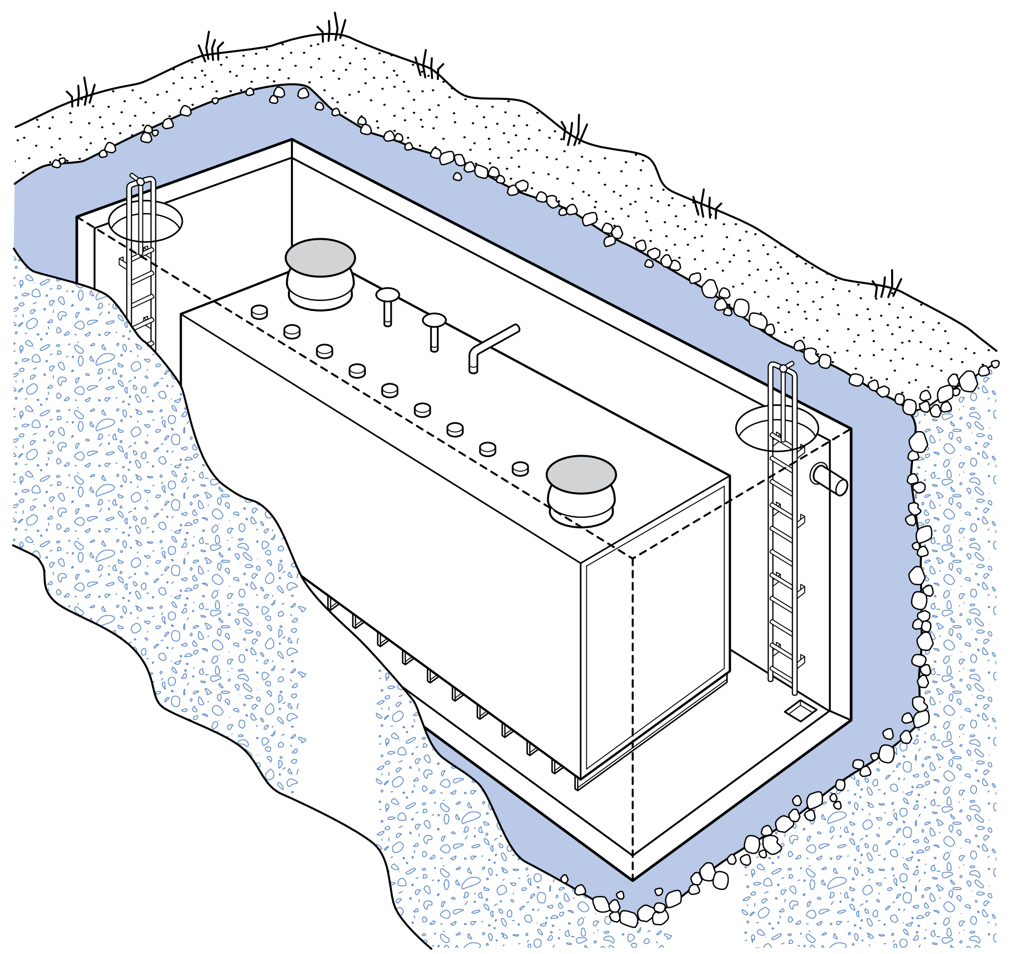
66.24.16.2 Storage of combustible materials and empty or full drums or barrels shall not be permitted within the storage tank building. [**30:**24.16.2]

66.25 Storage Tank Vaults

66.25.1 Scope. This section shall apply to the design, construction, and installation of vaults for aboveground tanks. [**30:**25.1]

Section 66.25 covers storage tank vaults. Vaults provide a secure installation and a high degree of protection for a liquid storage tank.

Exhibit 66.53



Typical underground storage tank vault.

Exhibit 66.53 is a diagram of a typical storage tank vault that is installed below grade and backfilled. Exhibit 66.54 shows an on-site installation of a vault and its storage tank.

66.25.2 Definitions Specific to Section 66.25. (Reserved)

66.25.3 General Requirements.

66.25.3.1* Storage Tank Selection and Arrangement.

A.66.25.3.1 Inspections are recommended for shop fabricated aboveground tanks. One guide is SP001, *Standard for Inspection of Aboveground Storage Tanks*, which is published by the Steel Tank Institute. In addition, the tank owner might desire to conduct additional inspections to ensure the ongoing integrity of tanks and equipment. Because the interior of a vault will ordinarily remain dry and temperature-moderated, environmental effects on tanks and equipment inside vaults will be reduced as compared to aboveground tanks that are not protected from weather exposure. Accordingly, inspection and maintenance frequencies for exterior surfaces of tanks and piping in vaults are typically less critical than for aboveground tanks installed outdoors. Nevertheless, inspection

Exhibit 66.54

Vault and its storage tank being installed at a service station site. (Courtesy of Core Engineered Solutions, Inc.)

and maintenance of emergency vents and overfill prevention devices are still necessary. [**30:**A.25.3.1]

Clearance between the shell of a tank or equipment in a vault and the interior vault wall should be sufficient to accommodate visual inspections and maintenance that might be needed. In addition, consideration should be given to the need for inspection and maintenance of tank interior surfaces that may be impacted by internal corrosion. [**30:**A.25.3.1]

Clearance should be adequate to permit the following:

(1) Entry into the vault interior by an inspector or maintenance worker
(2) Access to manipulate, repair, or replace any equipment or fittings in the vault
(3) Access within the vault to visually inspect, either by direct sight or with the aid of an optical vision extension tools, interior vault surfaces and exterior surfaces of tanks and equipment, to determine the source of any leakage that may occur, and to conduct any needed repairs

[**30:**A.25.3.1]

Because vaults are designed to provide for entry by inspectors or maintenance workers, consideration should also be given to providing access for rescue by emergency responders who might be called upon to rescue an individual from a vault. Such consideration can include providing a minimum access hatch dimension of 36 in. (915 mm) and a minimum dimension for walkways in vault interior spaces of 30 in. (760 mm) to permit an emergency responder with an SCBA to maneuver and providing, in some cases, a second means of access to the vault interior. [**30:**A.25.3.1]

66.25.3.1.1 Aboveground tanks shall be permitted to be installed in vaults that meet the requirements of this section. [**30:**25.3.1.1]

66.25.3.1.2 Vaults shall be constructed and listed in accordance with UL 2245, *Standard for Below-Grade Vaults for Flammable Liquid Storage Tanks*. [**30:**25.3.1.2]

66.25.3.1.3 Except as modified by the provisions of this section, vaults shall meet all other applicable provisions of this *Code*. [**30:**25.3.1.3]

66.25.3.1.4 Tanks installed in storage tank vaults shall be listed for aboveground use. [**30:**25.3.1.4]

66.25.3.1.5 Each tank shall be in its own vault and shall be completely enclosed by the vault. [**30:**25.3.1.5]

66.25.3.1.6 Sufficient clearance between the tank and the vault shall be provided to allow for visual inspection and maintenance of the tank and its appurtenances. [**30:**25.3.1.6]

66.25.3.1.7 Backfill shall not be permitted around the tank. [**30:**25.3.1.7]

Δ **66.25.3.1.8** Dispensing devices shall be permitted to be installed on the tops of vaults. Dispensing devices used for motor fuels shall be installed in accordance with NFPA 30A. [**30:**25.3.1.8]

66.25.3.1.9 At each entry point into the vault, a warning sign indicating the need for procedures for safe entry into confined spaces shall be posted. Each entry point shall be secured against unauthorized entry and vandalism. [**30:**25.3.1.9]

The interior of the vault qualifies as a permit-required confined space in accordance with 29 CFR 1910.146, "Permit-Required Confined Spaces."

66.25.3.2 Storage Tank Appurtenances.

66.25.3.2.1 An approved means of overfill protection shall be provided for the tanks in the vaults. The use of ball float valves shall be prohibited. [**30:**25.3.2.1]

Ball float valves cannot be used as a means for overfill protection because of the potential for damage to the tank. If the tank is filled using a pumped delivery, closure of the ball float would cause immediate and potentially damaging excess pressure in the tank.

66.25.3.2.2 Fill connections for vaults installed inside buildings shall comply with 66.22.13.4. [**30:**25.3.2.2]

66.25.3.3 Vault Arrangement.

66.25.3.3.1 Vaults shall be permitted to be either above or below grade. [**30:**25.3.3.1]

A vault can be installed completely buried, with its top at grade or with its top partly or wholly above grade. See Exhibit 66.55.

66.25.4 Location of Storage Tank Vaults. In lieu of the separation distance requirements given in 66.22.4, separation distances between the vault and any of the following shall be permitted to be reduced to 0 ft (0 m), as measured from the outer perimeter of the vault wall:

(1) Any property line that is or can be built upon
(2) The near and far sides of a public way
(3) The nearest important building on the same property

[**30:**25.4]

Given the robust construction of a vault, the protection from an exposure fire provided by the vault to the tank and by the requirements imposed by this chapter, applying the separation distances required for an exposed tank cannot be justified.

66.25.5* Construction and Installation of Storage Tank Vaults.

A.66.25.5 Some of the specifications for vault design and construction include the following:

(1) The walls and floor of the vault are to be constructed of reinforced concrete at least 6 in. (50 mm) thick.
(2) The top and floor of the vault and the tank foundation must be designed to withstand all anticipated loading, including loading from vehicular traffic, where applicable.
(3) The walls and floor of a belowgrade vault must be designed to withstand anticipated soil and hydrostatic loading.
(4) The vault must be liquidtight.
(5) The vault enclosure must have no openings except those necessary for access to, inspection of, and filling, emptying, and venting of the tank.

Exhibit 66.55

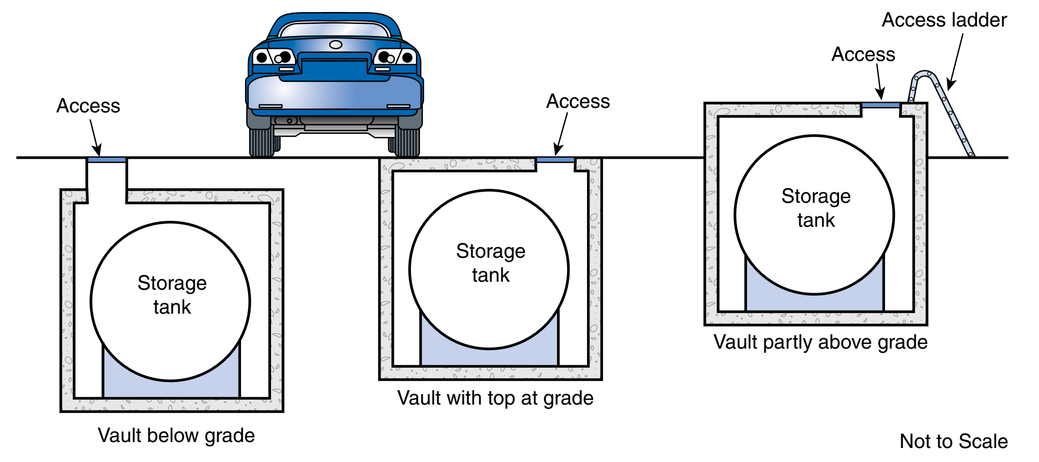


Diagram showing vault installations with respect to grade.

(6) The vault must be provided with connections to permit ventilation to dilute, disperse, and remove any vapors prior to personnel entering the vault.
(7) The vault must be provided with a means for personnel entry.
(8) The vault must be provided with an approved means to admit a fire suppression agent.

[**30:**A.25.5]

66.25.5.1 Construction Requirements. Vaults shall be designed and constructed in accordance with 66.25.5.1.1 through 66.25.5.1.4. [**30:**25.5.1]

66.25.5.1.1 The top of an abovegrade vault that contains a tank storing Class I liquid or Class II liquid stored at a temperature above its flash point shall be constructed of noncombustible material and shall be designed to be weaker than the walls of the vault to ensure that the thrust of any explosion occurring inside the vault is directed upward before destructive internal pressure develops within the vault. [**30:**25.5.1.1]

66.25.5.1.2 The top of an at-grade or belowgrade vault that contains a tank storing Class I liquid or Class II liquid stored at a temperature above its flash point shall be designed to relieve or contain the force of any explosion occurring inside the vault. [**30:**25.5.1.2]

To effectively vent an explosion within a belowgrade vault, the design has to incorporate a duct that extends to a safe distance above grade. This duct has to be strong enough so that it does not fail before the deflagration vent can operate. See NFPA 68, *Standard on Explosion Protection by Deflagration Venting*. Alternatively, the vault can be designed to withstand the overpressure of an explosion. This technique is known as *deflagration pressure containment* and is the option almost universally chosen. See Chapter 13 of NFPA 69.

66.25.5.1.3 Adjacent vaults shall be permitted to share a common wall. [**30:**25.5.1.3]

66.25.5.1.4 Where required, the vault shall be wind and earthquake resistant, in accordance with recognized engineering standards. [**30:**25.5.1.4]

66.25.5.2 Installation Requirements. Storage tank vaults shall be installed in accordance with the requirements of 66.25.5.2.1 and 66.25.5.2.2. [**30:**25.5.2]

66.25.5.2.1 Each vault and its tank shall be anchored to resist uplifting by groundwater or flooding, including when the tank is empty. [**30:**25.5.2.1]

66.25.5.2.2 Vaults that are not resistant to damage from the impact of a motor vehicle shall be protected by collision barriers. [**30:**25.5.2.2]

66.25.6 Reserved.

66.25.7 Reserved.

66.25.8 Reserved.

66.25.9 Containment, Drainage, and Spill Control for Storage Tank Vaults.

66.25.9.1 Means shall be provided to recover liquid from the vault. [**30:**25.9.1]

66.25.9.2 If a pump is used to meet this requirement, the pump shall not be permanently installed in the vault. [**30:**25.9.2]

66.25.9.3 Electric-powered portable pumps shall be approved for use in Class I, Division 1 locations, as defined in *NFPA 70*. [**30:**25.9.3]

66.25.10 Ventilation Systems for Storage Tank Vaults.

66.25.10.1 Vaults that contain tanks storing Class I liquids shall be ventilated at a rate of not less than 1 cfm/ft^2 of floor area (0.3 m^3/min/m^2), but not less than 150 cfm (4 m^3/min). [**30:**25.10.1]

66.25.10.2 Such ventilation shall operate continuously or shall be designed to operate upon activation of a vapor and liquid detection system. [**30:**25.10.2]

66.25.10.3 Failure of the exhaust airflow shall automatically shut down the dispensing system. [**30:**25.10.3]

66.25.10.4 The exhaust system shall be designed to provide air movement across all parts of the vault floor. [**30:**25.10.4]

66.25.10.5 Supply and exhaust ducts shall extend to within 3 in. (75 mm), but not more than 12 in. (300 mm) of the floor. [**30:**25.10.5]

Δ **66.25.10.6** The exhaust system shall be installed in accordance with the provisions of NFPA 91. [**30:**25.10.6]

66.25.11 Reserved.

66.25.12 Reserved.

66.25.13 Vents for Tanks Inside Storage Tank Vaults.

66.25.13.1 Vent pipes that are provided for normal tank venting shall terminate outside the vault and at least 12 ft (3.6 m) above ground level and shall meet the requirements of 66.27.8.1. [**30:**25.13.1]

66.25.13.2 Emergency vents shall be vaportight and shall be permitted to discharge inside the vault. Long-bolt manhole covers shall not be permitted for this purpose. [**30:**25.13.2]

Emergency vents are allowed to discharge inside the vault because they would operate only if an exposure fire within the vault is boiling the contents of the tank. Vapors released by the emergency vent would not materially add to the fire. The rationale is that it is safer for the vapors to be burned in the vault than to be discharged in quantity outside the vault, where they could be ignited and trigger a second fire.

Long-bolt manhole covers are not sufficiently vaportight to be used.

66.25.14 Reserved.

66.25.15 Detection and Alarm Systems for Storage Tank Vaults.

66.25.15.1 Each vault shall be provided with an approved vapor and liquid detection system that is equipped with on-site audible and visual warning devices with battery backup. [**30:**25.15.1]

66.25.15.2 The vapor detection system shall sound an alarm when the system detects vapors that reach or exceed 25 percent of the lower flammable limit of the liquid stored. [**30:**25.15.2]

66.25.15.3 Vapor detectors shall be located no higher than 12 in. (300 mm) above the lowest point in the vault. [**30:**25.15.3]

66.25.15.4 The liquid detection system shall sound an alarm upon detection of any liquid, including water. [**30:**25.15.4]

The liquid detection system is intended to sound an alarm not just for a spill but also for any infiltration of groundwater into the vault, which could indicate failure of the vault's floor, wall, or top or failure of a seal at the wall-to-top joint.

66.25.15.5 Liquid detectors shall be located in accordance with the manufacturer's instructions. [**30:**25.15.5]

66.25.15.6 Activation of either the vapor detection system or the liquid detection system shall cause a signal to be sounded at an approved, constantly attended location within the facility serving the tanks or at an approved location. [**30:**25.15.6]

66.25.16 Inspection and Maintenance of Storage Tank Vaults and Equipment. Vaults and their required equipment shall be maintained in accordance with the requirements of this section. [**30:**25.16]

66.26 Reserved

66.27 Piping Systems

66.27.1 Scope.

Section 66.27 covers piping systems used to transfer flammable and combustible liquid from one point to another (see Exhibit 66.56). Any piping system is susceptible to leaks or spills of liquids. Because of the fire hazard involved in handling flammable and combustible liquids, piping systems must be able to withstand the intense heat generated by fire for reasonable periods of time while emergency shutdown procedures are implemented and fire-fighting measures begin. Failure of pipes, valves, and fittings from exposure to a fire can turn a moderate hazard into an extreme emergency.

Exhibit 66.56

Piping in a process plant undergoing routine maintenance.

66.27.1.1 This section shall apply to the design, installation, testing, operation, and maintenance of piping systems for flammable and combustible liquids or vapors. Such piping systems shall include but not be limited to pipe, tubing, flanges, bolting, gaskets, valves, fittings, flexible connectors, the pressure-containing parts of other components including but not limited to expansion joints and strainers, and devices that serve such purposes as mixing, separating, snubbing, distributing, metering, control of flow, or secondary containment. [**30:**27.1.1]

66.27.1.2 This section shall not apply to any of the following:

(1) Tubing or casing on any oil or gas wells and any piping connected directly thereto
(2) Motor vehicles, aircraft, boats, or piping that are integral to a stationary engine assembly
(3) Piping within the scope of any applicable boiler and pressure vessel code

[**30:**27.1.2]

Paragraph 66.27.1.2 clearly identifies those elements of piping systems that are not addressed by the *Code*. Note that this chapter does not apply to the fuel supply piping that connects a stationary internal combustion engine with its primary fuel supply, often referred to as a "day tank," or its integral fuel tank, such as a "base tank." This chapter does apply to piping for any fuel storage tank from which the day tank is replenished. Although not specifically stated here, the same applies to fuel supply tanks for oil-burning appliances. The requirements of Chapter 8 of NFPA 31 apply to the tank that directly supplies the appliance, while this chapter applies to any storage tank upstream.

66.27.2 Definitions Specific to Section 66.27. For the purpose of this section, terms in this section shall have the definitions given. [**30:**27.2]

66.27.2.1 Corrosion Protection. A means to lessen or prevent the deterioration of the piping system from exposure to its contents or its environment. [**30:**27.2.1]

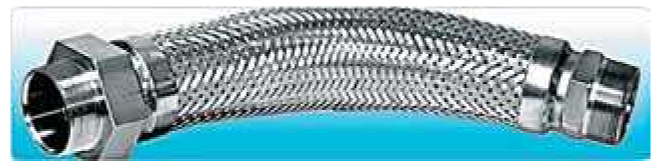
66.27.2.2 Flexible Connector. A connection joint in a piping system that allows differential movement of the piping system and limits system stress and mechanical damage. [**30:**27.2.2]

Flexible connectors are often needed between process equipment and connected piping systems to accommodate vibration or to absorb piping stresses developed by temperature and pressure changes in the process system. Flexible connectors are required to be listed (see 66.27.5.2), while hose need only be acceptable to the AHJ (see 66.18.4.7 and 66.18.5.2.1). Exhibit 66.57 shows a stainless steel flexible connector used for providing a flexible joint in fuel piping. For more information on flexible connectors, see the commentary to 66.27.5.2.

66.27.2.3 Leak. An unintended release of liquid or vapor from the piping system due to failure of the piping system. [**30:**27.2.3]

66.27.2.4 Low Melting Point Materials. Materials that melt at a low temperature, including but not limited to aluminum, copper, or brass; materials that soften on fire exposure, such as plastics; or nonductile materials, such as cast iron. [**30:**27.2.4]

Exhibit 66.57



Stainless steel flexible connector used for fuel service. (Courtesy of OPW)

With respect to metals, *low melting* describes metals that have melting points significantly lower than that of steel. For example, aluminum alloys melt at about 1225°F (660°C) and copper at about 2000°F (1090°C). Carbon steel and wrought iron have melting points around 2800°F (1540°C). Although not a low melting point material, cast iron is treated similarly because it is brittle and easily fractured. See the commentary for 66.27.4.2.

Plastics is a broad term that includes thermoset resins. Thermoset resins are usually liquids and are fashioned into their final form and thermally cured. Once cured, thermosets cannot be softened by heat. That being the case, not all piping fabricated from thermoset resins qualifies as a low melting point material. However, thermoset piping should still be evaluated to determine how well it can withstand an exposure fire.

66.27.2.5 Secondary Containment. Containment that is external to and separate from the primary piping system. [**30:**27.2.5]

66.27.3 General Requirements.

66.27.3.1 Performance Standards. The design, fabrication, assembly, test, and inspection of piping systems shall be suitable for the working pressures and structural stresses to be encountered by the piping system. Compliance with applicable sections of ASME B31, *Code for Pressure Piping*, and the provisions of this section shall be considered *prima facie* evidence of compliance with the foregoing provisions. [**30:**27.3.1]

Consideration of the expected (or normal) working pressures of the piping system and structural stresses to which it will be exposed is important, particularly when high vapor–pressure flammable liquids are involved or when tanks and piping systems are subject to heating. Heating can result from exposure to direct sunlight, from heat radiating off a process or piece of equipment, or from the liquid itself at elevated temperature.

66.27.3.2 Tightness of Piping. Piping systems shall be maintained liquidtight. A piping system that has leaks that constitute a hazard shall be repaired in a manner acceptable to the AHJ, or it shall be emptied of liquid, vapor freed, and no longer used. [**30:**27.3.2]

66.27.4 Materials of Construction for Piping Systems.

66.27.4.1 Materials Specifications. Pipe, valves, faucets, couplings, flexible connectors, fittings, and other pressure-containing parts shall meet the material specifications and pressure and temperature limitations of ASME B31, *Code for Pressure Piping*, except as provided for in 66.27.4.2, 66.27.4.3, and 66.27.4.4. [**30:**27.4.1]

66.27.4.2 Ductile Iron. Ductile (nodular) iron shall meet the specifications of ASTM A395, *Standard Specification for Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures*. [**30:**27.4.2]

Ductile (nodular) iron is another term for *malleable wrought iron*. This type of iron is distinct from cast iron, which should be used only for piping systems that handle Class IIIB liquids, in accordance with 66.27.4.3.3. Cast iron is brittle and fractures on impact. Malleable iron bends or deforms instead and is less likely to result in a serious leak if damaged.

Paragraph 66.27.4.2 does not apply to the internal working parts of a valve or other similar components of the piping system. These parts are referred to as "valve trim" and include such components as the valve gate or disk, the internal surfaces on which the gate or disk seats to stop or throttle flow, the stem, and the sleeves needed to guide the stem. These components are commonly fabricated from brass or bronze.

66.27.4.3 Materials of Construction for Valves. Valves at storage tanks, as required by 66.22.13 and 66.24.14, and their connections to the tank shall be of steel or ductile iron, except as provided for in 66.27.4.3.1, 66.27.4.3.2, or 66.27.4.4. [**30:**27.4.3]

66.27.4.3.1 Valves at storage tanks shall be permitted to be other than steel or ductile iron where the chemical characteristics of the liquid stored are not compatible with steel or where the valves are installed internally to the tank. [**30:**27.4.3.1]

Internally mounted shutoff valves, sometimes referred to as "fire-safe" valves, have their internal mechanism mounted inside the tank shell where the liquid can absorb heat, thus keeping the valve mechanism cool and avoiding failure of and leakage past the valve seat. See Exhibit 66.58. A fusible link is typically provided to automatically shut the valve if exposed to a fire. Because the components of the valve mechanism are protected from the thermal stress of the fire, they can be of materials other than steel or nodular iron, such as brass. These valves are not readily available in sizes larger than 4 in. (100 mm).

There are two negative features of this type of valve, particularly for sizes larger than 4 in. (100 mm). First, if part of the internal mechanism fails or breaks, access for repair usually involves draining the tank, then entering the tank to effect a repair, a procedure that is time-consuming, costly, and not without hazard. Second — this is significant only for situations involving large field-erected tanks [>75,000 gal (284 m^3)] — when the valve closes due to a fire, as it is designed to do, the option of pumping the contents of the tank to another tank that is removed from the fire is not available. Being able to pump out a fire-exposed tank is a valuable option in a fire situation, particularly where very large tanks are involved. For those reasons, the Technical Committee on Tank Storage and Piping Systems does not favor mandating internally mounted shutoff valves.

66.27.4.3.2* Valves installed externally to the tank shall be permitted to be other than steel or ductile iron if the material of construction has a ductility and melting point comparable to steel or ductile iron and is capable of withstanding the stresses and temperatures involved in fire exposure or the valves are otherwise protected from fire exposures, such as by materials having a fire resistance rating of not less than 2 hours. [**30:**27.4.3.2]

A.66.27.4.3.2 For further information, see ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, and ANSI/UL 1709, *Standard for Rapid Rise Fire Tests of Protection Materials for Structural Steel*. [**30:**A.27.4.3.2]

The reason for requiring steel or ductile iron wherever possible is to ensure that the valve or fittings are able to withstand the

Exhibit 66.58

stresses and temperatures created by fire exposure. An alternative to using steel, ductile iron, or materials of similar properties is to protect the valve so it will have a fire resistance rating of 2 hours.

66.27.4.3.3 Cast iron, brass, copper, aluminum, malleable iron, and similar materials shall be permitted to be used on tanks described in 66.22.4.2.1.1 or on tanks storing Class IIIB liquids where the tanks are located outdoors and not within a diked area or drainage path of a tank storing a Class I, Class II, or Class IIIA liquid. [**30:**27.4.3.3]

The relaxed requirement in 27.4.3.3 is justified by the fact that a spill of a Class IIIB liquid entails very little fire risk.

66.27.4.4 Low Melting Point Materials.

66.27.4.4.1 Low melting point materials, as defined in 66.27.2.4, shall be compatible with the liquids being handled and shall be used within the pressure and temperature limitations of ASME B31, *Code for Pressure Piping*. [**30:**27.4.4.1]

66.27.4.4.2 Low melting point materials shall not be used as part of a tank's normal or emergency vent piping. [**30:**27.4.4.2]

This provision is intended to prevent situations in which an exposure fire causes the vent piping to soften, shrink, and close in on itself to the point where its capacity is restricted or blocked completely.

66.27.4.4.3 Low melting point materials shall be permitted to be used underground. [**30:**27.4.4.3]

66.27.4.4.4 Low melting point materials shall be permitted to be used outdoors aboveground, outside a dike, outside a remote impounding area, or inside buildings, provided they meet one of the following conditions:

(1) They are resistant to damage by fire.
(2) They are located so that any leakage resulting from failure will not expose persons, important buildings, tanks, or structures.
(3) They are located where leakage can be controlled by operation of one or more accessible, remotely located valves.

[**30:**27.4.4.4]

66.27.4.4.5 Low melting point materials shall be permitted to be used within a dike or within a remote impounding area provided they meet one of the following:

(1) They are connected above the normal operating liquid level of the tank.
(2) They are connected below the normal operating liquid level of the tank and one of the following conditions is met:
    (a) The stored liquid is a Class IIIB liquid, the tank is located outdoors, and the piping is not exposed to a potential spill or leak of Class I, Class II or Class IIIA liquid.
    (b) The low melting point material is protected from fire exposure, such as by using materials that have a fire resistance of not less than 2 hours.

[**30:**27.4.4.5]

Exhibit 66.59

Internally lined valve. (Courtesy of Aegis Flow Technologies)

66.27.4.4.6 Piping systems of these materials shall be designed and built in accordance with recognized standards of design for the particular materials chosen or with approved equivalent standards or shall be listed. [**30:**27.4.4.6]

66.27.4.5 Lining Materials. Piping, valves, and fittings shall be permitted to have combustible or noncombustible linings. [**30:**27.4.5]

Depending on the liquids being handled, corrosion can be a serious problem in piping, valves, and fittings, often leading to early failure or leaks. Linings made of plastic or rubber-based materials can be useful in preventing corrosion, thus preserving the integrity of the piping system and lengthening its life span. See Exhibit 66.59.

66.27.4.6 Nonmetallic Piping.

66.27.4.6.1 Piping systems of nonmetallic materials, including piping systems incorporating secondary containment, shall be designed and built in accordance with recognized standards of design or approved equivalents and shall be installed in accordance with 66.27.4.4. [**30:**27.4.6.1]

The *Code* treats nonmetallic piping systems and components in essentially the same way it treats piping and piping components of low melting point metallic materials. The susceptibility of these piping systems to damage by fire is considered to be equivalent. Nonmetallic piping might be indicated where the piping is exposed to a particularly corrosive environment, such as a process area where corrosive vapors are released.

66.27.4.6.2 Nonmetallic piping shall be built and used within the scope of their approvals or within the scope of UL 971, *Standard for Nonmetallic Underground Piping for Flammable Liquids*. [**30:**27.4.6.2]

66.27.4.6.3 Nonmetallic piping systems and components shall be installed in accordance with manufacturer's instructions. [**30:**27.4.6.3]

66.27.5 Pipe Joints.

66.27.5.1 Tightness of Pipe Joints.

66.27.5.1.1 Joints shall be made liquidtight and shall be welded, flanged, threaded, or mechanically attached. [**30:**27.5.1.1]

To prevent the loss of liquid, all joints must be liquidtight. This is particularly critical with the more hazardous Class I liquids and explains the requirement of 66.27.5.1.4 for welded joints in concealed areas of a building.

Some weeping is to be expected at some points in a piping system, for example, from valve stem packing glands or from a gasket flange where the flange might need additional tightening. Such weeping is quite minor and is eventually taken care of during routine maintenance.

66.27.5.1.2* Joints shall be designed and installed so that the mechanical strength of the joint will not be impaired if exposed to a fire. [**30:**27.5.1.2]

A.66.27.5.1.2 It is expected that some joints might leak under fire conditions but will not come apart. [**30:**A.27.5.1.2]

66.27.5.1.3 Threaded joints shall be made with a suitable thread sealant or lubricant. [**30:**27.5.1.3]

66.27.5.1.4 Joints in piping systems handling Class I liquids shall be welded when located in concealed spaces within buildings. [**30:**27.5.1.4]

66.27.5.2 Flexible Connectors. Flexible connectors shall be listed and labeled in accordance with UL 2039, *Standard for Flexible Connector Pipe for Fuels,* and shall be installed in accordance with 66.27.5.3. [**30:**27.5.2]

Flexible connectors are used in piping systems wherever the connection would be subject to movement or vibration in normal use. Examples include connections between pumps and fixed piping and at piping headers where connections are made and broken. See Exhibit 66.57

Flexible connectors are often used in underground piping systems to avoid damage to the piping system should the tank move due to, for example, an unusually high groundwater level. Before the advent of flexible connectors in underground service, swing joints made with screwed elbows and short lengths of pipe were used to provide flexibility in underground piping systems. The arrangement of pipe and elbows allowed movement to occur around several axes of rotation, so that shifting of the tank did not break the piping connection. These arrangements were found to complicate the proper installation of emergency shutoff valves under dispensers and to be frequent sources of leaks at their many joints. Because of the EPA's rules on the installation of underground storage tank systems, swing joints have been, for the most part, supplanted by flexible connectors. The appropriate listing document is now referenced.

66.27.5.3 Friction Joints.

66.27.5.3.1 Pipe joints dependent upon the friction characteristics of combustible materials for mechanical continuity or liquidtightness of piping shall only be used outside of buildings above ground, except as provided for in 66.27.5.3.3, or below ground. [**30:**27.5.3.1]

The restrictions on pipe joints that depend on friction or resiliency to maintain tightness are necessary because of their susceptibility to softening under fire exposure and because frost heaves can shift underground piping or supports for aboveground piping and thus disengage the joint. This latter problem is particularly noticeable in the northern latitudes, often in motor fuel dispensing facilities. NFPA 30 generally limits use of this type of joint to underground piping and aboveground piping outside buildings. In the latter case, the piping must be designed and installed so that disengagement of the connection will not occur. Alternatively, as set forth in 66.27.5.3.2, the piping must be located and installed so that a release from the pipe joints will not result in an exposure hazard, and the piping must be remotely controlled. See 66.27.5.3.3 and its commentary for use of these friction joints inside a building.

66.27.5.3.2 Where such joints are used aboveground, either the piping shall be secured to prevent disengagement at the fitting or the piping system shall be so designed that any spill or leak resulting from disengagement will not expose persons, important buildings, or structures and can be controlled by remote valves. [**30:**27.5.3.2]

66.27.5.3.3 Pipe joints dependent on the friction characteristics of their components shall be permitted to be used inside buildings provided both of the following are met:

(1) They are located where leakage can be controlled by operation of an accessible, remotely located valve that is outside the fire risk area.
(2) The mechanical strength and liquidtightness of the joint is not dependent on the resiliency of a combustible material or component.

[**30:**27.5.3.3]

The provision in 66.27.5.3.3 was incorporated into NFPA 30 to accommodate the use of special piping components that are manufactured for easy disassembly and reassembly. These piping system components were originally developed for use in the food processing industry, then found acceptance in the pharmaceutical industry, where U.S. Food and Drug Administration rules mandate frequent flushing and cleaning of piping systems.

These piping system components have now found widespread use in the semiconductor industry, which uses some very volatile flammable liquids and where even minute contamination of fluids cannot be tolerated. Therefore, frequent cleaning of piping systems is the norm and ease of breaking down components of the system is critical.

66.27.6 Installation of Piping Systems.

66.27.6.1 General Requirements. Piping systems shall be supported and protected against physical damage, including damage from stresses arising from settlement, vibration, expansion, or contraction. The installation of nonmetallic piping shall be in accordance with the manufacturer's instructions. [**30:**27.6.1]

66.27.6.2* Load-Bearing Supports. Load-bearing piping supports that are located in areas with a high fire exposure risk shall be protected by one or more of the following:

(1) Drainage to a safe location to prevent liquid from accumulating under pipeways
(2) Fire-resistive construction
(3) Fire-resistant protective coatings or systems
(4) Water spray systems designed and installed in accordance with NFPA 15
(5) Other alternate means acceptable to the AHJ

[**30:**27.6.2]

A.66.27.6.2 API 2218, *Fireproofing Practices in Petroleum and Petrochemical Processing Plants*, contains guidance on selecting and installing fire-resistant coatings to protect exposed steel supports from a high-challenge fire exposure. It also contains a general discussion on determining need for such protection and estimating the extent of the area exposed. [**30:**A.27.6.2]

In refineries, process plants, bulk plants and terminals, and other bulk storage facilities, it is common practice to install piping above ground or overhead on supports, thus leaving the piping and its supports exposed to fires. Failure of piping supports can lead to rapid and extensive spread of the original fire. Paragraph 66.27.6.2 addresses those concerns by requiring protection for load-bearing supports using one of four acceptable options, with the flexibility of allowing other equally effective means if approved by the AHJ.

66.27.6.3 Pipe Penetrations. Piping that passes through or pierces a dike wall or the wall of a structure shall be designed to prevent damaging stresses and leakage due to settlement or fire exposure. [**30:**27.6.3]

66.27.6.4* Corrosion Protection. Aboveground piping systems that are subject to external corrosion shall be suitably protected. Underground piping systems shall be protected against corrosion in accordance with 66.23.3.5. [**30:**27.6.4]

A.66.27.6.4 Buried steel piping should be coated with a suitable material and should be cathodically protected. Galvanized steel pipe, by itself and without other corrosion protection methods, is not acceptable for underground piping. Steel swing joints and stainless steel flexible connectors should also be made corrosion resistant when in contact with the soil. Thus, such fittings should also be coated and cathodically protected when installed between nonmetallic, compatible tanks and piping, such as fiberglass-reinforced plastic. [**30:**A.27.6.4]

The *Code* requires underground storage tanks to be protected from external corrosion. More important, the piping system and all its elements must be similarly protected. Most leaks that occur in underground storage tank systems originate in some part of the piping system.

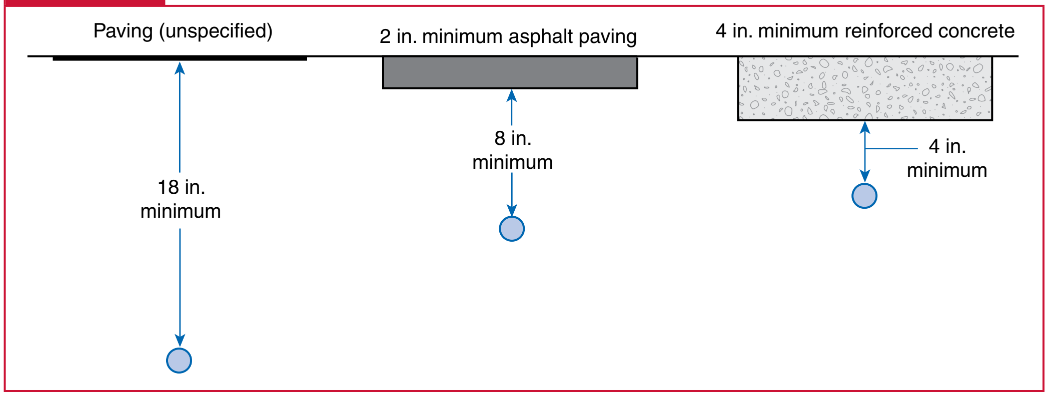
66.27.6.5 Installation of Underground Piping. Underground piping shall be installed in accordance with 27.6.5 of NFPA 30.

The requirements of 66.27.6.5 provide for proper installation procedures for underground (buried) piping, including depth of burial and lateral and vertical clearance between parallel runs of piping, and are based on long-accepted industry practices. The intent is to provide buried piping with firm support to resist movement that might result in leaking, broken joints, or undue stress on the pipe itself. See Exhibits 66.60 and 66.61 for illustrations of the intent of these provisions

66.27.6.6 Valves.

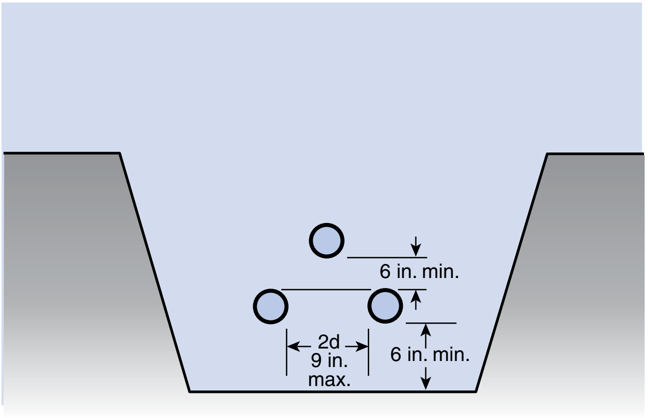
The number of valves actually needed to meet the requirements of 66.27.6.6 and their location in the piping system vary considerably from one installation to another because each piping system differs from another in some respect. No two systems are identical, and the design of each is dictated by operating considerations. Each piping system must, therefore, be evaluated on its own merits, based on good engineering practice. If

Exhibit 66.60



Burial depth for underground piping subject to loading from vehicular traffic.

Exhibit 66.61



Horizontal and vertical separation of underground parallel runs of piping.

consideration is given to general safety guidelines and to the potential results of failure, a determination of the number and placement of valves can be made. Check valves are required only if backflow is possible.

66.27.6.6.1 Piping systems shall contain valves to operate the system properly and to isolate the equipment in the event of an emergency. [**30:**27.6.6.1]

66.27.6.6.2 Piping systems in connection with pumps shall contain valves to properly control the flow of liquid both in normal operation and in the event of an emergency. [**30:**27.6.6.2]

66.27.6.6.3 Each connection to a piping system by which equipment such as tank cars, tank vehicles, or marine vessels discharges liquids into storage tanks shall be provided with a check valve for automatic protection against backflow if the piping arrangement is such that backflow from the system is possible. *(See also 66.22.13.1.)* [**30:**27.6.6.3]

66.27.6.7 Common Loading and Unloading Piping. If loading and unloading is done through a common pipe system, a check valve shall not be required. However, an isolation valve shall be provided. This valve shall be located so that it is accessible or shall be remotely operable. [**30:**27.6.7]

The use of check valves is not mandatory where the same piping system is used for both loading and unloading, but valves are required to isolate the piping system in an emergency so that the flow of liquid can be stopped, and the valves must be readily accessible to operating personnel or be remotely operable during the emergency.

66.27.7 Testing of Piping Systems.

Tests are not a guarantee that a piping system is or will remain leak free; they are one method to help ensure that the system will perform as desired under normal circumstances and predictable emergency situations. Three methods to help ensure performance are acceptable:

1. Meeting the requirements of ASME B31, *Code for Pressure Piping*
2. Hydrostatically testing to 150 percent of the maximum system design pressure
3. Pneumatically testing to 110 percent of the maximum system design pressure

In any case, tests must be conducted for at least 10 minutes or until a complete visual inspection of all joints and connections can be made. The reason for the percentage differences between the pneumatic and hydrostatic test limits is safety. A piping system that is overpressurized with water or other liquid contains much less potential energy than one that is overpressurized with air, nitrogen, or other gas, simply because water and similar fluids are noncompressible, whereas gases can be greatly compressed. In the event of failure, a piping system undergoing a hydrostatic test quickly depressurizes, minimizing the chance for a catastrophic rupture. A pneumatic failure, on the other hand, sometimes involves a violent rupture of the system being tested. As in the testing of tanks, the piping should be cleaned and purged of any flammable vapors, and flammable or combustible liquids should not be used as the test fluid.

Subsection 66.27.7 applies to all new piping systems and any piping system that has undergone major repair or replacement. Minor repairs — such as replacement of a gasket, repair of a valve packing gland, or tightening of flange bolts — would not require testing.

66.27.7.1 Initial Testing. Unless tested in accordance with the applicable sections of ASME B31, *Code for Pressure Piping*, all piping shall be tested before being covered, enclosed, or placed in use. [**30:**27.7.1]

66.27.7.1.1 Testing shall be done hydrostatically to 150 percent of the maximum anticipated pressure of the system or pneumatically to 110 percent of the maximum anticipated pressure of the system, and the test pressure shall be maintained while a complete visual inspection of all joints and connections is conducted. [**30:**27.7.1.1]

66.27.7.1.2 In no case shall the test pressure be less than a gauge pressure of 5 psi (35 kPa) measured at the highest point of the system, and in no case shall the test pressure be maintained for less than 10 minutes. [**30:**27.7.1.2]

66.27.7.2 Initial Testing of Secondary Containment Piping. The interstitial space of secondary containment–type piping shall be tested hydrostatically or with air pressure at a gauge pressure of 5 psi (35 kPa) or shall be tested in accordance with its listing or with the manufacturer's instructions. [**30:**27.7.2]

66.27.7.2.1 The pressure source shall be disconnected from the interstitial space to ensure that the test is being conducted on a closed system. [**30:**27.7.2.1]

66.27.7.2.2 The pressure shall be maintained for a minimum of 1 hour. [**30:**27.7.2.2]

66.27.7.3 Testing During Maintenance. Existing piping shall be tested in accordance with this subsection if the piping is leaking. [**30:**27.7.3]

66.27.7.3.1 Piping that could contain a Class I, Class II, or Class IIIA liquid or vapor shall not be tested using air. [**30:**27.7.3.1]

66.27.8 Vent Piping. Vent piping shall be designed, constructed, and installed in accordance with this section. [**30:**27.8]

66.27.8.1 Vent Piping for Aboveground Storage Tanks.

The provisions of 66.27.8.1 through 66.27.8.1.6 are intended to ensure that flammable vapors are discharged high enough above grade level and far enough away from openings into buildings that they dissipate before being able to accumulate where they might be ignited. Remember that these provisions apply only to fire and explosion hazards. The vent termination locations permitted here might not be suitable if the vapors are also toxic, irritating, or corrosive or have an objectionable odor.

The 5 ft (1.5 m) separation from building openings and the 12 ft (3.6 m) elevation above ground level are based on an engineering estimate of the distance from the end of a vent pipe that an ignitible concentration of vapors can exist. If the hazard extends 5 ft (1.5 m) down, its edge is 12 minus 5, or 7 ft (2 m), above grade, so that ignition is not considered a likely event by any action of a person on the ground.

The size of the hazardous volume can be estimated by taking the case of hexane, as described in the following example.

Example

Consider hexane, whose LFL is about 1.1 percent by volume. For simplicity, use 1 percent. A sphere of 5 ft (1.5 m) radius has a volume of 524 ft^3 (14.8 m^3). If the LFL is 1 percent, then, for a sphere of 5 ft radius to enclose an atmosphere at the LFL requires 5.24 ft^3 (0.15 m^3) of pure hexane vapor. At 60°F (15.6°C), hexane has a vapor pressure of 100 mm of mercury (13.3 kPa), so the vapors discharging from the vent would be 100/760, or 13 percent hexane — too rich to burn. These vapors would produce 5.236/0.13, or 40 ft^3 (1.13 m^3) of vapor, more than enough to fill the 5 ft (1.5 m) sphere with a mixture at the LFL. Assume that the vapor is discharged into air moving at 1 mph, or 88 ft/min (1609 m/sec). (At that speed, the leaves on trees do not move and smoke goes straight up.) The vapors would be diluted out of the hazardous range long before they filled a 5 ft (1.5 m) radius sphere. The conclusion is that the 5 ft (1.5 m) rule gives ample protection.

When vent piping is modified by the addition of items such as devices to absorb or adsorb unwanted components from the stream being vented, the devices should not unduly restrict the flow of vapors. Also, the piping should not be modified in such a way that liquid collecting in low points could either permit the tank to be overpressurized or start a siphoning action that could implode the tank.

66.27.8.1.1 Where the outlets of vent pipes for tanks storing Class I liquids are adjacent to buildings or public ways, they shall be located so that vapors are released at a safe point outside of buildings and not less than 12 ft (3.6 m) above the adjacent ground level. [**30:**27.8.1.1]

66.27.8.1.2 Vapors shall be discharged upward or horizontally away from adjacent walls. [**30:**27.8.1.2]

66.27.8.1.3 Vent outlets shall be located so that vapors will not be trapped by eaves or other obstructions and shall be at least 5 ft (1.5 m) from building openings and at least 15 ft (4.5 m) from powered ventilation air intake devices. [**30:**27.8.1.3]

66.27.8.1.4 Manifolding of vent piping shall be prohibited except where required for special purposes such as vapor recovery, vapor conservation, or air pollution control. [**30:**27.8.1.4]

From a fire safety standpoint, manifolding of vent piping is discouraged because it creates a potential explosion hazard. The entire vent system might, at some time, contain a vapor-air mixture within the flammable range and thus allow a direct path for flame to travel from the vapor space of one tank to that of others, if the vapors were to be ignited. Listed flame arresters that are designed to prevent flame propagation through piping must be installed within a specified distance from the open end of the pipe. The listing is based on ignition at the open end, where the pressure is initially atmospheric.

In the piping systems considered here, ignition occurring in one of the tanks can also propagate toward the open end. So-called flame-checks used in piping that feeds premixed air-gas mixtures to burners are usually of small diameter and can prevent propagation in only one direction. In a vent system, flame propagation can proceed in *both* directions, and so the flame arrester must be able to function bidirectionally.

66.27.8.1.4.1 Where vent piping is manifolded, pipe sizes shall be capable of discharging, within the pressure limitations of the system, the vapors they are required to handle when all manifolded tanks are subject to the same fire exposure. [**30:**27.8.1.4.1]

66.27.8.1.5 Vent piping for tanks storing Class I liquids shall not be manifolded with vent piping for tanks storing Class II or Class III liquids unless positive means are provided to prevent the following:

(1) Vapors of Class I liquids from entering tanks storing Class II or Class III liquids
(2) Contamination
(3) Possible change in classification of the less volatile liquid

[**30:**27.8.1.5]

66.27.8.1.6* Extension of Emergency Vent Piping. Piping to or from approved emergency vent devices for atmospheric and low-pressure tanks shall be sized to provide emergency vent flows that limit the back pressure to less than the maximum pressure permitted by the design of the tank. Piping to or from approved emergency vent devices for pressure vessels shall be sized in accordance with the ASME *Boiler and Pressure Vessel Code*. [**30:**27.8.1.6]

A.66.27.8.1.6 Vent sizing formulae and prescriptive vent sizes, such as those established by ANSI/UL 142, *Standard for Steel*

Aboveground Tanks for Flammable and Combustible Liquids, are typically based on the direct installation of a venting device onto a tank. When the outlet of a vent must be extended to a remote location, such as for tanks located in buildings, which require vent discharges, to be located outside, a significant reduction in vent flow can occur unless the size of the vent and connecting piping is increased. In such cases, the size of vents and vent pipe extensions should be calculated to ensure that a tank will not be overpressurized during a fire exposure. [**30:**A.27.8.1.6]

The text of A.66.27.8.1.6 is self-explanatory, but the increasing use of emergency generators powered by diesel engine prime movers has resulted in more instances in which tank vent piping is extended from a basement-level fuel storage tank up through all floors of the building to the roof. Providing the tank with automatic shutdown of delivery needs to be considered so that fuel is not inadvertently backed up into the vent line, which could subject the tank to a static pressure for which it might not be designed.

66.27.8.2 Vent Piping for Underground Tanks.

The treatment of vents for underground tanks differs slightly from that for aboveground tanks for several reasons:

- Buried tanks are of the horizontal cylindrical type (except on rare occasions).
- Buried tanks cannot be seen when being filled or emptied.
- The contents of buried tanks are never heated by the sun or severely chilled in cold weather.

66.27.8.2.1* Vent pipes from underground tanks storing Class I liquids shall be located so that the discharge point is outside of buildings, higher than the fill pipe opening, and not less than 12 ft (3.6 m) above the adjacent ground level. [**30:**27.8.2.1]

A.66.27.8.2.1 API RP 500, *Recommended Practice for Classification of Locations for Electrical Installations at Petroleum Facilities Classified as Class I, Division 1 and Division 2,* and API RP 505, *Recommended Practice for Classification of Locations for Electrical Installations at Petroleum Facilities Classified as Class I, Zone 0, Zone 1, and Zone 2,* establish a 10 ft (3 m) classified zone around most tank vents that are potential sources of ignitible vapors. However, neither document provides specific distances for a belowgrade tank. Applying these strategies to 66.27.8.2.1 resulted in a minimum height for these tank vents of 10 ft (3 m) above grade. Since the majority of these vents exist at retail service station tanks, and since vehicles and other publicly introduced ignition sources could be located close to the vent, an additional 2 ft (0.6 m) was added to the minimum height as a safety factor to ensure the vehicle does not introduce a potential ignition source into the vapor space surrounding the vent. This results in a total height for the vent stack from a belowgrade tank of 12 ft (3.6 m). [**30:**A.27.8.2.1]

66.27.8.2.2 Vent pipe outlets shall be located and directed so that vapors will not accumulate or travel to an unsafe location, enter building openings, or be trapped under eaves and shall be at least 5 ft (1.5 m) from building openings and at least 15 ft (4.5 m) from powered ventilation air intake devices. [**30:**27.8.2.2]

66.27.8.2.3 Vent pipes shall not be obstructed by devices provided for vapor recovery or other purposes unless the tank and associated piping and equipment are otherwise protected to limit backpressure development to less than the maximum working pressure of the tank and equipment by the provision of pressure-vacuum vents, rupture discs, or other tank-venting devices installed in the tank vent lines. [**30:**27.8.2.3]

66.27.8.2.4 Vent outlets and devices shall be protected to minimize the possibility of blockage from weather, dirt, or insect nests. [**30:**27.8.2.4]

66.27.8.2.5 Vent piping shall be sized in accordance with Table 66.23.6.2. [**30:**27.8.2.5]

66.27.8.2.6 Vent pipes from tanks storing Class II or Class IIIA liquids shall terminate outside of the building and higher than the fill pipe opening. [**30:**27.8.2.6]

By their omission from this paragraph, vents for Class IIIB liquids are allowed to terminate indoors. However, doing so is not considered safe for heated Class IIIB liquids.

66.27.8.2.7 Vent outlets shall be above normal snow level. [**30:**27.8.2.7]

66.27.8.2.8 Vent pipes shall be permitted to be fitted with return bends, coarse screens, or other devices to minimize ingress of foreign material. [**30:**27.8.2.8]

66.27.8.2.9 Vent pipes and vapor return piping shall be installed without sags or traps in which liquid can collect. [**30:**27.8.2.9]

66.27.8.2.10 Condensate tanks, if utilized, shall be installed and maintained so that blocking of the vapor return piping by liquid is prevented. [**30:**27.8.2.10]

66.27.8.2.11 Vent pipes and condensate tanks shall be located so that they will not be subjected to physical damage. The tank end of the vent pipe shall enter the tank through the top. [**30:**27.8.2.11]

66.27.8.2.12 Where tank vent piping is manifolded, pipe sizes shall be such as to discharge, within the pressure limitations of the system, the vapors they could be required to handle when manifolded tanks are filled simultaneously. [**30:**27.8.2.12]

66.27.8.2.12.1 Float-type check valves installed in tank openings connected to manifolded vent piping to prevent product contamination shall be permitted to be used, provided that the tank pressure will not exceed that permitted by 23.5.3.2 of NFPA 30 when the valves close. [**30:**27.8.2.12.1]

66.27.8.2.13 Vent piping for tanks storing Class I liquids shall not be manifolded with vent piping for tanks storing Class II or Class III liquids unless positive means are provided to prevent the following:

(1) Vapors of Class I liquids from entering tanks storing Class II or Class III liquids
(2) Contamination
(3) Possible change in classification of the less volatile liquid

[**30:**27.8.2.13]

66.27.9 Bonding and Grounding. Piping systems shall be bonded and grounded in accordance with 66.6.5.4. [**30:**27.9]

66.27.10* Identification and Marking of Piping Systems. Each loading and unloading riser shall be marked to identify the product for which it is to be used. [**30:**27.10]

A.66.27.10 Where loading and unloading risers for Class II or Class IIIA liquids are located in the same immediate area as loading and unloading risers for Class I liquids, consideration should be given to providing positive means, such as different pipe sizes, connection devices, special locks, or other methods designed to prevent the erroneous transfer of Class I liquids into or from any container or tank used for Class II or Class IIIA liquids. Note that such consideration might not be necessary for water-miscible liquids, where the class is determined by the concentration of liquid in water, or where the equipment is cleaned between transfers. [**30:**A.27.10]

66.27.11 Special Requirements for Marine Piping Systems.

66.27.11.1 Where piping is from a floating structure or pier, an approved flexible connector shall be permitted between the fixed shore piping and the piping on the floating structure or pier and between separate sections of the floating structure to accommodate changes in water level. [**30:**27.11.1]

Ensuring adequate flexibility of piping on and between floating structures is important. In such installations, failure of piping can release liquid that, if ignited, could result in a serious fire. The spread of burning liquid on water is likely to endanger all the wharf piping, since much of it is frequently installed beneath the wharf surface to provide clear space for handling of dry cargo. In addition, the wharf structure would not be able to withstand the effects of a prolonged fire in most instances.

66.27.11.2 The interior of the flexible connectors shall be compatible with the liquid handled. [**30:**27.11.2]

66.27.11.3 The exterior of the flexible connectors shall be resistant to or shielded from salt water and fresh water, ultraviolet radiation, physical damage, and damage by fire. [**30:**27.11.3]

66.27.11.4 The flexible connectors shall be suitable for the intended pressures and shall be tested in accordance with 66.27.7. [**30:**27.11.4]

66.27.12 Removal from Service of Piping Systems. Piping systems taken out of service or abandoned shall be temporarily or permanently closed in accordance with 66.27.12. [**30:**27.12]

66.27.12.1 Temporary Closure. (Reserved)

66.27.12.2 Permanent Closure in Place. (Reserved)

66.27.12.3 Permanent Removal. (Reserved)

66.28 Bulk Loading and Unloading Facilities for Tank Cars and Tank Vehicles

66.28.1 Scope. This section shall apply to operations involving the loading or unloading of tank cars and tank vehicles. [**30:**28.1]

66.28.2 Reserved.

66.28.3 General Requirements.

66.28.3.1 Bonding and Grounding and Stray Currents.

66.28.3.1.1 Bonding for the control of static electricity shall not be required where the following conditions exist:

(1) Where tank cars and tank vehicles are loaded exclusively with products that do not have static-accumulating properties, such as asphalts (including cutback asphalts), most crude oils, residual oils, and water-soluble liquids
(2) Where no Class I liquids are handled at the loading facility and where the tank cars and tank vehicles loaded are used exclusively for Class II and Class III liquids at temperatures below their flash points
(3) Where tank cars and tank vehicles are loaded or unloaded through closed connections

[**30:**28.3.1.1]

66.28.3.1.2* Loading and unloading facilities that are used to load liquids into tank vehicles through open domes shall be provided with a means for electrically bonding to protect against static electricity hazards. [**30:**28.3.1.2]

A.66.28.3.1.2 The use of nonconductive materials in the fill pipe assembly should be avoided to prevent any electrical discontinuity in the piping of the system. Serious accidents have occurred when nonconductive materials, such as plastic or rubber hose, have been used in the fill pipe assembly. [**30:**A.28.3.1.2]

Filling tank vehicles at high flow rates through open domes has always presented a risk of ignition by static discharge, and the requirement in 66.28.3.1.2 is an attempt to minimize the problem. Bonding the vehicle to the fill line ensures that it and the dome opening are at equal potential and minimizes the chance for static discharge between the two. Normally, either the vehicle or the fill line (or both) are grounded so that static charge can be bled off to earth. In practice, bonding should be required during all top-loading and top-unloading operations, because the operator usually has no knowledge about previous cargoes. For additional information, see NFPA 77 and API 2003.

The bonding methods specified are usually effective in preventing the buildup of a static charge. As noted in 66.28.3.1.1, liquids that inherently do not accumulate a charge do not require bonding. Understand, however, that bonding will not totally eliminate the problem inside the tank, because the charge residing on the surface of the liquid will not be bled off to the tank shell. (On rare occasions, nonconductive liquids might accumulate enough charge to lead to nonincendive corona discharge.) When the liquid being loaded has a low conductivity, charge generation is reduced by discharging the liquid close to the bottom of the tank.

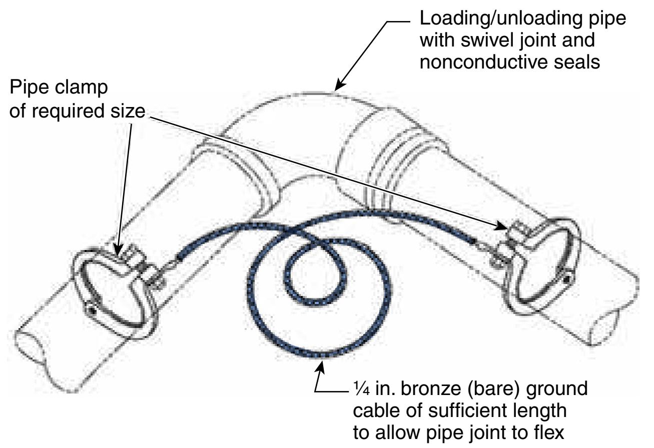
66.28.3.1.2.1 Such means shall consist of a metallic bond wire that is permanently electrically connected to the fill pipe assembly or to some part of the rack structure that is in electrical contact with the fill pipe assembly. [**30:**28.3.1.2.1]

66.28.3.1.2.2 The free end of this wire shall be provided with a clamp or an equivalent device for convenient attachment to some metallic part that is in electrical contact with the cargo tank of the tank vehicle. [**30:**28.3.1.2.2]

66.28.3.1.2.3 All parts of the fill pipe assembly, including, but not limited to, the drop tube, rack structure and piping, shall form a continuous electrically conductive path that is directed to ground through the rack assembly or by conductive wiring. [**30:**28.3.1.2.3]

Where gaskets and seals in movable parts of the loading/unloading system might interfere with the ground path, jumper wires might have to be installed to ensure continuity. See Exhibit 66.62 for an example of the use of bonding jumpers around seals.

Exhibit 66.62



Use of jumper wires to ensure continuity around a gasketed swivel joint. (Source: ACA, Generation and Control of Static Electricity)

66.28.3.1.3 Loading and unloading facilities that are used to transfer liquids into and from tank cars through open domes shall be protected against stray currents by permanently bonding the fill pipe to at least one rail and to the facility structure, if of metal. [**30:**28.3.1.3]

Stray currents can result where there is a major defect in an electrical installation in the area of the loading or unloading facility. If the defect can be identified, it should be corrected. Permanent rail-to-pipe rack bonding should always be provided. If stray currents cannot be controlled, the best practice is to electrically isolate the piping at the loading rack from its supply lines and bond that piping to the rail adjacent to the rack. Temporary bonding during loading and unloading operations is likely to be inadequate and should not be used.

Stray currents are not a problem with tank vehicles, because the rubber tires afford adequate insulation.

66.28.3.1.3.1 Multiple pipelines that enter the area shall be permanently bonded together. [**30:**28.3.1.3.1]

66.28.3.1.3.2 In areas where excessive stray currents are known to exist, all pipelines entering the area shall be provided with insulating sections to electrically isolate them from the facility piping.

*Exception: These precautions need not be required where only Class II or Class III liquids, at temperatures below their flash points, are handled and where there is no probability that tank cars will contain vapors from previous cargoes of Class I liquids. [**30:**28.3.1.3.2]*

66.28.4 Location of Loading and Unloading Facilities.

66.28.4.1 Tank vehicle and tank car loading and unloading facilities shall be separated from aboveground tanks, warehouses, other plant buildings, or the nearest line of adjoining property that can be built upon by a distance of at least 25 ft (7.6 m) for Class I liquids and for Class II and Class III liquids handled at temperatures at or above their flash points and at least 15 ft (4.6 m) for Class II and Class III liquids handled at temperatures below their flash points, measured from the nearest fill spout or transfer connection. [**30:**28.4.1]

66.28.4.2* These distances shall be permitted to be reduced if there is suitable protection for exposures. [**30:**28.4.2]

A.66.28.4.2 Use of fixed fire protection systems, dikes, fire-rated barriers, or a combination of any of these can provide suitable protection from exposures. [**30:**A.28.4.2]

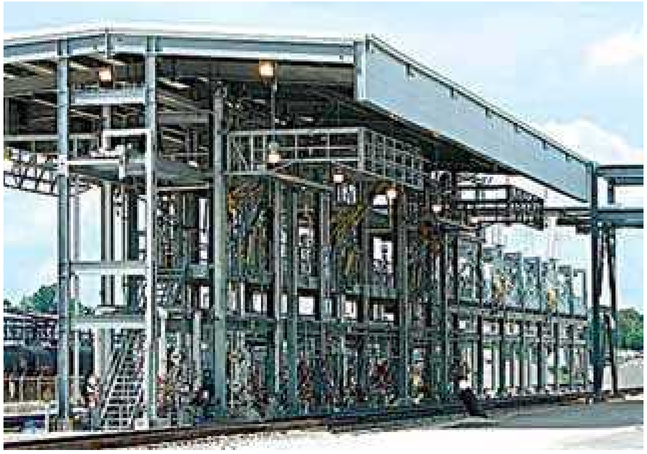
A loading/unloading station would be considered an "important building" or important structure within the context of NFPA 30. Therefore, the separation distances specified in 66.28.4.1 take precedence over those specified in Tables 66.22.4.1.3, 66.22.4.1.5, and 66.22.4.1.6 that relate to separation between a tank and the nearest important building, but only where the separation distances in those tables are less than what is required by 66.28.4.1. If the tables in Section 66.22 call for separation that exceeds those in 66.28.4.1, the greater distances apply. The reason for the separation specified by 66.28.4.1 is to increase the chance of controlling a fire originating at a tank vehicle before it spreads to nearby tanks or buildings. The specified distances reflect the fact that there is increased possibility of a spill, due to the making and breaking of connections between the fixed piping and the tank vehicles.

Paragraph 66.28.4.2 uses the term *protection for exposures*. Fixed fire protection as indicated here might meet the requirement of protection for exposures, provided that either the exposure protection systems are automatically activated or plant personnel are trained and available to put the systems into service. The AHJ can determine whether fixed fire protection justifies a reduced separation distance.

66.28.4.3 Buildings for pumps or shelters for personnel shall be permitted to be a part of the facility. [**30:**28.4.3]

66.28.5 Roofed Structures. A loading or unloading facility that has a canopy or roof that does not limit the dissipation of heat or dispersion of flammable vapors and does not restrict firefighting access and control shall be treated as an outdoor facility. [**30:**28.5]

Exhibit 66.63



Loading rack protected with a canopy. (Courtesy of Carbis, Inc.)

See Exhibit 66.63 for an example of a canopy at a loading facility.

66.28.6 Reserved.

66.28.7 Reserved.

66.28.8 Reserved.

66.28.9* Containment, Drainage, and Spill Control. Loading and unloading facilities shall be provided with drainage systems or other means to contain spills. [**30:**28.9]

A.66.28.9 The intent of this requirement is to prevent the spread of uncontrolled, spilled liquid from traveling beyond the loading or unloading area and exposing surrounding equipment and buildings. [**30:**A.28.9]

Exhibit 66.64 shows a rail tank car loading/unloading position being retrofitted with spill retention capability.

66.28.10 Equipment.

66.28.10.1 Equipment such as piping, pumps, and meters used for the transfer of Class I liquids between storage tanks and the fill stem of the loading facility shall not be used for the transfer of Class II or Class III liquids unless one of the following conditions exists:

(1) Only water-miscible liquid mixtures are handled, and the class of the mixture is determined by the concentration of liquid in water.
(2) The equipment is cleaned between transfers.

[**30:**28.10.1]

66.28.10.2 Remote pumps located in underground tanks shall have a listed leak detection device installed on the pump discharge side that will indicate if the piping system is not essentially liquid-tight. [**30:**28.10.2]

66.28.10.2.1 This device shall be checked and tested at least annually according to the manufacturer's specifications to ensure proper installation and operation. [**30:**28.10.2.1]

Exhibit 66.64

Rail tank car loading/unloading position being retrofitted with spill retention capability. (Courtesy of UltraTech International, Inc.)

66.28.11 Operating Requirements.

66.28.11.1 Loading and Unloading of Tank Vehicles.

66.28.11.1.1 Liquids shall be loaded only into cargo tanks whose material of construction is compatible with the chemical characteristics of the liquid. The liquid being loaded shall also be chemically compatible with the liquid hauled on the previous load unless the cargo tank has been cleaned. [**30:**28.11.1.1]

Two different hazards are addressed here. First, it is imperative that the liquid and the material of construction of the cargo tank itself or of the tank liner, if the cargo tank is lined, be mutually compatible to prevent damage to the cargo tank. Second, the presence of an incompatible residue in the cargo tank from a previous load means that an unwanted chemical reaction could develop between the residue and the new load. Such a reaction might involve the development of gases and might not become apparent until the cargo tank is closed, leading to possible overpressure damage.

66.28.11.1.2 Before loading tank vehicles through open domes, a bonding connection shall be made to the vehicle or tank before dome covers are raised and shall remain in place until filling is completed and all dome covers have been closed and secured, unless one of the conditions of 66.28.3.1 exists. [**30:**28.11.1.2]

See Exhibit 66.65 for a bonding connection being made to a tank vehicle.

66.28.11.1.3 When transferring Class I liquids, or Class II or Class III liquids at temperatures at or above their flash points, engines of tank vehicles or motors of auxiliary or portable pumps shall be shut down during the making and breaking of hose connections. [**30:**28.11.1.3]

Exhibit 66.65

Bonding cable attached to a tank vehicle prior to loading cargo. (Courtesy of Newson Gale Inc.)

Any engine represents a potential ignition source. Making and breaking hose connections usually results in the release of a small quantity of liquid or vapor. The intent here is to control the ignition source, given the inevitable presence of small liquid or vapor releases.

66.28.11.1.4 If loading or unloading is done without requiring the use of the motor of the tank vehicle, the motor shall be shut down throughout any transfer operations involving Class I liquids. [**30:**28.11.1.4]

66.28.11.1.5* Filling through open domes into tank vehicles that contain vapor–air mixtures within the flammable range or where the liquid being filled can form such a mixture shall be by means of a downspout that extends to within 6 in. (150 mm) of the bottom of the tank unless the liquid is not an accumulator of static electric charges. [**30:**28.11.1.5]

Δ **A.66.28.11.1.5** NFPA 77 provides additional information on static electricity protection. [**30:**A.28.11.1.5]

66.28.11.1.6 When top loading a tank vehicle with Class I or Class II liquids without a vapor control system, valves used for the final control of flow shall be of the self-closing type and shall be manually held open except where automatic means are provided for shutting off the flow when the vehicle is full. [**30:**28.11.1.6]

66.28.11.1.6.1 Automatic shutoff systems shall be provided with a manual shutoff valve located at a safe distance from the loading nozzle to stop the flow if the automatic system fails. [**30:**28.11.1.6.1]

66.28.11.1.6.2 When top loading a tank vehicle with vapor control, flow control shall be in accordance with 66.28.11.1.8 and 66.28.11.1.9. [**30:**28.11.1.6.2]

66.28.11.1.7 When bottom loading a tank vehicle, a positive means shall be provided for loading a predetermined quantity of liquid, together with a secondary automatic shutoff control to prevent overfill. [**30:**28.11.1.7]

66.28.11.1.7.1 The connecting components between the loading rack and the tank vehicle that are required to operate the secondary control shall be functionally compatible. [**30:**28.11.1.7.1]

66.28.11.1.7.2 The connection between the liquid loading hose or pipe and the tank vehicle piping shall be by means of a dry disconnect coupling. [**30:**28.11.1.7.2]

The requirements in 66.28.11.1.7 and its subparagraphs are intended to provide safeguards against overfilling of tank vehicles. When the practice of top loading prevailed and an operator was required to be on the top of the tank to observe the fill mark, a manually operated valve was an acceptable safeguard. With the advent of bottom-loading practices, it became unnecessary for the operator to be on the top of the tank, but other safeguards were required. The usual solution has been to employ a preset delivery meter that automatically stops the flow of liquid when a preset quantity has been delivered to the tank. Because this meter is not completely adequate, the additional requirement for a second automatic shutoff device (electrical or otherwise) to stop the flow of liquid when the tank is full has been deemed necessary. Such dual shutoff systems are considered adequate where vapor recovery is employed, so that it is unnecessary to open the top openings of the tank during filling.

The purpose of a dry disconnect coupling as required in 66.28.11.1.7.2 is to eliminate spills when the fill hose is disconnected from the vehicle.

66.28.11.1.8 When bottom loading a tank vehicle that is equipped for vapor control, but when vapor control is not used, the tank shall be vented to the atmosphere, at a height not lower than the top of the cargo tank of the vehicle, to prevent pressurization of the tank. [**30:**28.11.1.8]

The intent of this requirement is that vapor be released only where there is a reasonable chance for dissipation. Vapor return connections are frequently at about the same level as liquid connections. If vapor return is not being used, means must be provided to limit vapor release near ground level and to release the vapor at least as high as the top of the tank or to pipe the vapor to a safe remote location.

66.28.11.1.8.1 Connections to the facility's vapor control system shall be designed to prevent the escape of vapor to the atmosphere when the system is not connected to a tank vehicle. [**30:**28.11.1.8.1]

66.28.11.1.9 When bottom loading is used, reduced flow rates (until the fill opening is submerged), splash deflectors, or other devices shall be used to prevent splashing and to minimize turbulence. [**30:**28.11.1.9]

This requirement is intended to minimize the development of static electric charges that can be generated by splash filling. Such charges can reside in the bulk of the liquid or can be present in the liquid droplets in the vapor space.

66.28.11.1.10 Metal or conductive objects, such as gauge tapes, sample containers, and thermometers, shall not be lowered into or suspended in a compartment while the compartment is being filled or immediately after cessation of pumping, in order to permit the relaxation of charge. [**30:**28.11.1.10]

Any ungrounded conductive object that is lowered into the cargo tank will accumulate a static electric charge by inductance, if the charge in the liquid is not allowed to relax or to bleed off to ground. As the object is withdrawn from the cargo tank, the accumulated charge might discharge to ground via proximity to or contact with the dome — therefore, the requirement for the relaxation period exists. Even after the relaxation period, any conductive object lowered into the cargo tank should be bonded to the tank itself.

66.28.11.1.11 Hose materials used for transfer shall be compatible with the liquids being handled. [**30:**28.11.1.11]

66.28.11.2 Loading and Unloading of Tank Cars.

66.28.11.2.1 Liquids shall be loaded only into tank cars whose material of construction is compatible with the chemical characteristics of the liquid. The liquid being loaded shall also be chemically compatible with the liquid hauled on the previous load unless the tank car has been cleaned. [**30:**28.11.2.1]

66.28.11.2.2* Filling through open domes into tank cars that contain vapor–air mixtures within the flammable range, or where the liquid being filled can form such a mixture, shall be by means of a downspout that extends to within 6 in. (150 mm) of the bottom of the tank unless the liquid is not an accumulator of static electric charges. [**30:**28.11.2.2]

A.66.28.11.2.2 NFPA 77 provides additional information on static electricity protection. [**30:**A.28.11.2.2]

66.28.11.2.3 When bottom loading is used, reduced flow rates (until the fill opening is submerged), splash deflectors, or other devices shall be used to prevent splashing and to minimize turbulence. [**30:**28.11.2.3]

66.28.11.2.4 Metal or conductive objects, such as gauge tapes, sample containers, and thermometers, shall not be lowered into or suspended in a compartment while the compartment is being filled or immediately after cessation of pumping, in order to permit the relaxation of charge. [**30:**28.11.2.4]

66.28.11.2.5 Hose materials used for transfer shall be compatible with the liquids being handled. [**30:**28.11.2.5]

66.28.11.3* Switch Loading. To prevent hazards due to a change in flash point of liquids, any tank car or tank vehicle that has previously contained a Class I liquid shall not be loaded with a Class II or Class III liquid unless proper precautions are taken. [**30:**28.11.3]

Δ **A.66.28.11.3** The term *switch loading* describes a situation that warrants special consideration. [**30:**A.28.11.3]

When a tank is emptied of a cargo of Class I liquid, a mixture of vapor and air is left, which can be, and often is, within the flammable range. When such a tank is refilled with a Class I liquid, any charge that reaches the tank shell will be bled off by the required bond wire. Also, there will be no flammable mixture at the surface of the rising oil level because the Class I liquid produces at its surface a mixture too rich to be ignitible. This is the situation commonly existing in tank vehicles in gasoline service. If, as occasionally happens, a static charge does accumulate on the surface sufficient to produce a spark, it occurs in a too-rich, nonignitible atmosphere and thus causes no harm. [**30:**A.28.11.3]

A very different situation arises if the liquid is "switch loaded," that is, when a Class II or Class III liquid is loaded into a tank vehicle that previously contained a Class I liquid. [**30:**A.28.11.3]

Class II or Class III liquids are not necessarily more potent static generators than the Class I liquid previously loaded, but the atmosphere in contact with the rising oil surface is not enriched to bring it out of the flammable range. If circumstances are such that a spark should occur either across the oil surface or from the oil surface to some other object, the spark occurs in a mixture that can be within the flammable range, and an explosion can result. [**30:**A.28.11.3]

It is emphasized that bonding the tank to the fill stem is not sufficient; a majority of the recorded explosions have occurred when it was believed the tank had been adequately bonded. The electrostatic potential that is responsible for the spark exists inside the tank on the surface of the liquid and cannot be removed by bonding. Measures to reduce the chance of such internal static ignition can be one or more of the following:

(1) Avoid spark promoters. Conductive objects floating on the oil surface increase the charge of sparking to the tank wall. Metal gauge rods or other objects projecting into the vapor space can create a spark gap as the rising liquid level approaches the projection. A common precaution is to require that fill pipes (downspouts) reach as close to the bottom of the tank as practicable. Any operation such as sampling, taking oil temperature, or gauging that involves lowering a conductive object through an opening into the vapor space on the oil should be deferred until at least 1 minute after flow has ceased. This will permit any surface charge to relax.
(2) Reduce the static generation by one or more of the following:
    (a) Avoid splash filling and upward spraying of oil where bottom filling is used.
    (b) Employ reduced fill rates at the start of filling through downspouts, until the end of the spout is submerged. Some consider 3 ft/sec (0.9 m/sec) to be a suitable precaution.
    (c) Where filters are employed, provide relaxation time in the piping downstream from the filters. A relation time of 30 seconds is considered by some to be a suitable precaution.
(3) Eliminate the flammable mixture before switch loadings by gas freeing or inerting.

[**30:**A.28.11.3]

See NFPA 77 and NFPA 385 for further information. [**30:**A.28.11.3]

66.28.11.4 The person responsible for loading or unloading shall remain in attendance during the operation or be able to locally or remotely monitor and control the operation for the duration of the operation. [**30:**28.11.4]

Exception: A responsible person shall not be required where a hazards analysis shows that the loading or unloading operation can be safely shut down in an emergency. [30:28.11.4]

66.28.11.4.1* The responsible person shall be trained to recognize unsafe conditions and take appropriate actions. [**30:**28.11.4.1]

A.66.28.11.4.1 Emergency and safety procedures include, but are not limited to, the following:

(1) Procedures for bonding and grounding the tank vehicle
(2) Proper use of portable extinguishers
(3) Procedures for recognizing and eliminating sources of ignition
(4) Procedures for recognizing and understanding contingency plans for handling a spill or leak
(5) Procedures for notifying the appropriate agencies in an emergency

[**30:**A.28.11.4.1]

66.29 Wharves

66.29.1 Scope.

66.29.1.1 This section shall apply to all wharves, as defined in 3.3.288, whose primary purpose is the bulk transfer of liquids. [**30:**29.1.1]

Δ **66.29.1.2** This section shall not apply to the following:

(1) Marine service stations, as covered in Chapter 30 and NFPA 30A
(2) Marinas and boatyards, as covered in Chapter 28 and NFPA 303
(3) Wharves that handle liquefied petroleum gas, as covered in Chapter 69 and NFPA 58, *Liquefied Petroleum Gas Code*, or liquefied natural gas, as covered in NFPA 59A

[**30:**29.1.2]

66.29.2 Reserved.

66.29.3 General Requirements.

Δ **66.29.3.1** General-purpose wharves that handle bulk transfer of liquids and other commodities shall meet the requirements of Section 28.2 and NFPA 307. [**30:**29.3.1]

By "general-purpose wharves," the *Code* means wharves or piers that handle commodities other than flammable and combustible liquids, as opposed to those that handle liquids only.

66.29.3.2 Incidental handling of packaged cargo of liquids and loading or unloading of general cargo, such as ships' stores, during transfer of liquids shall be conducted only when approved by the wharf supervisor and the senior officer of the vessel. [**30:**29.3.2]

The handling of packaged cargo and stores during transfer of liquid cargo does not constitute an unreasonable risk, if the activity is confined to areas remote from the liquids loading connection. It is the joint responsibility of the ship's officers and the wharf representatives to prescribe times and places for such transfers to be safely carried out.

66.29.3.3 Wharves at which liquid cargoes are to be transferred in bulk to or from tank vessels shall be at least 100 ft (30 m) from any bridge over a navigable waterway or from any entrance to or superstructure of a vehicular or railroad tunnel under a waterway. [**30:**29.3.3]

This provision recognizes the possibility that a spill or other accident during the loading or unloading of liquid cargoes would represent a potentially severe threat to a bridge or the entrance to or superstructure of a tunnel. The exposure to fire of the structure of a tunnel beneath the waterway, although addressed, would be greatly reduced.

66.29.3.4 The termination of the loading or unloading fixed piping shall be at least 200 ft (60 m) from any bridge or from any entrance to or superstructure of a tunnel. [**30:**29.3.4]

66.29.3.5 The substructure and deck of the wharf shall be designed for the use intended. [**30:**29.3.5]

66.29.3.6 The deck of the wharf shall be permitted to be of any material that will afford the desired combination of flexibility, resistance to shock, durability, strength, and fire resistance. [**30:**29.3.6]

66.29.3.7 Heavy timber construction shall be permitted. [**30:**29.3.7]

66.29.3.8 Tanks used exclusively for ballast water or Class II or Class III liquids stored at temperatures below their flash points shall be permitted to be installed on a wharf designed to support the weight of the tank and its contents. [**30:**29.3.8]

The installation of tanks for Class II and Class III liquids stored at temperatures below their flash points is permitted on structurally sound wharves because of the reduced fire risk with these liquids. Ballast water tanks can be installed on the wharves for the same reason, although it is obvious that the problem of supporting large tanks will usually dictate that they be installed on shore.

66.29.3.9 Loading pumps capable of building up pressures that exceed the safe working pressure of cargo hose or loading arms shall be provided with bypasses, relief valves, or other arrangements to protect the loading facilities against excessive pressure. [**30:**29.3.9]

66.29.3.9.1 Relief devices shall be tested at least annually to determine that they function satisfactorily at their set pressure. [**30:**29.3.9.1]

66.29.3.10 All pressure hose and couplings shall be inspected at intervals recommended by the manufacturer for the service in which they are used. [**30:**29.3.10]

66.29.3.10.1 With the hose extended, the hose and couplings shall be tested using the in-service maximum operating pressure. [**30:**29.3.10.1]

66.29.3.10.2 Any hose showing material deterioration, signs of leakage, or weakness in its carcass or at the couplings shall be withdrawn from service and repaired or discarded. [**30:**29.3.10.2]

66.29.3.10.3 The hose materials used for transfer shall be compatible with the liquids being handled. [**30:**29.3.10.3]

66.29.3.11 Piping, valves, and fittings shall meet applicable requirements of Section 66.27 and shall also meet the following requirements:

(1) Flexibility of piping shall be assured by layout and arrangement of piping supports so that motion of the wharf structure resulting from wave action, currents, tides, or the mooring of vessels will not subject the piping to excessive strain.

Ensuring an appropriate degree of flexibility in piping systems on wharves is important because a wharf structure might be subject to movement from the impact of vessels during mooring and from the action of wind, waves, and tides. Failure of piping under those circumstances could release liquid that, if ignited, might result in a serious fire. The spread of burning liquid on water is likely to endanger all the piping, because much of the piping is frequently installed beneath the wharf surface to provide clear space for handling of dry cargo. In addition, the wharf structure will not be able to withstand the effects of a prolonged fire in most instances.

(2) Pipe joints that depend on the friction characteristics of combustible materials or on the grooving of pipe ends for mechanical continuity of piping shall not be permitted.
(3) Swivel joints shall be permitted to be used in piping to which hose are connected and for articulated swivel-joint transfer systems, provided the design is such that the mechanical strength of the joint will not be impaired if the packing materials should fail, for example, by exposure to fire.
(4) Each line conveying Class I or Class II liquids leading to a wharf shall be provided with a readily accessible block valve located on shore near the approach to the wharf and outside of any diked area. Where more than one line is involved, the valves shall be identified as to their specific lines and grouped in one location.

The intent here is that pipelines leading to the wharf be equipped with block valves located on shore, so they are accessible for operation even if fire results in burning liquid floating on the water, making it impossible to reach valves located on the wharf itself. In some places, it might be desirable to install additional block valves at points where a group of loading positions are served, as on a T-headed wharf.

(5) Means shall be provided for easy access to any cargo line valves that are located below the wharf deck.

[**30:**29.3.11]

The intent of this requirement is to make it easy to operate valves located below the wharf deck by means of trap doors or similar arrangements, while keeping the wharf surface unobstructed for the passage of motor vehicles. Such trap doors are usually conspicuously painted, and the parking of vehicles or staging of dry cargo over them is forbidden.

66.29.3.12 Pipelines on wharves that handle Class I or Class II liquids, or Class III liquids at temperatures at or above their flash points, shall be bonded and grounded. [**30:**29.3.12]

Wharf pipelines usually have screwed or welded flange connections and are thus electrically continuous, eliminating the need for any special bonding. However, if for any reason nonconductive connections are installed, a survey should be made to determine the desirability of placing electrical bonds around them.

66.29.3.12.1 Insulating flanges or joints shall be installed for protection against stray currents. [**30:**29.3.12.1]

Insulating connections for cargo hose are intended to isolate the vessel from possible stray currents originating on shore. Therefore, bonds around them are obviously undesirable. If the presence of continuous or intermittent stray currents in shore piping is revealed by test, all wharf piping should be electrically isolated from the shore piping with insulating connections.

66.29.3.12.2 Bonding and grounding connections on all pipelines shall be located on the wharf side of insulating flanges, if used, and shall be accessible for inspection. [**30:**29.3.12.2]

66.29.3.12.3 Bonding between the wharf and the vessel shall not be required. [**30:**29.3.12.3]

66.29.3.13 Hose or articulated swivel-joint pipe connections used for cargo transfer shall be capable of accommodating the combined effects of change in draft and change in tide. Hose shall be supported to avoid kinking and damage from chafing. [**30:**29.3.13]

66.29.3.14 Mooring lines shall be kept adjusted to prevent surge of the vessel from placing stress on the cargo transfer system. [**30:**29.3.14]

66.29.3.15 Material shall not be placed on wharves in such a manner as to obstruct access to fire-fighting equipment or important pipeline control valves. [**30:**29.3.15]

66.29.3.16 Where the wharf is accessible to vehicle traffic, an unobstructed roadway to the shore end of the wharf shall be maintained for access of fire-fighting apparatus. [**30:**29.3.16]

66.29.3.17 Loading or unloading shall not commence until the wharf supervisor and the person in charge of the tank vessel agree that the tank vessel is properly moored and all connections are properly made. [**30:**29.3.17]

66.29.3.18 Mechanical work shall not be performed on the wharf during cargo transfer, except under special authorization based on a review of the area involved, methods to be employed, and precautions necessary. [**30:**29.3.18]

66.29.3.19 Sources of ignition shall be controlled during transfer of liquids. [**30:**29.3.19]

66.29.3.20 Vehicular traffic and mechanical work including, but not limited to, welding, grinding, and other hot work, shall not be performed during cargo transfer except as authorized by the wharf supervisor and the senior officer on the vessel. [**30:**29.3.20]

66.29.3.21 Smoking shall be prohibited at all times on the wharf during cargo transfer operations. [**30:**29.3.21]

66.29.3.22 For marine terminals handling flammable liquids and combustible liquids at temperatures at or above their flash points, Figure 66.29.3.22 shall be used to determine the extent of classified areas for the purpose of installation of electrical equipment. [**30:**29.3.22]

66.29.3.23 Where a flammable atmosphere can exist in the vessel cargo compartment, cargo transfer systems shall be designed to limit the velocity of the incoming liquid stream to 3 ft (0.9 m) per second until the compartment inlet opening is sufficiently submerged to prevent splashing. [**30:**29.3.23]

66.29.3.24 Filters, pumps, wire screens, and other devices that can produce static electric charges through turbulence shall be so located to allow a minimum of 30 seconds of relaxation time prior to discharging cargo into the compartment. [**30:**29.3.24]

66.29.3.25* Spill collection shall be provided around manifold areas to prevent spread of liquids to other areas of the wharf or under the wharf. [**30:**29.3.25]

A.66.29.3.25 Where practical, the collection basin should be drained to a remote location. [**30:**A.29.3.25]

66.29.3.26 Vapor seals shall be provided on all drain lines leaving the wharf. [**30:**29.3.26]

66.29.3.27 Where required, wharves shall have a system to isolate and shut down the loading operation in the event of failure of a hose, loading arm, or manifold valve. This system shall meet all of the following requirements:

(1) If the protective system closes a valve on a gravity-fed or pipeline-fed loading system, it shall be designed to ensure the line is not subjected to damage from pressure surges.
(2) Emergency shutdown systems shall be permitted to be automatically or manually activated.

[**30:**29.3.27]

66.29.3.27.1 Manually activated device(s) shall be identified and accessible during an emergency. [**30:**29.3.27.1]

66.29.3.28* Fire protection and emergency response equipment for wharves shall be related to the products being handled, emergency response capability, size, location, frequency of use, and adjacent exposures. [**30:**29.3.28]

A.66.29.3.28 Because of the many variables involved, exact requirements cannot be provided. However, Table A.66.29.3.28 provides guidance on the level of fire protection typically provided at wharves and marine terminals handling flammable liquids. [**30:**A.29.3.28]

66.29.3.28.1 Where a fire water main is provided, the main shall be permitted to be wet or dry. In all cases, isolation valves and fire department connections shall be provided at the wharf-to-shore connection. [**30:**29.3.28.1]

66.29.3.28.2 Where a fire water main is provided, hydrants and monitors shall also be provided so that effective fire water streams

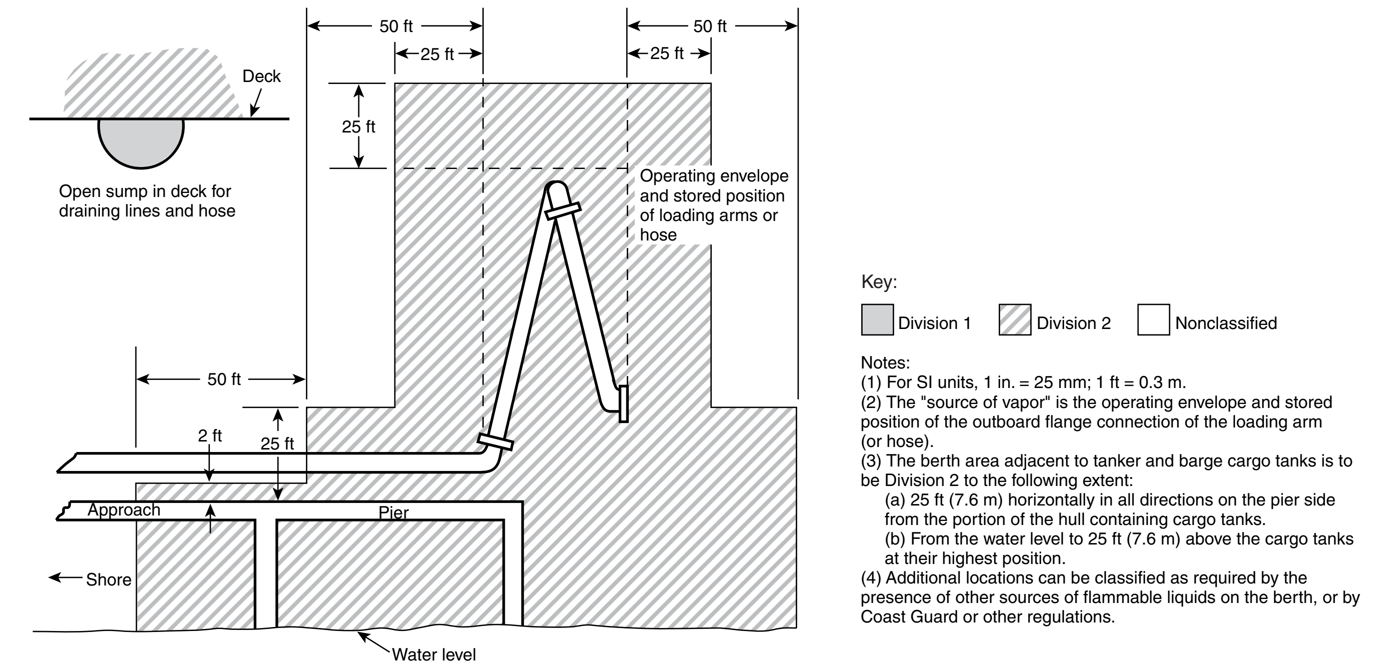


FIGURE 66.29.3.22 *Area Classification for a Marine Terminal Handling Flammable Liquids. [**30:** Figure 29.3.22]*

Δ *TABLE A.66.29.3.28 Typical Fire Protection for Wharves and Marine Terminals*

Locations	Water Demand (gpm)	Hydrant Monitors[a] (gpm)	Hose Reels	Fire Extinguisher Dry Chemical 120-B:C	Fire Extinguisher Dry Chemical 240-B:C Wheeled	International Shore Connection	Emergency Equipment Lockers	Monitors and Hose Foam Concentrate Required (gal)	Fire Boat Connection
Barge terminals	500–1000	Two 500	Two 1¼	2	NR	NR	1	100[b]	NR
Tankers 20,000 DWT and under	1000–2000	Two 500	Two 1¼	2	1	1	1	300[b]	2
20,001–70,000 DWT	2000	Two 1000	Four 1¼[c]	2	2[d]	2	1	2000	2
70,001 DWT and over	2000[e]	Two 1000	Four 1¼[c]	3	2[d]	2	1	2000[f]	2
Sea islands	2000–4000[e]	Three 1000	Four 1¼[c]	4	2	3	2	3000	2

For SI units, 1 gpm = 3.8 L/min; 1 gal = 3.8 L; 1 lb = 0.45 kg.

NR: Not required.

[a]A minimum of two 1½ in. (38 mm) hydrant outlets should be provided at each monitor riser.

[b]This can be provided by onshore mobile equipment.

[c]One hose reel at each berth should have foam capability.

[d]The proximity of adjacent berths can reduce total required.

[e]Under-dock systems are optional. Add water for under-dock system (0.16 × area).

[f]Under-dock systems are optional. Add foam for under-dock system (0.16 × 0.3 × 30 × area). [**30:** Table A.29.3.28]

can be applied to any berth or loading manifold from two directions. [**30:**29.3.28.2]

Δ **66.29.3.28.3** Fire water pumps, fire hose, fire water mains, foam systems, and other fire suppression equipment shall be maintained and tested in accordance with NFPA 25. [**30:**29.3.28.3]

66.29.3.28.4 Where no fire water main is provided, at least two 150 lb (68 kg) dry chemical extinguishers shall be provided. The extinguishers shall be located within 50 ft (15 m) of pump or manifold areas and shall be easily reached along emergency access paths. [**30:**29.3.28.4]

Flammable Solids

67

Flammable solid is defined in 3.3.248.2 as a solid substance, other than a substance defined as a blasting agent or explosive, that is liable to cause fire resulting from friction or retained heat from manufacture, that has an ignition temperature below 212°F (100°C), or that burns so vigorously or persistently when ignited that it creates a serious hazard. For requirements pertaining to the storage, use, and handling of flammable solids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, flammable solids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code.* The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

67.1 General

67.1.1 The storage, use, and handling of flammable solids shall comply with the requirements of Chapter 60.

Δ **67.1.2** The storage, use, and handling of flammable solids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

NFPA 400, *Hazardous Materials Code,* 2016 edition.

68 Highly Toxic and Toxic Solids and Liquids

Toxic material is defined in 3.3.180.14 as a material that produces a lethal dose or lethal concentration that falls within any of the following categories:

1. A chemical or substance that has a median lethal does (LD_{50}) of more than 50 mg/kg but not more than 500 mg/kg of body weight when administered orally to albino rats weighing between 200 g and 300 g each
2. A chemical or substance that has a median lethal dose (LD_{50}) of more than 200 mg/kg but not more than 1000 mg/kg of body weight when administered by continuous contact for 24 hours, or less if death occurs within 24 hours, with the bare skin of albino rabbits weighing between 2 kg and 3 kg each
3. A chemical or substance that has a median lethal concentration (LC_{50}) in air of more than 200 parts per million but not more than 2000 parts per million by volume of gas or vapor, or more than 2 mg/L but not more than 20 mg/L of mist, fume, or dust, when administered by continuous inhalation for 1 hour, or less if death occurs within 1 hour, to albino rats weighing between 200 g and 300 g each

A highly toxic material is defined in 3.3.180.7 as a material that produces a lethal dose or lethal concentration that falls within any of the following categories:

1. A chemical that has a median lethal dose (LD_{50}) of 50 mg/kg or less of body weight when administered orally to albino rats weighing between 200 g and 300 g each
2. A chemical that has a median lethal dose (LD_{50}) of 200 mg/kg or less of body weight when administered by continuous contact for 24 hours, or less if death occurs within 24 hours, with the bare skin of albino rabbits weighing between 2 kg and 3 kg each or albino rats weighing 200 g to 300 g each
3. A chemical that has a median lethal concentration (LC_{50}) in air of 200 parts per million by volume or less of gas or vapor, or 2 mg/L or less of mist, fume, or dust, when administered by continuous inhalation for 1 hour, or less if death occurs within 1 hour, to albino rats weighing between 200 g and 300 g each

For requirements pertaining to the storage, use, and handling of highly toxic solids and liquids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, highly toxic solids and liquids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

68.1 General

68.1.1 The storage, use, and handling of highly toxic and toxic solids and liquids shall comply with Chapter 60.

Δ **68.1.2** The storage, use, and handling of highly toxic and toxic solids and liquids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

Liquefied Petroleum Gases and Liquefied Natural Gases

69

Chapter 69 is based on text extracted from the 2017 edition of NFPA 58, *Liquefied Petroleum Gas Code*. NFPA 58 applies to the storage, handling, transportation, and use of liquefied petroleum gas (LP-Gas). NFPA 58 addresses virtually every aspect of LP-Gas distribution and use, but it does not cover the production of the gas itself.

69.1 General Provisions

69.1.1* Application.

A.69.1.1 See A.1.3.2.

Δ **69.1.1.1** The storage, use, and handling of liquefied petroleum gases (LP-Gas) shall comply with the requirements of this chapter; NFPA 58 and Sections 60.1 through 60.4 of this *Code*.

69.1.1.2 Where the provisions of Chapter 69 or NFPA 58 conflict with the provisions of Chapter 60, the provisions of this chapter and NFPA 58 shall apply.

69.1.1.3 Stationary Installations. Plans for stationary installations utilizing storage containers with aggregate water capacity exceeding 4000 gal (15.2 m^3), and all rooftop installations of ASME containers shall be submitted to the AHJ before the installation is started by the person or company that either installs or contracts to have the containers installed. *[See also 6.22.11.1(F) of NFPA 58.]* [**58:**4.3.1]

Plans should be submitted to the authority having jurisdiction (AHJ), which is usually a fire department or state fire marshal. In the absence of specific requirements from the AHJ, plans should include a site plan showing key distances and references to the *Code*, along with information regarding key equipment (e.g., container specifications, investigation of reused equipment). Subsection 6.29.3 of NFPA 58 requires a written fire safety analysis to be submitted for installations that have an aggregate water capacity of more than 4000 gal (15.2 m^3) subject to exposure from a single fire in heavily populated or congested areas. (See Supplement 1 of *NFPA 58: LP-Gas Code Handbook*, "Guidelines for Conducting a Fire Safety Analysis," and the *Fire Safety Analysis Manual for LP-Gas Storage Facilities* for more information.)

Note that 69.1.1.3 requires only that plans be submitted to, but not necessarily approved by, the AHJ. There are many differences in how the AHJ's office is organized in each state or locality, and it was decided that approval from the AHJ would not be a code requirement because of the difficulty some propane companies have experienced in receiving acknowledgment from the AHJ that plans were even received. It is left up to each state or locality to determine how to implement the requirements of this paragraph.

Because they are relatively simple and standard installation procedures are used, installations smaller than 4000 gal (15.2 m^3) do not require that plans be submitted. Smaller installations include most one- and two-family homes and typical smaller commercial services that use U.S. Department of Transportation (DOT) cylinders and/or ASME 500 gal (1.9 m^3) or 1000 gal (3.8 m^3) capacity containers. Some authorities, however, require approval of these small installations in heavily populated or congested areas. In such instances, the authorities will either amend 69.1.1.3 or adopt specific wording in the document that requires approval.

Some local authorities need to know of small tank installations for specific reasons. One reason that some localities require notification about or even permits for these small tanks is to verify that tanks installed in flood-prone areas are properly anchored to prevent flotation in accordance with 69.3.8.1.6. Some coastal communities inspect tanks for nothing other than proper anchoring in areas they consider to be flood prone.

69.1.2 Permits. Permits, where required, shall comply with Section 1.12.

Table 1.12.8(a) enables the AHJ to issue a permit for the storage, use, handling, or dispensing of LP-Gas in excess of 125 gal (0.5 m^3) water capacity; for an amount shown in Table 1.12.8(b); or for the installation or modification of LP-Gas systems.

69.2 LP-Gas Equipment and Appliances

Section 69.2 provides design, manufacture, marking, and performance requirements for individual LP-Gas components or complete systems, with the exception of the following:

1. Cargo tank vehicles (See Chapter 9 of NFPA 58.)
2. Engine fuel systems (excluding over-the-road vehicles) (See Chapter 11 of NFPA 58.)
3. Engine fuel systems for over-the-road vehicles (See Chapter 12 of NFPA 58.)

The sections in Chapter 5 of NFPA 58 include detailed information and requirements on the following topics:

- Containers, including cylinders and ASME containers
- Container appurtenances, including pressure relief devices, regulators, pressure regulators, overfilling prevention devices (OPDs), container connections, and various gauges
- Regulators and regulator vents
- Piping, including hose; fittings; and valves
- Valves other than container valves
- Hydrostatic relief valves
- Equipment, including pumps, compressors, meters, engines, and sight flow indicators
- Appliances
- Vaporizers, tank heaters, vaporizing burners, and gas-air mixers
- Vehicle fuel dispensers

69.2.1 Containers.

69.2.1.1 General.

69.2.1.1.1* Containers shall be designed, fabricated, tested, and marked (or stamped) in accordance with the regulations of the U.S. Department of Transportation (DOT 49 CFR); Federal Aviation Administration (FAA 14 CFR) the ASME *Boiler and Pressure Vessel Code*, Section VIII, "Rules for the Construction of Unfired Pressure Vessels"; or the API-ASME *Code for Unfired Pressure Vessels for Petroleum Liquids and Gases*, except for UG-125 through UG-136. [**58:**5.2.1.1]

The DOT has approved the use of composite cylinders only if they are fabricated under a DOT special permit. Composite cylinders have a 15-year service life and must be requalified every 5 years. These cylinders can be used for all applications not prohibited by NFPA 58, such as outdoor gas grills, industrial trucks, and other applications not located in buildings.

The Federal Aviation Administration (FAA) has been added to the list of construction regulations, coinciding with the changes in the scope of NFPA 58, to cover the use of containers in hot air balloons. The FAA has several regulations, referred to as airworthiness directives (AD), regarding the construction and appurtenance requirements of such containers.

A.69.2.1.1.1 Prior to April 1, 1967, regulations of the U.S. Department of Transportation were promulgated by the Interstate Commerce Commission. In Canada, the regulations of the Canadian Transport Commission apply and are available from the Canadian Transport Commission, Union Station, Ottawa, Canada. [**58:**A.5.2.1.1]

Construction of containers to the API-ASME *Code for Unfired Pressure Vessels for Petroleum Liquids and Gases* has not been authorized after July 1, 1961. [**58:**A.5.2.1.1]

The requirements for the construction of pressure vessels used to store LP-Gases are referenced in A.69.2.1.1.1 (requirements for nonpressurized refrigerated containers are located in Chapter 12 of NFPA 58). The referenced codes provide a level of safety such that the development of independent requirements in NFPA 58 for the construction of pressure vessels for LP-Gas is not necessary. In referencing the ASME *Boiler and Pressure Vessel Code*, the Technical Committee has made an exception to sections UG-125 through UG-136, which cover pressure relief devices. The requirements for pressure relief devices in the ASME *Boiler and Pressure Vessel Code* differ from those in UL 132, *Standard for Safety Relief Valves for Anhydrous Ammonia and LP-Gas*, which require larger pressure relief valves.

Pressurized LP-Gas containers in the United States, Canada, and other countries served by marketers based in the United States and Canada comply with 69.2.1.1.1. Many other countries that use NFPA 58 have their own container requirements. In the event that a container constructed to a different standard is to be filled in a jurisdiction that enforces NFPA 58, approval to fill that container must be obtained from the AHJ. For cylinders, the AHJ is the DOT. Given the relatively low cost of cylinders, it is easier to purchase a new cylinder than to petition the DOT for a variance. Cylinders manufactured to other than DOT specifications can be used in the United States but cannot be refilled.

The treatment of cylinders built to non-U.S. specifications is addressed in the preceding paragraphs. Because most states adopt and enforce the ASME *Boiler and Pressure Vessel Code*, the state boiler agency must be contacted. For example, when packaged propane equipment is imported with propane tanks, the AHJ should be contacted to determine how to proceed.

Intermodal containers, as shown in Exhibit 69.1, are shipping containers larger than cylinders that are mounted within a frame for shipment on railcars, trucks, and ships. The containers are similar to dry shipping containers. The United Nations (UN) accepts intermodal containers for international shipping. These containers must meet DOT specifications and ASME Code requirements. LP-Gas is shipped via intermodal containers to islands and inland areas that are accessible only by rivers or other bodies of water.

69.2.1.1.1.1 Used containers constructed to specifications of the Association of American Railroads shall not be installed. [**58:**5.2.1.1(A)]

Railcar tanks are not constructed to the ASME *Boiler and Pressure Vessel Code*; rather, they are constructed to the *Manual of Standards and Recommended Practices*, published by the Association

Exhibit 69.1

Intermodal container. (Courtesy of Permagas)

of American Railroads (AAR). The AAR code is concerned with the forces that a tank car will experience over its lifespan. Tank cars must be removed from service at the end of their prescribed 40-year service life.

69.2.1.1.1.2 Adherence to applicable ASME Code case interpretations and addenda that have been adopted and published by ASME 180 calendar days prior to the effective date of NFPA 58 shall be considered as compliant with the ASME Code. [**58:**5.2.1.1(B)]

69.2.1.1.1.3 Where containers fabricated to earlier editions of regulations, rules, or codes listed in 69.2.1.1.1, and of the Interstate Commerce Commission (ICC) *Rules for Construction of Unfired Pressure Vessels*, prior to April 1, 1967, are used, the requirements of Section 1.4 of NFPA 58 shall apply. [**58:**5.2.1.1(C)]

The intent and application of 69.2.1.1.1.3 is often misinterpreted with regard to containers that were built to the API-ASME code *Unfired Pressure Vessels for Petroleum Liquids and Gases* (specifications U-200 and U-201) and pre-1949 editions of the ASME *Boiler and Pressure Vessel Code* (specifications U-68 and U-69). Because these ASME containers have a very long service life when properly maintained, many remain in use and are sometimes relocated and reinstalled. However, not all containers built to the older editions of the ASME *Boiler and Pressure Vessel Code* can remain in use or be relocated and reinstalled, regardless of their condition. According to 69.4.2.2, a container must be found suitable for continued use before it is filled. In Section 1.4 of NFPA 58, the AHJ has the authority to make any code requirement retroactive where a "distinct hazard to life and property" exists. The reinstallation of containers built to older editions of the code must be reviewed by the AHJ to determine if any current requirements meet the threshold for retroactivity.

69.2.1.1.2 Containers that have been involved in a fire and show no distortion shall be requalified for continued service before being used or reinstalled. [**58:**5.2.1.2]

69.2.1.1.2.1 Cylinders shall be requalified by a manufacturer of that type of cylinder or by a repair facility approved by DOT. [**58:**5.2.1.2(A)]

If a cylinder has been subjected to fire, the shell — which is usually steel, aluminum, or fiberglass — can be weakened, and the cylinder must be requalified by a properly qualified repair facility authorized by the U.S. DOT or by Transport Canada. Paragraph 69.2.1.1.2.1, however, imposes additional restrictions for aluminum and composite cylinders exposed to fire.

69.2.1.1.2.2 ASME or API-ASME containers shall be retested using the hydrostatic test procedure applicable at the time of the original fabrication. [**58:**5.2.1.2(B)]

When an ASME container has been subjected to fire, it must be retested using the hydrostatic test procedure applicable at the time the container was originally made. The testing is required because the heat of the fire can alter the properties of the steel and reduce its ability to contain pressure. Based on equivalency, the AHJ can consider other nondestructive test methods as alternatives to the hydrostatic test. The following methods are listed in the ASME *Boiler and Pressure Vessel Code* and may be useful for finding flaws in a container that would prevent it from being placed back into service after a fire:

- Radiography
- Ultrasonic
- Magnetic particle
- Liquid penetrants
- Visual inspection
- Leak testing
- Electromagnetic testing
- Acoustic emission

It is important to remember that the ASME *Boiler and Pressure Vessel Code* is a construction code, not a maintenance or an inspection code, and other codes (e.g., 49 CFR, "Transportation"; *National Board Inspection Code* (NBIC); or NFPA 58) may allow or require hydrostatic pressure testing as a nondestructive test when needed. While a hydrostatic pressure test is considered nondestructive, it can result in damage to the pressure vessel if a significant flaw is detected. The person performing such tests must be familiar with both the code requirements used to construct the container and the test methods used to test the container.

69.2.1.1.2.3 All container appurtenances shall be replaced. [**58:**5.2.1.2(C)]

69.2.1.1.2.4 DOT 4E specification (aluminum) cylinders and composite cylinders involved in a fire shall be permanently removed from service. [**58:**5.2.1.2(D)]

DOT 4E aluminum cylinders must not be returned to service after a fire because exposure to even moderately high temperatures can affect the structural properties of aluminum and severely decrease its tensile strength. Composite cylinders exposed to fire can also be weakened, and the manufacturer should be consulted for guidance.

69.2.1.1.3 ASME paragraph U-68 or U-69 containers shall be permitted to be continued in use, installed, reinstalled, or placed back into service. Installation of containers shall be in accordance with all provisions listed in NFPA 58. *(See Section 5.2, Table 5.4.4.2, Table 5.9.2.5(A), and Annex D of NFPA 58.)* [**58:**5.2.1.3]

The requirement in 69.2.1.1.3 specifically states that ASME paragraph U-68 or U-69 containers can be continued in service and reinstalled.

69.2.1.1.4 Containers that show excessive denting, bulging, gouging, or corrosion shall be removed from service. [**58:**5.2.1.4]

All containers that show excessive dents, bulges, gouges, or corrosion must be removed from service because such defects can reduce the pressure capability of the container. Once removed from service, the container can be scrapped or repaired using methods that are in accordance with the code of manufacture.

69.2.1.1.5 Except for containers used in cargo tank vehicle service, ASME containers of 3000 gal (11.4 m^3) water capacity or less used to store anhydrous ammonia shall not be converted to LP-Gas fuel service. [**58:**5.2.1.5]

Paragraph 69.2.1.1.5 addresses problems that have occurred with portable pressure vessels of 3000 gal (11.4 m^3) or less that are mounted on wheels and used at farms for both propane and ammonia at different times. These containers are sometimes called "nurse tanks." Three fatal accidents were reported involving propane tanks that had formerly been in ammonia service. Larger containers are also used for both ammonia and propane, but because there have been no incidents reported with larger containers, the restriction applies only to containers of 3000 gal (11.4 m^3) or less.

The following safety hazards are associated with converting tanks from propane to ammonia use and vice versa:

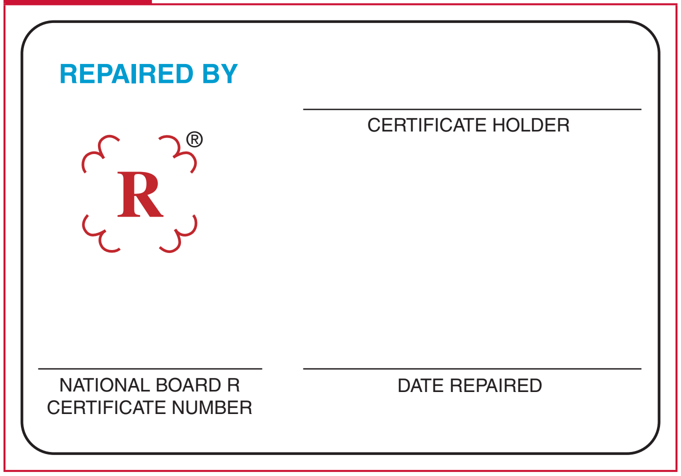
1. Potential overfilling of the container due to inappropriate dip tube length
2. Container failure from stress caused by corrosion cracking due to prior ammonia service
3. Improper sizing or material of relief valves (propane containers can use steel or brass valves, while ammonia tanks can only use steel valves because ammonia corrodes brass)
4. Accumulation of rust, which can form if the container is left open during a changeover and can lead to odor fade

69.2.1.1.6 Repairs or alteration of a container shall comply with the regulations, rules, or code under which the container was fabricated. Repairs or alteration to ASME containers shall be in accordance with the ANSI/NB23 *National Board Inspection Code*. [**58:**5.2.1.6]

69.2.1.1.7 Field welding shall be permitted only on saddle plates, lugs, pads, or brackets that are attached to the container by the container manufacturer. [**58:**5.2.1.7]

The heat of welding directly to the container can affect the strength of the material and change its characteristics so that it may no longer meet the requirements of the ASME *Boiler and Pressure Vessel Code*. Such heating can set up localized stresses that can reduce the strength of the material or container. Repairs to pressure vessels must meet the requirements of the NBIC and must be performed by a repair organization accredited by the National Board and authorized to utilize the "R" code symbol stamp. Following a repair and final inspection by a National Board–commissioned inspector, the repair organization will affix to the pressure vessel a "Repair" nameplate that is similar to the ASME nameplate (the ASME nameplate is not to be removed or altered). The requirements in the NBIC were developed to maintain the integrity of the pressure vessel after it has been placed in service (see Exhibit 69.2).

Exhibit 69.2



National Board "R" stamp. (Reprinted with permission of the National Board of Boiler and Pressure Vessel Inspectors)

69.2.1.1.8 Containers for general use shall not have individual water capacities greater than 120,000 gal (454 m^3). [**58:**5.2.1.8]

Containers installed for general use and in dispensing stations are limited in size per 69.2.1.1.8. However, the number of containers in general use is not limited. The term *general use*, which is not defined in the *Code*, refers to installations where LP-Gas is being stored for an end-use application, such as fuel. Thus, an LP-Gas bulk plant where most employees can be expected to be aware of the proper procedures for handling LP-Gas is not considered to be general use.

69.2.1.1.9 Dispensing systems not located in LP-Gas bulk plants, industrial plants, or industrial applications shall have an aggregate water capacity not greater than 30,000 gal (114 m^3). [**58:**5.2.1.9]

69.2.1.1.10 Heating or cooling coils shall not be installed inside storage containers. [**58:**5.2.1.10]

Internal container components such as heating and cooling coils can be inspected only when the container is emptied, purged, and declared safe for entry. It is possible that a container's components might not be inspected during the container's normal life of service. If not inspected, corrosion or other container component failure will not be observed and thus can never be repaired or taken out of service. If heating or cooling coils installed inside the storage container leak, the gas could enter the piping of the heating or cooling system because the LP-Gas pressure is normally higher than the pressure in the internal coil. Leakage into the heating or cooling system could result in a pressure that ruptures or creates leaks in the heating or cooling piping. Even if a break does not occur, a flammable product will be present in the heating or cooling system that could escape near an ignition source.

69.2.1.1.11 ASME containers installed underground, partially underground, or as mounded installations shall incorporate provisions for cathodic protection and shall be coated with a material recommended for the service that is applied in accordance with the coating manufacturer's instructions. [**58:**5.2.1.11]

This requirement for underground containers recognizes a long-standing practice to provide corrosion protection in addition to a corrosion-resistant coating. The method used is called *cathodic protection*, which commonly utilizes a metal that is more electrochemically reactive than steel so that it "sacrificially corrodes" instead of the steel tank. Typically, magnesium is used with underground containers of all types.

69.2.1.2 Portable Container Appurtenance Physical Damage Protection.

69.2.1.2.1 Cylinders shall incorporate protection against physical damage to cylinder appurtenances and immediate connections to such appurtenances when not in use by any of the following means:

(1) A ventilated cap
(2) A ventilated collar

The cap or collar described in 69.2.1.2.1 and shown in Exhibit 69.3 is required to provide physical protection for the valves and any other appurtenances connected to the cylinder.

Cylinders are portable and normally are transported from their regular use point to a filling point; there are inevitable occurrences in which the cylinder becomes involved in a transportation incident, falls over, or is dropped. If a removable cap is used, it must be in place prior to moving the cylinder. The cap also provides a lifting point for the cylinder. The valve must never be used for lifting a cylinder. Ventilation openings are required to permit discharge from the pressure relief valve to dissipate.

(3) A cylinder valve providing inherent protection as defined by DOT in 49 CFR 173.301(h)(3)

[**58:**5.2.6.1]

69.2.1.2.2 Protection of appurtenances of portable containers, skid tanks, and tanks for use as cargo tanks of more than 1000 lb (454 kg) water capacity [nominal 420 lb (191 kg) propane capacity] shall comply with 69.2.1.2.2.1 through 69.2.1.2.2.3. [**58:**5.2.6.2]

69.2.1.2.2.1 Appurtenance protection from physical damage shall be provided by recessing, by protective housings, or by location on the vehicle. [**58:**5.2.6.2(A)]

Exhibit 69.3

Cylinder collars. (Courtesy of Manchester Tank)

69.2.1.2.2.2 Appurtenance protection shall comply with the provisions under which the containers are fabricated. [**58:**5.2.6.2(B)]

69.2.1.2.2.3 Appurtenance protection shall be secured to the container in accordance with the ASME code under which the container was designed and built. [**58:**5.2.6.2(C)]

Paragraph 69.2.1.2.2.3 refers to the code under which the container was built, instead of specifying the safety factors to be used. Since the appurtenance protection is usually installed by the container manufacturer or assembler of a portable tank unit, it is reasonable to assume that the fabricator has access to the container construction code. This provision allows protection that was built to older editions of the construction code to continue in service.

• N **69.2.1.3 Portable Storage Containers.**

N **69.2.1.3.1** The legs or supports, or the lugs for the attachment of legs or supports, shall be secured to the container in accordance with the ASME code under which the container was designed and built. [**58:**5.2.7.1]

N **69.2.1.3.2** The attachment of a container to either a trailer or semitrailer running gear, or the attachments to the container to make it a vehicle, so that the unit can be moved by a conventional over-the-road tractor, shall comply with the DOT requirements for cargo tank service. [**58:**5.2.7.2]

N **69.2.1.3.3** Portable tank design and construction of a full framework, skids, or lugs for the attachment of skids, and protection of fittings shall be in accordance with DOT portable tank specifications. The bottom of the skids shall be not less than 2 in. (51 mm) or more than 12 in. (300 mm) below the outside bottom of the tank shell. [**58:**5.2.7.3]

69.2.1.4 Container Marking.

69.2.1.4.1 Cylinders shall be marked as provided in the regulations, rules, or code under which they are fabricated. [**58:**5.2.8.1]

69.2.1.4.1.1 Where LP-Gas and one or more other compressed gases are to be stored or used in the same area, the cylinders shall be marked "Flammable" and either "LP-Gas," "Propane," or "Butane," or shall be marked in accordance with the requirements of 49 CFR, "Transportation." [**58:**5.2.8.1(A)]

69.2.1.4.1.2 When being transported, cylinders shall be marked and labeled in accordance with 49 CFR, "Transportation." [**58:**5.2.8.1(B)]

Hazardous materials labels are normally printed on or affixed to cylinders containing such materials. They are color- and symbol-coded to afford easy and immediate recognition of the existing hazards. Cylinders containing propane require the label to appear as a diamond with a red background and to be at least 3.9 in.^{2} (2516 mm^2), unless the neck ring (as shown in Exhibit 69.4) listed in CGA C-7, *Guide to Classification and Labeling of Compressed Gases*, is used. The "2" represents the hazard class, which is compressed gas. Sometimes the number "2.1" will appear instead, which represents the hazard class division and denotes flammable gas.

Markings are printed on or affixed to packages of hazardous materials such as propane cylinders to convey additional information about the hazardous material being transported. Cylinders that contain hazardous materials must be marked with the proper name of the material (either "Liquefied Petroleum Gas" or "Propane") and the shipping identification number (usually "1075," but may also be "1978").

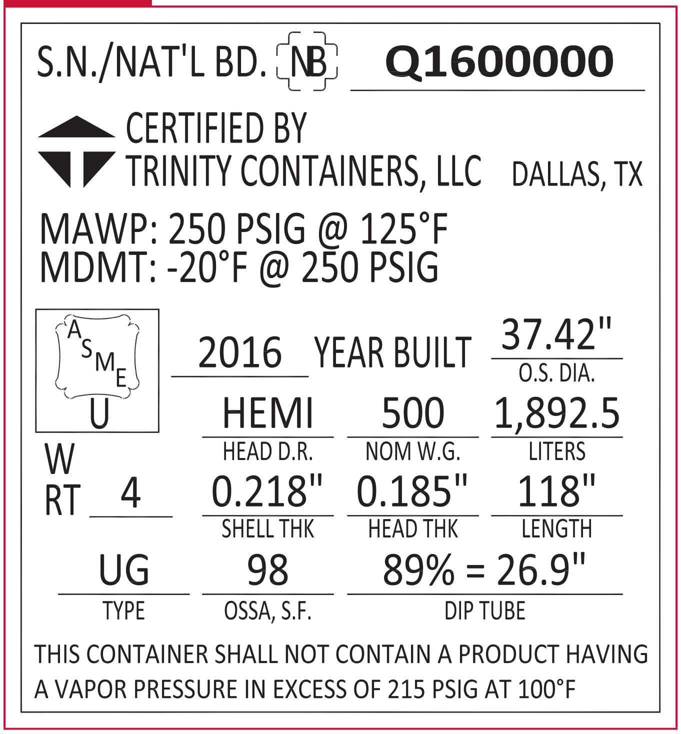
69.2.1.4.2* Cylinders shall be marked with the following information:

(1) Water capacity of the cylinder in pounds
(2) Tare weight of the cylinder in pounds, fitted for service [**58:**5.2.8.2]

Exhibit 69.4

Neck ring and DOT flammable gas label (red). (Courtesy of Labelmaster®)

Exhibit 69.5



Optional container listing on container nameplate. (Courtesy of Trinity Containers)

A.69.2.1.4.2 The tare weight is the cylinder weight plus the weight of all permanently attached valves and other fittings but does not include the weight of protecting devices that are removed in order to load the cylinder. [**58:**A.5.2.8.2]

69.2.1.4.3* The markings specified for ASME containers shall be on a stainless steel metal nameplate attached to the container, located to remain visible after the container is installed. [**58:**5.2.8.3]

A.69.2.1.4.3 Head design refers to the shape of the head. Shapes include hemispherical, semi-ellipsoidal, and others. *(Refer to the API-ASME Code for Unfired Pressure Vessels for Petroleum Liquids and Gases for more information.)* [**58:**A.5.2.8.3]

The container nameplate, as shown in Exhibit 69.5, must be stainless steel and attached to the container in a manner that eliminates the possibility of corrosion to the nameplate, fasteners, or the container. Container corrosion can occur if water is trapped between the nameplate and the container. The nameplate is usually attached to the container using a continuous stainless steel weld around the nameplate to comply with the requirement in 69.2.1.4.3.1 that the attachment not contribute to corrosion of the container. This provision is not in conflict with the ASME Code, but it is important to be aware of the provision if ordering a propane container from a fabricator that does not normally fabricate propane containers.

Paragraph 69.4.2.2.8 states that "containers shall be filled only after determination that they comply with the design, fabrication, inspection, marking, and requalification provisions of NFPA 58." Without a nameplate, a container does not comply with the marking requirements of NFPA 58. In addition, nameplates provide the operating parameters used in the design of the container and information on the materials used. If the nameplate is missing, it cannot be immediately determined whether the container complies with the design and fabrication requirements of NFPA 58. A frequent saying in the industry is, "If you don't have a nameplate, you don't have a tank," since filling of the tank is impossible without a nameplate.

If the manufacturer is still in business, and records of the container construction are available, it is relatively easy to obtain a replacement nameplate. The container may be filled once the replacement nameplate has been attached to the container, bringing it back into compliance with the marking requirements of the code.

Some states have their own rules for attaching a replacement nameplate; however, those nameplates might not be recognized outside the state that approved the replacement.

The rules of the National Board of Boiler and Pressure Vessel Inspectors (NBBI) restrict who may attach a replacement nameplate. The AHJ not only must be involved but also must approve and possibly witness the attachment.

The requirement for a nameplate in the ASME Code is of great importance, and removal of a nameplate for any reason is not permitted. When repainting ASME containers, the nameplate should be taped over to prevent obscuring the markings on the nameplate. If the nameplate is to be removed temporarily for container painting, the NBBI must be contacted to determine if removal is allowed and, if so, how. The instructions and documentation are included on form NB-136, which can be found on the NBBI website at www.nationalboard.org. It is important to have the documentation of a replaced nameplate when the tank is inspected.

The provisions for buried or mounded tanks in 69.2.1.4.3.2 require that duplicate nameplate information be provided in a visible location if the original nameplate is obscured. This additional marking permits verification of the container nameplate information without digging up an underground container, which could damage the container, the protective coating, or a cathodic protection system if one is used.

The information required by 69.2.1.4.3.3(12) through 69.2.1.4.3.3(14) was inserted to make the requirements of NFPA 58 consistent with the manufacturers' requirements in the ASME *Boiler and Pressure Vessel Code*. Containers manufactured prior to the 2004 edition of NFPA 58 are not required to display this new information on the nameplate.

69.2.1.4.3.1 The nameplate shall be attached in such a way as to minimize corrosion of the nameplate or its fastening means and not contribute to corrosion of the container. [**58:**5.2.8.3(A)]

69.2.1.4.3.2 Where the container is buried, mounded, insulated, or otherwise covered so the nameplate is obscured, the information contained on the nameplate shall be duplicated and installed on adjacent piping or on a structure in a clearly visible location. [**58:**5.2.8.3(B)]

69.2.1.4.3.3 Stationary ASME containers shall be marked with the following information:

(1) Service for which the container is designed (e.g., underground, aboveground, or both)
(2) Name and address of container supplier or trade name of container
(3) Water capacity of container in pounds or U.S. gallons
(4) MAWP in pounds per square inch
(5) Wording that reads "This container shall not contain a product that has a vapor pressure in excess of ___ psig at 100°F" *(see Table 5.2.4.2 of NFPA 58)*
(6) Outside surface area in square feet
(7) Year of manufacture
(8) Shell thickness and head thickness
(9) OL (overall length), OD (outside diameter), and HD (head design)
(10) Manufacturer's serial number
(11) ASME Code symbol
(12) Minimum design metal temperature ___°F at MAWP ____ psi
(13) Type of construction "W"
(14) Degree of radiography "RT-___"

[**58:**5.2.8.3(C)]

69.2.1.4.3.4 In addition to the markings required by this Code, nameplates on cargo tanks shall include the markings required by the ASME *Boiler and Pressure Vessel Code* and the DOT. [**58:**5.2.8.3(D)]

Note that 49 CFR 178.345-14 contains additional marking requirements for cargo tank motor vehicles that transport propane. In addition to the ASME nameplate provided with the tank, a specification plate must be permanently attached to the cargo tank by brazing or welding on the left side near the front, so that it is accessible for inspection. All plates must be maintained in a legible condition. The specification plate must have the following information stamped, embossed, or otherwise marked into the metal of the plate in characters at least 3/16 in. (4.8 mm) high:

1. Cargo tank motor vehicle manufacturer — "CTMV mfr."
2. Cargo tank motor vehicle certification date — "CTMV cert. date"
3. Cargo tank manufacturer — "CT mfr."
4. Cargo tank date of manufacture, including month and year — "CT date of mfr."
5. Maximum weight of lading, in pounds — "Max. Payload"
6. Lining materials, if applicable — "Lining"
7. Heating system design pressure, in psig, if applicable — "Heating sys. press."
8. Heating system design temperature, in degrees Fahrenheit, if applicable — "Heating sys. temp."
9. Cargo tank serial number, assigned by cargo tank manufacturer, if applicable — "CT serial"

69.2.1.4.4 Warning labels shall meet the following requirements:

(1) Warning labels shall be applied to all cylinders of 100 lb (45.4 kg) propane capacity or less that are not filled on site.
(2) Warning labels shall include information on the potential hazards of LP-Gas.

[**58:**5.2.8.4]

The requirements in 69.2.1.4.4 recognize the need to warn users who are not familiar with the properties and potential hazards of propane. Exhibits 69.6 and 69.7 show examples of different types of warning labels. Note that the cylinder sizes are based on propane capacity because propane and butane — both LP-Gases — have different densities and therefore different weights for a full cylinder of the same volume.

The term *filled on site* means that the cylinder was filled at the usage site and typically applies to cylinders permanently installed at buildings that are filled by a propane delivery truck (bobtail). Cylinders that are filled on site do not require a warning label because the consumer does not handle or install the cylinder.

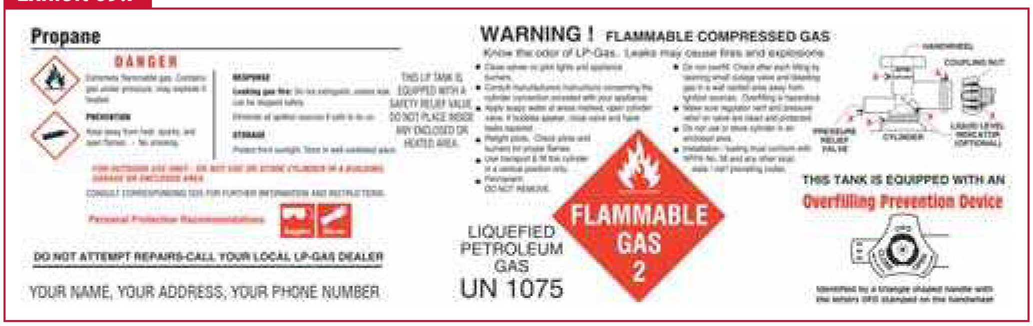
Warning labels are required only on portable cylinders of 100 lb (45.4 kg) propane capacity or less because these containers are most likely to be used by consumers of gas who may not be familiar with the hazards associated with LP-Gas. Larger cylinders are assumed to be handled only by propane companies, although this may not be the case universally.

The *Code* does not specify the text of a label, but it must include information on the potential hazards of LP-Gas as well as other information. Many labels include a warning that the cylinder must not be brought into buildings. This is true for most cylinders, but not all. In accordance with Section 6.20 of NFPA 58, certain cylinders may be brought into buildings. A warning stating that the cylinder may not be brought into buildings should not be placed on such cylinders. Although this may seem obvious, problems have arisen when inspectors have found cylinders that are permitted by Section 6.20 of NFPA 58 to be used in buildings with labels stating the opposite. This situation occurs because the most common size of propane cylinders is 20 lb (9.1 kg), and their most common use is with gas grills. Cylinder

Exhibit 69.6

Sample warning label intended for gas grill cylinders. (Courtesy of Screen Graphics of Florida)

Exhibit 69.7



Sample warning label intended for use on cylinders in commercial or industrial service. (Courtesy of Screen Graphics of Florida) manufacturers usually provide a warning label that anticipates use of the cylinder with gas grills unless otherwise specified.

The code does not specify the form of the label, only that it be applied to the cylinder. Because the term *apply* means "to put on," the label can be glued to the container or attached by a mechanical means such as a plastic strip. If the label is not on the cylinder but rather on an enclosure holding the cylinder or on a cylinder cover or other container, it has not been applied to the cylinder and does not meet the requirement of 69.2.1.4.4. If a decorative cover or plastic sleeve is used to cover a cylinder, the required label must be on the decorative cover in addition to the label on the cylinder because the warning must be visible to anyone using the cylinder.

69.2.1.4.5 All containers that contain unodorized LP-Gas products shall be marked "NOT ODORIZED." [**58:**5.2.8.5].

69.2.1.4.5.1 The marking shall have a contrasting background surrounded by a rectangular red border and with red letters in the sizes shown in Table 69.2.1.4.5.1. [**58:**5.2.8.5(A)]

***TABLE 69.2.1.4.5.1** "NOT ODORIZED" Label Size*

Water Capacity		Letter Height		Border Width	
gal	m³	in.	cm	in.	cm
≥499	≥1.89	4	10.0	½	1.3
49–498	0.19–1.88	1½	3.7	5/16	0.8
2.6–48	0.01–0.18	¾	1.8	¼	0.6
1–2.5	0.004–0.009	3/8	1.0	1/16	0.2

[**58:** Table 5.2.8.5(A)]

The marking "NOT ODORIZED" on ASME containers of unodorized propane provides important information to emergency responders (see Exhibit 69.8). The lack of odorant in a storage container adds to the potential hazard that both users and emergency responders face. By providing a visible marking, everyone working around stationary containers that hold unodorized LP-Gas is made aware of the absence of odorant and that alternative sensing devices must be used to locate suspected leaks.

Propane is permitted to be shipped and used without an odorant where the odorant would be harmful to a process or would serve no useful purpose, such as where propane is used as a chemical feedstock and the odorant could poison a catalyst, or where butane or propane is used as a propellant in aerosol cans. The application of butane or propane as an aerosol is not covered by NFPA 58 because this application is using LP-Gas as a delivery device rather than consuming it.

69.2.1.4.5.2 The markings shall be on both ends or on both sides of a container or on both sides and the rear of cargo tanks. [**58:**5.2.8.5(B)]

N **69.2.2 Reserved. [58:5.2]**

Exhibit 69.8

N **69.2.3 Reserved. [58:5.3]**

N **69.2.4 Reserved. [58:5.4]**

N **69.2.5 Reserved. [58:5.5]**

N **69.2.6 Containers with Attached Supports.**

N **69.2.6.1 Vertical ASME Containers.** Vertical ASME containers of over 125 gal (0.5 m³) water capacity for use in permanent installations in stationary service shall be designed with steel supports that allow the container to be mounted on and fastened to concrete foundations or supports. [**58:**5.6.1]

N **69.2.6.1.1** Steel supports shall be designed to make the container self-supporting without guy wires and to withstand the wind and seismic (earthquake) forces anticipated at the site. [**58:**5.6.1.1]

N **69.2.6.1.2** Steel supports shall be protected against fire exposure with a material having a fire resistance rating of at least 2 hours. [**58:**5.6.1.2]

N **69.2.6.1.3** Continuous steel skirts having only one opening of 18 in. (460 mm) or less in diameter shall have 2-hour fire protection applied to the outside of the skirt. [**58:**5.6.1.3]

Vertical containers such as the one shown in Exhibit 69.9 are used where space is not available for horizontal containers. Because

Exhibit 69.9

Vertical container. (Courtesy of LP Gas magazine)

the failure of a vertical tank's structural supports can result in severe damage to the container when it falls, there are special fire protection requirements for the supports. The 2-hour fire resistance rating can be obtained by using a protective material that may have been tested to the requirements of ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, a standard used to determine the fire resistance rating of structural elements. Vertical tanks are most often located at propane vehicle refueling stations, where space is usually at a premium. Larger vertical tanks have also been installed where land cost is very high, such as near New York City.

Paragraph 69.2.6.1.3 addresses vertical tanks equipped with continuous steel skirts, which are not normally found at propane dispensing locations but are more common in refineries. Their use is permitted where the skirt is protected with fire resistance–rated insulation on its exterior.

N **69.2.6.2 Skid Tanks.** Skid tanks shall have a secure steel frame to allow transportation of the skid tank when not filled with LP-Gas. [**58:**5.6.2]

N **69.2.6.3 Porta-Pacs.**

N **69.2.6.3.1** The legs or supports, or the lugs for the attachment of legs or supports, shall be secured to the container in accordance with the ASME code under which the container was designed and built. [**58:**5.6.3.1]

N **69.2.6.3.2** The ASME container shall be attached to either:

(1) A trailer or semitrailer running gear, or the attachments to the container to make it a vehicle, so that the unit can be moved by a conventional over-the-road tractor.
(2) A metal frame such that the container can be moved as a trailer if wheels are added, which shall be approved for stationary use, or on a flat rail car.
(3) Protection of appurtenances shall be in accordance with 69.2.1.2.
(4) Movable fuel storage tenders shall be secured to the trailer support structure for the service involved.

[**58:**5.6.3.2]

N **69.2.7 Reserved.**

N **69.2.8 Reserved.**

69.2.9 Container Appurtenances.

N **69.2.9.1 Materials.**

N **69.2.9.1.1** Container appurtenances and regulators shall be fabricated of materials that are compatible with LP-Gas, shall be resistant to the action of LP-Gas under service conditions.

N **(A)** The following materials shall not be used:

(1) Gray cast iron
(2) Nonmetallic materials for bonnets or bodies of valves or regulators

[**58:**5.9.1.1]

Gray cast iron is prohibited because it can be subject to cracking and failing due to mechanical shock or severe thermal shock under fire conditions. The requirement for using metallic materials for the bodies of valves and regulators ensures that, when exposed to the elements, fire, or mechanical abuse, the device can be reasonably expected to function without creating a safety hazard. Although there have been considerable improvements in the temperature and pressure capabilities of plastic materials, they still do not approach the melting or softening points of metals.

N **69.2.9.1.2*** Pressure-containing metal parts of appurtenances shall have a minimum melting point of 1500°F (816°C), except for the following:

(1) Fusible elements
(2) Approved or listed variable liquid level gauges used in containers of 3500 gal (13.2 m^3) water capacity or less

[**58:**5.9.1.2]

N **A.69.2.9.1.2** Materials with melting points exceeding 1500°F (816°C) include steel, ductile (nodular) iron, malleable iron, or brass, as follows:

(1) Ductile iron should meet the requirements of ASTM A395/A395M, *Standard Specification for Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures*, or equivalent and malleable iron should meet the requirements

of ASTM A47/A47M, *Standard Specification for Ferritic Malleable Iron Castings,* or equivalent.

(2) Approved or listed variable liquid level gauges used in containers of 3500 gal (13.2 m³) water capacity or less are exempt from the minimum melting point requirement.

(3) Cast-iron should not be used.

(4) Nonmetallic materials should not be used for bonnets or bodies of valves or regulators.

[**58:**A.5.9.1.2]

The melting point criteria for metal parts of appurtenances in 69.2.9.1.2 are intended to provide a degree of structural integrity in the event of exposure to fire and the application of water for fire control. However, appurtenance configuration, mass, and location on the container affect the degree of hazard to the appurtenance. Item (2) of 69.2.9.1.2 for liquid level gauges on smaller containers reflects this consideration.

Note that metal used for pressure-containing parts is required to have a melting point of at least 1500°F (816°C). Most metals and alloys become structurally unusable at temperatures approaching one-third to one-half their melting points, making materials with melting points below 1500°F (816°C) a potential safety concern in the event of fire exposure.

N **69.2.9.1.3** Container appurtenances shall have a service pressure of at least 250 psig (1.7 MPag). [**58:**5.9.1.3]

N **69.2.9.1.4** Gaskets used to retain LP-Gas in containers shall be resistant to the action of LP-Gas. [**58:**5.9.1.4]

N **69.2.9.1.4.1** Gaskets shall be made of metal or other material confined in metal having a melting point over 1500°F (816°C) or shall be protected against fire exposure. [**58:**5.9.1.4(A)]

N **69.2.9.1.4.2** When a flange is opened, the gasket shall be replaced. [**58:**5.9.1.4(B)]

N **69.2.9.1.4.3** Aluminum O-rings and spiral-wound metal gaskets shall be permitted. [**58:**5.9.1.4(C)]

N **69.2.9.1.4.4** Gaskets for use with approved or listed liquid level gauges for installation on a container of 3500 gal (13.2 m³) water capacity or less shall be exempt from the minimum melting point requirement. [**58:**5.9.1.4(D)]

LP-Gas systems must be able to maintain their integrity when subjected to fire. Therefore, the requirement in 69.2.9.1.4 that gaskets maintain their integrity when subjected to a temperature of 1500°F (816°C) limits their use to those materials that have the best chance of maintaining their integrity in a fire. Other gasket materials, such as Teflon® and rubber, are permitted only where the flange containing the gasket is protected against fire exposure. This protection, although not specified, must safeguard the gasket from temperatures that would degrade it in a reasonably expected fire condition. A thermal insulating material that would not be degraded in a fire situation can be used.

When a flange is opened, the gasket can be damaged, and the damage may not be visible to the person opening the flange. Therefore, gasket replacement is required.

Aluminum O-rings and spiral-wound metal gaskets are permitted because they have been listed for many years and have a long, successful track record. The manufacturer's instructions concerning reuse of these gaskets should be followed. Because these types of gaskets are designed to deform when tightened to seal, it is good practice to replace them when a flange is opened, as the gasket manufacturer may recommend.

69.2.10 Piping (Including Hose), Fittings, and Valves. Piping (including hose), fittings, and valves shall comply with Section 5.9 of NFPA 58.

69.3 Installation of LP-Gas Systems

Section 69.3 includes information needed for the installation of the most commonly encountered LP-Gas systems and individual components. Note that systems that are installed on vehicles, that are highly specialized, or that are not as common have been separated into three chapters in NFPA 58: Chapter 9, Vehicular Transportation of LP-Gas; Chapter 11, Engine Fuel Systems; and Chapter 13, Refrigerated Containers.

Δ **69.3.1* Application.** Section 69.3 shall apply to the following:

(1) Location and field installation of LP-Gas systems that use components, subassemblies, container assemblies, and container systems that are fabricated in accordance with Chapter 5 of NFPA 58

(2) Location of containers and liquid transfer systems

(3) Installation of container appurtenances and regulators

(4) Installation of piping (including flexible connectors and hose), hydrostatic relief valves, and piping service limitations

(5) Installation of equipment

(6) Testing of piping systems

(7) Location of containers not connected for use

[**58:**6.1.1]

A.69.3.1 Section 6.5 of NFPA 58 includes general provisions that are applicable to most stationary systems. Sections 6.7 through 6.15 of NFPA 58 extend and modify Section 6.5 of NFPA 58 for systems installed for specific purposes. [**58:**A.6.1.1]

N **69.3.2 Nonapplication.** This chapter does not apply to the following:

(1) Refrigerated containers

(2) Installation of systems used in the highway transportation of LP-Gas

[**58:**6.1.2]

69.3.3 Location of Containers.

69.3.3.1 LP-Gas containers shall be located outside of buildings unless they are specifically allowed to be located inside of buildings. [**58:**6.2.1]

Δ **69.3.3.2** LP-Gas containers shall be allowed in buildings only for the following applications:

(1) Cylinders as specifically provided for in Section 6.22 of NFPA 58
(2) Containers of less than 125 gal (0.5 m^3) water capacity for the purposes of being filled in buildings or structures complying with Chapter 10 of NFPA 58
(3) Containers on LP-Gas vehicles complying with, and parked or garaged in accordance with, Chapter 9 of NFPA 58
(4) Containers used with LP-Gas portable engine fuel systems complying with 11.15.1 of NFPA 58
(5) Containers used with LP-Gas stationary engine fuel systems complying with Section 6.28 of NFPA 58
(6) Containers used with LP-Gas–fueled industrial trucks complying with 11.13.4 of NFPA 58
(7) Containers on LP-Gas–fueled vehicles garaged in accordance with Section 11.16 of NFPA 58
(8) Cylinders awaiting use, resale, or exchange when stored in accordance with Section 69.5.2 and 69.5.3

[**58:**6.2.2]

Because propane is a flammable gas, NFPA 58 has always required that LP-Gas containers be located outdoors, with the stated exceptions in 69.3.3.2. A flammable gas leak outdoors dissipates much more quickly and with less chance of reaching a source of ignition than a leak occurring indoors.

The code recognizes that there are a limited number of necessary uses of propane cylinders in buildings and structures, and those uses are listed in 69.3.3.2. Permitted uses are based on safeguards that minimize the possibility of a release of LP-Gas that could lead to ignition. Safeguards include limiting the size of the container, controlling the presence of ignition sources, and even designing the room or building to minimize the consequences of an explosion or fire.

In some European countries, LP-Gas is used in a totally different manner than it is in the United States. In those countries, it is standard practice for LP-Gas containers to be located not only within buildings, but within multistory apartment buildings, providing fuel for cooking and other applications where central heating systems are not utilized. The LP-Gas distribution system in those countries also has some differences in the manner in which LP-Gas is delivered, because most residences use LP-Gas cylinders that are exchanged rather than filled on site. Note that there may be significant differences in building construction, cylinder refilling, and cylinder filling practices between the United States and Canada and other countries that allow different uses of cylinders.

In addition to the general prohibition of using cylinders indoors, it is also prohibited to store cylinders, whether empty or full, inside a residential building. Requirements for storage of cylinders awaiting use or sale and exceptions for necessary uses are located in Chapter 8 of NFPA 58.

N **69.3.4 Location of Containers Not Connected for Use.**

The requirements in 69.3.4, which were newly added in the 2018 edition of the *Code*, address those containers that are removed from service yet remain on site.

Before this revision, there were no requirements concerning the safe placement of ASME tanks, whether empty or full, when they were not attached in a system. Several AHJs found that new supplying companies would disconnect the competitor's tank and then set the old tank aside, sometimes in an unsafe location or condition. Previously, NFPA 58 did not address placement after disconnection.

In previous editions of NFPA 58, a full 1000 gal (3.8 m^3) tank, for example, could be set right beside a residence if it was not connected for use. The requirement that it had to be at least 10 ft (3 m) from the building applied in previous editions of the code only if it was connected to a system, according to the scope statement of Chapter 6 of NFPA 58. If that tank rolled over and the pressure relief valve no longer communicated with the vapor space that also would not violate the requirements in previous versions of the code. This new subsection was written to recognize that a prohibition of these and other hazards had to be addressed.

N **69.3.4.1** Cylinders awaiting use, resale, or exchange shall be stored in accordance with Chapter 8. [**58:**6.3.1]

Paragraph 69.3.4.1 is a reminder that cylinders [containers complying with DOT specifications] not in use have requirements in Chapter 8 of NFPA 58.

N **69.3.4.2** ASME containers of 4,000 gal (15.2 m^3) or less that have been removed from service but that contain LP-Gas shall be stored outside of buildings in accordance with either 69.3.4.2(1) or 69.3.4.2(2):

(1) Containers shall be located either at a bulk plant or in an approved area.

The Technical Committee recognizes that storing containers at a bulk plant or in an area acceptable to the AHJ is considered to be storage in a controlled area.

The requirements in 69.3.4.2 were written to allow an exception for those containers stored outside a bulk plant, since employees who work in bulk plants are more familiar with the hazards of a container containing a highly flammable substance.

(2) Containers not complying with 69.3.4.2(1) shall comply with the following:
  (a) Containers shall be located in a manner that will minimize exposure to physical damage.

Item (2)(a) allows a newly disconnected tank to be placed near a roadway or other traveled location (so the tank owner has easier access for removal) as long as it is located in such a way that minimizes the possibility of vehicular impact. If it is located at a construction site, the possibility that something may run into or fall on the tank must be considered.

  (b) Containers shall be oriented so that the pressure relief valve remains in communication with the vapor space.

Item (2)(b) requires that the tank be set so that the relief valve communicates with the vapor space and will continue to do so for reasons explained in 69.3.8.1.1. Preventing the tank from

Exhibit 69.10

Disconnected ASME tank set in an unsafe manner. (Courtesy of Randy Renfrow, North Carolina Department of Agriculture and Consumer Services)

rolling over protects children who may be playing on or around the tank while it is still at their house. Exhibit 69.10 shows a disconnected tank set in a questionable manner. Some questions to consider are as follows: Would the blocks keeping it from rolling over? If a child removed the blocks, would the tank roll over?

(c) Containers shall not be located on roofs of buildings.
(d) Valve outlets on ASME containers shall be plugged or capped.
(e) Where screw-on-type caps or collars are utilized on ASME containers, they shall be in place whenever this type of container is stored regardless of the fill level of the container.

Items (2)(d) and (2)(e) require further protection against accidental release of product. Plugging or capping the outlet makes it less likely that a person unfamiliar with the risks of opening the valves on tanks will release the product. Ensuring that a cap or a collar is in place for older ASME containers further guards against accidental release of product.

(f) The location of ASME containers shall comply with the "Aboveground Containers" column and the "Between Containers" column of Table 69.3.5.1.1 with respect to important buildings and lines of adjoining property that can be built upon.
(g) Where the provisions of 69.3.4.2(2)(f) are impractical, alternative storage locations for containers shall be approved by the authority having jurisdiction.

[**58:**6.3.2]

Item (2)(f) recognizes that the separation requirements for attached tanks also serve well for tanks that are not attached. It also requires that underground tanks meet the separation requirements for aboveground tanks when they are placed above ground and are awaiting removal.

Item (2)(g) recognizes that there may be special situations where the requirements of (2)(f) are impractical and gives direction to the AHJ to determine alternative storage locations for these situations.

69.3.5 Container Separation Distances.

69.3.5.1 Aboveground Containers. [58:6.4.1]

69.3.5.1.1* Containers installed outside of buildings, whether of the portable type replaced on a cylinder exchange basis or permanently installed and refilled at the installation, shall be located with respect to the adjacent containers, important building, group of buildings, or line of adjoining property that can be built upon, in accordance with Table 69.3.5.1.1, Table 69.3.6.1.2, 69.3.5.1.2 through 69.3.5.1.3, 69.3.5.3, 69.3.5.4.1 through 69.3.5.4.4, and 69.3.6.3.6 through 69.3.6.3.11. [**58:**6.4.1.1]

The requirement in 69.3.5.1.1 has been in NFPA 58 since at least the 1967 version of that code. It is a critical part of the code and the most widely used.

The requirements in 69.3.5 through 69.3.7 and Section 6.29 of NFPA 58 provide location and point-of-transfer requirements for containers. These requirements are critical to understanding the application of Table 6.4.1.1.

The siting criteria in 69.3.5.1.1 require that a container be located a specified distance from other containers, an important building or group of buildings, or a line of adjoining property that can be built upon. These separation distances are intended to reflect the container's relative exposure hazard due to the presence of the items cited and vice versa.

The distances are based on a combination of the following factors:

- Potential hazard of LP-Gas
- Size and type of equipment used to contain the gas
- Possibility of leaks (which can ignite)
- Need for fuel in buildings

The distances are not based on a worst-case scenario in which the LP-Gas container fails catastrophically, releasing its contents in a few seconds. During the approximately 80-year history of NFPA 58, experience with LP-Gas containers located near buildings has not identified that such incidents occur.

Research has been conducted to evaluate the effects of radiant heat from fires to LP-Gas containers. Raj, in the article "Exposure of a Liquefied Gas Container to an External Fire," discussed this evaluation, the associated mathematical model, and detailed results with and without the effects of wind in the peer-reviewed *Journal of Hazardous Materials*.

The maximum steel container surface temperatures where in contact with vapor are presented in Commentary Table 69.1. Several different container sizes are provided.

The temperature at which the yield strength of a propane tank's steel begins to decrease is close to 800°F (427°C). Based on that temperature, there is no threat of propane tank failure from radiant heat due to an external fire occurring at the minimum separation distances specified in Table 69.3.5.1.1.

In general, two phrases that appear in the text of 69.3.5.1.1 continue to cause confusion among users and enforcers: "important building" and "line of adjoining property that can be built upon."

TABLE 69.3.5.1.1 Separation Distances Between Containers, Important Buildings, and Line of Adjoining Property That Can Be Built Upon

Water Capacity per Container		Minimum Distances					
		Mounded or Underground Containers[a]		Aboveground Containers		Between Containers[b]	
gal	m³	ft	m	ft	m	ft	m
<25[c]	<0.5[c]	10	3	0[d]	0[d]	0	0
125–250	0.5–1.0	10	3	10	3	0	0

[**58:**Table 6.4.1.1]

COMMENTARY TABLE 69.1 *Maximum Steel Container Surface Temperatures in Contact with Vapor Space Where Exposed to Fire*

Container Size (w.c.)		Maximum Temperature Attained (30-minute Exposure)	
gal	m³	°F	°C
1,000	3.8	660	349
2,000	7.6	648	342
4,000	15.2	507	264
12,000	45.4	507	264
18,000	68.1	437	225
30,000	114.0	384	195
60,000	227.0	340	171

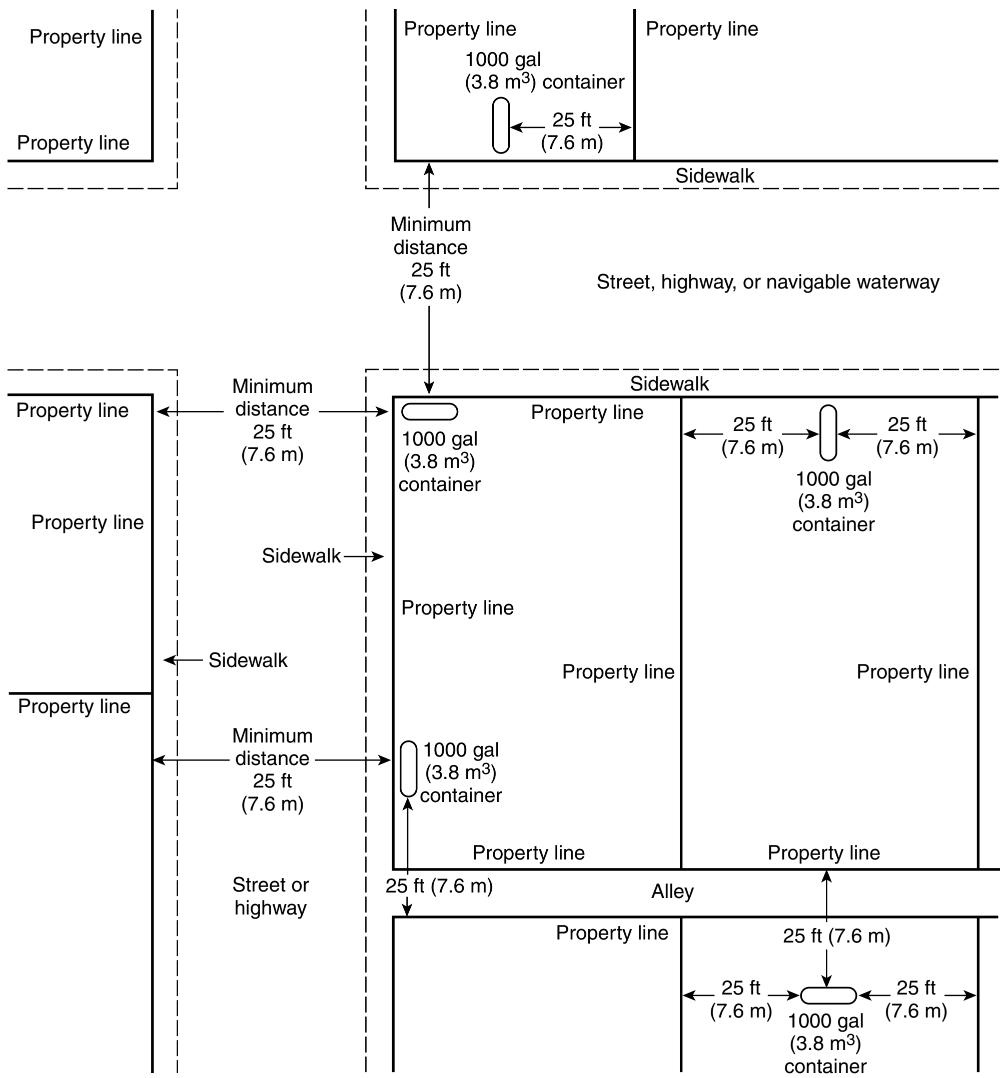
A.69.3.5.1.1 When applying Table 69.3.5.1.1 to cylinders, which have their capacities expressed in pounds, the first table entry, <125 gal (<0.5 m³), includes all cylinders. Cylinders have a maximum capacity of 1000 lb or 119 gal (454 kg or 3.8 m³) (water capacity). [**58:**A.6.4.1.1]

The "Line of Adjoining Property that can be built upon" refers to the property boundaries of the plot adjacent to the one upon which the tank is located. This is illustrated in Figure A.69.3.5.1.1 taking into consideration a condition that involves property on the other side of a street, highway, navigable waterway, or other right of way. The minimum distance limitation is from the tank to the property line where that property line is common to plots of ground of different ownership and would also apply between the tank and the property line of the far side of a street or other public right of way. [**58:**A.6.4.1.1]

69.3.5.1.2 When the provisions of 6.30.3 through 6.30.5 of NFPA 58 are met, the minimum distance from an ASME container to a building shall be reduced by one-half for ASME containers of 2001 gal through 30,000 gal (7.6 m³ through 114 m³) water capacity. [**58:**6.4.1.2]

Paragraph 69.3.5.1.2 recognizes the alternative installation requirements of 6.30.4 and 6.30.5 of NFPA 58 for redundant fail-safe product control methods and low emission transfer, respectively. In accordance with those subsections in NFPA 58, the separation distance can be reduced.

69.3.5.1.3 The 25 ft (7.6 m) minimum distance from aboveground ASME containers of 501 gal through 2000 gal (1.9 m³ through 7.6 m³) water capacity to buildings, a group of buildings, or the



△ ***FIGURE A.69.3.5.1.1*** *Illustration of Separation Distances from Containers to the Line of Adjoining Property that can be Built Upon. [**58:**Figure A.6.4.1.1]*

line of adjoining property that can be built upon shall be reduced to 10 ft (3 m) for a single ASME container of 1200 gal (4.5 m³) or less water capacity where such container is at least 25 ft (7.6 m) from any other LP-Gas container of more than 125 gal (0.5 m³) water capacity. [**58:**6.4.1.3]

Paragraph 69.3.5.1.3, often called the "restaurant exemption," provides a special case that allows the installation of one LP-Gas container of 1200 gal (4.5 m³) or less 10 ft (3 m) from a building rather than the 25 ft (7.6 m) required in Table 69.3.5.1.1. The 10 ft (3 m) spacing of one container with 1200 gal (4.5 m³) or less water capacity is allowed only if one such container is installed and there are no other LP-Gas containers of more than 125 gal (0.5 m³) water capacity within 25 ft (7.6 m). The provision was created because of the limited space often found in commercial areas, and it has continued to be used because fire records do not indicate a problem with the reduced distance.

Note that the 25 ft (7.6 m) separation distance to other LP-Gas containers is applicable in all cases, even if two different users would like to install containers less than 25 ft (7.6 m) apart.

69.3.5.2 Underground or Mounded ASME Containers.

69.3.5.2.1 Minimum distances for underground or mounded ASME containers of 2001 gal through 30,000 gal (7.6 m³ through 114 m³) water capacity, incorporating all the provisions of Section 6.30 of NFPA 58, shall be reduced to 10 ft (3 m). [**58:**6.4.2.1]

The reduced distances for underground or mounded containers reflect the fact that they are not subject to boiling liquid expanding vapor explosions (BLEVEs) from fire exposure, and the features provided in Section 6.30 of NFPA 58 reduce the potential for uncontrolled release of product that could result in an explosion hazard.

Paragraphs 69.3.5.2.2 69.3.5.2.3 provide important information in measuring the distances required in 69.3.5.2.1. Although they may appear redundant to one another, 69.3.5.2.2 and 69.3.5.2.3 do not address the same issues. Paragraph 69.3.5.2.2 addresses the clearances for fire safety purposes, while 69.3.5.2.3 addresses spacing requirements to allow heavy equipment to have access to the containers as well as to create an access easement for utilities.

69.3.5.2.2 Distances for all underground and mounded ASME containers shall be measured from the container surface. [**58:**6.4.2.2]

Note that 69.3.5.2.2 requires that the measurement of separation distances from an underground or mounded ASME container be taken from the nearest surface of the container rather than the pressure relief valve discharge, which is used in 69.3.5.4.

69.3.5.2.3 No part of an underground or mounded ASME container shall be less than 10 ft (3 m) from a building or line of adjoining property that can be built upon. [**58:**6.4.2.3]

It is stated in this *Code* that no part of an underground tank is permitted be within 10 ft (3 m) of a building. However, there may be situations where there is a property line that may be built upon, but an underground tank may be desired less than 10 ft (3 m) from that line (e.g., a coastal or remote area with limited space). If such an installation is requested and there is guaranteed assurance that no building will be located within 10 ft (3 m) horizontally from any surface of the tank, even across the property line, then the intent to keep the tank away from buildings is met. This type of situation is allowed by the *Code* via the equivalency provisions in Section 1.4.

69.3.5.3 Minimum Separation Distances for ASME Containers.

69.3.5.3.1 The minimum separation distances specified in Table 69.3.5.1.1 between containers and buildings of noncombustible construction devoted exclusively to gas manufacturing and distribution operations shall be reduced to 10 ft (3 m). [**58:**6.4.3.1]

Paragraph 69.3.5.3.1 allows a reduction of the separation distances [from 50 ft (15 m) to 10 ft (3 m)] of containers to buildings used only for gas manufacturing and distribution because workers in a building covered by this provision are employed in the transfer of liquid LP-Gas and have had initial and refresher training in its hazards. In addition, because the building is constructed of noncombustible materials, the potential exposure to the container from a building fire is greatly reduced. The separation distance from containers to other buildings on the site and to buildings on adjacent sites cannot be reduced.

69.3.5.3.2 If the aggregate water capacity of a multicontainer installation is 501 gal (1.9 m³) or more and the installation is comprised of individual containers, each with a water capacity of less than 125 gal (0.5 m³), the minimum distance shall comply with Table 69.3.5.1.1 and 69.3.5.3.2.1 through 69.3.5.3.2.3. [**58:**6.4.3.2]

69.3.5.3.2.1 The aggregate capacity shall be used rather than the capacity per container. [**58:**6.4.3.2(A)]

69.3.5.3.2.2 If more than one such installation is made, each installation shall be separated from any other installation by at least 25 ft (7.6 m). [**58:**6.4.3.2(B)]

69.3.5.3.2.3 The minimum distances between containers shall not be applied to installations covered by 69.3.5.3.2. [**58:**6.4.3.2(C)]

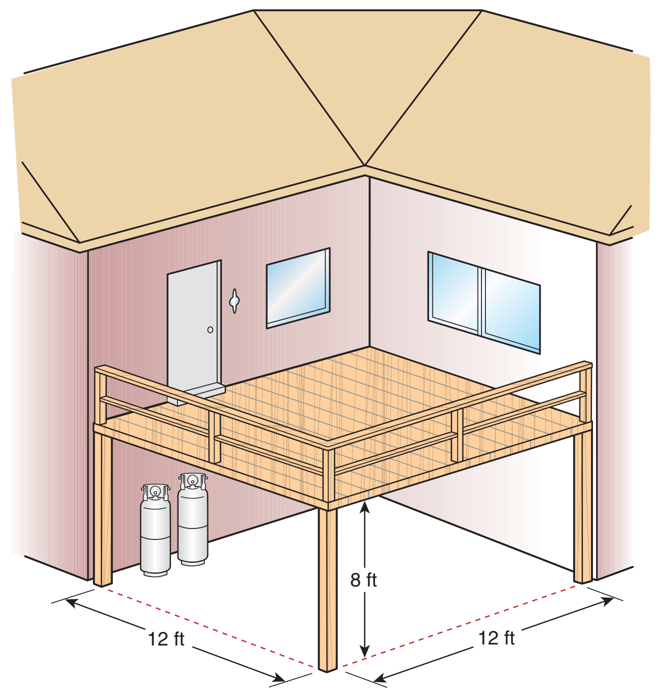
69.3.5.4 Separation Distance Between Container Pressure Relief Valve and Building Openings.

69.3.5.4.1 Cylinders shall not be located and installed underneath any building sunless the space is open to the atmosphere for 50 percent of its perimeter or more. [**58:**6.4.4.1]

Paragraph 69.3.5.4.1 provides guidance to *Code* users who install cylinders outdoors that are protected from the weather. It establishes that a minimum of 50 percent of the perimeter of an enclosed area be open to the atmosphere. See Exhibit 69.11, which shows a deck with two sides completely open. Cylinders can be installed under a deck like the one in the exhibit.

Although NFPA 58 is not a building code, it does provide safety requirements for the installation of propane containers that help achieve the safe occupancy and use of buildings. Note that NFPA *101*®, *Life Safety Code*®, prohibits LP-Gas containers

Exhibit 69.11



Total wall enclosure area = (12 ft × 8 ft) × 4 = 384 ft²
Minimum required open area = 384 ft² × 50% = 192 ft²

Illustration of 50 percent open perimeter of the space below a deck.

from being located under egress paths from upper-level rooms. This would preclude locating containers under a stairway or ramp that is the best practical way to evacuate — for example, a second-floor apartment or an elevated beach house.

69.3.5.4.2 ASME containers of less than 125 gal (0.5 m^3) water capacity shall be located and installed so that the discharge from pressure relief devices shall not terminate in or beneath any building. [**58:**6.4.4.2]

69.3.5.4.3* The distance measured horizontally from the point of discharge of a container pressure relief valve to any building opening below the level of such discharge shall be in accordance with Table 69.3.5.4.3. [**58:**6.4.4.3]

TABLE 69.3.5.4.3 *Separation Distance Between Container Pressure Relief Valve and Building Openings*

Container Type	Exchange or Filled on Site at the Point of Use	Distance Horizontally from Relief Valve Discharge to Opening Below Discharge		Discharge from Relief Valve, Vent Discharge, and Filling Connection to Exterior Source of Ignition, Openings into Direct-Vent Appliances, and Mechanical Ventilation Air Intakes	
		ft	m	ft	m
Cylinder	Exchange	3	0.9	5	1.5
Cylinder	Filled on site at the point of use	3	0.9	10	3.0
ASME	Filled on site at the point of use	5	1.5	10	3.0

[**58:**Table 6.4.4.3]

A.69.3.5.4.3 Building openings in the context of 69.3.5.4.3 are any opening that communicates air from the exterior to the interior of the building, including windows, doors, or dryer vent terminations below the level of the relief valve discharge. [**58:**A.6.4.4.3]

Table 69.3.5.4.3 highlights the differences in location requirements between cylinders and ASME containers. The table also highlights the different requirements between cylinders filled on site and cylinders that are exchanged. An exchanged cylinder is one that is transported full to the consumer site to be exchanged with an empty cylinder. Note that the distance is greater for containers (both cylinders and ASME tanks) filled at the point of use because the fixed maximum liquid level gauge (referred to as "Vent Discharge" in the table) is usually open and discharges propane into the air while the cylinder is being filled. There is also a small discharge of propane when the hose assembly is disconnected from the container filler valve. Both of these releases are a possible ignition hazard and warrant the extra separation distance.

Table 69.3.5.4.3 applies to cylinders installed alongside a building. The requirements are intended to achieve the following:

- Minimize the possibility of LP-Gas escaping through the cylinder pressure relief valve and entering a building. Pressure relief valve operation is most likely to occur if the container has been overfilled or the container is heated due to exposure to intense sunlight or another source of heat.
- Minimize the possibility of any LP-Gas released through the relief valve providing fuel for a fire or igniting.

Note that the required distance to a pressure relief valve on a cylinder from a building opening is 3 ft (1 m), and the required distance for a pressure relief valve on an ASME container is 5 ft (1.5 m). This difference recognizes the following:

1. The start-to-discharge setting for a relief valve on a cylinder is higher than that for an ASME container [nominally 375 psig (2.6 MPag) and 250 psig (1.7 MPag), respectively], resulting in a lower probability of a discharge of LP-Gas occurring from a DOT cylinder than from an ASME container.
2. The cylinder relief valve is smaller than the relief valves used on large ASME containers. The discharge flow is correspondingly less.

The "building opening" cited in 69.3.5.4.3 is normally a door or a window, which can be either closed or open. When open, doors and windows can have air flow through them in either direction due to natural breezes.

Building openings also include crawl space vents. Recent construction trends have resulted in these vents on residences being spaced 6 ft (1.8 m) on center. As such, a container may not be placed between them and next to the building and still have the required separation from the opening. Sealing the vent could be an option if it does not violate the venting requirements of the crawl space; however, doing so may result in inadequate ventilation of the space.

Where the airflow is caused by a mechanical air movement system, such as a direct-vent appliance or a mechanical ventilation air intake, a 5 ft (1.5 m) distance for exchanged cylinders or a 10 ft (3 m) distance for cylinders or ASME containers filled at the point of use is specified. The reason for this requirement is because the directed airflow into the building could pick up LP-Gas.

Although direct-vent appliances do not represent a pathway for LP-Gas into the building, they do draw in outside air for combustion. If this air contains LP-Gas in ignitible proportions, the appliance ignition or burner flame can be an ignition source, and because of the small volume within which the flammable mixture is contained, an overpressure event may be possible.

Mechanical ventilation system air intakes are an obvious pathway for LP-Gas into a building interior. A mechanical ventilation system air outlet — for example, a kitchen exhaust fan — is considered to be a building opening, much like a door or window, and may actually draw air into the building when it is not operating. While the fan may incorporate a damper to minimize reverse flow, such dampers rarely seal tightly and are known to deform and allow reverse flow after some time in use.

See Exhibit 69.12 for an illustration of the requirements in Table 69.3.5.1.1 and Table 69.3.5.4.3.

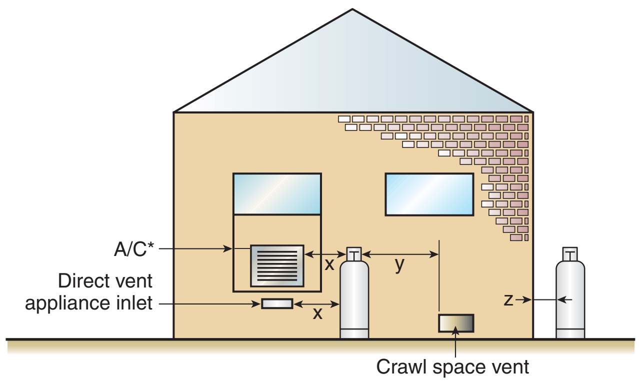
69.3.5.4.4 The distance measured in any direction from the point of discharge of a container pressure relief valve, vent of a fixed maximum liquid level gauge on a container, and the container filling connection to exterior sources of ignition, openings into direct-vent (sealed combustion system) appliances, and mechanical ventilation air intakes shall be in accordance with Table 69.3.5.4.3. [**58:**6.4.4.4]

Work on the dispersion of flammable gases from relief valves has been conducted by the Battelle Memorial Institute and is reported in the paper by Hoehne, Luce, and Miga titled "The Effect of Velocity, Temperature, and Gas Molecular Weight on Flammability Limits in Wind-Blown Jets of Hydrocarbon Gases." That report forms a basis for API STD 521, *Pressure-Relieving and Depressuring Systems*.

The results of one test on dispersion of flammable gases from relief valves are shown in Exhibit 69.13. While this reports just one test, which was not intended to be a thorough study, it is the only data available. Discharge of liquid from a fixed maximum liquid level gauge for as long as 3 minutes is an abnormal condition because, normally, the gauge discharge valve is closed by the person filling the container when liquid first appears. A lack of wind is conducive to the formation of high concentrations of LP-Gas, but it is a rare occurrence. In spite of the severity of the test conditions as compared to field experience, the concentration of LP-Gas at 10 ft (3 m) did not exceed 20 percent of the lower flammable limit (LFL), or a safety factor of 5.

The required separation for containers filled on site also reflects the small but distinct possibility that the filler valve may

Exhibit 69.12



Distance to outdoor sources of ignition and building openings (source: Table 69.3.5.4.3)

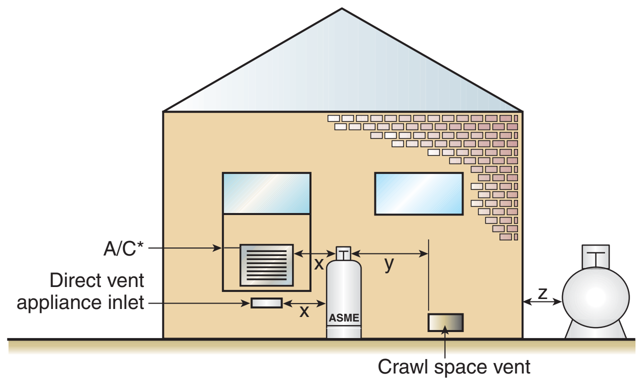
Filling method	Distance X	Distance Y
Filled by exchange	5 ft	3 ft
Filled at the point of use	10 ft	5 ft

* or other exterior source of ignition

Distance to building, cylinders - Z (source: Table 69.3.5.1.1)

One container 125 gal or less	0 ft
Multiple containers, 125 gal or less with aggregate < 501 gal	0 ft
Multiple containers, 125 gal or less with aggregate > 501 gal	Per Table 69.3.5.1.1 (using aggregate water capacity)

(a) Location of Cylinders



Distance to outdoor sources of ignition and building openings (source: Table 69.3.5.4.3)

Filling method	Distance X	Distance Y
Filled by exchange	5 ft	5 ft
Filled at the point of use	10 ft	5 ft

* or other exterior source of ignition

Distance to building - Z, ASME containers up to 2000 gal (source: Table 69.3.5.1.1)

One container 125 gal or less	0 ft
126–500 gal	10 ft
One container, 501–1200 gal	10 ft (see 69.3.5.1.3)
501–1200 gal	25 ft

(b) Location of ASME Containers

Locations of cylinders and ASME containers.

Concentration of propane-air mixture resulting from discharge of liquid propane from a fixed liquid level gauge on a cylinder. (Courtesy of Wilbur Walls)

not close properly after the container is filled. If the filler valve fails to close when the fill nozzle is removed, gas will be released through the valve and can result in fire and injury to transfer personnel.

69.3.5.4.5 Access at the ends or sides of individual underground containers having a water capacity of 125 gal (0.5 m^3) or more shall be provided in multicontainer installations to facilitate working with cranes or hoists. [**58:**6.4.4.5]

Paragraph 69.3.5.4.5 requires that access to an underground container installation be provided to allow cranes and hoists to service or remove the containers. Minimum clearance around the container installation is not required because many cranes can extend to allow access to the containers from a single point.

69.3.6 Other Container Location Requirements.

69.3.6.1 ASME Multi-Container Requirements.

69.3.6.1.1 Where storage containers having an aggregate water capacity of more than 4000 gal (15.2 m^3) are located in heavily populated or congested areas, the siting provisions of 69.3.5.1.1 and Table 69.3.5.1.1 shall be permitted to be modified as indicated by the fire safety analysis described in 6.29.3 of NFPA 58. [**58:**6.5.1.1]

The text in 69.3.6.1.1 establishes an additional requirement for larger installations in populated and congested areas, allowing the AHJ to require an analysis of local conditions.

In the United States and Canada, LP-Gas installations are usually found in rural and suburban areas or in commercial and industrial areas, where the hazards are commensurate with other operations and exposure to the public has been limited accordingly. Inevitably, exceptions to these locations occur and the versatility of LP-Gas has increased the number of LP-Gas installations. Installations are common in towns and cities not supplied by a utility gas system. In other countries, propane installations can be found in similar locations or throughout the country, depending on the availability of other fuels.

Paragraph 69.3.6.1.1 recognizes that larger installations in populated or congested areas may warrant further attention to the general siting criteria in 69.3.5.1.1. Some *Code* users misinterpret 69.3.6.1.1 to mean that, where storage exceeds 4000 gal (15.2 m^3), the separation distances of Table 69.3.5.1.1 should be increased. This is not necessarily the case. In addition, attempts have been made to force propane facilities to be relocated if buildings have been allowed to be constructed closer than the spacing requirements of Table 69.3.5.1.1 after the propane facility has been installed.

Increasing the distances may be impossible in a heavily populated or congested area. What 69.3.6.1.1 does state is that the distances provided in 69.3.5.1.1 and Table 69.3.5.1.1 can be modified based on the results of a fire safety analysis. The requirements for the fire safety analysis are provided in 6.29.3 of NFPA 58.

The phrase "heavily populated or congested areas" is not defined. The phrase is subject to interpretation by the AHJ; often, zoning criteria will come into play. For example, an area including buildings that house an institutional occupancy — such as a prison or a hospital — in which the occupants are incarcerated or nonambulatory and unable to respond to an emergency without assistance may be considered congested or heavily populated.

69.3.6.1.2 Aboveground multicontainer installations comprised of ASME containers having an individual water capacity of 12,000 gal (45 m^3) or more and installed for use in a single location shall be limited to the number of containers in one group, with each group separated from the next group in accordance with the degree of fire protection provided in Table 69.3.6.1.2. [**58:**6.5.1.2]

69.3.6.1.3 Where the provisions of 6.30.3 and 6.30.4 of NFPA 58 are met, the minimum separation distance between groups of ASME containers protected by hose stream only shall be one-half the distances required in Table 69.3.6.1.2. [**58:**6.5.1.3]

This reduced spacing is allowed because the provisions of 6.30.3 and 6.30.4 of NFPA 58 enhance the product control performance of the containment system. For example, 6.30.3 requires internal valves to be installed having both remote and automatic (thermally activated) shutoff capability, as well as positive shutoff valves. In addition, 6.30.4 of NFPA 58 requires ESVs with remote and thermal activation.

69.3.6.2 Underground and Mounded ASME Containers.

69.3.6.2.1 Underground or mounded ASME containers shall be located in accordance with 69.3.6.2.2 and 69.3.6.2.3. [**58:**6.5.2.1]

69.3.6.2.2 Underground or mounded containers shall be located outside of any buildings. [**58:**6.5.2.2]

Δ *TABLE 69.3.6.1.2 Maximum Number of Containers in a Group and Their Separation Distances*

Fire Protection Provided by	Maximum Number of Containers in One Group	Minimum Separation Between Groups	
		ft	m
Hose streams only *(see 6.5.1.2 and 6.29.3.1 of NFPA 58)*	6	50	15
Fixed monitor nozzles per 6.29.6.3 of NFPA 58	6	25	7.6
Fixed water spray per 6.29.6.1 of NFPA 58	9	25	7.6
Insulation per 6.29.5.1 of NFPA 58	9	25	7.6

[**58:** Table 6.5.1.2]

69.3.6.2.3 Buildings shall not be constructed over any underground or mounded containers. [**58:**6.5.2.3]

The requirement that underground and mounded containers be installed outdoors (and not beneath buildings) is consistent with the requirements for aboveground containers.

N **69.3.6.2.4** The sides of adjacent containers shall be separated in accordance with Table 69.3.5.1.1 but shall not be separated by less than 3 ft (1 m). [**58:**6.4.2.4]

N **69.3.6.2.5** Where containers are installed parallel with ends in line, the number of containers in one group shall not be limited. [**58:**6.4.2.5]

N **69.3.6.2.6** Where more than one row of containers is installed, the adjacent ends of the containers in each row shall be separated by not less than 10 ft (3 m). [**58:**6.4.2.6]

A minimum separation distance of 3 ft (1 m) for underground and mounded containers is required in 69.3.6.2.4 to allow for movement that cannot be observed. This minimum separation is also required between rows of containers to allow heavy equipment access, if needed (see Exhibit 69.14).

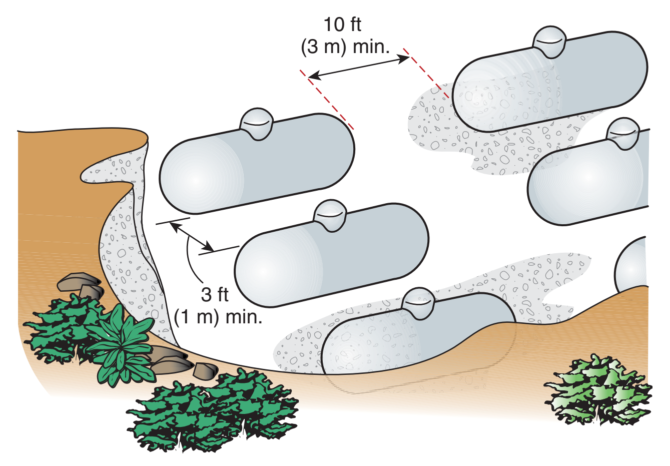
69.3.6.3 Additional Container Installation Requirements.

69.3.6.3.1 Additional container installation requirements shall comply with 69.3.6.3.2 through 69.3.6.3.13 and 69.3.6.4. [**58:**6.5.3.1]

69.3.6.3.2 Containers shall not be stacked one above the other. [**58:**6.5.3.2]

The purpose of the requirement in 69.3.6.3.2 is to avoid incidents where a gas release from one container can cause fire impingement on a container installed above it.

Exhibit 69.14



Separation of mounded or underground containers.

A literal reading of the words indicates that such an installation is prohibited. However, the intent of 69.3.6.3.2 is to prevent interaction between containers in a fire situation. One of two scenarios would have to occur for a negative impact from this type of scenario:

1. An underground container catches fire and affects the aboveground container.
2. An aboveground container on fire affects an underground container installed beneath it.

One of the concerns for such an installation would be the location of the relief valve discharge of the underground container. Depending on the installation, it may be prudent to pipe the relief valve discharge of the underground container to a point where it is higher than the top of, or cannot impinge on, an aboveground container installed above it. In such cases, care must be taken to ensure that the relief valve discharge piping cannot affect the operation of the relief valve.

It should be noted that there are other reasons not related to safety that make such an installation preferable. One reason in particular would be that maintenance of either container will become more difficult, especially that of the underground container.

69.3.6.3.3* Combustible materials shall not accumulate or be stored within 10 ft (3 m) of a container. [**58:**6.5.3.3]

Δ **A.69.3.6.3.3** Clearance is required between combustible materials and propane containers in order to minimize the effects of fires on the container. The requirement to maintain separation between the container and stored combustible materials is needed so that an accumulation of materials that may represent a hazard to the container does not occur. The term "stored" is intended to denote materials that are purposely placed. Vegetation of any type located near or under the container is not considered to be a hazard. [**58:**]

69.3.6.3.4* The area under containers shall be graded or shall have dikes or curbs installed so that the flow or accumulation of flammable liquids with flash points below 200°F (93.4°C) is prevented. [**58:**6.5.3.4]

A.69.3.6.3.4 For information on flash point see NFPA 30 [**58:**A.6.5.3.4]

The requirement in 69.3.6.3.4 is intended to be applied where LP-Gas containers are installed in close proximity to other flammable liquid storage containers. Paragraph 69.3.6.3.5 indicates the required separation from containers used to store flammable or combustible liquids that have a wall or dike constructed between them and the LP-Gas container.

Flash point is the temperature at which a flammable liquid can vaporize in sufficient quantity to form a flammable mixture of vapor and air. A liquid's flash point is determined by a test in which a sample of the liquid in an open cup is heated until its vapors can be ignited. Gases, such as propane and butane, do not have a flash point because they cannot be contained in an open cup at room temperature, although it is possible to measure a flash point by refrigerating propane or butane and using a refrigerated cup.

Propane will remain a liquid below –40°F (–40°C) but, even at such low temperatures, a flash point provides no useful information because the presence of flammable gas is assumed in the event of leakage. Flash point has value in dealing with flammable liquids because it advises when to be concerned about ignition of vapors (e.g., gasoline) and when not to be concerned (e.g., motor oil).

Liquids with flash points below 100°F (37.8°C) are classified as Class I (flammable) liquids in NFPA 30, *Flammable and Combustible Liquids Code*. Examples of Class I (flammable) liquids are gasoline and many alcohols. Liquids with a flash point between 100°F and 140°F (37.8°C and 60.0°C) are classified as Class II (combustible) liquids. Examples of Class II (combustible) liquids include diesel fuel and kerosene.

69.3.6.3.5 LP-Gas containers shall be located at least 10 ft (3 m) from the centerline of the wall of diked areas containing flammable or Class II combustible liquids. [**58:**6.5.3.5]

69.3.6.3.6 The minimum horizontal separation between aboveground LP-Gas containers and aboveground tanks containing liquids having flash points below 200°F (93.4°C) shall be 20 ft (6 m). [**58:**6.5.3.6]

Paragraphs 69.3.6.3.5 and 69.3.6.3.6 are intended to keep flammable or combustible liquids from accumulating under or around LP-Gas containers. Paragraph 69.3.6.3.6 addresses the mutual exposure between flammable liquids tanks and LP-Gas containers. This requirement was derived through a cooperative effort between the NFPA technical committees responsible for NFPA 30 and NFPA 58. The minimum separation distance of 20 ft (6 m) facilitates cooling and fire-extinguishing activities by fire departments. Paragraphs 69.3.6.3.7 and 69.3.6.3.8 point out exceptions to this distance where mitigation measures are utilized.

69.3.6.3.7 The requirements of 69.3.6.3.6 shall not apply where LP-Gas containers of 125 gal (0.5 m^3) or less water capacity are installed adjacent to fuel oil supply tanks of 660 gal (2.5 m^3) or less capacity. [**58:**6.5.3.7]

The requirement in 69.3.6.3.7 recognizes the reduced hazard that smaller storage containers present and the fact that many installations are limited in space, making it impractical to comply with the 20 ft (6 m) separation distance. Industry experience has shown that these installations are not a safety problem. The interpretation is that the maximum capacity of both containers must be met for the exception to apply.

69.3.6.3.8 No horizontal separation shall be required between aboveground LP-Gas containers and underground tanks containing flammable or combustible liquids installed in accordance with NFPA 30. [**58:**6.5.3.8]

Δ **69.3.6.3.9*** The minimum separation between LP-Gas containers and oxygen or gaseous hydrogen containers shall be in accordance with NFPA 55. [**58:**6.5.3.9]

A.69.3.6.3.9 Also see NFPA 51 for oxygen systems. [**58:**A.6.5.3.9]

69.3.6.3.10 Where protective structures having a minimum fire resistance rating of 2 hours interrupt the line of sight between uninsulated portions of the oxygen or hydrogen containers and the LP-Gas containers, no minimum distance shall apply. [**58:**6.5.3.10]

Δ **69.3.6.3.11** The minimum separation between LP-Gas containers and liquefied hydrogen containers shall be in accordance with NFPA 55. [**58:**6.5.3.11]

The separation requirements between oxygen, gaseous hydrogen, and liquefied hydrogen containers and systems should be obtained from NFPA 55, *Compressed Gases and Cryogenic Fluids Code*. Rather than recreating those portions of NFPA 55, users are referred to NFPA 55 for complete coverage.

Paragraph 69.3.6.3.10 is an exception to 69.3.6.3.9 and permits an elimination of separation where the required 2-hour fire resistance–rated assembly is installed. This assembly is considered sufficient to protect the container from fire impingement.

69.3.6.3.12 Where LP-Gas cylinders are to be stored or used in the same area with other compressed gases, the cylinders shall be marked to identify their content in accordance with ANSI/CGA C-7, *Guide to the Preparation of Precautionary Labeling and Marking of Compressed Gas Containers*. [**58:**6.5.3.12]

69.3.6.3.13 An aboveground LP-Gas container and any of its parts shall not be located within 6 ft (1.8 m) of a vertical plane beneath overhead electric power lines that are over 600 volts, nominal. [**58:**6.5.3.13]

The requirement in 69.3.6.3.13 reflects the possibility of an accident occurring should a power line break and lead to container failure through arc penetration or ignition of the pressure relief valve discharge.

69.3.6.4* Structure Requirements.

A.69.3.6.4 The presence of such structures can create significant hazards, such as the following:

(1) Pocketing of escaping gas
(2) Interference with application of cooling water by fire departments
(3) Redirection of flames against containers
(4) Impeding the egress of personnel in an emergency
[**58:**A.6.5.4]

69.3.6.4.1 Structures such as fire walls, fences, earth or concrete barriers, and other similar structures shall not be permitted around or over installed nonrefrigerated containers unless specifically allowed. [**58:**6.5.4.1]

69.3.6.4.2 Structures partially enclosing containers shall be permitted if designed in accordance with a sound fire protection analysis. [**58:**6.5.4.2]

69.3.6.4.3 Structures used to prevent flammable or combustible liquid accumulation or flow shall be permitted in accordance with 69.3.6.3.4. [**58:**6.5.4.3]

69.3.6.4.4 Structures between LP-Gas containers and gaseous hydrogen containers shall be permitted in accordance with 69.3.6.3.10. [**58:**6.5.4.4]

69.3.6.4.5 Structures such as fences shall be permitted in accordance with 6.21.4 of NFPA 58. [**58:**6.5.4.5]

69.3.7 Location of Transfer Operations.

Subsection 69.3.7 deals with the filling of portable containers and with the filling of stationary containers when not filled at the container (i.e., via fixed piping to a point remote from the container where the filling hose is connected). It does not apply to the filling of stationary containers where the point of transfer is located at the container. Subsection 69.3.7 is not in conflict with Subsection 69.3.5, as is sometimes thought. Subsection 69.3.5 applies to the location of containers, while Subsection 69.3.7 applies to points of transfer, that is, a location where the filling hose connection is made and broken to fill various containers.

Paragraph 69.3.7.1.6 permits a container in a stationary installation to be filled at the container itself as long as it is in compliance with 69.3.5. Where the filling point is piped to another location (not at the container), 69.3.7.2.1 becomes applicable.

The location of portable cylinders being filled is not covered in 69.3.5. The applicable subsection is 69.3.5, with the pertinent requirements found in 69.3.7.2.2. Note that the storage of cylinders awaiting sale or use is covered in Chapter 8 of NFPA 58.

69.3.7.1 Transfer of Liquids.

69.3.7.1.1* Liquid shall be transferred into containers, including containers mounted on vehicles, only outdoors or in structures specially designed for such purpose. [**58:**6.7.1.1]

A.69.3.7.1.1 It is the intent to allow transfer of liquid into containers in open areas under canopies or roofs where 50 percent or more of the perimeter is not enclosed. [**58:**A.6.7.1.1]

The location of portable containers being filled is of concern. If filling is to be done in a building, the building must meet the requirements of Chapter 10 of NFPA 58. It is the intent of those requirements that if filling occurs in a structure open to the outdoors and at least 50 percent of its perimeter is not enclosed, it is considered outdoors.

69.3.7.1.2 The transfer of liquid into containers mounted on vehicles shall not take place within a building but shall be permitted to take place under a weather shelter or canopy. *(See 6.27.3.3 of NFPA 58.)* [**58:**6.7.1.2]

The reference to 6.27.3.3 of NFPA 58 guides the user to more information on the limits of a weather shelter. For example, that referenced paragraph requires that a minimum of 50 percent of the perimeter under a weather shelter or canopy not be enclosed.

69.3.7.1.3 Structures housing transfer operations or converted for such use after December 31, 1972, shall comply with Chapter 10 of NFPA 58. [**58:**6.7.1.3]

69.3.7.1.4 The transfer of liquid into containers on the roofs of structures shall be permitted, provided that the installation conforms to the requirements specified in 6.8.7 and 6.22.11 of NFPA 58. [**58:**6.7.1.4]

69.3.7.1.5 The transfer hose shall not be routed in or through any building except those specified in 69.3.7.1.3. [**58:**6.7.1.5]

The prohibition of routing delivery hoses through buildings resulted from reports in at least one area where row houses are common and where there is no street access for the bobtail to the containers. The shortest route for the hose was into the building through the front door and out the back door to the cylinder. The practice of routing the hose through a building increased the possibility of hose damage and the potential for subsequent leakage in an enclosed area.

69.3.7.1.6 Filling of containers located outdoors in stationary installations in accordance with 69.3.5 shall be permitted to be filled at that location. [**58:**6.7.1.6]

This *Code* requirement, which is often misunderstood, simply states that if the hose end valve of a delivery vehicle is connected to a fill valve that is attached directly to the container, the provisions of 69.3.7 do not apply as long as the container itself has been installed in accordance with the spacing requirements of 69.3.5.

69.3.7.2 Container Point of Transfer Location Requirements.

Δ **69.3.7.2.1** If the point of transfer of containers located outdoors in stationary installations is not located at the container, it shall be located in accordance with Table 69.3.7.2.1. [**58:**6.7.2.1]

Where a portable container is filled, or where the filling connection of a stationary container is located remote from the container, hazards exist that are not addressed by the spacing distances in 69.3.5. These hazards are addressed in Table 69.3.7.2.1, including not only the hazards to the surroundings from the filling process but to the LP-Gas installation from the surroundings as well.

Δ ***TABLE 69.3.7.2.1*** *Distance Between Point of Transfer and Exposures*

Part	Exposure	Minimum Horizontal Distance ft	m
A	Buildings,[a] mobile homes, recreational vehicles, and modular homes with at least 1-hour fire-rated walls[b]	10[c]	3.1
B	Buildings[a] with other than at least 1-hour fire-rated walls[b]	25[c]	7.6[c]
C	Building wall openings or pits at or below the level of the point of transfer	25[c]	7.6[c]
D	Line of adjoining property that can be built upon	25[c]	7.6[c]
E	Outdoor places of public assembly, including schoolyards, athletic fields, and playgrounds	50[c]	15[c]
F	Public ways, including public streets, highways, thoroughfares, and sidewalks		
	(1) From points of transfer for LP-Gas dispensing systems	10	3.1
	(2) From other points of transfer	25[c]	7.6[c]
G	Driveways[d]	5	1.5
H	Mainline railroad track centerlines	25	7.6
I	Containers[e] other than those being filled	10	3.1
J	Flammable and Class II combustible liquid[f] dispensers and the fill connections of containers	10[c]	3.1[c]
K	Flammable and Class II combustible liquid aboveground containers, and filling connections of underground containers	20	6.1
L	Stored or accumulated combustible materials	10	3.1

[a]For the purpose of the table, buildings also include structures such as tents and box trailers at construction sites.

[b]See ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or UL 263, *Standard for Fire Tests for Building Construction and Materials*.

[c]See 69.3.7.3.4.

[d]Not applicable to driveways and points of transfer at vehicle fuel dispensers.

[e]Not applicable to filling connections at the storage container or to dispensing vehicle fuel dispenser units of 4000 gal (15.2 m^3) water capacity or less when used for filling containers not mounted on vehicles.

[f]NFPA 30 defines these as follows: Class I flammable liquids include those having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psia (276 kPa) at 100°F (37.8°C). Class II combustible liquids include those having a flash point at or above 100°F (37.8°C) and below 140°F (60°C).

[**58:** Table 6.7.2.1]

Part A of Table 69.3.7.2.1 includes mobile homes, recreational vehicles (RVs), and modular homes. Part J identifies a safe spacing from points of LP-Gas transfer to flammable liquids, Class II combustible liquids dispensers, and the fill connections of aboveground and underground containers.

Refer to NFPA 30A, *Code for Motor Fuel Dispensing Facilities and Repair Garages*, when installing propane-dispensing facilities at service stations that also dispense other vehicle fuels such as gasoline, diesel fuel, compressed natural gas (CNG), and hydrogen.

69.3.7.2.2 Containers not located in stationary installations shall be filled at a location determined by the point of transfer in accordance with Table 69.3.7.2.1. [**58:**6.7.2.2]

69.3.7.3 Separation Distance from Point of Transfer.

69.3.7.3.1 If the point of transfer is a component of a system covered by Section 6.26 or Chapter 11 of NFPA 58, the requirements of parts A, B, and C of Table 69.3.7.2.1 shall not apply to the structure containing the point of transfer. [**58:**6.7.3.1]

69.3.7.3.2 If LP-Gas is vented to the atmosphere under the conditions stipulated in 7.3.1(5) of NFPA 58, the distances in Table 69.3.7.2.1 shall be doubled. [**58:**6.7.3.2]

69.3.7.3.3 If the point of transfer is housed in a structure complying with Chapter 10 of NFPA 58, and the common walls comply with 10.2.1 of NFPA 58, separation distances in Table 69.3.7.2.1 shall not be required where the common walls comply with 10.3.1.3 of NFPA 58. [**58:**6.7.3.3]

The requirements of Chapter 10 of NFPA 58 pertain to buildings or structures housing LP-Gas facilities. Paragraph 10.3.1.3 of NFPA 58 requires a fire resistance rating of at least 1 hour for the common walls that separate the portion of the structure housing the LP-Gas facility from the rest of the structure, with openings protected by a fire door with a rating of at least 1½ hours. In addition, the wall must be designed to withstand a static pressure of 100 lb/ft^2 (4.8 kPa). Under these conditions, the distances in Table 69.3.7.2.1 can be reduced and, because no lower limit is provided, the distances can be reduced to zero. Consultation with the AHJ may be appropriate regarding distance reductions.

69.3.7.3.4 The distances in Table 69.3.7.2.1, parts B, C, D, E, F(2), and J, shall be reduced by one-half where the system incorporates the provisions of low emission transfer as provided in 6.30.5 of NFPA 58. [**58:**6.7.3.4]

69.3.8 Installation of Containers.

69.3.8.1 General Requirements.

69.3.8.1.1 Containers shall be positioned so that the pressure relief valve is in direct communication with the vapor space of the container. [**58:**6.8.1.1]

Positioning the container so that the pressure relief valve is in direct communication with the vapor space is important for several reasons, including minimal release of LP-Gas and cooling by the liquid phase change.

Tilting, inverting, or laying a cylinder on its side so that liquid LP-Gas can be withdrawn is not permitted, in part because liquid in the container comes into contact with the pressure relief device. Liquid withdrawal fittings are available that allow the proper position of the relief valve to be maintained.

Because cylinders do not normally have liquid withdrawal valves, it is common practice when emptying a cylinder at a bulk plant to temporarily orient the container in a way that allows the withdrawal of liquid from the service (vapor) valve. While the container is tilted or otherwise positioned to put the liquid in contact with the service valve, the liquid is also in communication with the pressure relief valve. This action is not a violation of 69.3.8.1.1 because the text addresses containers that are installed. Additionally, when cylinders are inverted to remove liquid, a transfer is occurring and will be attended (see 69.4.2.1.2). Those in attendance will observe any abnormal situations and correct them, something that probably would not be done for an installed container.

Δ **69.3.8.1.2** LP-Gas containers or systems that are installed within 10 ft (3 m) of public vehicular thoroughfares shall be provided with a means of vehicular barrier protection. [**58:**6.8.1.2]

Paragraph 69.3.8.1.2 is intentionally written as a performance requirement and is not meant to provide specific guidelines as to when protection is needed or the nature of the protection. Any potential threat to containers and the means of mitigation of those threats are to be determined by and are the responsibility of the *Code* user or the AHJ.

Discussions about the intent of this paragraph and others dealing with protection are widespread. As a result, a number of different devices and concepts have been proposed. Many of these are included in the annex material associated with the definition for *vehicular barrier protection (VBP)* (see A.3.3.88 of NFPA 58).

The local AHJ should be contacted to determine the expected level of protection and acceptable types of barriers.

69.3.8.1.3 Field welding on containers shall be limited to nonpressure parts such as saddle plates, wear plates, or brackets installed by the container manufacturer. [**58:**6.8.1.3]

Field welding on pressure vessels can be done only by persons qualified in accordance with the relevant pressure vessel code requirements. Heating a pressure vessel can affect the properties of the steel and must not be done unless the individual has the proper knowledge of those effects. Therefore, unless the person possesses the proper qualifications, only those parts of the system that do not affect the pressure vessel itself are permitted to be welded in the field.

Welding on an ASME pressure vessel can be performed only by welders who have received an "R" stamp certification from the NBBI. This certification permits them to repair pressure vessels such as LP-Gas containers. After the weld is complete, the NBBI "R" will be stamped on the vessel near the weld. Exhibit 69.2 shows an "R" stamp certificate.

Paragraph 69.3.8.1.3 does permit welding to take place on parts that are not part of the pressure vessel container, such as saddle plates, wear plates, and brackets.

69.3.8.1.4* Aboveground containers shall be painted. [**58:**6.8.1.4]

A.69.3.8.1.4 Generally, a light-reflecting color paint is preferred unless the system is installed in an extremely cold climate. [**58:**A.6.8.1.4]

Steel LP-Gas cylinders and ASME containers are painted for corrosion protection. Although NFPA 58 does not stipulate paint colors, color does affect the rate of heat absorption from solar radiation and the consequent pressure in the container. This heat absorption can result in operation of a pressure relief device in very warm climates. In very cold climates, a dark color may be appropriate to enhance propane vaporization in the container. Vaporization will not occur below about −40°F (−40°C).

White paint with a titanium oxide pigment is able to reflect 90 to 95 percent of solar light. Yellow paint made with a medium yellow chrome pigment reflects about 80 percent of light. Aluminum reflects about 70 percent. Other colors reflect less than 15 percent, and black reflects no solar radiation.

69.3.8.1.5 Containers shall be installed so that all container operating appurtenances are accessible. [**58:**6.8.1.5]

This requirement prevents containers from being installed with valves, gauges, or controls that are inaccessible. Occasionally a storage container must be evacuated before it is moved or for other reasons. Fittings for container evacuation eliminate the need to roll a container on its side to pump it out. Many other installation situations in which the container appurtenances may not be accessible will occur unless attention is given to the container position before installation.

69.3.8.1.6 Where necessary to prevent flotation due to possible high flood waters around aboveground or mounded containers, or high water table for those underground and partially underground, containers shall be securely anchored. [**58:**6.8.1.6]

Anchorage of ASME containers usually consists of strapping or bolting the container to concrete pads or foundations or by using mobile home–type helix anchors. The design of an anchorage system can be complicated and may require a civil engineer to determine an appropriate method, based on the soil conditions and anticipated flood levels. However, some jurisdictions may have published approved methods for use based on the type of flooding that may occur.

Anchorage of larger cylinders can be accomplished by strapping or chaining through the foot-ring or by strapping over the cylinder. Chaining or strapping the cylinder to a building or other support can anchor smaller cylinders. When using chains to anchor a cylinder, care should be taken not to damage cylinder paint. Anchors are available for securing manufactured housing, and these have been used for propane containers.

In practice, ASME containers are more likely to be anchored than are cylinders. Cylinders, which are usually smaller than ASME containers, might not be anchored because of their smaller size, unless required by local ordinance. Therefore, smaller cylinders can be separated from their connections and be carried away in a flood. Even with their valves open, these cylinders generally do not significantly contribute to overall flood damage, but they can complicate the recovery effort, especially if houses moved by flooding are on top of containers. There are also concerns related to the loss of property (i.e., the containers) and hazards to navigation.

The anchoring system should be designed in such a way as to keep the container from inverting. Anchoring the container by passing cables through only the lifting lugs will rarely prevent the container from inverting, likely causing the container to float upside down and the connecting piping to break and release liquid propane.

69.3.8.2 Installation of Cylinders.

69.3.8.2.1 Cylinders shall be installed only aboveground and shall be set upon a firm foundation or otherwise be firmly secured. *(See 69.3.8.2.2.)* [**58:**6.8.2.1]

Cylinders are designed primarily for transportation purposes with the understanding that they are used as storage for fuel. Cylinders are allowed to be installed below grade, but not buried in the ground. In an earlier edition of NFPA 58, it was written that cylinders could be installed in the niche of a slope or terrace wall as long as the container and regulator did not contact the ground and the compartment or recess was ventilated and drained.

Although traditional materials such as concrete blocks and treated wood may be used, the term "firm foundation" is used in 69.3.8.2.1 to provide a performance criterion that would avoid unnecessary restrictions on the use of innovative materials such as plastics and composite materials. Wood can be used as a foundation for cylinders, but it must be monitored. If the wood rots, it no longer provides a firm foundation and could allow the cylinder to come in contact with the soil; corrosion of the cylinder could then occur.

69.3.8.2.2 The cylinder shall not be in contact with the soil. [**58:**6.8.2.2]

69.3.8.2.3 Flexibility shall be provided in the connecting piping. *(See 69.3.8.2.4.)* [**58:**6.8.2.3]

Flexibility in the connecting piping is generally obtained by the use of a "pigtail," which is a short length of copper tubing with connectors on both ends. Pigtails are available from suppliers in a variety of lengths and are shipped without bends. They are bent into a circular shape when installed. Pigtails connect the cylinder service valve to the regulator that is attached to the piping system downstream. Copper is a good material for this use because it allows small amounts of vibration and movement due to settling without fracturing the connector. However, significant vibration and repeated movement can cause copper to become brittle and fail. If that occurs, a pigtail with a larger diameter may be successful; otherwise, an alternative means must be provided.

69.3.8.2.4 Where flexible connectors are used, they shall comply with 6.11.6 of NFPA 58. [**58:**6.8.2.4]

69.3.9 Internal Valves.

69.3.9.1 The requirements of 69.3.9.2 through 69.3.9.5 shall be required for internal valves in liquid service that are installed in containers of over 4000 gal (15.2 m^3) water capacity by July 1, 2003. [**58:**6.13.1]

69.3.9.2 Internal valves shall be installed in accordance with 5.9.4.2 and Table 5.9.4.2 of NFPA 58 on containers of over 4000 gal (15.2 m^3) water capacity. [**58:**6.13.2]

69.3.9.3 Thermal Activation.

69.3.9.3.1 Automatic shutdown of internal valves in liquid service shall be provided using thermal (fire) actuation. [**58:**6.13.3.1]

69.3.9.3.2 The thermal sensing element of the internal valve shall be within 5 ft (1.5 m) of the internal valve. [**58:**6.13.3.2]

69.3.9.4 Remote Shutdown Station.

69.3.9.4.1 At least one remote shutdown station for internal valves in liquid service shall be installed in accordance with the following:

(1) Not less than 25 ft (7.6 m) or more than 100 ft (30 m) from the liquid transfer point
(2) Not less than 25 ft (7.6 m) from the internal valves that are being controlled
(3) Along a path of egress from the liquid transfer point

[**58:**6.13.4.1]

69.3.9.4.2 This requirement shall be retroactive to all internal valves required by NFPA 58. [**58:**6.13.4.2]

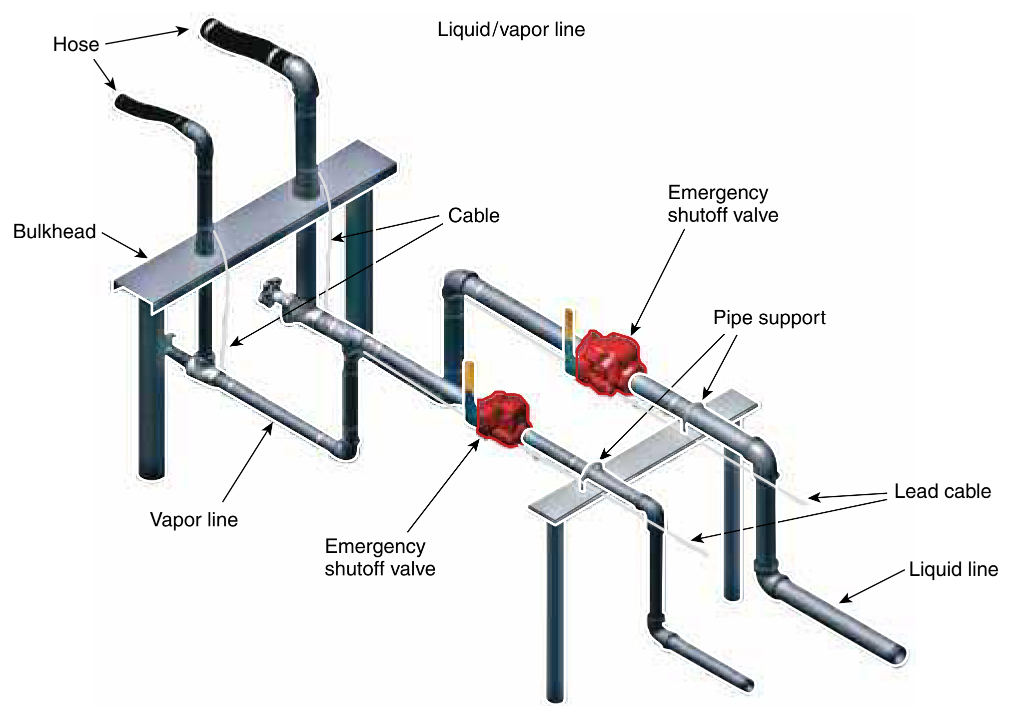
69.3.9.5 Emergency remote shutdown stations shall be identified by a sign, visible from the point of transfer, incorporating the words "Propane — Container Liquid Valve Emergency Shutoff" in block letters of not less than 2 in. (51 mm) in height on a background of contrasting colors to the letters. [**58:**6.13.5]

69.3.10 Emergency Shutoff Valves.

Subsection 69.3.10 requires both an automatic and a manual means of stopping the escape of LP-Gas, other than by an excess-flow check valve, from the storage container downstream of the emergency shutoff valve (ESV). There are installations in which the container capacity exceeds 4000 gal (15.2 m^3) — which would require an ESV — but the size of the hoses or swivel-type piping for handling liquid and vapor is smaller than 1½ in. (39 mm) and 1¼ in. (32 mm), respectively, so an ESV is not required.

Exhibit 69.15 shows how ESVs are installed. Two ESVs are shown in the drawing, one for liquid and one for vapor, as is commonly used for transfers to and from bobtails, transports, and railcars. Pull-away protection is accomplished by the bulkhead, which anchors the plant-side piping if the hose is pulled away by the vehicle. This installation uses a mechanically operated

Exhibit 69.15



Installation of emergency shutoff valves at unloading station. (Courtesy of RegO® Products)

ESV. Note the lead cables leading away from the hoses. These are connected to the shutoff point required in 69.3.10.12.1 and close the ESV when pulled. The cable on the vehicle side of the ESV demonstrates a way to shut off the valve if a pull-away occurs, in which case the cable will be pulled by the hose or dislocated piping, closing the valve. This method is not specifically required by NFPA 58, but it is an inexpensive way to provide a quicker closing of an ESV in a pull-away incident.

69.3.10.1 On new installations and on existing installations, stationary container storage systems with an aggregate water capacity of more than 4000 gal (15.2 m^3) utilizing a liquid transfer line that is 1½ in. (39 mm) or larger, and a pressure equalizing vapor line that is 1¼ in. (32 mm) or larger, shall be equipped with emergency shutoff valves. [**58:**6.14.1]

69.3.10.2 An emergency shutoff valve shall be installed in the transfer lines of the fixed piping transfer system within 20 ft (6 m) of lineal pipe from the nearest end of the hose or swivel-type piping connections. [**58:**6.14.2]

69.3.10.3 When the flow is only into the container, a backflow check valve shall be permitted to be used in lieu of an emergency shutoff valve if installed in the piping transfer system downstream of the hose or swivel-type piping connections. [**58:**6.14.3]

69.3.10.4 The backflow check valve shall have a metal-to-metal seat or a primary resilient seat with metal back-up, not hinged with combustible material, and shall be designed for this specific application. [**58:**6.14.4]

69.3.10.5 Where there are two or more liquid or vapor lines with hoses or swivel-type piping connected of the sizes designated, an emergency shutoff valve or a backflow check valve, where allowed, shall be installed in each leg of the piping. [**58:**6.14.5]

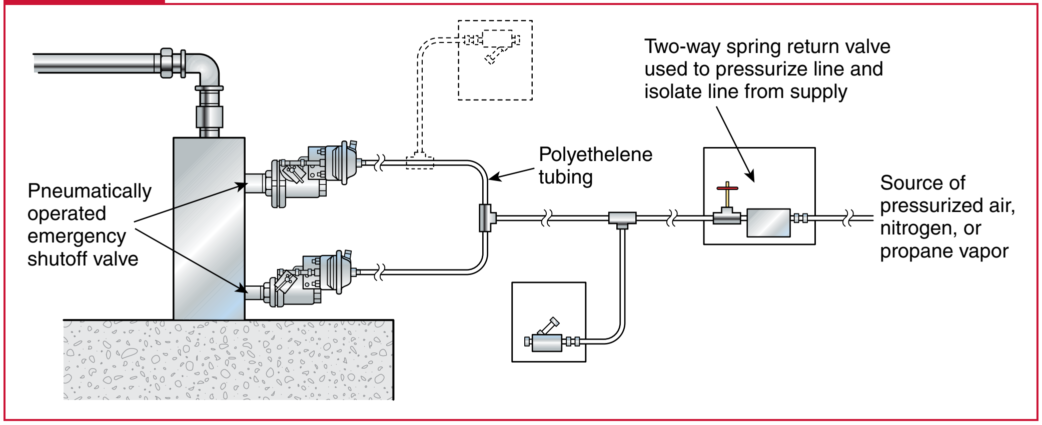
Where flow is in two directions, an ESV is required in each leg. Listing of ESVs is not required, but most manufacturers elect to list the valves because listing assists in the approval process. Where flow is only into the container, a check valve can be used, provided it is "designed for the specific application." Although that particular phrase is not defined in NFPA 58, it is intended to indicate a check valve that will be able to withstand the forces and flows of the fluid on the valve and its moving parts over an extended time where it is used.

Exhibit 69.16 illustrates a pneumatically operated ESV (See Exhibit 69.15 for a mechanically operated ESV).

69.3.10.6 Emergency shutoff valves shall be installed so that the temperature-sensitive element in the valve, or a supplemental temperature-sensitive element that operates at a maximum temperature of 250°F (121°C) that is connected to actuate the valve, is not more than 5 ft (1.5 m) from the nearest end of the hose or swivel-type piping connected to the line in which the valve is installed. [**58:**6.14.6]

Automatic actuation of an ESV occurs when the element that is part of or attached to the valve reacts to the heat from a fire. The element could be the pressurized plastic tubing that carries the compressed air, nitrogen, or LP-Gas vapor (see Section 6.12

Exhibit 69.16



Installation of pneumatically operated emergency shutoff valve. (Courtesy of National Propane Gas Association)

of NFPA 58) used to operate the ESV. The loss of pressure in the plastic tubing causes the reaction of the ESV. If the tubing is installed along the piping system, it will react before the LP-Gas in the piping would react.

Paragraph 69.3.10.6 states that a supplemental element within 5 ft (1.5 m) of the ESV can be installed in lieu of incorporating the temperature-sensitive element in the ESV. Some installations utilize additional elements to shut the valve in the event of fire in a location remote from the ESV.

69.3.10.7 Temperature-sensitive elements of emergency shutoff valves shall not be painted, nor shall they have any ornamental finishes applied after manufacture. [**58:**6.14.7]

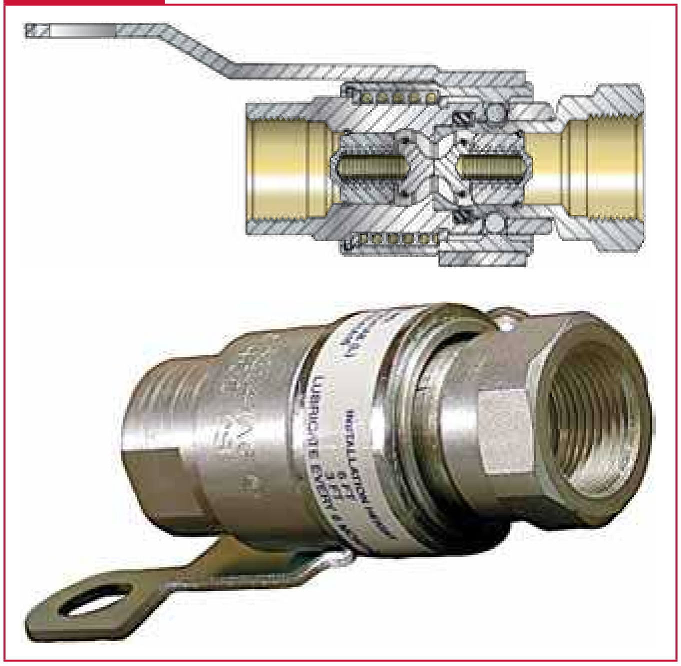
69.3.10.8* The emergency shutoff valves or backflow check valves shall be installed in the fixed piping so that any break resulting from a pull will occur on the hose or swivel-type piping side of the connection while retaining intact the valves and piping on the plant side of the connection. [**58:**6.14.8]

A.69.3.10.8 Anchorage can be accomplished by the use of concrete bulkheads or equivalent anchorage or by the use of a weakness or shear fitting. [**58:**A.6.14.8]

The feature described in 69.3.10.8 is commonly referred to as "pull-away protection." The valve or the piping system is designed so that if the vehicle moves away without disconnecting from the system, the piping system breaks in such a way that the vehicle side fails instead of the plant side. This ensures a smaller quantity of product is released than if the plant side of the system were to fail. Exhibit 69.15 shows one common way to accomplish "pull-away protection." Exhibit 69.17 illustrates a pull-away valve. This provision also applies to transfer from railroad tank cars directly into tank trucks with no intermediate storage. The code requires the same safety and pull-away protection for trackside transfer as for fixed installations.

69.3.10.9 Where emergency shutoff valves are required to be installed in accordance with 69.3.10.2, a means shall be incorporated to actuate the emergency shutoff valves in the event of a break of the fixed piping resulting from a pull on the hose. [**58:**6.14.9]

Exhibit 69.17



Pull-away valve. (Courtesy of RegO® Products)

69.3.10.10 Emergency shutoff valves required by NFPA 58 shall be tested annually for the functions required by 5.13.2.3(2) and (3) of NFPA 58, and the results of the test shall be documented. [**58:**6.14.10]

This requirement references 5.13.2.3 of NFPA 58 and includes testing for activation of the ESV by manual shutoff at the installed location and by manual shutoff from the remote location.

The test method for ESVs is not specified in NFPA 58; the valves can be tested in place by releasing propane from a storage tank into the atmosphere or into an empty bobtail for transport. The valves can also be removed and tested in a test facility.

Documentation of these tests is important so the AHJ can verify that the tests were done. Without documentation, many AHJs view the testing as not having occurred, spurring the common phrase, "Document it or it did not happen." In some areas, the AHJ requests permission to observe the tests. In locations where the AHJ performs an inspection that includes testing the ESVs, and a written record of the test exists, that test and record meet the requirements of 6.13.10 of NFPA 58.

69.3.10.11 Backflow check valves installed in lieu of emergency shutoff valves shall be checked annually for proper operation, and the results of the test shall be documented. [**58:**6.14.11]

69.3.10.12 All new and existing emergency shutoff valves shall comply with 69.3.10.12.1 through 69.3.10.12.3. [**58:**6.14.12]

69.3.10.12.1 Each emergency shutoff valve shall have at least one clearly identified and easily accessible manually operated remote emergency shutoff device. [**58:**6.14.12.1]

69.3.10.12.2 The shutoff device shall be located not less than 25 ft (7.6 m) or more than 100 ft (30 m) in the path of egress from the emergency shutoff valve. [**58:**6.14.12.2]

69.3.10.12.3 Where an emergency shutoff valve is used in lieu of an internal valve in compliance with 5.9.4.2(D)(2) of NFPA 58, the remote shutoff device shall be installed in accordance with 69.3.9.4 and 69.3.9.5. [**58:**6.14.12.3]

Note that the phrase "new and existing" in 69.3.10.12 makes the requirements in 69.3.10.12.1 through 69.3.10.12.3 retroactive to all installations.

In addition to automatic actuation, an ESV must be installed so that it can be operated manually both from a remote location and from its installed location. The term *remote* describes the ability to activate the ESV from a location far enough from the point of transfer to be considered safe. Here, in the installation chapter, *remote* has been mandated to be between 25 ft and 100 ft (7.6 m and 30 m) from the valve and in the path of egress from where the ESV is installed.

In some locations, strict compliance with the distance requirement can present problems. For instance, if the section of a yard from 20 ft to 110 ft (6 m to 33.5 m) from the valve is where trucks travel, putting the remote location at exactly 100 ft (30 m) may mean it is likely to be destroyed by a passing truck. In that case, the AHJ could approve a location at 115 ft (35 m) in accordance with Section 1.4. The intent of having the remote location in the path of egress recognizes that the transfer employee will be better able to actuate the remote closure device while utilizing this path. It will also keep from drawing the transfer employee further into the site, possibly into a more dangerous location. The path of egress is generally considered to be along the same path used to enter the facility, especially when the site is fenced.

69.3.10.13 Emergency shutoff valves for railroad tank car transfer systems shall be in accordance with 6.21.2.6, 6.30.4, 7.2.3.7, and 7.2.3.8 of NFPA 58. [**58:**6.14.13]

69.3.11* Installation in Areas of Heavy Snowfall.

A.69.3.11 Gas leaks have resulted from snow or ice accumulations on gas systems, and snow or ice shedding from roofs onto gas systems. In these incidents, external fires have occurred and in some cases gas has migrated into or under buildings, resulting in interior fires or explosions. Selection of appropriate methods of protection should be based upon the installation and anticipated snow and or ice loading. Possible methods of protection include the following:

(1) Minimizing the extent of above-ground piping.
(2) Locating above-ground piping, regulators, and meters above anticipated snow accumulations.
(3) Locating above-ground piping, regulators and meters on the gable end of buildings, rather than under eaves, to prevent damage from snow or ice shedding off of roofs.
(4) Protecting above-ground piping, regulators, and meters with extended roof overhangs or dedicated covers.
(5) Adding additional support above-ground piping, regulators and meters to withstand anticipated snow or ice loading.

[**58:**A.6.18]

N **69.3.11.1** In areas where the ground snow load is equal to or exceeds 100 psf (488 kg/m^2), piping, regulators, meters, and other equipment installed in the piping system shall be protected from the forces of accumulated snow. [**58:**6.18.1]

The application of this requirement has been expanded in the 2017 edition of NFPA 58 to include any locations that exceed 100 psf (488 kgf/m^2). The definition of *ground snow load* was changed in the 2017 edition of NFPA 58; it now includes reference to ASCE 7, *Minimum Design Loads for Buildings and Other Structures*, and the 50-year ground snow load.

The force of accumulated snow can damage piping, meters, and regulators outside of buildings. Exhibit 69.18 shows a method of meter protection that can be used in areas prone to heavy snowfall. Specific protection requirements are not mandated because it is difficult to make one rule that covers all potential snowfalls. Several municipalities in the area of the Sierra Nevada Mountains have enacted specific rules on the subject of heavy snowfall that can be used as a potential model for installation requirements.

69.3.12 LP-Gas Systems in Buildings or on Building Roofs or Exterior Balconies.

69.3.12.1 Application.

Δ **69.3.12.1.1** Subsection 69.3.12 shall apply to the installation of the following LP-Gas systems in buildings or structures:

(1) Cylinders inside of buildings or on the roofs or exterior balconies of buildings
(2) Systems in which the liquid is piped from outside containers into buildings or onto the roof

[**58:**6.22.1.1]

Exhibit 69.18

A method of meter protection in heavy snow areas. (Courtesy of Dead River Company)

69.3.12.1.2 The phrase *cylinders in use* shall mean connected for use. [**58:**6.22.1.2]

69.3.12.1.2.1 The use of cylinders indoors shall be only for the purposes specified in 6.22.4 through 6.22.10 of NFPA 58. [**58:**6.22.1.2(A)]

69.3.12.1.2.2 The use of cylinders indoors shall be limited to those conditions where operational requirements make the indoor use of cylinders necessary and location outside is impractical. [**58:**6.22.1.2(B)]

The use of cylinders indoors, as well as on balconies and roofs of buildings, is permitted only for the purposes specified in 6.22.4 through 6.22.10 of NFPA 58. All other uses, including normal, routine comfort heating, are prohibited. Cylinder systems having capacities larger than 1 lb (0.45 kg) of LP-Gas and the associated storage of such cylinders indoors are limited to the following uses:

- Construction and renovation of buildings
- Industrial applications
- Education
- Research
- Training
- Temporary heating in cases of emergency

These limited applications acknowledge the good experience and presence of trained personnel in industrial uses and the temporary nature and lack of alternative fuel sources for certain appliances needed at certain times in buildings.

Where the indoor use of LP-Gas cylinders is permitted, the user or installer must first attempt to locate the cylinders outdoors. Only if it is impractical to locate the cylinders outdoors is the installer permitted to locate the cylinders indoors. In determining whether an outdoor location is impractical, consultation with the AHJ may be required.

69.3.12.1.2.3 The use of cylinders on roofs shall be limited to those conditions where operational requirements make the use of cylinders necessary and location other than on roofs of buildings or structures is impractical. [**58:**6.22.1.2(C)]

Provisions for the installation of cylinders on roofs were originally incorporated into the *Code* to provide fuel for emergency generators and microwave relay stations. The provisions also have been applied where providing cylinders on roofs that serve penthouses and in hospitals. Again, such systems are permitted only where the use of cylinders is necessary and other outdoor locations are impractical.

69.3.12.1.2.4 Liquid LP-Gas shall be piped into buildings or structures only for the purposes specified in 6.11.1.1(D) of NFPA 58. [**58:**6.22.1.2(D)]

Although LP-Gas vapor at pressures up to and including 20 psig (138 kPag) can be piped into buildings, there are certain limitations for piping liquid LP-Gas at pressures exceeding 20 psig (138 kPag) into buildings. These limitations are covered in 6.11.1.1 and 6.11.1.3 of NFPA 58. Liquid LP-Gas piping into buildings or structures is also limited due to the hazards of a release. After reaching atmospheric pressure, liquid LP-Gas will instantly change states to a vapor, and the flow rate of fuel through a leak would be much higher than if it were vapor piping.

69.3.12.1.3 Storage of cylinders awaiting use shall be in accordance with Chapter 8 of NFPA 58. [**58:**6.22.1.3]

69.3.12.1.4 Transportation of cylinders within a building shall be in accordance with 6.22.3.6 of NFPA 58. [**58:**6.22.1.4]

Δ **69.3.12.1.5** The following provisions shall be required in addition to those specified in Sections 6.2 and 6.4 of NFPA 58:

(1) Liquid transfer systems shall be in accordance with Chapter 7 of NFPA 58.
(2) Engine fuel systems used inside buildings shall be in accordance with Chapter 11 of NFPA 58.
(3) LP-Gas transport or cargo tank vehicles stored, serviced, or repaired in buildings shall be in accordance with Chapter 9 of NFPA 58.

[**58:**6.22.1.5]

69.3.12.2 Additional Equipment Requirements for Cylinders, Equipment, Piping, and Appliances Used in Buildings, Building Roofs, and Exterior Balconies.

69.3.12.2.1 Cylinders shall be in accordance with the following:

(1) Cylinders shall not exceed 245 lb (111 kg) water capacity [nominal 100 lb (45 kg) propane capacity] each.

Basic considerations are given in 69.3.12.2.1 regarding the type of cylinder to be used. The cylinder must have a maximum

LP-Gas capacity of 100 lb (45 kg). This size is the largest size that can be easily moved by personnel from a practical standpoint. There have been some 500 gal (1.9 m^3) ASME tanks used at different floor levels on large construction sites. Such use was, and continues to be, prohibited by the *Code*. The NFPA 58 approach to the use of ASME bulk tanks is to locate them at ground level on the outside or on the roof (with approval of the AHJ) and pipe the LP-Gas into the building.

(2) Cylinders shall comply with other applicable provisions of Section 5.2 of NFPA 58, and they shall be equipped as provided in Section 5.9 of NFPA 58.
(3) Cylinders shall be marked in accordance with 5.2.8.1 and 5.2.8.2 of NFPA 58.
(4) Cylinders with propane capacities greater than 2 lb (0.9 kg) shall be equipped as provided in Table 5.9.4.1(B) of NFPA 58, and an excess-flow valve shall be provided for vapor service when used indoors.

The requirements in items (2) through (4) refer the code user to Table 5.9.4.1(B) of NFPA 58 for the proper appurtenances to be installed on the cylinder. This table has two separate columns for cylinders, and the requirements differ based on the type of service.

In addition to the requirements of Table 5.9.4.1(B) of NFPA 58, cylinders in vapor service used indoors must have an excess-flow valve installed per 69.3.12.2.1(4). This provides a higher level of safety by providing excess-flow protection in the event of a pipe or hose failure inside a building; therefore, standard vapor service cylinders — including those used for gas grills — cannot be used in buildings unless they are fitted with an excess-flow valve. The excess-flow valve must be selected for proper closing flow, and sizing can be difficult for those used on portable cylinders because the flow can vary with tank pressure (and temperature) and with the length of the discharge hose or piping.

(5) Cylinder valves shall be protected in accordance with 5.2.6.1 of NFPA 58.

Item (5) refers to 5.2.6.1 of NFPA 58, which requires that all cylinder valves be protected against physical damage by a ventilated cap or collar. Recessing the valve into the container is also permitted by DOT cylinder regulations, but this procedure is rarely used for LP-Gas cylinders. Note that when a removable cap is used, it must be in place when the container is not in use.

(6) Cylinders having water capacities greater than 2.7 lb (1.2 kg) and connected for use shall stand on a firm and substantially level surface.

The term *firm (surface)* is used here, but it is not defined in the *Code*. It is intended to mean a level surface on which the cylinder will not sink or tip due to its weight. Concrete and masonry surfaces can be used, but they are not required for cylinders in buildings.

(7) Cylinders shall be secured in an upright position if necessary.

The requirement in item (7) emphasizes the importance of maintaining the cylinder in the proper orientation so that the following occurs:

- The pressure relief device is in communication with the vapor space in the cylinder (see commentary following 69.5.2.1.2 for more information on why a vapor discharge is favorable over a liquid discharge on a cylinder).
- Stress is not placed on piping attached to the cylinder, which could cause a break or leakage.
- The cylinder is not subject to impact if there is traffic nearby.

(8) Cylinders and the valve-protecting devices used with them shall be oriented to minimize the possibility of impingement of the pressure relief device discharge on the cylinder and adjacent cylinders.

[**58:**6.22.2.1]

As required in 69.3.12.2.1(8), it is important that the cylinder pressure relief discharge be directed through a hole in the cap or collar. In positioning a group of cylinders, attention should be given to ensure that pressure relief valves are not directed at adjacent cylinders.

69.3.12.2.2 Manifolds and fittings connecting cylinders to pressure regulator inlets shall be designed for at least 250 psig (1.7 MPag) service pressure. [**58:**6.22.2.2]

Because the manifold will be carrying gas at the same pressure as the gas in the cylinder, it must be designed with a pressure rating of at least 250 psig (1.7 MPag).

69.3.12.2.3 Piping shall comply with Section 5.11 of NFPA 58 and shall have a pressure rating of 250 psig (1.7 MPag). [**58:**6.22.2.3]

69.3.12.2.4 Liquid piping and vapor piping at pressures above 125 psig (0.9 MPag) shall be installed in accordance with 6.11.3 of NFPA 58. [**58:**6.22.2.4]

Δ **69.3.12.2.5** Hose, hose connections, and flexible connectors shall comply with the following:

(1) Hose used at pressures above 5 psig (34 kPag) shall be designed for a pressure of at least 350 psig (2.4 MPag).
(2) Hose used at a pressure of 5 psig (34 kPag) or less and used in agricultural buildings not normally occupied by the public shall be designed for the operating pressure of the hose.

The allowance in item (2) provides an alternative to the hose designed for a pressure of 350 psig (2.4 MPag) if the hose is to be used at low pressures of 5 psig (34 kPag) in agricultural buildings not normally occupied by the public. This alternative came about because LP-Gas installations are frequently located in buildings used for poultry breeding, and the 350 psig (2.4 MPag) hose was a problem due to its stiffness and resulted in kinking where bends were needed. The paramount life safety concerns in 69.3.12 are relaxed for poultry breeding and similar agricultural buildings, which are infrequently occupied by people.

(3) Hose shall comply with 5.10.6 of NFPA 58.
(4) Hose shall be installed in accordance with 6.23.4 of NFPA 58.
(5) Hose shall be as short as practical, without kinking or straining the hose or causing it to be close enough to a burner to be damaged by heat.
(6) Hoses greater than 10 ft (3 m) in length shall be protected from damage.

[**58:**6.22.2.5]

Although basic provisions for hose are given by reference to 5.10.6 of NFPA 58 in (3) (note: The *Code* contains an error and section 69.3.12.2.5(3) should reference 5.11.6 of NFPA 58), the following two important exceptions are taken:

1. Hose used in buildings must be designed for a 350 psig (2.4 MPag) working pressure. This requirement is intended not only to account for the pressures involved, but to ensure that a stronger type of hose is used in this service. This is particularly a concern at construction sites where abrasions and damage due to rough usage can be encountered. [Note that this hose is required in 5.11.6.4 of NFPA 58 only for pressures over 5 psig (34 kPag) used in all other applications.]
2. The length of hose is not restricted to a specific length for connecting to appliances [see 6.23.4.2(1) of NFPA 58], although it must be kept as short as is practical. In addition, if the length of hose exceeds 10 ft (3 m), either it must be installed in a manner that protects it from damage or additional external protective devices, such as conduit, must be used.

Δ **69.3.12.2.6*** Portable heaters, including salamanders, shall comply with the following:

(1) Portable heaters shall be equipped with an approved automatic device to shut off the flow of gas to the main burner and to the pilot, if used, in the event of flame extinguishment or combustion failure.
(2) Portable heaters shall be self-supporting unless designed for cylinder mounting.
(3) Portable heaters shall not be installed utilizing cylinder valves, connectors, regulators, manifolds, piping, or tubing as structural supports.
(4) Portable heaters having an input of more than 50,000 Btu/hr (53 MJ/hr) shall be equipped with either a pilot that must be lighted and proved before the main burner can be turned on or an approved electric ignition system.

[**58:**6.22.2.6]

A.69.3.12.2.6 The requirement for a pilot or an electronic ignition system became effective for heaters with inputs over 50,000 Btu/hr manufactured on or after May 17, 1967. [**58:**A.6.22.2.6]

Paragraph 69.3.12.2.6 is intended to provide basic requirements for AHJs to use in approving portable heaters. Although standards exist for the listing of portable heaters, not all heaters are tested and listed.

Δ **69.3.12.2.7** The provisions of 69.3.12.2.6 shall not be applicable to the following:

(1) Tar kettle burners, hand torches, or melting pots
(2) Portable heaters with less than 7500 Btu/hr (8 MJ/hr) input if used with cylinders having a maximum water capacity of 2.7 lb (1.2 kg) and filled with not more than 16.8 oz (0.522 kg) of LP-Gas

[**58:**6.22.2.7]

All portable heaters used indoors must have flame failure protection except for the following:

- Attended appliances, such as tar kettle burners, hand torches, or melting pots
- Smaller heaters of less than 7500 Btu (8 MJ/hr) capacity connected to a 1 lb (0.45 kg) LP-Gas cylinder

Flame failure protection is provided by an approved automatic device that shuts off the flow of gas to the main burner and the pilot (where a pilot is used) if the flame is not sensed. Additionally, these small portable heaters designed for cylinder mounting must not use valves, piping, regulators, or other equipment as structural supports for the heater.

If the provisions of 69.3.12.2.7 are not followed, the possibility of operators being burned during the ignition of heaters may exist when they use larger heaters designed to operate at higher inlet pressures. Unless a proven pilot light or electronic ignition is used, a large flame rollout can occur. Pilots on these larger heaters may experience premature thermocouple failure or outages due to wind or other factors. Another problem occurs if operators bypass these controls.

The intent of this system is to prevent the release of large amounts of unignited gas, which can result in an explosion/fire hazard.

69.3.12.3 Buildings Under Construction or Undergoing Major Renovation.

Δ **69.3.12.3.1** Where cylinders are used and transported in buildings or structures under construction or undergoing major renovation and such buildings are not occupied by the public, the requirements of 69.3.12.3.2 through 69.3.12.3.10 shall apply. [**58:**6.22.4.1]

69.3.12.3.2 The use and transportation of cylinders in the unoccupied portions of buildings or structures under construction or undergoing major renovation that are partially occupied by the public shall be approved by the AHJ. [**58:**6.22.4.2]

This requirement specifically extends coverage to the movement and use of cylinders in buildings that are under construction or undergoing major renovation. The term *major renovation* is not defined in NFPA 58, therefore the AHJ should be consulted before cylinders are used in a building being renovated. Buildings undergoing minor renovations are addressed in 69.3.12.4. Approval is required prior to the use or transport of cylinders in unoccupied portions of buildings that are partially occupied by the public.

69.3.12.3.3 Cylinders, equipment, piping, and appliances shall comply with 69.3.12.2. [**58:**6.22.4.3]

69.3.12.3.4 Heaters used for temporary heating shall be located at least 6 ft (1.8 m) from any cylinder. (*See 69.3.12.3.5 for an exception to this requirement.*) [**58:**6.22.4.4]

69.3.12.3.5 Integral heater-cylinder units specifically designed for the attachment of the heater to the cylinder, or to a supporting standard attached to the cylinder, and designed and installed to prevent direct or radiant heat application to the cylinder shall be exempt from the spacing requirement of 69.3.12.3.4. [**58:**6.22.4.5]

69.3.12.3.6 Blower-type and radiant-type units shall not be directed toward any cylinder within 20 ft (6.1 m). [**58:**6.22.4.6]

The concern behind 69.3.12.3.4 through 69.3.12.3.6 is the protection of cylinders used to fuel heating appliances from overheating from proximity to another heating appliance. Overheating can result in the release of propane through the pressure relief device. A minimum 6 ft (1.8 m) separation between heaters used for temporary heating and other LP-Gas cylinders is required under all circumstances. In addition, blower-type and radiant-type heaters cannot be directed toward any cylinder within a 20 ft (6.1 m) distance. The infrared or larger blower-type units have a more pronounced effect on heat transmission in the direction they are aimed; therefore, the greater separation distance to cylinders is required.

69.3.12.3.7 If two or more heater-cylinder units of either the integral or nonintegral type are located in an unpartitioned area on the same floor, the cylinder(s) of each such unit shall be separated from the cylinder(s) of any other such unit by at least 20 ft (6.1 m). [**58:**6.22.4.7]

69.3.12.3.8 If heaters are connected to cylinders manifolded together for use in an unpartitioned area on the same floor, the total water capacity of cylinders manifolded together serving any one heater shall not be greater than 735 lb (333 kg) [nominal 300 lb (136 kg) propane capacity]. If there is more than one such manifold, it shall be separated from any other by at least 20 ft (6.1 m). [**58:**6.22.4.8]

The LP-Gas maximum of 300 lb (136 kg) for manifolded systems has a long history in NFPA 58. A distance of 20 ft (6.1 m) is set out for the separation of different manifolded systems in the same unpartitioned floor area.

69.3.12.3.9 Where cylinders are manifolded together for connection to a heater(s) on another floor, the following shall apply.

(1) Heaters shall not be installed on the same floors with manifolded cylinders.
(2) The total water capacity of the cylinders connected to any one manifold shall not be greater than 2450 lb (1111 kg) [nominal 1000 lb (454 kg) propane capacity]
(3) Manifolds of more than 735 lb (333 kg) water capacity [nominal 300 lb (136 kg) propane capacity], if located in the same unpartitioned area, shall be separated from each other by at least 50 ft (15 m).

[**58:**6.22.4.9]

Where cylinders are installed on a floor level different from that where the heaters are located, the allowable quantities of propane gas are greater. This is due to the fact that the heaters represent a source of ignition and pose less of a threat when they are not on the same floor level as the cylinders.

69.3.12.3.10 Where compliance with the provisions of 69.3.12.3.6 through 69.3.12.3.9 is impractical, alternate installation provisions shall be allowed with the approval of the AHJ. [**58:**6.22.4.10]

69.3.12.4 Buildings Undergoing Minor Renovation When Frequented by the Public.

Δ **69.3.12.4.1** Cylinders used and transported for repair or minor renovation in buildings frequented by the public during the hours the public normally occupies the building shall comply with the following:

(1) The maximum water capacity of individual cylinders shall be 50 lb (23 kg) [nominal 20 lb (9.1 kg) propane capacity], and the number of cylinders in the building shall not exceed the number of workers assigned to the use of the propane.
(2) Cylinders having a water capacity greater than 2.7 lb (1.2 kg) shall not be left unattended.

[**58:**6.22.5.1]

69.3.12.4.2 During the hours the building is not open to the public, cylinders used and transported within the building for repair or minor renovation and with a water capacity greater than 2.7 lb (1.2 kg) shall not be left unattended. [**58:**6.22.5.2]

Building renovation during hours when the public is present requires special considerations. For example, the number of cylinders must not exceed the number of workers assigned to them, and the cylinders are not to be left unattended at any time.

When the building is not occupied by the general public, 69.3.12.4.2 lifts the restrictions on cylinder size and number of cylinders in the space.

69.3.12.5 Buildings Housing Industrial Occupancies.

69.3.12.5.1 Cylinders used in buildings housing industrial occupancies for processing, research, or experimental purposes shall comply with 69.3.12.5.1.1 and 69.3.12.5.1.2. [**58:**6.22.6.1]

69.3.12.5.1.1 If cylinders are manifolded together, the total water capacity of the connected cylinders shall be not more than 735 lb (333 kg) [nominal 300 lb (136 kg) propane capacity]. If there is more than one such manifold in a room, it shall be separated from any other by at least 20 ft (6.1 m). [**58:**6.22.6.1(A)]

69.3.12.5.1.2 The amount of LP-Gas in cylinders for research and experimental use in the building shall be limited to the smallest practical quantity. [**58:**6.22.6.1(B)]

69.3.12.5.2 The use of cylinders to supply fuel for temporary heating in buildings housing industrial occupancies with essentially noncombustible contents shall comply with the requirements in 69.3.12.3 for cylinders in buildings under construction. [**58:**6.22.6.2]

69.3.12.5.3 The use of fuel cylinders for temporary heating shall be permitted only where portable equipment for space heating is essential and a permanent heating installation is not practical. [**58:**6.22.6.3]

69.3.12.6 Buildings Housing Educational and Institutional Occupancies.

69.3.12.6.1 The use of cylinders in classrooms shall be prohibited unless they are used temporarily for classroom demonstrations in accordance with 69.3.12.8.1. [**58:**6.22.7.1]

Δ **69.3.12.6.2** Where cylinders are used in buildings housing educational and institutional laboratory occupancies for research and experimental purposes, the following shall apply:

(1) The maximum water capacity of individual cylinders used shall be 50 lb (23 kg) [nominal 20 lb (9.1 kg) propane capacity] if used in educational occupancies and 12 lb (5.4 kg) [nominal 5 lb (2 kg) propane capacity] if used in institutional occupancies.
(2) If more than one such cylinder is located in the same room, the cylinders shall be separated by at least 20 ft (6.1 m).
(3) Cylinders not connected for use shall be stored in accordance with Chapter 8 of NFPA 58.
(4) Cylinders shall not be stored in a laboratory room.

[**58:**6.22.7.2]

The maximum size cylinder for educational buildings is 20 lb (9.1 kg) of propane and 5 lb (2 kg) of propane for institutional occupancies, with a separation of 20 ft (6.1 m) if more than one container is located in the same room. Containers are not allowed in classrooms unless they are used in accordance with 69.3.12.8.1 for demonstration purposes. The storage of containers in educational and institutional occupancies must be in accordance with Chapter 8 of NFPA 58.

Note that the NFPA *101* definition of an educational occupancy covers through high school (grade 12). Educational facilities beyond grade 12 are generally considered to be the following occupancies:

- Instructional building: business occupancy
- Classrooms under 50 persons: business occupancy
- Classrooms 50 persons and over: assembly occupancy
- Laboratories, instructional: business occupancy
- Laboratories, noninstructional: industrial occupancy

For additional information, see NFPA *101* for proper occupancy classification of educational facilities beyond grade 12. Note that NFPA *101* classifications are for life safety purposes. The limits of propane cylinder size in NFPA 58 still apply. It would be a violation of that code to install a 20 lb (9.1 kg) LP-Gas tank in a high school chemistry laboratory to supply Bunsen burners on the student lab tables, connected by permanently installed piping.

The requirements of NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, apply to laboratories used for educational purposes beyond grade 12 and for other laboratories.

69.3.12.7 Temporary Heating and Food Service Appliances in Buildings in Emergencies.

Δ **69.3.12.7.1** Cylinders shall not be used in buildings for temporary emergency heating purposes except when all of the following conditions are met:

(1) The permanent heating system is temporarily out of service.
(2) Heat is necessary to prevent damage to the buildings or contents.
(3) The cylinders and heaters comply with, and are used and transported in accordance with, 69.3.12.2 and 69.3.12.3.
(4) The temporary heating equipment is not left unattended.
(5) Air for combustion and ventilation is provided in accordance with NFPA 54.

[**58:**6.22.8.1]

Cylinders used for temporary heating are strictly an emergency measure, to be used only if the permanent heating system is temporarily out of service. The requirement in 69.3.12.7.1 is not intended to apply to supplemental or zone heating. Emergency heating equipment must be attended at all times.

NFPA 54, *National Fuel Gas Code*, contains extensive requirements to ensure that gas-burning appliances have sufficient air for complete combustion and ventilation to ensure that no harmful products of combustion can accumulate in buildings. These requirements are located in Section 9.3 of NFPA 54 and should be reviewed prior to the installation of temporary heating equipment. This is especially important if the temporary heating equipment does not use the same venting provisions as the equipment it temporarily replaces.

69.3.12.7.2 When a public emergency has been declared and gas, fuel, or electrical service has been interrupted, portable listed LP-Gas commercial food service appliances meeting the requirements of 69.3.12.8.4 shall be permitted to be temporarily used inside affected buildings. [**58:**6.22.8.2]

69.3.12.7.3 The portable appliances used shall be discontinued and removed from the building at the time the permanently installed appliances are placed back in operation. [**58:**6.22.8.3]

These appliances are needed and commonly used in certain areas after natural disasters such as floods, ice storms, and hurricanes, where service from utilities supplying gas and electricity may be interrupted. Paragraph 69.3.12.7.3 mandates that the portable appliances and the cylinders used to fuel them must be removed from the building when permanent appliances are back in service.

69.3.12.8 Use in Buildings for Demonstrations or Training, and Use of Small Cylinders for Self-Contained Torch Assemblies and Food Service Appliances.

Δ **69.3.12.8.1** Cylinders used temporarily inside buildings for public exhibitions or demonstrations, including use in classroom demonstrations, shall be in accordance with the following:

(1) The maximum water capacity of a cylinder shall be 12 lb (5.4 kg) [nominal 5 lb (2 kg) propane capacity].
(2) If more than one such cylinder is located in a room, the cylinders shall be separated by at least 20 ft (6.1 m).

[**58:**6.22.9.1]

Cylinders up to 5 lb (2 kg) propane capacity may be used temporarily in buildings for exhibitions or demonstrations. The use of a 20 lb (9.1 kg) cylinder filled with 5 lb (2 kg) of propane is not permitted, however, because there is no easy way to verify that only 5 lb (2 kg) of propane is in the cylinder. This provision permits the demonstration of a portable cooking device with a 5 lb (2 kg) LP-Gas cylinder at an indoor trade show to demonstrate cooking equipment, but it does not permit an identical device to be used at the show to prepare food for sale. For cooking in restaurants and by caterers, 69.3.12.8.4 does permit the use of stoves fueled by 10 oz (0.28 kg) nonrefillable butane cylinders.

If the food preparation itself is primarily for demonstration, then the use is allowed. If the preparation is primarily for the sale of the prepared food, then 5 lb (2 kg) cylinders are prohibited. The reasoning behind this distinction is that a demonstration of cooking is not "rushed" and is being monitored closely by the cook and the audience. A commercial cooking operation, however, may be characterized by a lower level of supervision of the equipment and a much higher volume of food. Simply stated, if the food is given away, as would be done in a school or trade show, 5 lb (2 kg) cylinders are allowed. If the food is sold, the preparation method is considered normal use and not a demonstration, and 5 lb (2 kg) cylinders are not allowed.

Δ **69.3.12.8.2** Cylinders used temporarily in buildings for training purposes related to the installation and use of LP-Gas systems shall be in accordance with the following:

(1) The maximum water capacity of individual cylinders shall be 245 lb (111 kg) [nominal 100 lb (45 kg) propane capacity], but not more than 20 lb (9.1 kg) of propane shall be placed in a single cylinder.
(2) If more than one such cylinder is located in the same room, the cylinders shall be separated by at least 20 ft (6.1 m).
(3) The training location shall be acceptable to the AHJ.
(4) Cylinders shall be promptly removed from the building when the training class has terminated.

[**58:**6.22.9.2]

Where used for LP-Gas–related training in buildings, 100 lb (45 kg) propane cylinders are permitted to be used, but they may be filled with only 20 lb (9.1 kg) of propane and approval of the AHJ is required. Note that the requirement in 69.3.12.8.2 differs from 69.3.12.8.1, which covers public exhibitions or demonstrations where only small containers of 5 lb (2 kg) propane capacity maximum are permitted.

Δ **69.3.12.8.3*** Cylinders used in buildings as part of approved self-contained torch assemblies or similar appliances shall be in accordance with the following:

(1) Cylinders used in buildings shall comply with UL 147A, *Standard for Nonrefillable (Disposable) Type Fuel Gas Cylinder Assemblies.*
(2) Cylinders shall have a maximum water capacity of 2.7 lb (1.2 kg).

[**58:**6.22.9.3]

A.69.3.12.8.3 The weight of the cylinders will be affected by the specific gravity of the LP-Gas. Weights varying from 16.0 oz to 16.8 oz (454 g to 476 g) are recognized as being within the range of what is nominal. [**58:**A.6.22.9.3]

A cylinder of 2.7 lb (1.2 kg) water capacity will hold about 1.09 lb (0.49 kg) of propane [2.7 lb (1.2 kg) water capacity × 0.504 specific gravity (lb propane/lb water) × 80 percent (fill level)]. The cylinders are sometimes called "1 pound cylinders" and are usually sold with a net weight as required by consumer protection laws. These small cylinders are usually filled by automatic filling machinery, and some weight variation is normal and expected. Therefore, a filling target of over 1 lb (0.45 kg) is set so that, at the lowest filling level, 1 lb (0.45 kg) will be provided. The normal weight ranges for these 1 lb (0.45 kg) cylinders are provided in A.6.69.3.12.8.3. The vast majority of the 1 lb (0.45 kg) cylinders are disposable — these disposable cylinders are prohibited by DOT regulations and 69.4.2.2.8 from being refilled — and must be disposed of or recycled after use. Refillable 1 lb (0.45 kg) cylinders are available, and only this type can be refilled.

Paragraph 69.3.12.8.3 relates to, and limits the use of, LP-Gas cylinders with a propane capacity of up to 1 lb (0.45 kg). The provision permits the use of portable appliances that are fueled by butane and propane, such as curling irons and cigarette lighters, and the cylinders used to refill them. The requirement that 1 lb (0.45 kg) cylinders comply with UL 147A, *Standard for Nonrefillable (Disposable) Type Fuel Gas Cylinder Assemblies*, establishes minimum safety standards for these cylinders above those required by the DOT.

Note that the use of cylinders of this size with portable cooking appliances is not mentioned and is therefore prohibited in buildings, except as permitted in restaurants and attended commercial food catering by 69.3.12.8.4 and in emergency cooking as permitted by 69.3.12.7.2.

Δ **69.3.12.8.4** Cylinders used with commercial food service appliances shall be used inside restaurants and in attended commercial food catering operations in accordance with the following:

(1) Cylinders and appliances shall be listed.
(2) Commercial food service appliances shall not have more than two 10 oz (296 ml) nonrefillable butane gas cylinders, each having a maximum capacity of 1.08 lb (0.490 kg).

(3) Cylinders shall comply with UL 147B, *Standard for Nonrefillable (Disposable) Type Metal Container Assemblies for Butane*.
(4) Cylinders shall be connected directly to the appliance and shall not be manifolded.
(5) Cylinders shall be an integral part of the listed, approved, commercial food service device and shall be connected without the use of a rubber hose.
(6) Storage of cylinders shall be in accordance with 8.3.1 of NFPA 58.

[**58:**6.22.9.4]

Direct connection enhances safety because hoses are inherently subject to wear and abuse. The number of cylinders connected at one time is limited to two, and the containers cannot be manifolded. This arrangement permits a two-burner stove to have each burner fed from a separate cylinder and limits the amount of leakage in the event of a problem. See Exhibit 69.19 for an example of a butane-fueled portable cooking appliance.

Note that only certain small cylinders with strict limitations are allowed. Cylinders must be nonrefillable, must be listed to UL 147B, *Standard for Nonrefillable (Disposable) Type Metal Container Assemblies for Butane*, and cannot contain more than 10 oz (0.28 kg) of butane.

Exhibit 69.20 shows a listed butane cylinder for use with portable cooking appliances. Note the indentations on the upper rim seal of the cylinder. These indentations are known as "rim relief," which is a designed weak point that fails upon overpressure to ensure that "rocketing" of the cylinder is minimized. The cutaway section shows the internal vapor tube that is in the top of the cylinder when the cylinder is properly placed in its area of the stove. A notch in the flange at the top of the cylinder ensures proper orientation.

69.3.12.9 Cylinders on Roofs or Exterior Balconies.

69.3.12.9.1 Where cylinders are installed permanently on roofs of buildings, the buildings shall be of fire-resistant construction or noncombustible construction having essentially noncombustible contents, or of other construction or contents that are protected with automatic sprinklers. [**58:**6.22.11.1]

Exhibit 69.19

Butane-fueled portable cooking appliance. (Courtesy of ChefMaster)

Exhibit 69.20

Listed butane cylinder for portable cooking appliance. (Courtesy of ChefMaster)

69.3.12.9.1.1 The total water capacity of cylinders connected to any one manifold shall be not greater than 980 lb (445 kg) [nominal 400 lb (181 kg) propane capacity]. If more than one manifold is located on the roof, it shall be separated from any other by at least 50 ft (15 m). [**58:**6.22.11.1(A)]

69.3.12.9.1.2 Cylinders shall be located in areas where there is free air circulation, at least 10 ft (3 m) from building openings (such as windows and doors), and at least 20 ft (6.1 m) from air intakes of air-conditioning and ventilating systems. [**58:**6.22.11.1(B)]

The requirement for separating cylinders from air intakes into buildings relates to the release of gas that may occur and the need to prevent that gas from being brought into the building and potentially ignited.

69.3.12.9.1.3 Cylinders shall not be located on roofs that are entirely enclosed by parapets more than 18 in. (460 mm) high unless the parapets are breached with low-level ventilation openings not more than 20 ft (6.1 m) apart, or unless all openings communicating with the interior of the building are at or above the top of the parapets. [**58:**6.22.11.1(C)]

69.3.12.9.1.4 Piping shall be in accordance with 69.3.12.2.3 through 69.3.12.2.5. [**58:**6.22.11.1(D)]

69.3.12.9.1.5 Hose shall not be used for connection to cylinders. [**58:**6.22.11.1(E)]

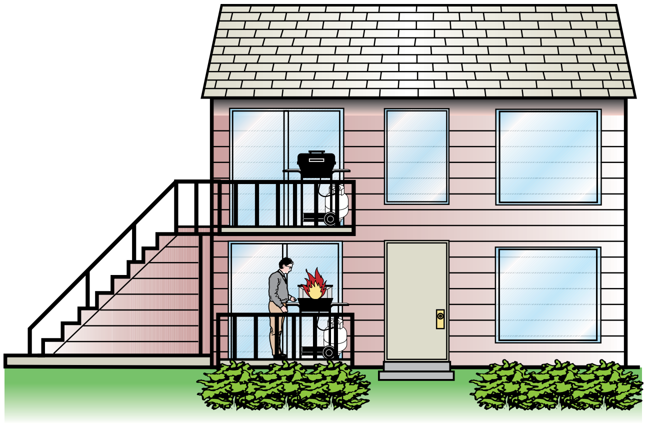
69.3.12.9.1.6 The fire department shall be advised of each installation. [**58:**6.22.11.1(F)]

69.3.12.9.2 Cylinders having water capacities greater than 2.7 lb (1 kg) [nominal 1 lb (0.5 kg) LP-Gas capacity] shall not be located

Exhibit 69.21

Prohibited Locations of Grills with Cylinders on Balconies. (Courtesy of Richard Fredenburg, North Carolina Department of Agriculture and Consumer Services)

Exhibit 69.22



Permitted location of cylinders on balconies located one above the other in a two-unit dwelling.

on decks or balconies of dwellings of two or more living units above the first floor unless they are served by exterior stairways. [**58:**6.22.11.2]

Exhibit 69.21 shows an example of how consumers might violate this prohibition. The balconies in this exhibit are part of an eight-unit condominium, and five of the units had grills with 20 lb (9.1 kg) cylinders on their balconies and no exterior stairways. In some instances, consumers might respond to a removal request by storing the cylinders in even more dangerous locations, such as inside the residence or garage. One secure solution for this location could be a community "exchange cabinet" in a safe, unobtrusive location.

The prohibition of cylinders above the first floor in multiple family dwellings of two or more living units reflects concerns for storage and transportation within these buildings, including elevators, egress of occupants from the upper floors in the event of an emergency, and the exposure to surrounding living units in the event of a leak or fire on a balcony. Note that a living unit may have more than one floor.

In multiple-family dwellings of two living units located one above the other, gas grill cylinders are permitted on balconies that are accessed from exterior stairways to each balcony, as shown in Exhibit 69.22.

69.3.13 Installation of Appliances.

69.3.13.1 Installation of Patio Heaters.

69.3.13.1.1 Patio heaters utilizing an integral LP-Gas container greater than 1.08 lb (0.49 kg) propane capacity shall comply with 69.3.13.1.2 and 69.3.13.1.3. [**58:**6.23.2.1]

69.3.13.1.2 Patio heaters shall be listed and used in accordance with their listing and the manufacturer's instructions. [**58:**6.23.2.2]

The requirement addressing patio heaters in 69.3.13.1.1 recognizes the growing use of portable outdoor appliances to heat areas where the climate is too cool to sit or stand outside comfortably. They are generally used in restaurants with outdoor seating areas to enable the areas to be used for longer periods. They are also sometimes used where attendants, such as those working for a valet parking service, wait outside. (See Exhibit 69.23.)

69.3.13.1.3 Patio heaters shall not be located within 5 ft (1.5 m) of exits from an assembly occupancy. [**58:**6.23.2.3]

69.3.13.2 Hose for Portable Appliances.

69.3.13.2.1 The requirements of 69.3.13 shall apply to hoses used on the low-pressure side of regulators to connect portable appliances. [**58:**6.23.3.1]

Δ **69.3.13.2.2** Where used inside buildings, the following shall apply:

(1) The hose shall be the minimum practical length and shall be in accordance with 69.3.12.2.5.
(2) The hose shall not extend from one room to another or pass through any partitions, walls, ceilings, or floors except as provided by 69.3.12.3.9.
(3) The hose shall not be concealed from view or used in concealed locations.

[**58:**6.23.3.2]

It is important for the hose to be visible so that any wear or damage it sustains can be readily detected. Hose that is longer than needed can be looped under equipment and be partially hidden. Hose hidden in walls, partitions, ceilings, and floors cannot be inspected for wear or damage.

69.3.13.2.3 Where installed outside of buildings, the hose length shall be permitted to exceed 10 ft (3.3 m) but shall be as short as practical. [**58:**6.23.3.3]

Exhibit 69.23

Patio heaters. (Courtesy of Richard Fredenburg, North Carolina Department of Agriculture and Consumer Services)

69.3.13.2.4 Hose shall be securely connected to the appliance. [**58:**6.23.3.4]

69.3.13.2.5 The use of rubber slip ends shall not be permitted. [**58:**6.23.3.5]

69.3.13.2.6 A shutoff valve shall be provided in the piping immediately upstream of the inlet connection of the hose. [**58:**6.23.3.6]

A shutoff valve is required at the point where the hose connects to the piping system to permit the appliance to be isolated from the piping system should it be necessary to conduct maintenance or repairs on the hose or appliance.

69.3.13.2.7 Where more than one such appliance shutoff is located near another, the valves shall be marked to indicate which appliance is connected to each valve. [**58:**6.23.3.7]

69.3.13.2.8 Hose shall be protected against physical damage. [**58:**6.23.3.8]

Because hose is vulnerable to mechanical and thermal damage and has a limited service life, hose should be used only where necessary and where it can be readily inspected and maintained. The requirements for hose and hose connectors are located in 5.11.6 of NFPA 58.

69.3.14 LP-Gas Systems on Vehicles (Other Than Engine Fuel Systems).

Δ **69.3.14.1* Application.** Subsection 69.3.14 shall apply to the following:

(1) Nonengine fuel systems on all vehicles
(2) Installations served by exchangeable (removable) cylinder systems and by permanently mounted containers

[**58:**6.26.1]

A.69.3.14.1 Typical non-engine fuel systems include those on commercial, industrial, construction, and public service vehicles such as trucks, semitrailers, trailers, portable tar kettles, road surface heating equipment, mobile laboratories, clinics, and mobile cooking units (such as catering and canteen vehicles). [**58:**A.6.26.1]

A variety of LP-Gas systems are installed on vehicles where the gas is not used as a vehicle engine fuel. Examples of this include the following:

- Vehicles (usually trailers) with mounted tar kettles used in the construction industry for heating tar for roofing
- Food-warming delivery vehicles, such as pretzel or hot dog carts and larger hot dog or lunch wagons
- Service vehicles that need a source of heated water, such as those used by carpet cleaning services
- Food trucks where the propane is used to prepare food

Δ **69.3.14.2 Nonapplication.** Subsection 69.3.14 shall not apply to the following:

(1) Systems installed on mobile homes
(2) Systems installed on recreational vehicles
(3) Cargo tank vehicles, cargo tank vehicles (trailers and semitrailers), and similar units used to transport LP-Gas as cargo, which are covered by Chapter 9 of NFPA 58
(4) LP-Gas engine fuel systems on the vehicles, which are covered by Chapter 11 of NFPA 58

[**58:**6.26.2]

69.3.14.3 Container Installation Requirements.

69.3.14.3.1 Containers shall comply with 69.3.14.3.1.1 through 69.3.14.3.1.5. [**58:**6.26.3.1]

69.3.14.3.1.1 ASME mobile containers shall in accordance with one of the following:

(1) A MAWP of 312 psig (2.2 MPag) or higher where installed in enclosed spaces of vehicles
(2) A MAWP of 312 psig (2.2 MPag) or higher where installed on passenger vehicles
(3) A MAWP of 250 psig (1.7 MPag) or higher for containers where installed on the exterior of nonpassenger vehicles

[**58:**6.26.3.1(A)]

69.3.14.3.1.2 LP-Gas fuel containers used on passenger-carrying vehicles shall not exceed 200 gal (0.8 m^3) aggregate water capacity. [**58:**6.26.3.1(B)]

69.3.14.3.1.3 The capacity of individual LP-Gas containers on highway nonpassenger vehicles shall be 1000 gal (3.8 m^3) or in accordance with U.S. Department of Transportation regulations. [**58:**6.26.3.1(C)]

Prior to the 2018 edition of the *Code*, there was a table summarizing the various maximum water capacities for containers on highway nonpassenger vehicles. This table has been removed and replaced with a single requirement summarizing the previous information and referencing DOT regulations.

N **69.3.14.3.1.4** The capacity of cargo tank motor vehicles shall not be limited by NFPA 58. [**58:**6.26.3.1(D)]

69.3.14.3.1.5 Containers designed for stationary service only and not in compliance with the container appurtenance protection requirements of 5.2.6 of NFPA 58 shall not be used. [**58:**6.26.3.1(E)]

69.3.14.3.2 ASME containers and cylinders utilized for the purposes covered by 69.3.14 shall not be installed, transported, or stored (even temporarily) inside any vehicle covered by 69.3.14, except for ASME containers installed in accordance with 69.3.14.3.4.9, Chapter 9 of NFPA 58, or DOT regulations. [**58:**6.26.3.2]

69.3.14.3.3 The LP-Gas supply system, including the containers, shall be installed either on the outside of the vehicle or in a recess or cabinet vaportight to the inside of the vehicle but accessible from and vented to the outside, with the vents located near the top and bottom of the enclosure and 3 ft (1 m) horizontally away from any opening into the vehicle below the level of the vents. [**58:**6.26.3.3]

69.3.14.3.4 Containers shall be mounted securely on the vehicle or within the enclosing recess or cabinet. [**58:**6.26.3.4]

69.3.14.3.4.1 Containers shall be installed with road clearance in accordance with 11.8.3 of NFPA 58. [**58:**6.26.3.4(A)]

69.3.14.3.4.2 Fuel containers shall be mounted to prevent jarring loose and slipping or rotating, and the fastenings shall be designed and constructed to withstand, without permanent visible deformation, static loading in any direction equal to four times the weight of the container filled with fuel. [**58:**6.26.3.4(B)]

69.3.14.3.4.3 Where containers are mounted within a vehicle housing, the securing of the housing to the vehicle shall comply with this provision. Any removable portions of the housing or cabinet shall be secured while in transit. [**58:**6.26.3.4(C)]

69.3.14.3.4.4 Field welding on containers shall be limited to attachments to nonpressure parts such as saddle plates, wear plates, or brackets applied by the container manufacturer. [**58:**6.26.3.4(D)]

69.3.14.3.4.5 All container valves, appurtenances, and connections shall be protected to prevent damage from accidental contacts with stationary objects; from loose objects, stones, mud, or ice thrown up from the ground or floor; and from damage due to overturn or similar vehicular accident. [**58:**6.26.3.4(E)]

As with vehicle propulsion engine fuel containers, exterior containers and appurtenances must be protected against material thrown up from the road, as set forth in 69.3.14.3.4.5. Slush and other hazards thrown up from the road must not block the regulator vent, and splashguards or the practice of locating the regulator in a compartment can protect from these hazards. A blocked vent can lead to higher than normal pressures in the utilization system and can lead to pilot failure and improper appliance operation. Appurtenances on a container, particularly on those mounted below the vehicle, should be installed so that they are accessible for maintenance and readily accessible if needed for normal operations such as operation of the fixed maximum liquid level gauge during filling.

69.3.14.3.4.6 Permanently mounted ASME containers shall be located on the vehicle to provide the protection specified in 69.3.14.3.4.5. [**58:**6.26.3.4(F)]

69.3.14.3.4.7 Cylinders shall have permanent protection for cylinder valves and connections. [**58:**6.26.3.4(G)]

69.3.14.3.4.8 Where cylinders are located on the outside of a vehicle, weather protection shall be provided. [**58:**6.26.3.4(H)]

69.3.14.3.4.9 Containers mounted on the interior of passenger-carrying vehicles shall be installed in compliance with Section 11.9 of NFPA 58. Pressure relief valve installations for such containers shall comply with 11.8.5 of NFPA 58. [**58:**6.26.3.4(I)]

The container mounting arrangement must be strong enough to remain intact and to protect the container and its appurtenances and connections from damage caused by collisions, road debris, and weather. These provisions do not apply to engine fuel containers, as stated by the reference in 69.3.14.3.4.9 to Chapter 11 of NFPA 58.

Δ **69.3.14.3.5** Cylinders installed on portable tar kettles alongside the kettle, on the vehicle frame, or on road surface heating equipment shall be protected from radiant or convected heat from open flame or other burners by the use of a heat shield or by the location of the cylinder(s) on the vehicle. In addition, the following shall apply:

(1) Cylinder valves shall be closed when burners are not in use.
(2) Cylinders shall not be refilled while burners are in use as provided in 7.2.3.2(B) of NFPA 58.

[**58:**6.26.3.5]

Cylinders should be mounted so that no wear takes place; for example, chains can cut grooves in cylinders due to vehicular motion. Most tar kettles use liquid burners, so the right type of cylinder and appurtenances must be used. The word "liquid" is stamped on the cylinder next to the liquid withdrawal connection. A metal barrier or some other physical protection is required between the tar kettle and the cylinder to protect the cylinder from becoming overheated due to its proximity to the tar kettle.

69.3.14.4 Installation of Container Appurtenances.

Δ **69.3.14.4.1** Container appurtenances shall be installed in accordance with the following:

(1) Pressure relief valve installation on ASME containers installed in the interior of vehicles complying with Section 11.9 of NFPA 58 shall comply with 11.8.5 of NFPA 58.
(2) Pressure relief valve installations on ASME containers installed on the outside of vehicles shall comply with 11.8.5 of NFPA 58 and 69.3.14.3.3.
(3) Main shutoff valves on containers for liquid and vapor shall be readily accessible.
(4) Cylinders shall be designed to be filled in either the vertical or horizontal position, or if they are the universal type, they are permitted to be filled in either position.
(5) All container inlets, outlets, or valves installed in container inlets or outlets, except pressure relief devices and gauging devices, shall be labeled to designate whether they communicate with the vapor or liquid space.
(6) Containers from which only vapor is to be withdrawn shall be installed and equipped with connections to minimize the possibility of the accidental withdrawal of liquid.

[**58:**6.26.4.1]

The three following types of fuel container installations affect how the pressure relief valve is installed and located:

1. Cylinders in a cabinet or recess in accordance with 69.3.14.3.3, for which the pressure relief valve is not required to be piped away
2. Containers installed in the interior of passenger-carrying vehicles, which are permitted in Section 11.9, with relief valve piped away in accordance with 11.8.5.2 of NFPA 58
3. Containers mounted on the exterior of vehicles, which is allowed per 69.3.14.3.3

Paragraph 11.8.5.2(F) of NFPA 58 provides specific requirements for the pressure relief valve pipeaway system, if used. Also refer to 11.8.5.2(F) of NFPA 58 for requirements for protecting the pressure relief valve outlet (valve or discharge piping) from being plugged with dirt, asphalt, or water.

69.3.14.4.2 Regulators shall be installed in accordance with 6.10.2 of NFPA 58 and 69.3.14.4.2.1 through 69.3.14.4.2.5. [**58:**6.26.4.2]

69.3.14.4.2.1 Regulators shall be installed with the pressure relief vent opening pointing vertically downward to allow for drainage of moisture collected on the diaphragm of the regulator. [**58:**6.26.4.2(A)]

69.3.14.4.2.2 Regulators not installed in compartments shall be equipped with a durable cover designed to protect the regulator vent opening from sleet, snow, freezing rain, ice, mud, and wheel spray. [**58:**6.26.4.2(B)]

69.3.14.4.2.3 If vehicle-mounted regulators are installed at or below the floor level, they shall be installed in a compartment that provides protection against the weather and wheel spray. [**58:**6.26.4.2(C)]

Δ **69.3.14.4.2.4** Regulator compartments shall comply with the following:

(1) The compartment shall be of sufficient size to allow tool operation for connection to and replacement of the regulator(s).
(2) The compartment shall be vaportight to the interior of the vehicle.
(3) The compartment shall have a 1 in.^{2} (650 mm^2) minimum vent opening to the exterior located within 1 in. (25 mm) of the bottom of the compartment.
(4) The compartment shall not contain flame or spark-producing equipment.

[**58:**6.26.4.2(D)]

69.3.14.4.2.5 A regulator vent outlet shall be at least 2 in. (51 mm) above the compartment vent opening. [**58:**6.26.4.2(E)]

Two-stage pressure regulation must be used in all systems covered in 69.3.14. Multiple regulators provide several safety features, which are described in the commentary following 6.10.2.3 in NFPA 58: *LP-Gas Code Handbook*.

Regulators (and cylinders) used on vehicles are usually installed in a compartment for security and to comply with the requirement for protection of regulators from sleet, snow, freezing rain, and so forth. The enclosure cannot contain electrical devices that are a source of ignition and must be ventilated to allow any released propane to disperse. Louvers in the compartment or its door are typically used to provide this required ventilation. Louvers must communicate with the outdoors and not to the interior of the vehicle.

69.3.14.5 Piping.

69.3.14.5.1 Piping shall be installed in accordance with 6.11.3 of NFPA 58 and 69.3.14.5.1.1 through 69.3.14.5.1.13. [**58:**6.26.5.1]

The main lines and branch connections must be kept outside the vehicle so that, if leakage occurs, gas will not accumulate in the vehicle. To avoid compounding problems in the event of collisions, overturns, and disconnection of vehicles, fuel lines cannot be connected between two vehicular units. These types of risks are regarded as greater than the corresponding risks in a system located completely on one vehicle.

69.3.14.5.1.1 Steel tubing shall have a minimum wall thickness of 0.049 in. (1.2 mm). [**58:**6.26.5.1(A)]

Steel tubing in vehicular installations has been specified as having a minimum 0.049 in. (1.2 mm) wall thickness to provide strength against vibration and to provide an additional tolerance for corrosion.

69.3.14.5.1.2 A flexible connector shall be installed between the regulator outlet and the fixed piping system to protect against expansion, contraction, jarring, and vibration strains. [**58:**6.26.5.1(B)]

69.3.14.5.1.3 Flexibility shall be provided in the piping between a cylinder and the gas piping system or regulator. [**58:**6.26.5.1(C)]

69.3.14.5.1.4 Flexible connectors shall be installed in accordance with 6.11.6 of NFPA 58. [**58:**6.26.5.1(D)]

69.3.14.5.1.5 Flexible connectors longer than the length allowed in the *Code*, or fuel lines qthat incorporate hose, shall be used only where approved. [**58:**6.26.5.1(E)]

69.3.14.5.1.6 The piping system shall be designed, installed, supported, and secured to minimize the possibility of damage due to vibration, strains, or wear and to preclude any loosening while in transit. [**58:**6.26.5.1(F)]

69.3.14.5.1.7 Piping shall be installed in a protected location. [**58:**6.26.5.1(G)]

Δ **69.3.14.5.1.8** Where piping is installed outside the vehicle, it shall be installed as follows:

(1) Piping shall be under the vehicle and below any insulation or false bottom.
(2) Fastening or other protection shall be installed to prevent damage due to vibration or abrasion.
(3) At each point where piping passes through sheet metal or a structural member, a rubber grommet or equivalent protection shall be installed to prevent chafing.

[**58:**6.26.5.1(H)]

69.3.14.5.1.9 Gas piping shall be installed to enter the vehicle through the floor directly beneath or adjacent to the appliance served. [**58:**6.26.5.1(I)]

69.3.14.5.1.10 If a branch line is installed, the tee connection shall be located in the main gas line under the floor and outside the vehicle. [**58:**6.26.5.1(J)]

69.3.14.5.1.11 Exposed parts of the fixed piping system either shall be of corrosion-resistant material or shall be coated or protected to minimize exterior corrosion. [**58:**6.26.5.1(K)]

69.3.14.5.1.12 Hydrostatic relief valves shall be installed in isolated sections of liquid piping as provided in Section 6.15 of NFPA 58. [**58:**6.26.5.1(L)]

Δ **69.3.14.5.1.13** Piping systems, including hose, shall be proven free of leaks in accordance with Section 6.16 of NFPA 58. [**58:**6.26.5.1(M)]

69.3.14.5.2 There shall be no fuel connection between a tractor and trailer or other vehicle units. [**58:**6.26.5.2]

69.3.14.6 Equipment Installation. Equipment shall be installed in accordance with Section 6.20 of NFPA 58 and 69.3.14.6.1 and 69.3.14.6.2. [**58:**6.26.6]

69.3.14.6.1 Installation shall be made in accordance with the manufacturer's recommendations and, in the case of approved equipment, as provided in the approval. [**58:**6.26.6.1]

69.3.14.6.2 Equipment installed on vehicles shall be protected against vehicular damage as provided for container appurtenances and connections in 69.3.14.3.4.5. [**58:**6.26.6.2]

69.3.14.7 Appliance Installation on Vehicles.

69.3.14.7.1 Paragraph 69.3.14.7 shall apply to the installation of all appliances on vehicles. It shall not apply to engines. [**58:**6.26.7.1]

69.3.14.7.2 All appliances covered by 69.3.14.7 installed on vehicles shall be approved. [**58:**6.26.7.2]

69.3.14.7.3 Where the device or appliance, such as a cargo heater or cooler, is designed to be in operation while the vehicle is in transit, means, such as an excess flow valve to stop the flow of gas in the event of a line break, shall be installed. [**58:**6.26.7.3]

Appliances used in vehicles and the vibration that occurs while vehicles are in transit can result in fittings loosening or becoming disconnected. This requirement recognizes that possibility and requires a positive means of stopping the flow if fittings are disconnected. Even though excess-flow valves are given as an example of protection, other types of protection can be used. Excess-flow valves will close only when the design flow is reached, and they might not operate in the event of a partial separation of a fitting. If the vehicle comes under DOT regulations, reference should be made to the DOT requirements that may apply.

69.3.14.7.4 Gas-fired heating appliances shall be equipped with shutoffs in accordance with 5.23.7(A) of NFPA 58 except for portable heaters used with cylinders having a maximum water capacity of 2.7 lb (1.2 kg), portable torches, melting pots, and tar kettles. [**58:**6.26.7.4]

69.3.14.7.5 Gas-fired heating appliances, other than ranges and illuminating appliances installed on vehicles intended for human occupancy, shall be designed or installed to provide for a complete separation of the combustion system from the atmosphere inside the vehicle. [**58:**6.26.7.5]

The concept of isolating the combustion system of appliances — except ranges in vehicle interiors where passengers might be — is consistent with all other vehicle standards on this subject, including the standards for RVs. No portable or conventional room heaters should be used inside such vehicles. Isolation may be accomplished through the use of direct-vent type heaters and water heaters or through separation by installing the appliance in a compartment with provisions for outside air. The range is an attended appliance and need not be isolated, but it should never be used for comfort heating.

Although extensive requirements for the installation of appliances fueled by LP-Gas are included in NFPA 54, that code is limited to appliances that are connected to a fixed building piping system. The appliances covered under NFPA 58 are those not normally connected to a fixed building piping system.

69.3.14.7.6* Where unvented-type heaters that are designed to protect cargo are used on vehicles not intended for human occupancy, provisions shall be made to provide air from the outside for combustion and dispose of the products of combustion to the outside. [**58:**6.26.7.6]

A.69.3.14.7.6 Requirements for the design of containers are located in Section 5.2 of NFPA 58. Requirements for container appurtenances are located in Section 5.3 of NFPA 58. [**58:**A.6.26.7.6]

69.3.14.7.7 Appliances installed in the cargo space of a vehicle shall be readily accessible whether the vehicle is loaded or empty. [**58:**6.26.7.7]

69.3.14.7.8 Appliances shall be constructed or otherwise protected to minimize possible damage or impaired operation due to cargo shifting or handling. [**58:**6.26.7.8]

69.3.14.7.9 Appliances shall be located so that a fire at any appliance will not block egress of persons from the vehicle. [**58:**6.26.7.9]

Δ **69.3.14.7.10** A permanent caution plate shall be affixed to either the appliance or the vehicle outside of any enclosure, shall be adjacent to the container(s), and shall include the following instructions:

CAUTION:

(1) Be sure all appliance valves are closed before opening container valve.
(2) Connections at the appliances, regulators, and containers shall be checked periodically for leaks with soapy water or its equivalent.
(3) Never use a match or flame to check for leaks.
(4) Container valves shall be closed when equipment is not in use.

[**58:**6.26.7.10]

69.3.14.7.11 Gas-fired heating appliances and water heaters shall be equipped with automatic devices designed to shut off the flow of gas to the main burner and the pilot in the event the pilot flame is extinguished. [**58:**6.26.7.11]

• **69.3.14.8 Parking, Servicing, and Repair.**

69.3.14.8.1 Where vehicles with LP-Gas fuel systems used for purposes other than propulsion are parked, serviced, or repaired inside buildings, the requirements of 69.3.14.8.2 through 69.3.14.8.4 shall apply. [**58:**6.26.8.1]

69.3.14.8.2 The fuel system shall be leak-free, and the container(s) shall not be filled beyond the limits specified in Chapter 7 of NFPA 58. [**58:**6.26.8.2]

Specific requirements for the parking, servicing, and repair of vehicles that have non–engine fuel LP-Gas systems are provided in 69.3.14.8.1. RVs are not addressed because they are covered by NFPA 1192, *Standard on Recreational Vehicles*. Subsection 6.26.8 of NFPA 58 also does not address manufactured housing, which is covered under federal regulations, or vehicles used to transport LP-Gas as cargo, which are covered under Chapter 9 of NFPA 58.

The requirements in 69.3.14.8 are similar to those for vehicles using LP-Gas as an engine fuel. Vehicles having a total LP-Gas capacity of more than 300 lb (136 kg) are required to follow the more detailed requirements of Section 9.7 of NFPA 58.

69.3.14.8.3 The container shutoff valve shall be closed, except that the container shutoff valve shall not be required to be closed when fuel is required for test or repair. [**58:**6.26.8.3]

69.3.14.8.4 The vehicle shall not be parked near sources of heat, open flames, or similar sources of ignition, or near unventilated pits. [**58:**6.26.8.4]

69.3.14.8.5 Vehicles having containers with water capacities larger than 300 gal (1.1 m^3) shall comply with the requirements of Section 9.7 of NFPA 58. [**58:**6.26.8.5]

69.3.15 Vehicle Fuel Dispenser and Dispensing Systems.

Section 69.3.15 provides requirements in one place for vehicle fuel dispensers and dispensing stations or propane vehicle fueling stations, as shown in Exhibit 69.24. Refer to NFPA 30A, which includes a separate chapter — Chapter 12 — to address the requirements for installing propane dispensers at service stations.

Propane and CNG have been identified as alternative fuels to gasoline for powering motor vehicles. The use of propane or CNG can result in a reduction in engine emissions such as carbon monoxide and unburned hydrocarbons.

Governments all over the world are working with industry and environmental groups to promote the use of alternative vehicle fuels — including propane, CNG, electricity and hydrogen — in fleet operations and in privately owned personal vehicles. The selection of fuels usually is based on a combination of perceived safety, cost, and local availability. Promotion of the use of alternative fuels has led to a need to promote these fuels beyond the typical private fleet dispensing operations and to make them available at existing commercial gasoline automotive service stations.

Table 6.7.2.1 of NFPA 58 specifies distances from points of transfer and exposures. This table applies to the location of the filling of cylinders that are not installed, which includes all cylinders brought to a dispensing station for filling. The table provides separation distances from points of transfer, such as the hose end, to several exposures. Possible exposures include public

Exhibit 69.24

Dispensing station for propane vehicles. (Courtesy of CleanFuel USA)

ways, buildings with and without fire-resistive walls, mainline railroad track centerlines, outdoor places of public assembly, and flammable liquids dispensers.

69.3.15.1 Application.

69.3.15.1.1 Subsection 69.3.15 includes the location, installation, and operation of vehicle fuel dispensers and dispensing systems. [**58:**6.27.1.1]

69.3.15.1.2 The provisions of 69.3.3 and 69.3.5, as modified by 69.3.15, shall apply. [**58:**6.27.1.2]

69.3.15.2 Location.

69.3.15.2.1 Location of vehicle fuel dispensers and dispensing systems shall be in accordance with Table 69.3.7.2.1. [**58:**6.27.2.1]

69.3.15.2.2 Vehicle fuel dispensers and dispensing systems shall be located away from pits in accordance with Table 69.3.7.2.1, with no drains or blow-offs from the unit directed toward or within 15 ft (4.6 m) of a sewer system's opening. [**58:**6.27.2.2]

69.3.15.3 General Installation Provisions.

69.3.15.3.1 Vehicle fuel dispensers and dispensing systems shall be installed in accordance with the manufacturer's installation instructions. [**58:**6.27.3.1]

Vehicle fuel dispensers and dispensing stations are typically manufactured as complete units for installation in the field. Some of these units are listed, but even if they are not, the manufacturer's installation instructions must be followed.

Questions concerning the safety of installing dispensing stations have been raised for locations where local ordinances prohibit aboveground tanks from being in front of buildings. Generally, resorting to the use of an underground tank is the solution, though there are some design considerations that must be resolved before this is done.

Propane is stored as a liquefied gas under pressure. Dispenser pumps are normally at the low point of the piping between the tank and the meter to have as much net positive suction head (NPSH) as possible available at the pump. This positive pressure is to keep the propane from boiling and introducing vapor into the metering system or causing cavitation in the pump. Both of these situations are undesirable, because vapor in the meter affects accuracy and cavitation is detrimental to pump life. If the pump for an underground tank is located at ground level, it likely will not have sufficient NPSH.

If the pump is placed underground at the bottom of the tank, there are concerns for maintenance accessibility. If it is accessible, there may be a violation for having a pit too close to the point of transfer. It also may violate the manufacturer's installation instructions.

69.3.15.3.2 Vehicle fuel dispensers and dispensing systems shall not be located within a building or structure, unless they comply with Chapter 10 of NFPA 58. [**58:**6.27.3.2]

This requirement is another example of the restriction against piping liquid LP-Gas into a building or structure that is not specifically designed in accordance with Chapter 10 of NFPA 58.

69.3.15.3.3 Where a vehicle fuel dispenser or dispensing system is installed under a weather shelter or canopy, the area shall be ventilated and shall not be enclosed for more than 50 percent of its perimeter. [**58:**6.27.3.3]

These requirements are concerned with the need to disperse any vapors that may be released during the fueling process to avoid the formation of a flammable propane–air mixture. The requirement also provides guidance on how much of a weather shelter can be installed without the area being considered an indoor location. If an installation is considered to be an indoor type, compliance with Chapter 10 of NFPA 58 is mandated.

69.3.15.3.4 Control for the pump used to transfer LP-Gas through the unit into containers shall be provided at the device in order to minimize the possibility of leakage or accidental discharge. [**58:**6.27.3.4]

This requirement does not necessarily reduce the possibility of a leak occurring, but it can reduce the impact of the leak by allowing the operator to quickly stop the flow of product from the pump.

69.3.15.3.5 A device that shuts off the flow of gas when flow exceeds the predetermined flow rate shall be installed as close as practical to the point where the dispenser hose connects to the liquid piping. [**58:**6.27.3.5]

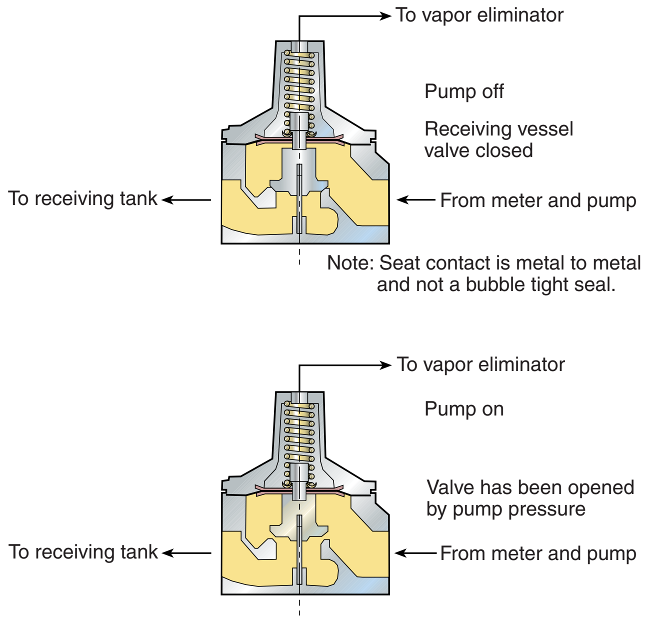
This requirement has been revised in the 2018 edition of the *Code* to permit the use of systems other than excess-flow check valves. Specifying only an excess-flow check valve prevents the use of other valves that incorporate the same function. It is with this knowledge in mind that, instead of referring to specific devices, the requirement was revised in NFPA 58 to refer to devices in general.

A differential back pressure valve is used with an LP-Gas meter measuring liquid. The purpose of the differential back pressure valve is to ensure that vapor is not introduced into the metering system. Vapor passing through a meter designed for liquid would cause an inaccurate delivery. The differential back pressure valve works in conjunction with the vapor eliminator (located upstream of the meter) to stop flow through the meter when vapor is detected in the piping upstream of the meter. See Exhibit 69.25 for a graphical explanation of the operation of a differential back pressure valve.

A valve working in conjunction with an electronic register as part of the dispenser can be set to close when the register detects a predetermined flow rate. Additionally, excess-flow and differential back pressure valves serve separate purposes. A differential back pressure valve is part of the metering system and is designed to prevent vapor from entering the meter by closing itself when vapor is detected in the vapor eliminator. The valve is closed when the pump is off, which prevents release of LP-Gas if there is a leak downstream of the valve. When the pump is on and the product is flowing, the differential back pressure valve may not close if there is a rupture downstream of the valve.

Paragraph 69.3.15.3.5 requires either an excess-flow valve or a differential pressure or meter assembly to be installed at the point that the dispenser hose connects to the liquid piping in the dispenser unit.

Exhibit 69.25



Operation of differential back pressure valve. (Courtesy of Liquid Controls, Inc.)

69.3.15.3.6 Piping and the dispensing hose shall be provided with hydrostatic relief valves in accordance with Section 6.15 of NFPA 58. [**58:**6.27.3.6]

69.3.15.3.7 Protection against trespassing and tampering shall be in accordance with 6.21.4 of NFPA 58. [**58:**6.27.3.7]

Security at dispensing stations is important, both for filling cylinders and for buildings. Access to the dispenser and its controls must be limited to trained operators, and the equipment must be secured to prevent tampering when not attended. Options in 6.21.4 of NFPA 58 include fences and locking the equipment.

Δ **69.3.15.3.8** The container liquid withdrawal opening used with vehicle fuel dispensers and dispensing stations shall be equipped with one of the following:

(1) An internal valve fitted for remote closure and automatic shutoff using thermal (fire) actuation
(2) A positive shutoff valve that is located as close to the container as practical in combination with an excess-flow valve installed in the container, plus an emergency shutoff valve that is fitted for remote closure and installed downstream in the line as close as practical to the positive shutoff valve

[**58:**6.27.3.8]

69.3.15.3.9 An identified and accessible remote emergency shutoff device for either the internal valve or the emergency shutoff valve required by 69.3.15.3.8(1) or 69.3.15.3.8(2) shall be installed not less than 3 ft (1 m) or more than 100 ft (30 m) from the liquid transfer point. [**58:**6.27.3.9]

69.3.15.3.10 Emergency shutoff valves and internal valves that are fitted for remote closure as required in this section shall be tested annually for proper operation. [**58:**6.27.3.10]

Paragraphs 69.3.15.3.8 through 69.3.15.3.10 recognize that remote closures with thermal actuation are important devices for providing a safe way to shut off product releases in the event of an emergency. Generally, dispensers are located in public areas. Equipping dispenser stations with remote shutoffs fitted with thermal actuation will provide an additional level of safety for dispensers. Testing is also required to verify that the shutoff devices remain in good operating condition.

69.3.15.3.11 A manual shutoff valve and an excess-flow check valve shall be located in the liquid line between the pump and the dispenser inlet where the dispensing device is installed at a remote location and is not part of a complete storage and dispensing unit mounted on a common base. [**58:**6.27.3.11]

69.3.15.3.12 All dispensers shall be installed either on a concrete foundation or shall be part of a complete storage and dispensing unit mounted on a common base and installed in accordance with 6.8.3.1(F) of NFPA 58. [**58:**6.27.3.12]

Anchorage of a dispenser helps to ensure that the breakaway device mandated in 69.3.15.4.2 operates properly. Physical protection is also required and is often needed in areas where vehicular traffic is normal.

69.3.15.3.13 Vehicle barrier protection (VBP) shall be provided for containers serving liquid dispensers where those containers are located within 10 ft of a vehicle thoroughfare or parking location. Such protection shall be either 69.3.15.3.13.1 or 69.3.15.3.13.2. [**58:**6.27.3.13]

69.3.15.3.13.1 Concrete filled guard posts constructed of steel not less than 4 in. (102 mm) in diameter, with the following characteristics:

(1) Spaced not more than 4 ft (1219 mm) between posts on center
(2) Set not less than 3 ft (900 mm) deep in a concrete footing of not less than 15 in. (380 mm) diameter
(3) Set with the top of the posts not less than 3 ft (900 mm) above ground
(4) Located not less than 3 ft (900 mm) from the protected installation

[**58:**6.27.3.13(A)]

69.3.15.3.13.2 Equivalent protection in lieu of guard posts shall be a minimum of 3 ft (900 mm) in height and shall resist a force of 6000 lb (26,690 N) applied 3 ft (900 mm) above the adjacent ground surface. [**58:**6.27.3.13(B)]

In the 2017 edition of NFPA 58, the 12,000 lb (53,380 N) requirement was revised to 6,000 lb (26,690 N) after a research paper prepared for the National Propane Gas Association, "Evaluation of Collision Protection Provided by Vehicle Impact Bollards and Propane Cylinder Exchange Cabinets," was presented to the Technical Committee on Liquefied Petroleum Gases that stated the previous requirements did not originate from DOT regulations and were unnecessary as stated.

Previously, the lack of specificity in the *Code* led to a wide range of interpretations by AHJs, resulting in confusion. The *Code* now provides a clear set of requirements for consistent enforcement.

69.3.15.3.14 Where the dispenser is not mounted on a common base with its storage container and the dispensing unit is located within 10 ft of a vehicle thoroughfare, parking location, or a engine fuel filling station, the dispenser shall be provided with VBP. [**58:**6.27.3.14]

69.3.15.3.15 Dispensers shall be protected from physical damage. [**58:**6.27.3.15]

69.3.15.3.16 A listed quick-acting shutoff valve shall be installed at the discharge end of the transfer hose. [**58:**6.27.3.16]

A listed quick-acting shutoff valve must be installed at the end of the transfer hose, which helps the operator of the dispenser quickly shut off the flow of liquid when the vehicle fuel tank or the cylinder reaches its maximum capacity. A gate valve or globe valve does not meet this requirement because it can take a few seconds to screw the valves closed, time during which the container can become significantly overfilled. By using a listed quick-acting shutoff valve, flow can be stopped quickly.

69.3.15.3.17 An identified and accessible switch or circuit breaker shall be installed outside at a location not less than 20 ft (6.1 m) or more than 100 ft (30.5 m) from the dispenser to shut off the power in the event of a fire, an accident, or other emergency. [**58:**6.27.3.17]

Paragraph 69.3.15.3.17 provides specific minimum and maximum distances from a shutoff switch to the dispenser. The outside location is required because enforcers were finding that, where it was indoors, such equipment was being made inaccessible by the storage or display of items being sold at the same location. A sign or other marking (see 69.3.15.3.18) must identify the location of the switch so that the dispenser can be shut off either from the vicinity of the dispenser or from a remote location.

There are places where limiting the switch location to the specified distance can result in an installation that fails to meet the intent of the requirement, such as a lot where the specified distance range is in an area where vehicles are moving about. In such a location, the AHJ may allow the distance to be slightly extended in order to provide a safe and useful installation. Reducing the distance may make it inaccessible in the event of a release, especially if it results in a fire, so it should not be considered. In all such instances, the AHJ should be consulted prior to the installation.

69.3.15.3.18 The markings for the switches or breakers shall be visible at the point of liquid transfer. [**58:**6.27.3.18]

It is important that the markings locating the switches or breakers be legible from the transfer point and that obstructions and signs not be placed in such a way that the markings are hidden.

69.3.15.4 Installation of Vehicle Fuel Dispensers.

Δ **69.3.15.4.1** Hose shall comply with the following:

(1) Hose length shall not exceed 18 ft (5.5 m) unless approved by the AHJ.
(2) All hose shall be listed.
(3) When not in use, the hose shall be secured to protect the hose from damage.

[**58:**6.27.4.1]

This provision is modeled after 12.2.4 of NFPA 30A. The 18 ft (5.5 m) limit on hose length comes from the U.S. Bureau of Weights and Measures. The normal maximum hose length may be exceeded when necessary, with the approval of the AHJ.

The AHJ must consider whether the excess-flow valve at the hose or piping interface will still function if the hose fails near the delivery end. A long hose can restrict flow enough so that the excess-flow valve will fail to close.

Δ **69.3.15.4.2** A listed emergency breakaway device shall be installed and shall comply with UL 567, *Standard for Emergency Breakaway Fittings, Swivel Connectors, and Pipe-Connection Fittings for Petroleum Products and LP-Gas,* and be designed to retain liquid on both sides of the breakaway point, or other devices affording equivalent protection approved by the AHJ. [**58:**6.27.4.2]

Pull-away incidents have occurred with gasoline, diesel, and propane fuel dispensers. Anchorage of the breakaway device in accordance with the manufacturer's instructions is required to ensure that the dispenser operates properly. If the dispenser does not provide anchorage, a separate post or other means of anchorage may be necessary.

69.3.15.4.3 Vehicle fuel dispensers shall be located as follows:

(1) Conventional systems shall be at least 10 ft (3.0 m) from any dispensing device for Class I or Class II liquids.
(2) Low-emission transfer systems in accordance with Section 6.30.5 of NFPA 58 shall be at least 5 ft (2 m) from any dispensing device for Class I or Class II liquids.

[**58:**6.27.4.3]

See NFPA 30 for information on classification of liquids. Gasoline, for example, is a Class I liquid.

69.4 LP-Gas Liquid Transfer

The transfer of liquid LP-Gas to or from stationary storage containers, transportation vehicles (highway and rail), and portable containers requires connections and disconnections of couplings by transfer personnel. The likelihood of releasing LP-Gas into the atmosphere is greatest during these operations. Section 69.4 provides safety requirements for when liquid LP-Gas is transferred from one container to another and for when liquid or vapor LP-Gas is vented and purged to the atmosphere.

Section 69.4 addresses the following important aspects related to liquid transfer of LP-Gas:

- Operational safety of transfer operations (including training and qualification requirements, operational requirements, controlling sources of ignition, filling/evacuating containers, and hose inspection)
- Venting LP-Gas to atmosphere (including the acceptable conditions)
- Quantity of LP-Gas in containers (including the maximum allowable quantity)

69.4.1* Scope.

A.69.4.1 Ignition source control at transfer locations is covered in Section 6.25 of NFPA 58. Fire protection is covered in Section 6.29 of NFPA 58. [**58:**A.7.1]

69.4.1.1 Section 69.4 applies to transfers of liquid LP-Gas from one container to another wherever this transfer involves connections and disconnections in the transfer system or the venting of LP-Gas to the atmosphere. [**58:**7.1.1]

69.4.1.2 Section 69.4 also applies to operational safety and methods for determining the quantity of LP-Gas permitted in containers. [**58:**7.1.2]

The probability of the release of LP-Gas, especially liquid LP-Gas, is greatest during liquid transfer operations. While release is an operational necessity, it can and should be minimized. Accurate container filling is necessary to avoid release through pressure relief devices after the container has been filled. Therefore, the *Code* has always thoroughly addressed these operations. Exhibit 69.26 is an example of a transfer operation showing the filling of cargo tank vehicles at a pipeline terminal.

69.4.2 Operational Safety.

69.4.2.1 Transfer Personnel.

69.4.2.1.1 Transfer operations shall be conducted by qualified personnel meeting the provisions of Section 4.4 of NFPA 58. [**58:**7.2.1.1]

Exhibit 69.26

Transport trailers loading at a pipeline terminal.

69.4.2.1.2 At least one qualified person shall remain in attendance at the transfer operation from the time connections are made until the transfer is completed, shutoff valves are closed, and lines are disconnected. [**58:**7.2.1.2]

Liquid transfer operation is considered to have the greatest risk of discharge of flammable gas into the atmosphere. The individual performing the transfer must be fully qualified in such work and sufficiently familiar with the operation of equipment to stop the transfer operation and minimize the loss of product should an emergency arise.

The term *in attendance* in 69.4.2.1.2 clarifies the intent of the requirement, which is that the qualified person must view the transfer operation and be able to take action if needed at any time. The entire transfer operation may not be viewable from one location. For example, if an operator is filling a tank at a building, the tank may not be visible from where the bobtail is parked. In this example, the operator must choose the best location to ensure that the tank is not overfilled. During the time the bobtail cannot be seen, the operator must use all his or her senses (e.g., listening to the truck engine for speed changes that could indicate releases, listening for the escape of hissing gas, looking for vapor clouds) to monitor the transfer process. If the operator needs to leave the location, the transfer operation must be stopped during that absence according to DOT regulations in 49 CFR 177.834(i)(1), "Loading," and (2), "Unloading."

A qualified operator is considered to be in attendance when he or she is standing at the cargo tank vehicle, sitting in the cab of the vehicle, or sitting in a booth or guardhouse with the cargo tank vehicle in clear sight. The qualified operator must be awake and aware of the transfer during the operation. If the complete transfer system is not visible from one location and the transfer is lengthy — for example, during the unloading of a transport — it is prudent for the operator to check the entire system for leakage during the transfer.

69.4.2.1.3 Transfer personnel shall exercise caution to ensure that the LP-Gases transferred are those for which the transfer system and the containers to be filled are designed. [**58:**7.2.1.3]

Accidents can occur if propane or a mixture of propane and butane is placed in containers suitable only for butane. The pressure relief device is set to a lower pressure for butane and can result in a release of flammable gas during its operation if a different LP-Gas is transferred into the container. The ASME container nameplate and the cylinder collar or body are marked with the design pressure of the container.

69.4.2.2 Filling and Evacuating of Containers.

69.4.2.2.1 Transfer of LP-Gas to and from a container shall be accomplished only by qualified individuals trained in proper handling and operating procedures meeting the requirements of Section 4.4 of NFPA 58 and in emergency response procedures. [**58:**7.2.2.1]

Training in emergency response procedures is required so that, in the event of an incident, personnel are prepared and able to take prompt action to minimize the extent of loss, damage, or fire. The transfer personnel filling the containers may be the only individuals who regularly view or inspect some containers.

Employee turnover at dispensing sites such as hardware stores, gas stations, and convenience stores may be high and could provide an extra challenge in ensuring all operators are properly trained. It is critical that both initial training and refresher training be provided.

69.4.2.2.2 When noncompliance with Section 5.2 and Section 5.9 of NFPA 58 is found, the container owner and user shall be notified in writing. [**58:**7.2.2.2]

When it is determined that a container does not comply with Section 5.2 or Section 5.9 of NFPA 58, the owner or operator of the container must be notified in writing. This important requirement relies on 69.4.2.2.1, which mandates that personnel who transfer LP-Gas are qualified. Paragraph 69.4.2.2.1 is especially important given the trend in some areas toward greater numbers of fixed containers owned by users who may not be aware of the requirements of Sections 5.2 and 5.9 of NFPA 58.

Paragraph 69.4.2.2.2 does not specify who must provide the notification, and there has been some confusion over who can notify the owner or operator of a container. Clearly, the qualified operator must make the determination that the container is not suitable to be filled, but the container filler is not required to notify the owner or operator. The filler can provide written notification at the container location, or it can be provided by other employees of the propane company. The requirement states that there must be written notification. The point at which an individual determines that there is a problem with the container is the essential first step for initiating the written notification. If this individual fails to either present the notice or inform the next individual involved in the process, there is no possibility for the notification required by 69.4.2.2.2 to occur.

69.4.2.2.3 Injection of compressed air, oxygen, or any oxidizing gas into containers to transfer LP-Gas liquid shall be prohibited. [**58:**7.2.2.3]

The use of compressed air, oxygen, or other oxidizing gases to transfer LP-Gas is extremely dangerous because it can create a flammable gas mixture within the container. A flammable gas mixture being fed into an appliance can ignite and the flame can travel back to the container, which can result in an explosion. Special care should be taken where propane cylinders are sold to customers using the propane as a cutting fuel in conjunction with oxygen. NFPA 51, *Standard for the Design and Installation of Oxygen–Fuel Gas Systems for Welding, Cutting, and Allied Processes*, provides the necessary safety requirements to prevent oxygen and fuel gases from mixing. The use of LP-Gas with oxygen is not covered under this *Code*.

This requirement does not prohibit injecting an inert gas into a container. Hot air balloon pilots regularly add nitrogen to their propane containers to increase the pressure and ensure that there will be sufficient flow of liquid propane to the burners, since operating at a higher altitude can lead to lowered fuel temperature or pressure. Nitrogen is not an oxidizing gas.

69.4.2.2.4 When evacuating a container owned by others, the qualified person(s) performing the transfer shall not inject any material other than LP-Gas into the container. [**58:**7.2.2.4]

69.4.2.2.5* Valve outlets on refillable cylinders of 108 lb (49 kg) water capacity [nominal 45 lb (20 kg) propane capacity] or less shall be equipped with a redundant pressure-tight seal or one of the following listed connections: CGA 790, CGA 791, or CGA 810, as described in CGA V-1, *Standard Compressed Gas Cylinder Valve Outlet and Inlet Connections*. [**58:**7.2.2.5]

The CGA 790 connection is a left-handed, threaded connection that was widely used for gas grill connections until the recent introduction of couplings that do not require tools. The CGA 791 is a newer threaded connection incorporating a square thread that is found on the majority of gas grills today. The CGA 810 is a "quick connect" fitting offered on some gas grills today. Both the CGA 791 and CGA 810 connections incorporate a redundant seal, which allows flow only when the cylinder is properly connected for use.

Paragraph 5.9.3.4 of NFPA 58 requires these portable cylinders to be equipped with the CGA 791 or CGA 810 connection, which are described in the commentary following 5.9.3.4 of NFPA 58: *LP-Gas Code Handbook*.

It is not the intent of 69.4.2.2.5 to require a cap or plug to be installed on a cylinder using a CGA 791 connection or a CGA 810 connection, because those connections will allow gas to be removed from the cylinder only when the connection is made. This stipulation was needed because many enforcers saw the plastic plugs as proof of redundant sealing and were requiring them for the CGA 791 and CGA 810 connections. However, no plug was produced for those connections, so a separate plug is not needed. If a plug is put into a CGA 791 or CGA 810 connection, it will defeat the redundant seal. However, a damaged O-ring on the plug would then allow the cylinder to leak.

A.69.4.2.2.5 Examples of an effective seal are a POL plug or cap. Listed quick-closing couplings with CGA V-1 connection numbers 790 (fork lift ACME connection), 791 (portable cylinder ACME/POL connection), and 810 (socket/plug quick connection) have secondary seals. Therefore, plugs or caps for these connections are not required or recommended. [**58:**A.7.2.2.5]

69.4.2.2.6 Where redundant pressure seals are used, they shall be in place whenever the cylinder is not connected for use. [**58:**7.2.2.6]

69.4.2.2.7 Nonrefillable (disposable) and new unused cylinders shall not be required to be equipped with valve outlet seals. [**58:**7.2.2.7]

While it may appear that 69.4.2.2.7 is in conflict with 69.4.2.2.5, note that 69.4.2.2.5 applies to cylinders of 45 lb (20 kg) propane capacity and less, while 69.4.2.2.7 applies to nonrefillable (disposable) cylinders that usually have a capacity of 1 lb (0.45 kg) or less. The largest possible disposable cylinder for flammable gases is about 1.1 lb (0.50 kg) propane capacity. A conflict between 69.4.2.2.7 and 69.4.2.2.5 does not exist where cylinders follow the DOT requirements.

69.4.2.2.8 Containers shall be filled only after determination that they comply with the design, fabrication, inspection, marking, and requalification provisions of NFPA 58. [**58:**7.2.2.8]

There are several reasons that NFPA 58 does not hold a specific individual responsible for determining whether a container complies with the requirements of the applicable pressure vessel code. One reason worth noting is that, in most cases, the individual filling a container is more qualified than the owner to determine that the container is code compliant. The provision in 69.4.2.2.8 places a great deal of responsibility on the filler, who is required by this *Code* to be properly trained on filling the container. If at any point the filler does not follow the training, it is considered a violation of this *Code*.

To fulfill this requirement, the filler must be familiar with marking and inspection requirements, which requires considerable training. There are millions of 20 lb (9.1 kg) cylinders owned by the public, and owners of portable cylinders often are not aware of the requalification that is necessary 12 years after the date of manufacture and every 5 to 12 years thereafter (see 5.2.2 and Annex C of NFPA 58).

When filling cylinders, the filler must be careful to verify that the cylinder requalification period has not been exceeded. If a cylinder is out of date, it cannot be filled, and the owner should be notified of his or her responsibility to have the cylinder requalified prior to filling. The filler should check for corrosion on easily visible surfaces and in the area within the foot ring at the bottom of portable cylinders. Many propane companies establish policies to guide cylinder fillers in this determination.

Exhibit 69.27 shows a container being filled. Note the bobtail remote shutoff in the operator's left hand, which meets the

Exhibit 69.27

Filling a storage container. (Courtesy of Richard Fredenburg and Tart Propane)

DOT requirement for a remote shutdown system. The operator can stop the truck pump and close the tank valve by pressing the button on the remote.

Newer composite cylinders also must be requalified. The methods used for metal cylinders cannot be used for composite cylinders. The filler should refer to the information provided by the cylinder manufacturer for the frequency and method of requalification. If such information is not readily available, the U.S. DOT can provide the frequency and the procedures that must be used.

Subsection 5.9.3 of NFPA 58 for overfilling prevention device (OPD) valves on most cylinders of 4 lb to 40 lb (1.8 kg to 18 kg) propane capacity requires an OPD device to be in place on every cylinder before it is filled. This requirement applies to all new cylinders manufactured after the September 30, 1998, retrofit requirement became effective on April 1, 2002, for all cylinders (see 5.9.3.2 of NFPA 58).

The filler must check cylinders for the OPD valve before filling (see 69.4.2.2.16). It should be noted that in the United States, some states have not adopted editions of NFPA 58 that require an OPD, and other states have adopted editions of NFPA 58 that require an OPD but have not adopted the OPD requirements specifically. The OPD requirements cannot be enforced for refilling cylinders in those states, but many propane marketers make the NFPA 58 OPD requirements their company policy. Because all cylinders of 4 lb to 40 lb (1.8 kg to 18 kg) propane capacity manufactured after September 1998 have an OPD, the number of non-OPD cylinders is diminishing and will continue to diminish.

Fillers of ASME tanks must check the condition of the tank before starting to fill (see 69.4.2.2.16). The filler is not, however, expected to discover difficult-to-determine conditions such as internal corrosion, worn valve seats, or other conditions that are not reasonably apparent. The filler should be alert to visible corrosion, indications of leakage, missing piping components, and the absence of a nameplate. If any of these conditions is present, the filler should report it to the owner (see 69.4.2.2.2).

Exhibit 69.28 shows a cylinder filling facility. When the cylinder (not shown) is filled to its correct filling weight, the automatic shutoff valve on the hose inlet will activate and automatically stop the flow.

69.4.2.2.9 Prior to refilling a cylinder that has a cylinder sleeve, the cylinder sleeve shall be removed to facilitate the visual inspection of the cylinder. [**58:**7.2.2.9]

This requirement was added to solve a problem created by the use of plastic sleeves by cylinder exchange companies. The sleeves contain product information and the necessary consumer warning information. It was discovered that many of the sleeves were being left on during the refilling process, making it impossible to see if the cylinder was corroding under the sleeve, as shown in Exhibit 69.29. The sleeve can allow water to collect between it and the cylinder, causing corrosion. Requiring the sleeve to be removed prior to filling is a simple way to identify any corrosion.

69.4.2.2.12 "Single trip," "nonrefillable," or "disposable" cylinders shall not be refilled with LP-Gas. [**58:**7.2.2.12]

Single-trip, nonrefillable, or disposable cylinders are not designed for extended service. Their small size increases the chance that they will be overfilled when commonly available filling equipment and procedures are used. The cylinders are designed for filling by weight and are equipped with connections that will not fit correctly with common filling equipment. However, adapters for refilling such cylinders are widely available because refillable cylinders come in the same sizes as nonrefillable cylinders. There are various resources for showing the public how to fill nonrefillable cylinders against the design of the cylinder; following such instructions should be actively discouraged.

Δ **69.4.2.2.13** Containers shall comply with the following with regard to service or design pressure requirements:

(1) The service pressure marked on the cylinder shall be not less than 80 percent of the vapor pressure of the LP-Gas for which the cylinder is designed at 130°F (54.4°C).
(2) The maximum allowable working pressure (MAWP) for ASME containers shall be in accordance with Table 5.2.4.2 of NFPA 58.

[**58:**7.2.2.13]

Table 5.2.4.2 of NFPA 58 establishes a requirement that ASME pressure vessels for propane service have a design pressure of 250 psig (1.7 MPag). If used in the interior of vehicles or as engine fuel containers (if built after April 1, 2001), the design pressure is increased to 312 psig (2.2 MPag). See 5.2.4.4 and 5.2.4.5 of NFPA 58 for more information on the maximum allowable working pressure (MAWP) of engine fuel containers.

N **69.4.2.2.14** Universal cylinders shall be permitted to be filled when in the vertical position or in the horizontal position when the positioning slot is in the correct orientation. [**58:**7.2.2.14]

The requirement in 69.4.2.2.14 was added in the 2018 edition of the *Code* to clarify that universal cylinders are designed and permitted to be filled in either orientation. The location of openings and the internal arrangement of the piping for fill valves, relief valves, and fixed liquid level devices are such that safe filling and determination of proper filling can be made either when the cylinder is vertical or when it is horizontal and the positioning slot is at the bottom. Orientations other than vertical and horizontal (slot down) are not allowed.

Note that it is not a requirement that the positioning slot be in the correct orientation and engaged during filling. Depending on the device and the requirements of that device, including relevant safety standards, the cylinder may be filled whether or not it is installed on the device it fuels. Also note that, if it is installed on the device, it must be the required distance from a source of ignition (e.g., hot exhaust pipes, active electrical equipment).

69.4.2.2.15 Transfer of refrigerated product shall be made only into systems that are designed to accept refrigerated product. [**58:**7.2.2.15]

69.4.2.2.16 A container shall not be filled if the container assembly does not meet the requirements for continued service. [**58:**7.2.2.16]

The term *container assembly* is defined in NFPA 58 as "an assembly consisting of the container and fittings for all container openings such as shutoff valves, excess-flow valves, liquid level gauging devices, pressure relief devices, and protective housings."

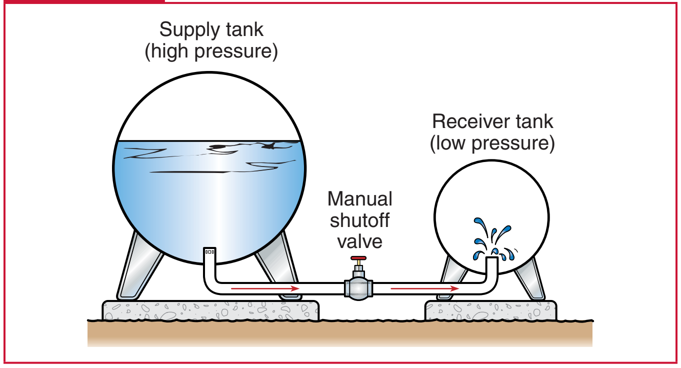
There are several reported cases where a fill valve adapter has been left attached to a fill valve because the fill valve failed to seat properly after filling. Such adapters are temporary and are intended to prevent release of the product until the fill valve can be replaced or repaired. A container assembly with an adapter does not meet the requirements for continued service because the internal back-flow check devices of the fill valve are disabled. The external back-flow check device in the adapter provides temporary safety, but it should not be relied on for continued protection. This paragraph requires that the container not be filled until the fill valve correction is made.

69.4.2.2.17 Transfer hoses larger than ½ in. (12 mm) internal diameter shall not be used for making connections to individual cylinders being filled indoors. [**58:**7.2.2.17]

69.4.2.3 Arrangement and Operation of Transfer Systems.

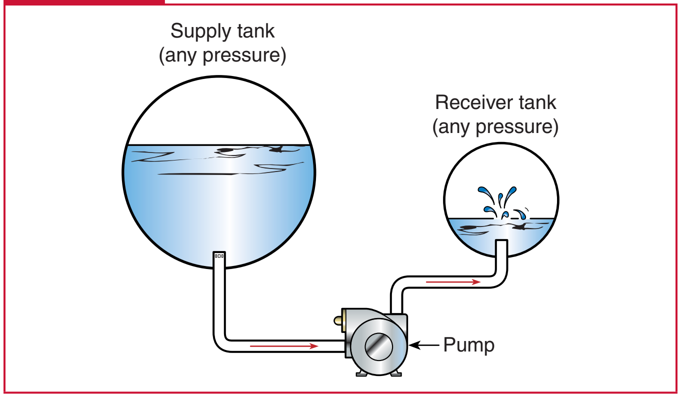
LP-Gas can be transferred by pressure differential using gravity (as shown in Exhibit 69.30), pumps (as shown in Exhibit 69.31), or compressors to provide the force necessary for transfer. Transfer by gravity is not common, but it is sometimes used to transfer LP-Gas into forklift cylinders at the customer's location.

Exhibit 69.30



Liquid transfer by pressure differential or gravity. (Courtesy of National Propane Gas Association)

Exhibit 69.31



Liquid transfer by pump. (Courtesy of National Propane Gas Association)

The pressure differential method of transferring LP-Gas works when the pressure in the container to be filled is lower than that in the supply container. Liquid will flow until the pressures in the containers are equal. To fill a container, it will probably be necessary to reduce the pressure inside it by opening the valve to the atmosphere prior to transferring product. This procedure is often viewed as unreliable and can cause atmospheric contamination of the receiving container.

Compressors are used to unload railroad tank cars and some transport trucks. A compressor takes vapor from the container that will be receiving the product and transfers the vapor to the container from which the liquid is being unloaded. This vapor transfer creates a higher pressure in the container being unloaded than in the receiving container, causing the liquid to flow into the receiving container. When all the liquid has been transferred, the residual vapors in the unloading railroad tank car or transport vehicle can be recovered and placed into the receiving vessel by reversing the flow through the compressor piping.

It is advantageous to have vapor enter at the bottom of the receiving container so that it will pass through the cooler liquid, making it easier to condense. If the vapor enters at the top of the receiving container, the heat of compression will warm the vapor and increase pressure in the receiving container, slowing the transfer operation. Care must be taken when opening valves, because doing so rapidly can result in the closing (also known as "slugging") of any excess-flow check valves that have been installed.

Pumping is the usual liquid transfer method for operations such as delivery to a fixed container, transfer from bulk storage into bobtail delivery trucks, and unloading of transport vehicles. With both pump and compressor transfer methods, it is important to have proper correlation between the design size of both the piping and the excess-flow check valve so that the valve does not close prematurely. Proper excess-flow valve sizing is also important from a safety standpoint because the size of the line must permit sufficient flow to allow the valve to operate if there is a break or rupture in the line.

69.4.2.3.1 Public access to areas where LP-Gas is stored and transferred shall be prohibited, except where necessary for the conduct of normal business activities. [**58:**7.2.3.1]

Areas where LP-Gas is stored or handled present hazards that are not apparent to those who are untrained in the properties of LP-Gas and the equipment used at the site. Therefore, the public is normally excluded from these areas. Many bulk plants invite their customers to bring cylinders to a drop-off point or a refilling point; these areas are normally open to the public, and this practice is permitted.

69.4.2.3.2 Sources of ignition shall be turned off during transfer operations, while connections or disconnections are made, or while LP-Gas is being vented to the atmosphere. [**58:**7.2.3.2]

Δ **69.4.2.3.2.1** Internal combustion engines within 15 ft (4.6 m) of a point of transfer shall be shut down while such transfer operations are in progress, with the exception of the following:

(1) Engines of LP-Gas cargo tank vehicles, constructed and operated in compliance with Chapter 9 of NFPA 58, while such engines are driving transfer pumps or compressors on these vehicles to load containers in accordance with 6.6.2.2 of NFPA 58
(2) Portable engines with shielded ignition systems and exhaust system spark-arresters located at least 10 ft (3 m) from a point of transfer while such engines are driving transfer pumps or compressors
(3) Engines for industrial (and forklift) trucks powered by LP-Gas used in buildings as provided in Section 11.13 of NFPA 58

[**58:**7.2.3.2(A)]

Item 2 was added in the 2018 edition of the *Code* to coincide with the separation requirements in 69.4.2.3.3 and the shielded ignition and exhaust system spark arrester requirements in 6.20.3.3 of NFPA 58. This allows an exception for safety devices and practices that mitigate possible source of ignition hazards.

Vehicle engines must be allowed to operate when the engine drives a pump or a compressor used to transfer LP-Gas and when the truck is entering or leaving filling stations. An operating gasoline-fueled internal combustion engine normally does not create sparks or have surfaces hot enough to ignite propane and will stall in a propane-rich environment due to lack of air for proper combustion. Similarly, a diesel engine may not ignite released LP-Gas, but damage can occur if gas is sucked into the air intake and causes the engine to accelerate uncontrollably. This is one reason for the operator to be in attendance and carefully monitoring the transfer process.

69.4.2.3.2.2 Smoking, open flame, portable electrical tools, and extension lights capable of igniting LP-Gas shall not be permitted within 25 ft (7.6 m) of a point of transfer while filling operations are in progress. [**58:**7.2.3.2(B)]

The spacing of sources of ignition and LP-Gas transfer operations is consistent with DOT regulations for separation distances for smoking. Note that this requirement applies only to portable sources of ignition and not to fixed electrical sources of ignition, which are covered in Section 6.25 of NFPA 58.

69.4.2.3.2.3 Metal cutting, grinding, oxygen–fuel gas cutting, brazing, soldering, or welding shall not be permitted within 35 ft (10.7 m) of a point of transfer while filling operations are in progress. [**58:**7.2.3.2(C)]

The 35 ft (10.7 m) separation distance between points of transfer and sources of ignition correlates with the requirements of NFPA 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work*. The 35 ft (10.7 m) distance is necessary because slag or sparks created during hot work have been shown to travel some distance horizontally and, at this time, there has been no indication to the committee that such a distance is insufficient in length.

69.4.2.3.2.4 Materials that have been heated above the ignition temperature of LP-Gas shall be cooled before LP-Gas transfer is started. [**58:**7.2.3.2(D)]

69.4.2.3.2.5 Sources of ignition shall be turned off during the filling of any LP-Gas container on the vehicle. [**58:**7.2.3.2(E)]

Ignition sources on vehicles being fueled and those waiting to be fueled must be controlled. Special care should be taken when containers on recreational vehicles (RVs) are filled, because several fires have been reported where containers were being filled without the extinguishment of pilot flames or other sources of ignition during refueling. Some RVs have appliances such as furnaces and ranges with sources of ignition that operate automatically, and it may be appropriate to turn all circuit breakers to the "off" position to prevent them from operating.

69.4.2.3.3 Cargo tank vehicles unloading into storage containers shall be at least 10 ft (3.0 m) from the container and so positioned that the shutoff valves on both the truck and the container are readily accessible. [**58:**7.2.3.3]

69.4.2.3.4 The cargo tank vehicle shall not transfer LP-Gas into dispensing station system while parked on a public way. [**58:**7.2.3.4]

Operations involving the unloading of cargo tank vehicles are required to have a minimum separation of 10 ft (3 m) from the cargo tank vehicle to the container receiving the product. It is important to have the cargo tank vehicle located such that the operating controls on both the truck and the tank being filled are accessible in an emergency.

The prohibition of street parking is intended to avoid risks associated with accidental vehicle collisions during a transfer operation. Traffic in the area is expected while vehicles arrive with engine fuel containers to be filled or empty cylinders to be turned in. This prohibition does not apply to cargo tank vehicles transferring into containers at other locations.

The station shown in Exhibit 69.32 shows the vapor and liquid connections of a truck unloading station.

69.4.2.3.5 Transfers to containers serving agricultural or industrial equipment requiring refueling in the field shall comply with 69.4.2.3.5.1 and 69.4.2.3.5.2. [**58:**7.2.3.5]

69.4.2.3.5.1* Where the intake of air-moving equipment is less than 50 ft (15 m) from a point of transfer, it shall be shut down while containers are being refilled. [**58:**7.2.3.5(A)]

A.69.4.2.3.5.1 Air-moving equipment includes large blowers on crop dryers, space heaters, and some central heating equipment. Equipment employing open flames includes flame cultivators, weed burners, and tar kettles. [**58:**A.7.2.3.5(A)]

Exhibit 69.32

Truck unloading station. (Courtesy of Richard Fredenburg, North Carolina Department of Agriculture and Consumer Services)

69.4.2.3.5.2 Equipment employing open flames or equipment with integral containers shall be shut down while refueling. [**58:**7.2.3.5(B)]

Agricultural and industrial installations present hazards different from those presented by residential fuel applications because they generally use more LP-Gas. The safety precautions required in 69.4.2.3.5 recognize common sources of ignition that can contribute to accidents during transfer. Open flames may be used in weed burners, flame cultivation, vaporizing burners, industrial heaters, and various other applications.

Δ **69.4.2.3.6** During the time railroad tank cars are on sidings for loading or unloading, the following shall apply:

(1) A caution sign, with wording such as "STOP. TANK CAR CONNECTED," shall be placed at the active end(s) of the siding while the car is connected, as required by DOT regulations.

Exhibit 69.33 shows a "Stop, Car Connected" warning sign on the track leading to a transfer station. Note that a derailer has been placed on the track with a sign. The derailer will cause a car passing over it to derail, and the train's engineer will be aware of the derailing and stop the train.

(2) Wheel chocks shall be placed to prevent movement of the car in either direction.

[**58:**7.2.3.6]

This requirement reiterates an important DOT regulation. Accidents have occurred in cases where railroad tank cars have been moved with the unloading hose or connections still in place. In one reported situation, a tank car was partially unloaded and the hoses disconnected when the workers incorrectly assumed that

Exhibit 69.33

"Stop" and "Derail" signs on a track. (Courtesy of Eastern Propane Corp.)

the container was empty and moved the tank car. To prevent such incidents from occurring, the wheel stops (also known as chock blocks) and the warning sign should always be in place until the tank car has been completely unloaded and the railroad personnel have been advised to move the tank car.

Exhibits 69.34 and 69.35 show tank car loading and unloading installations. Note the small plastic tubing strapped to the hoses in Exhibit 69.34. This tubing carries pressurized gas, which opens the emergency shutoff valves used to connect to the tank car. In case of fire, the tubing will fail and the emergency shutoff valves will close.

Δ **69.4.2.3.7** Where a hose or swivel-type piping is used for loading or unloading railroad tank cars, it shall be protected as follows:

(1) An emergency shutoff valve shall be installed at the railroad tank car end of the hose or swivel-type piping where flow into or out of the railroad tank car is possible.
(2) An emergency shutoff valve or a backflow check valve shall be installed on the railroad tank car end of the hose or swivel piping where flow is only into the railroad tank car.

[**58:**7.2.3.7]

Exhibit 69.36 shows a railroad tank car–unloading tower. Note the platform access to tank car domes. The emergency shutoff valve or check valve is located at the end of the swivel piping shown above the platform.

69.4.2.3.8 Where cargo tank vehicles are filled directly from railroad tank cars on a private track with nonstationary storage tanks involved, the following requirements shall be met:

(1) Transfer protection shall be provided in accordance with 69.3.10.
(2) Ignition source control shall be in accordance with Section 6.25 of NFPA 58.
(3) Control of ignition sources during transfer shall be provided in accordance with 69.4.2.3.2.
(4) Fire extinguishers shall be provided in accordance with 9.4.7 of NFPA 58.
(5) Transfer personnel shall meet the provisions of 69.4.2.1.
(6) Cargo tank vehicles shall meet the requirements of 69.4.2.3.
(7) The points of transfer shall be located in accordance with 69.3.7.2.1 with respect to exposures.
(8) Provision for anchorage and breakaway shall be provided on the cargo tank vehicle side for transfer from a railroad tank car directly into a cargo tank vehicle.
(9) The provisions of Chapter 15 of NFPA 58 shall apply to all LP-Gas transfers performed in accordance with 69.4.2.3.8.

[**58:**7.2.3.8]

Exhibit 69.34

Exhibit 69.35

Close-up of tank car dome. (Courtesy of Eastern Propane Corp.)

Exhibit 69.36

Railcar unloading tower. (Courtesy of Eastern Propane Gas Inc.)

The requirements 69.4.2.3.8 are needed to permit the unloading of railcars where they cannot be unloaded directly into storage tanks. For example, this type of transfer is allowed when sections of rail mainlines are abandoned, when rail service to an area is discontinued, or when railcars cannot reach their normal unloading location due to emergency situations. Requiring that safety features equivalent to those of fixed transfer facilities be installed is intended to prevent the tank truck from moving and breaking a hose or piping system.

Δ **69.4.2.3.9** Where cargo tank vehicles are filled from other cargo tank vehicles or cargo tanks, the following requirements shall apply:

(1) Transfer between cargo tanks or cargo tank vehicles where one is used as a bulk plant shall be temporary installations that comply with 4.3.2, 6.21.1, 6.21.2, 6.21.4 through 6.21.6 of NFPA 58, and 69.4.2.3.1.

Both cargo tank vehicles and cargo tanks are used as alternatives to fixed storage, normally found at bulk and industrial plants. Product is transferred from one cargo tank vehicle or cargo tank to another cargo tank vehicle. Typically, transfer of product takes place from a cargo tank transport vehicle [9000 gal to 11,000 gal (34 m^3 to 42 m^3) water capacity] into a bobtail [typically 2500 gal to 5000 gal (9.5 m^3 to 19 m^3) water capacity].

The requirements in 69.4.2.3.9 are similar to those in 69.4.2.3.8 for transfer from railcars directly to cargo tank vehicles.

(2) Arrangements and operations of the transfer system shall be in accordance with the following:
   (a) The point of transfer shall be in accordance with Table 69.3.7.2.1.
   (b) Sources of ignition within the transfer area shall be controlled during the transfer operation as specified in 69.4.2.3.2.
   (c) Fire extinguishers shall be provided in accordance with 9.4.7 of NFPA 58.

(3) Cargo tanks shall comply with the requirements of 69.4.2.2.8.

(4) Provisions designed either to prevent a pull-away during a transfer operation or to stop the flow of products from both cargo tank vehicles or cargo tanks in the event of a pull-away shall be incorporated.

The requirement in 69.4.2.3.9(4) does not specify a particular device, but it does require the use of a system that will achieve the desired performance of stopping product flow in case a pull-away occurs.

(5) Off-truck remote shutoff devices that meet 49 CFR 173.315(n) requirements and are installed on the cargo tank vehicle unloading the product shall satisfy the requirements of 69.4.2.3.9(4).

The requirement in item (5) specifically permits the use of an active shutdown device such as a radio-controlled device with an activator carried by the truck driver. The radio-controlled device, when activated by the driver, will stop the pump, shut off the engine, and close the primary internal valve on the cargo tank vehicle that is unloading product. Such devices are required by the DOT for all cargo tank vehicles of 3500 gal (13 m^3) or less. The device must be capable of performing at a distance of 150 ft (46 m) from the cargo tank vehicle. It must also be able to activate the shutdown system when tested at 300 ft (91 m) under optimum conditions.

Cargo tank vehicles of more than 3500 gal (13 m^3) in the United States are required by the DOT to have a passive shutoff device that will stop the flow of propane from the cargo tank vehicle upon hose separation. Products used to comply with this requirement include a special hose with an incorporated shutoff feature that activates if the hose coupling separates and a truck-mounted sensor that activates if pump discharge pressure increases. If a separation occurs with this system, the pump discharge pressure will increase due to the stoppage of flow.

Exhibit 69.37 shows a truck-mounted sensor on a larger cargo tank vehicle (transport), located at the discharge of the pump. It continually monitors the offloading process for changes that signify broken or damaged hoses, fittings, or piping. A leak is detected and stopped by the closure of the tank internal valves(s). The sensor also closes the internal valve if there is a loss of power or if the trailer parking brake is released (also known as a "fail close" or "fail safe" condition on the valve). Also shown is the control box, the vapor internal valve, the manual operators that open and close the internal valves, and the air operator. Note that vapor and liquid control handles and valve caps are color coded to indicate vapor and liquid piping.

(6) Cargo tank vehicle LP-Gas transfers that are for the sole purpose of testing, maintaining, or repairing the cargo tank vehicle shall be exempt from the requirements of 69.4.2.3.9(1).

[**58:**7.2.3.9]

The requirement in item (6) is intended to exempt vehicles that are undergoing testing, repair, or maintenance operations that routinely occur on cargo tank motor vehicles.

69.4.2.4 Hose Inspection.

69.4.2.4.1 Hose assemblies shall be observed for leakage or for damage that could impair their integrity before each use. [**58:**7.2.4.1]

69.4.2.4.2 The hose assemblies specified in 69.4.2.4.1 shall be inspected at least annually. [**58:**7.2.4.2]

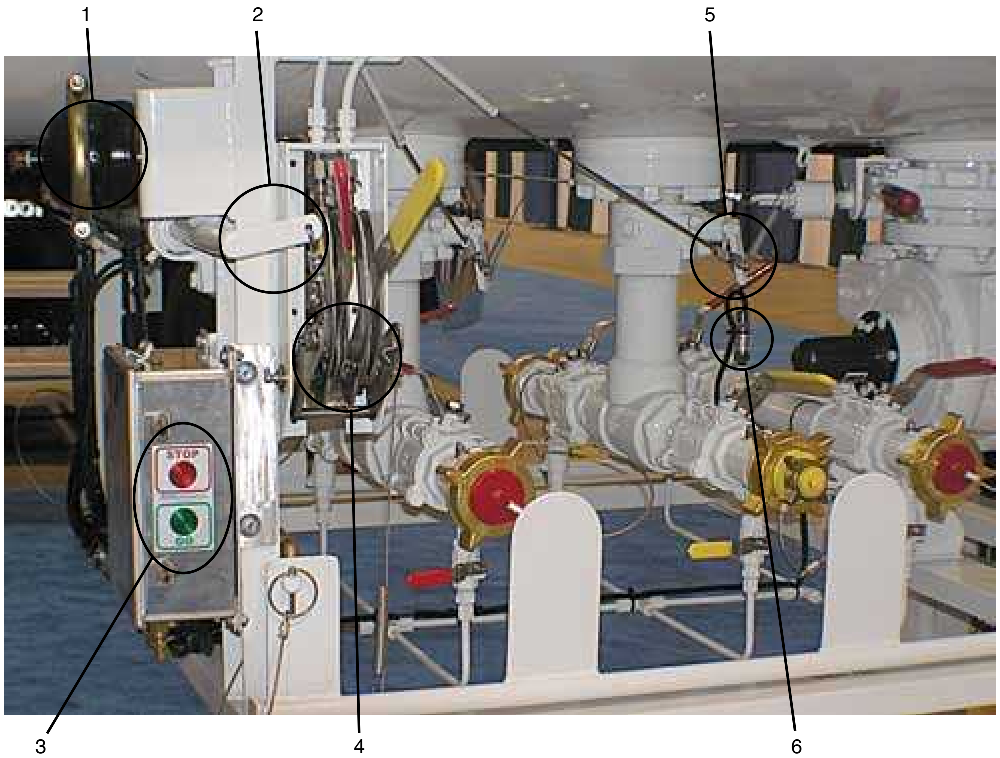
Δ **69.4.2.4.3** Inspection of pressurized hose assemblies shall include inspection for the following:

(1) Damage to outer cover that exposes reinforcement
(2) Kinked or flattened hose
(3) Soft spots or bulges in hose
(4) Couplings that have slipped on the hose, are damaged, have missing parts, or have loose bolts
(5) Leakage other than permeability leakage

[**58:**7.2.4.3]

69.4.2.4.4 Hose assemblies shall be replaced, repaired, or continued in service based on the results of the inspection. [**58:**7.2.4.4]

Exhibit 69.37



1. Air-operated shutdown actuator
2. Linkage/rod between spring chamber and valve operator
3. Passive shutdown controller
4. Manual operator to open/close vapor and liquid internal valves
5. Internal valve handle and cable linkage to valve operator with fusible link
6. Pressure sensor installed in pump discharge line, which sends signal to passive controller indicating that pump pressure is being maintained

Passive transport shutdown system. (Courtesy of Mississippi Tank Company)

69.4.2.4.5 Leaking or damaged hose shall be immediately repaired or removed from service. [**58:**7.2.4.5]

Hose assemblies are the weak link in liquid transfer operations. Hose is inherently weaker than pipe and has a much shorter lifespan, which can be further reduced by the effects of weather and physical damage (e.g., being dragged over earth, gravel, or barbed wire fences) and from other abrasive actions (e.g., pump-induced vibrations when in contact with gravel, concrete, or other rough surfaces). Bending hose beyond the maximum bending radius (kinking) can also cause damage. Hose ends can become loose and start leaking, or they can separate from couplers. Hose couplers can wear and not fit tightly, which may result in loosening caused by vibration.

Periodic inspection of hose assemblies is a requirement for safe transfer operations. However, disagreement remains over what should be included in the procedures. Some propane companies have established daily and periodic inspection procedures.

Pressure testing of hose assemblies is a subject that has been discussed often over the years by AHJs, cargo tank vehicle operators, and propane companies. Recent requirements by the DOT for cargo tank vehicle hose have mandated pressure testing of new and refitted hose assemblies in truck unloading services. Exhibit 69.38 shows a hose swivel end fitting, which can aid in kinking prevention.

69.4.3 Venting LP-Gas to the Atmosphere.

An increasing concern about venting LP-Gas to the atmosphere is the adverse environmental impact of the released propane. Unburned hydrocarbons in the air can combine with other chemicals to create smog or increased levels of ozone. The U.S. Environmental Protection Agency (EPA) has become more interested in recent years in any releases of unburned hydrocarbons (also known as “fugitive gas emissions”), which could result in more restrictions on venting LP-Gases.

Exhibit 69.38

Hose swivel end fitting. (Courtesy of Full Circle)

Δ **69.4.3.1 General.** LP-Gas in either liquid or vapor form shall not be vented to the atmosphere unless it is vented under the following conditions:

(1) Venting of LP-Gas shall be permitted where the maximum flow from fixed liquid level, rotary, or slip tube gauges does not exceed that from a No. 54 drill orifice.

It is necessary to vent both vapor and a small amount of liquid from fixed maximum liquid level, rotary, and slip tube gauges. Venting should be done with consideration for potential ignition hazards within the surroundings. To prevent LP-Gas from entering a building, it should not be discharged close to a window. A No. 54 drill size limits the vented LP-Gas to an amount that should dissipate rapidly.

(2) Venting of LP-Gas between shutoff valves before disconnecting the liquid transfer line from the container shall be permitted.
(3) Venting of LP-Gas, where necessary, shall be permitted to be performed by the use of bleeder valves.

If it is necessary to bleed off liquid from a pipe or a hose, the bleeding off must be done slowly and carefully. If bleeding off is not done correctly, a potential hazard to operating personnel created by the rapid discharge could result. The vapor ignition hazard area is also increased because of the conversion of liquid to vapor. Also, if the venting is too rapid, the cooled liquid remaining in the pipe or hose may slow or stop vaporizing and inhibit further release of liquid built up in the system. When the line is opened or the hose disconnected, a large release of the remaining product could then occur due to the leftover liquid.

(4) Venting of LP-Gas shall be permitted for the purposes described in 69.4.3.1(1) and 69.4.3.1(2) within structures designed for container filling in accordance with Chapter 10 of NFPA 58.

Buildings constructed to comply with Chapter 10 of NFPA 58 are built specifically to house LP-Gas transfer operations and have no open flames or electrical sources of ignition.

(5) Venting of LP-Gas listed liquid transfer pumps using such vapor as a source of energy shall be permitted where the rate of discharge does not exceed the discharge from a No. 31 drill size orifice.

This exception to the requirement on minimizing venting to the atmosphere has been in the *Code* for many years. It allows a piston pump powered by pressurized propane vapor to be used; however, piston pumps have not been available for many years.

(6) Venting of LP-Gas for purging in accordance with 7.3.2 of NFPA 58 shall be permitted.
(7) Venting of LP-Gas shall be permitted for emergencies.

The need for emergency venting is most common in cargo vehicle and railroad tank car accidents in which a tank is damaged and failure is considered possible. These situations often require the services of experts.

Teams of experts that specialize in response to railcar and truck accidents have been organized on a state or regional basis and are available to assist emergency responders in the event of a transportation emergency. One such group for chemical cargoes is the Chemical Transportation Emergency Center (CHEMTREC), which is operated by the American Chemistry Council (ACC). CHEMTREC provides a toll-free number (1-800-424-9300) for hazardous materials spills and incident emergencies. Frequently, local propane distributors assist in accidents involving propane cargoes through state or regional associations.

(8) Venting of LP-Gas vapor utilized as the pressure source in remote shutdown systems for internal valves and emergency shutoff valves shall be permitted.

[**58:**7.3.1]

Remote shutdown stations are often located at the gate or along the fence at a bulk plant. Consideration should be given to not placing ignition sources near these remote stations that utilize and could vent LP-Gas vapor.

69.5 Storage of Cylinders Awaiting Use, Resale, or Exchange

69.5.1 Scope.

Section 69.5 applies only to cylinders, which is defined as follows: “A portable container with a marked water capacity of 1000 lb (454 kg) or less that is designed to transport and store LP-Gas.”

The DOT specifications in 49 CFR 171.8 limit cylinders to 1000 lb (454 kg) water capacity, which is approximately 420 lb

(191 kg) propane capacity. DOT cylinders are portable storage containers that can be used in transportation, as well as installed and used in a stationary installation. The definition of *cylinder* does not include the following:

1. **ASME containers.** These are designed to be installed at one location and are not permitted to be transported when they contain more than 5 percent propane (with one exception covered in 9.6.2.2 of NFPA 58). Chapter 8 of NFPA 58 does not apply to ASME containers not connected for use, as they would be at a propane distribution facility.
2. **Cylinders made to specifications of other countries.** Under international treaties, the DOT permits these cylinders to be used, but not refilled, in the United States.

Δ **69.5.1.1** The provisions of Section 69.5 apply to the storage of cylinders of 1000 lb (454 kg) water capacity or less, whether filled, partially filled, or empty, as follows:

(1) At consumer sites or dispensing systems, where not connected for use
(2) In storage for resale or exchange by dealer or reseller

[**58:**8.1.1]

69.5.1.2 Section 69.5 does not apply to new or unused cylinders. [**58:**8.1.2]

69.5.1.3 Section 69.5 does not apply to cylinders stored at bulk plants. [**58:**8.1.3]

The current provisions of NFPA 58 do not differentiate between storage at a resale location or a user location, but they do stipulate what is to be done if portable cylinders are stored in conventional buildings (whether frequented by the public or not), outside of buildings, and in special buildings or rooms meeting the requirements of Chapter 10 of NFPA 58. The provisions of Chapter 8 of NFPA 58 apply only to the storage of cylinders on the premises of consumers, at dispensing stations, and at locations for resale or exchange by the cylinder dealer or reseller.

69.5.2 General Provisions.

69.5.2.1 General Location of Cylinders.

69.5.2.1.1 Cylinders in storage shall be located to minimize exposure to excessive temperature rises, physical damage, or tampering. [**58:**8.2.1.1]

Because of the smaller size of the cylinders covered in Chapter 8 of NFPA 58, the temperature of their contents tends to fluctuate more directly with ambient air temperatures or solar radiation than does the temperature of larger containers. These cylinders should not relieve LP-Gas through their pressure relief devices until the temperature of their contents exceeds 130°F (54°C), at which point the cylinder may become liquid full. These high temperatures could be reached in some extremely hot climates or in poorly located, poorly constructed, or unventilated storage locations.

In addition to temperature control, physical damage protection may be needed in storage locations. Certain facilities have considerable vehicular traffic — for example, forklift trucks — and require these precautions. Finally, tampering is a valid consideration. Although small portable cylinders, such as those used with grills, will not flow gas even if the valve is opened by hand, it is still important to provide protection from tampering, which could affect the safety devices.

69.5.2.1.2 Cylinders in storage having individual water capacity greater than 2.7 lb (1.1 kg) [nominal 1 lb (0.45 kg) LP-Gas capacity] shall be positioned so that the pressure relief valve is in direct communication with the vapor space of the cylinder. [**58:**8.2.1.2]

The requirement that cylinders, other than very small cylinders, be stored so that the pressure relief valve is in the vapor space of the cylinder is an important safety concept that is repeated in several locations in the *Code*. The requirement is important because the capacity of pressure relief valves is based on gas flow, not liquid flow. If the pressure in a cylinder were sufficiently high to cause the pressure relief valve to operate, and the pressure relief valve were in communication with the liquid space of the cylinder, the following might occur:

- It might take more time to reduce the pressure in the container, since liquid is denser than gas and would therefore require a larger flow of liquid before resetting the valve.
- Liquid discharged from the cylinder would vaporize almost instantly, resulting in approximately 270 times as much vapor by volume as a gaseous release. If fire were the cause of the pressure relief valve operation, a liquid release would provide more fuel to the fire than a gaseous release.
- Liquid discharge would reduce the volume of liquid inside the container that would have contributed to the autorefrigeration reaction. Autorefrigeration occurs when the vapor pressure in the container decreases and causes the liquid to change phases. The liquid utilizes heat from the container as it changes phases, and the decrease in temperature of the container reduces the overall pressure in the container.

Cylinders less than 2.7 lb (1.1 kg) water capacity [about 1 lb (0.45 kg) of propane] are excluded from this requirement. Examples of such cylinders are those used for handheld soldering torches, portable stoves, camping equipment, and refillable portable appliances such as cigarette lighters (see Exhibit 69.39). These small cylinders are normally stored in cardboard shipping containers, and the proper storage orientation should be indicated on the shipping container.

69.5.2.1.3 Cylinders stored in buildings in accordance with 69.5.3 shall not be located near exits, near stairways, or in areas normally used, or intended to be used, for the safe egress of occupants. [**58:**8.2.1.3]

69.5.2.1.4 If empty cylinders that have been in LP-Gas service are stored indoors, they shall be considered as full cylinders for the

Exhibit 69.39

Cylinder used for portable appliance (camp stove).

purposes of determining the maximum quantities of LP-Gas permitted by 69.5.3.1, 69.5.3.2.1, and 69.5.3.3.1. [**58:**8.2.1.4]

Once filled, an LP-Gas cylinder seldom becomes completely empty. At the very least, the cylinder will usually be full of vapor and may contain some liquid or a residue that could contain the flammable odorant. If empty cylinders were not counted as full cylinders, it would be impossible for an enforcing authority to determine whether the storage limits were being exceeded without weighing all the cylinders.

69.5.2.1.5 Cylinders shall not be stored on roofs. [**58:**8.2.1.5]

Rooftops are largely out of sight and out of mind and are often places where combustible materials accumulate. Although the location of cylinders connected for use is permitted on rooftops, the storage of spare cylinders is not. Even an "empty" cylinder can complicate fire control activities. Rooftops are generally difficult locations to control, and adding a possible hazard to the area increases the difficulty for responding fire fighters should an emergency occur. In addition, the temperatures on roofs very often exceed ambient temperatures by several degrees.

69.5.2.2 Protection of Valves on Cylinders in Storage.

69.5.2.2.1 Cylinder valves shall be protected as required by 69.2.1.2.1 and 69.4.2.2.5. [**58:**8.2.2.1]

69.5.2.2.2 Screw-on-type caps or collars shall be in place on all cylinders stored, regardless of whether they are full, partially full, or empty, and cylinder outlet valves shall be closed. [**58:**8.2.2.2]

Protection for all cylinder valves is required by the DOT requirements for containers of hazardous materials. Smaller portable cylinders typically use a metal protective collar around the cylinder valve, while larger cylinders typically found in stationary service may have a screw-on cap or a dome cover.

69.5.2.2.3 Valve outlets on cylinders less than 108 lb (49 kg) water capacity [nominal 45 lb (20 kg) propane capacity] shall be plugged, capped, or sealed in accordance with 69.4.2.2.5. [**58:**8.2.2.3]

See the commentary following 69.4.2.2.5 for more details on cylinder plugs and caps, including important information about when plugs should not be used.

69.5.3 Storage Within Buildings.

Paragraph 69.5.3.3 covers cylinders in buildings not frequented by the public (e.g., industrial occupancies), such as repair shops that use LP-Gas containers for process or equipment operations and for forklift trucks. In buildings not frequented by the public, more LP-Gas can be stored because the general public will not be exposed to the hazards or be in the area of storage.

If highway vehicles carrying containers installed as service equipment are parked inside buildings or private garages, those containers are not considered part of the 735 lb (334 kg) total maximum water capacity allowed in the building. Paragraph 69.5.3.3.4 does not limit the number of these vehicles inside a private garage.

Special buildings or rooms must meet the requirements of Chapter 10 of NFPA 58, as discussed in 69.5.3.4. These special buildings or rooms cannot adjoin the line of property occupied by areas used for public gatherings such as schools, churches, hospitals, and athletic fields.

Residential buildings include one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and apartments, and include basements or any storage areas in a common basement of a multiple-family building and attached or detached garages, as noted in 69.5.3.5.

69.5.3.1 General. Storage of cylinders in buildings shall be in accordance with Table 69.5.3.1(a) or Table 69.5.3.1(b) or the requirements of 69.5.3. [**58:**8.3.1]

69.5.3.2 Storage Within Buildings Frequented by the Public.

69.5.3.2.1 The quantity of LP-Gas in cylinders stored or displayed shall not exceed 200 lb (91 kg) in one location, with additional storage separated by 50 ft (15 m). The maximum quantity to be stored in one building shall not exceed 1000 lb (454 kg). [**58:**8.3.2.1]

69.5.3.2.1.1 Where the total quantity stored in a building exceeds 200 lb (91 kg), an approved sprinkler system that, at a minimum, meets the requirement of Section 13.3 and NFPA 13 for Ordinary Hazard (Group 2) shall be installed. [**58:**8.3.2.1(A)]

69.5.3.2.1.2 The sprinkler density shall be 0.300 gpm (12.2 L/min) over the most remote 2000 ft^2 (18.6 m^2) area, and the hose stream allowance shall be 250 gpm (946 L/min). [**58:**8.3.2.1(B)]

Two requirements are provided for storing between 200 lb (91 kg) and 1000 lb (454 kg) in 1 lb (0.45 kg) or smaller cylinders:

1. The specified sprinkler system must be installed.
2. Additional storage of 200 lb (91 kg) must be separated by 50 ft (15 m).

***TABLE 69.5.3.1(a)** Maximum Allowable Storage Quantities of LP-Gas in Other Than Industrial, Storage, and Mercantile Occupancies*

Occupancy	Assembly	Educational	Day Care	Health Care	Ambulatory Health Care	Detention and Correctional	One- and Two-Family Dwellings	Lodging or Rooming House	Hotel and Dormitory	Apartment	Residential Board and Care	Business
Maximum Allowable Quantity (MAQ):												
Storage (state units: lb, gal, etc.)	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb
MAQ increases for:							Maximum 1 lb cylinders			1 lb cylinder		
Total (including cabinets)	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb
Total for suppression	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb
Total for both cabinets and suppression	0	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb	2 lb
Attended catered food service per NFPA 58 in 10 oz maximum cylinders	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb
			15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb
Additional 10 oz cylinders w/ 2-hr fire wall	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb	15 lb
Other												
Total (including threshold) for other	20 lb	20 lb	0	5 lb								
	Flame effects per NFPA 160. Additional 20 lb units with 20 ft (6 m) separation.	In labs, not in classrooms. Additional 20 lb units with 20 ft (6 m) separation.		In labs only. Additional 5 lb units with 20 ft separation						Amounts per dwelling		

[**58:** Table 8.3.1(a)]
For SI units, 1 lb = 0.45 kg, 1 oz = 0.028 kg.

The term *most remote*, as used in 69.5.3.2.1.2, refers to the concept that the flow of water from the sprinkler heads is not uniform across the entire sprinkler system. Sprinklers that have longer piping runs, especially of smaller diameter pipe, are more remote from the water supply and provide a lower flow of water than those closer to the supply and/or with larger diameter pipe. This is due to dynamic head losses as water is slowed by the friction of flow through a pipe. The system is designed so that the minimum required discharge density is provided at the most demanding area. Those areas closer to the water supply will then receive water flow that exceeds the minimum requirements. This concept is further explored in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

69.5.3.2.2 The cylinders shall not exceed a water capacity of 2.7 lb (1.1 kg) [nominal 1 lb (0.45 kg) LP-Gas]. [**58:**8.3.2.2]

69.5.3.2.3 In restaurants and at food service locations, storage of 10 oz (283 g) butane nonrefillable containers shall be limited to not more than 24 containers and 24 additional 10 oz (283 g) butane nonrefillable containers stored in another location within the building where constructed with at least 2-hour fire wall protection. [**58:**8.3.2.3]

Paragraph 69.5.3.2.3 permits the storage of up to forty-eight 10-oz (283 g) butane nonrefillable cylinders in restaurants and food service locations. The requirement covers fuel for the portable butane-fired cooking appliances allowed in 69.3.12.8.4,

TABLE 69.5.3.1(b) Maximum Allowable Storage Quantities of LP-Gas in Mercantile, Industrial, and Storage Occupancies

Occupancy	Mercantile	Industrial	Storage
Maximum Allowable Quantity (MAQ):			
Storage (state units: lb, gal, etc.)	200 lb (1 lb maximum/ cylinder)	300 lb	300 lb
MAQ increases for:			
Total (including threshold) for cabinets	200 lb	300 lb	300 lb
Total (including threshold) for suppression	200 lb	300 lb	300 lb
Total (including threshold) for both cabinets and suppression	200 lb	300 lb	300 lb
Total (including threshold) for other (describe)	1000 lb Separation of groups of 200 lb by 50 ft and a sprinkler density of 0.300 gpm (1.1 L/min) over the most remote 2000 ft^2 (18.6 m^2) area and 250 gpm (946 L/min) hose stream allowance	Additional 300 lb 300 ft separation	10,000 lb In special rooms or buildings per Chapter 10 of NFPA 58

[58: Table 8.3.1(b)]

For SI units, 1 lb = 0.45 kg; 1 gpm = 3.8 L/min; 1 ft = 0.3 m; 1 ft^2 = 0.09 m^2.

recognizing that spare cylinders must be on hand for these appliances and that a reasonable number of cylinders must be allowed. These cylinders are constructed to DOT specification 2P or 2Q per 49 CFR 178.33, "Specification 2Q; inner nonrefillable metal receptacles" and to UL 147A, *Standard for Nonrefillable (Disposable) Type Fuel Gas Cylinder Assemblies*, or UL 147B. They are similar to aerosol containers.

69.5.3.3 Storage Within Buildings Not Frequented by the Public.

69.5.3.3.1 The maximum quantity of LP-Gas allowed in one storage location shall not exceed 735 lb (334 kg) water capacity [nominal 300 lb (136 kg) propane capacity]. [**58:**8.3.3.1]

69.5.3.3.2 Where additional storage locations are required on the same floor within the same building, they shall be separated by a minimum of 300 ft (91.4 m). [**58:**8.3.3.2]

69.5.3.3.3 Storage beyond the limitations described in 69.5.3.3.2 shall comply with 69.5.3.4. [**58:**8.3.3.3]

69.5.3.3.4 Cylinders carried as part of the service equipment on highway mobile vehicles shall not be part of the total storage capacity requirements of 69.5.3.3.1, where such vehicles are stored in private garages and carry no more than three cylinders with a total aggregate capacity per vehicle not exceeding 100 lb (45.4 kg) of propane. [**58:**8.3.3.4]

The requirement in 69.5.3.3.4 addresses the quantity of propane being carried by a vehicle for other than engine fuel use. It was originally developed to recognize the carrying of portable cylinders on telephone and electric utility service vehicles and the garaging of such vehicles in buildings owned and occupied by such firms. The current limit of up to three cylinders on a vehicle while maintaining the total quantity of 100 lb (45.4 kg) of LP-Gas recognizes that many utility vehicles carry multiple cylinders to meet service requirements.

69.5.3.3.5 Cylinder valves shall be closed when not in use. [**58:**8.3.3.5]

69.5.3.4 Storage Within Special Buildings or Rooms.

69.5.3.4.1 The maximum quantity of LP-Gas stored in special buildings or rooms shall be 10,000 lb (4540 kg). [**58:**8.3.4.1]

69.5.3.4.2 Special buildings or rooms for storing LP-Gas cylinders shall not be located where the buildings or rooms adjoin the line of property occupied by schools, churches, hospitals, athletic fields, or other points of public gathering. [**58:**8.3.4.2]

Δ **69.5.3.4.3** The construction of all special buildings and rooms specified in 69.5.3.4.2 shall comply with Chapter 10 of NFPA 58 and the following:

(1) Vents to the outside only shall be provided at both the top and bottom of the building and shall be located at least 5 ft (1.5 m) from any building opening.
(2) The entire area shall be classified for purposes of ignition source control in accordance with Section 6.25 of NFPA 58.

[**58:**8.3.4.3]

The phrase "special buildings or rooms" refers to buildings and rooms used only to store LP-Gas. The construction of these special buildings and rooms must comply with Chapter 10 of NFPA 58 and the additional provisions of 69.5.3.4.

69.5.3.5 Storage Within Residential Buildings. Storage of cylinders within a residential building, including the basement or any storage area in a common basement of a multiple-family building and attached or detached garages, shall be limited to cylinders each with a maximum water capacity of 2.7 lb (1.2 kg) and shall not exceed 5.4 lb (2.4 kg) aggregate water capacity per each living space unit. [**58:**8.3.5]

69.5.4 Storage Outside of Buildings.

Subsection 69.5.4 applies to cylinders stored in outdoor areas and includes retail locations as part of a commercial cylinder exchange and industrial locations for cylinders used on site.

69.5.4.1* Location of Storage Outside of Buildings.

A.69.5.4.1 The filling process in 69.5.4.1.4 refers to the time period beginning when a cylinder or cylinders are brought to a dispensing station to be filled and ending when the last cylinder is filled and all the cylinders are removed from the filling area. This is meant to define a continuous process, with the cylinders being unattended for only brief periods, such as operator breaks or lunch. [**58:**A.8.4.1]

Δ **69.5.4.1.1** Storage outside of buildings for cylinders awaiting use or resale or that are part of a cylinder exchange point shall be located as follows:

(1) At least 5 ft (1.5 m) from any doorway or opening in a building frequented by the public where occupants have at least two means of egress as defined by 3.3.182 and NFPA *101*
(2) At least 10 ft (3 m) from any doorway or opening in a building or sections of a building that has only one means of egress

The separation distance between cylinder storage and a doorway or opening in a building is to ensure that anyone in the building is able to leave in the event of propane release or fire in the cylinder storage area. The mandated distance is 5 ft (1.5 m) if there are two or more means of egress from the building and 10 ft (3 m) if there is only one means of egress.

(3) At least 20 ft (6.1 m) from any automotive service station fuel dispenser

[**58:**8.4.1.1]

The requirement in 69.5.4.1.1(3) for a 20 ft (6.1 m) separation between cylinder storage and gasoline or diesel fuel dispensers at a gas station addresses concerns over possible vehicle impact with cylinders, which could cause cylinder failure or leakage that would affect safe means of egress from buildings. Exposure to fires during vehicle fueling operations is also a concern. Cylinder exchange cabinets are frequently located near the exits of convenience stores, gas stations, and similar locations (see Exhibit 69.40).

Note that this requirement is not in conflict with 1.3.2(11) of NFPA 58, which states that propane vehicle fuel dispensers in multiple fuel refueling stations are not covered by this *Code*. This distance is meant for the storage requirements of the cylinders at these locations.

6,001–10,000	>2,721–4,540	20	6.1	20	6.1	20	6.1
>10,000	>4,540	25	7.6	25	7.6	25	7.6

*The minimum distance from a point of transfer associated with a dispensing system must comply with Table 69.3.5.2.1.

[**58:** Table 8.4.1.2]

69.5.4.1.2 Distances from cylinders in storage outside of buildings shall be in accordance with Table 69.5.4.1.2 with respect to the following:

(1) Nearest important building or group of buildings
(2) Line of adjoining property that can be built upon
(3) Busy thoroughfares or sidewalks on other than private property
(4) Line of adjoining property occupied by schools, churches, hospitals, athletic fields, or other points of public gathering
(5) Dispensing system

[**58:**8.4.1.2]

Column 5 in Table 69.5.4.1.2 covers the distance from a storage location to dispensing stations, recognizing the practice of offering filled cylinders to the public on an exchange basis rather than filling cylinders at a retail site. Column 5 requires a minimum spacing of 5 ft (1.5 m) from dispensing stations if on the same site.

Note also that 69.5.4.1.3 provides the option of using a noncombustible, 2-hour fire resistance–rated structure to provide a reduction in the separation distances specified in Table 69.5.4.1.2. The reason for this option is to bring NFPA 58 into agreement with common practices recognized for other compressed gas storage, based on alternatives that achieve the same level of fire protection.

69.5.4.1.3 Fire-Resistive Protective Structure.

69.5.4.1.3.1 The distances in Table 69.5.4.1.2 shall be reduced to 0 where a 2-hour fire-resistive protective structure made of noncombustible materials is provided that breaks the line of sight of the storage and the building. [**58:**8.4.1.3(A)]

69.5.4.1.3.2 For buildings with exterior walls rated 2-hour fire resistance and constructed of noncombustible materials not provided with eaves over the storage, the exterior wall shall be allowed in lieu of a protective structure to reduce the distance to 0. [**58:**8.4.1.3(B)]

69.5.4.1.4 Cylinders in the filling process shall not be considered to be in storage. [**58:**8.4.1.4]

Paragraph 69.5.4.1.4 clarifies that cylinders in the process of being filled are not covered by the 5 ft (1.5 m) spacing requirement from dispensing stations. The vague phrase "in the filling process" recognizes efficient filling practices in that it refers not only to the cylinder being filled but also to the group of cylinders being filled. Thus, a group of cylinders can be located within 5 ft (1.5 m) of a dispensing station, and all the cylinders in the group can be filled prior to any of them being moved to storage. No time limit is specified, but filling time is usually limited to the reasonable time it takes to perform the filling operation, allowing for brief periods for other activities such as lunches and breaks (see A.69.5.4.1).

69.5.4.2 Protection of Cylinders.

Δ **69.5.4.2.1*** Cylinders at a location open to the public shall be protected by either of the following:

(1) An enclosure in accordance with 6.21.4.2 of NFPA 58
(2) A lockable ventilated enclosure of metal exterior construction

[**58:**8.4.2.1]

The requirements that cabinets used for exchange cylinders must be ventilated and lockable are listed in 69.5.4.2.1 (see Exhibit 69.40). Ventilation is commonly accomplished by using expanded metal or screening for the sides of the locker. Requiring the cabinet to be locked prevents tampering with the cylinders in unattended locations. Note that storage would have to ensure that the pressure relief valve is in the vapor space of full containers, as required by 69.5.2.1.2. Note that 69.5.4.2.1(2) requires that the exterior construction of the cabinet be metal. The interior construction, however, can be of combustible components such as molded industrial fiberglass grates.

A.69.5.4.2.1 The shelves should be made of any material with a flame spread index, in accordance with ASTM E84, *Standard Test*

Method for Surface Burning Characteristics of Building Materials, or UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, of less than 25 and should be of sufficient strength to support the cylinders. [**58:**A.8.4.2.1]

69.5.4.2.2* Vehicular barrier protection (VBP) shall be provided where vehicle traffic is expected at the location, except where cylinders are protected in accordance with 69.5.4.2.1(2). [**58:**8.4.2.2]

A.69.5.4.2.2 Only minimal VBP, such as either parking bumpers (minimum of 6 inches above grade) or sidewalks (minimum of 6 inches above grade), may be needed for cylinder exchange cabinets. The storage cabinets associated with cylinder exchange may provide limited protection against physical damage to the stored cylinders. Examples of such protection include, but are not limited to:

(1) Guard rails
(2) Steel bollards
(3) Raised sidewalks (minimum of 6 in. in height)
(4) Fencing
(5) Ditches
(6) Berms (not to exceed 50% of the container perimeter)
(7) Jersey barriers
(8) Parking bumpers (minimum of 6 in. in height)
(9) Fencing/Gates
[**58:**A.8.4.2.2]

If vehicles are operated in areas where cylinders are stored, the cylinders must be protected from possible vehicle damage. In the 2017 edition of NFPA 58, this requirement was revised to no longer require VBP when the cylinders are protected by a lockable ventilated enclosure of metal exterior construction, as stated in 69.5.4.2.1(2).

69.5.4.3 Alternate Location and Protection of Storage. Where the provisions of 69.5.4.1 and 69.5.4.2.1 are impractical at construction sites or at buildings or structures undergoing major renovation or repairs, alternative storage of cylinders shall be acceptable to the AHJ. [**58:**8.4.3]

Where the provisions of 69.5.4.1 and 69.5.4.2.1 are impractical at construction sites or at buildings or structures undergoing major renovation or repairs, alternative storage of cylinders shall be acceptable to the AHJ.

69.5.5* Fire Protection and Electrical Area Classification.

Subsection 69.5.5 clarifies the application of the fire protection and electrical classification requirements to all locations that store more than 720 lb (327 kg) of LP-Gas. However, the requirements do not apply to cylinder storage at bulk plants because 69.5.1.3 exempts bulk plants from this chapter. Refer to Section 6.29 of NFPA 58 for the fire protection requirements for bulk plants.

A.69.5.5 See 6.29.4.3 of NFPA 58. [**58:**A.8.5]

Δ **69.5.5.1** Retail cylinder exchange locations shall be provided with at least one portable fire extinguisher in accordance with Section 4.7 of NFPA 58 having a minimum capacity of 10 lb (4.5 kg) dry chemical on the premises where retail cylinder exchange cabinets are storing more than 720 lb (327 kg) of propane. [**58:**8.5.1]

69.5.5.2 Storage locations, other than those complying with 69.5.5.1, where the aggregate quantity of propane stored is in excess of 720 lb (327 kg), shall be provided with at least one approved portable fire extinguisher in accordance with Section 4.7 of NFPA 58 having a minimum capacity of 18 lb (8.2 kg) dry chemical. [**58:**8.5.2]

69.5.5.3 The required fire extinguisher shall be located within 50 ft (15 m) travel distance of the propane storage location. [**58:**8.5.3]

• **69.5.5.4** The storage of cylinders awaiting resale shall be exempt from the electrical classification requirements of NFPA 58. [**58:**8.5.4]

Cylinder exchange locations are usually found at stores that may have ice machines, electrical switches, and electrical outlets near or next to the cylinder exchange cabinets. The area around cylinders awaiting resale is exempt from electrical area classification for the following two reasons:

1. The committee has received no reports on incidents involving exchange cabinets where an electrical ignition was a source of fire.
2. The DOT imposes no requirements for separation of cylinders in transportation from sources of ignition.

Therefore, such a restriction on cylinders awaiting sale was determined unnecessary and the exemption in 69.5.5.4 was written into the *Code*.

• 69.5.6 Automated Cylinder Exchange Stations.

As cylinder exchange becomes more popular, retailers have sought to provide their customers with this service outside of normal operating hours. There are several designs for automated cylinder exchange stations. Therefore, the minimum safety requirements reflect no specific design (see Exhibit 69.41).

69.5.6.1 Cylinder exchange cabinets that include an automated vending system for exchanging cylinders shall comply with the requirements in 69.5.6.2 through 69.5.6.6. [**58:**8.6.1]

Δ **69.5.6.2** Electrical equipment installed in cylinder storage compartments shall comply with the requirements for Class I, Division 2 equipment in accordance with *NFPA 70*. [**58:**8.6.2]

69.5.6.3 Cabinets shall be designed such that cylinders can be placed inside only in the upright position. [**58:**8.6.3]

69.5.6.4 Door releases for access to stored cylinders shall be permitted to be pneumatic, mechanical, or electrically powered. [**58:**8.6.4]

69.5.6.5 A manual override control shall be permitted for use by authorized personnel. [**58:**8.6.5]

69.5.6.6 The vending system shall not be capable of returning to automatic operation after a manual override until the system has been inspected and reset by authorized personnel. [**58:**8.6.6]

Exhibit 69.41

Two views of an automated vending propane station. (Courtesy of the Office of the State Fire Marshal of Illinois)

69.6 Vehicular Transportation of LP-Gas

69.6.1 Transportation in Portable Containers.

69.6.1.1 Transportation of Cylinders.

69.6.1.1.1 Cylinders having an individual water capacity not exceeding 1000 lb (454 kg) [nominal 420 lb (191 kg) propane capacity], when filled with LP-Gas, shall be transported in accordance with the requirements of 69.6.1. [**58:**9.3.2.1]

The maximum size of an individual cylinder permitted under DOT regulations is 1000 lb (454 kg) water capacity [nominal 420 lb (191 kg) of propane]. Portable ASME containers, which generally serve the same purpose as DOT cylinders, may be encountered and are also limited to this size for transportation. Exhibit 69.42 shows portable containers transported via open delivery truck.

69.6.1.1.2 Cylinders shall be constructed as provided in 69.2.1 and equipped in accordance with Section 5.9 of NFPA 58 for transportation as cylinders. [**58:**9.3.2.2]

Exhibit 69.42

Cylinders in an open portable container cargo vehicle (delivery truck). (Courtesy of Eastern Propane Corp.)

69.6.1.1.3 The quantity of LP-Gas in cylinders shall be in accordance with Chapter 7 of NFPA 58. [**58:**9.3.2.3]

All DOT cylinders are marked with the water capacity in pounds (kilograms). The water capacity is required because not all LP-Gases have the same specific gravity, therefore each has a different filling limit. Weight is used, not volume (as is done for ASME containers), because the cylinders are portable and can be placed on a scale. For propane, with a specific gravity between 0.504 and 0.510, the capacity of any cylinder (in pounds or kilograms) is obtained by multiplying the water capacity by 0.42. See Section 69.4 and Chapter 7 of NFPA 58 for a more detailed explanation.

Δ **69.6.1.1.4** Cylinder valves shall comply with the following:

(1) Valves of cylinders shall be protected in accordance with 69.2.1.2.1.
(2) Screw-on-type protecting caps or collars shall be secured in place.
(3) The provisions of 69.4.2.2.5 shall apply.

[**58:**9.3.2.4]

The requirements for cylinder valves are located in Chapter 5 of NFPA 58. Refer to commentary following 69.4.2.2.5 for the requirements referenced on cylinder valve plugs. The importance of providing protection for cylinder valves from damage cannot be overstated. A damaged or separated cylinder valve could result in an uncontrolled release of LP-Gas and perhaps even the propulsion of the cylinder itself.

69.6.1.1.5 The cargo space of the vehicle shall be isolated from the driver's compartment, the engine, and the engine's exhaust system. [**58:**9.3.2.5]

69.6.1.1.5.1 Open-bodied vehicles shall be considered to be in compliance with 69.6.1.1.5.

69.6.1.1.5.2 Closed-bodied vehicles having separate cargo, driver, and engine compartments shall be considered to be in compliance with 69.6.1.1.5. [**58:**9.3.2.5(B)]

69.6.1.1.5.3 Closed-bodied vehicles, such as passenger cars, vans, and station wagons, shall not be used for transporting more than 215 lb (98 kg) water capacity [nominal 90 lb (41 kg) propane capacity], but not more than 108 lb (49 kg) water capacity [nominal 45 lb (20 kg) propane capacity] per cylinder, unless the driver and engine compartments are separated from the cargo space by a vaportight partition that contains no means of access to the cargo space. [**58:**9.3.2.5(C)]

The transportation of privately owned cylinders in passenger automobiles is a safety concern that is addressed based on the vehicle type. The transportation of LP-Gas by private parties, where the transportation is not considered to be "in commerce" as defined by the DOT, is not regulated by the DOT, and therefore only the provisions of NFPA 58 apply. The provisions of Section 69.6 are applied in the following situations:

1. **What are the provisions for a cylinder transported in an open-bodied vehicle (such as a pickup truck) or in a closed-bodied vehicle with a vaportight partition between the cargo space and the driver and engine compartments?**

   In both cases, up to 1000 lb (454 kg) of LP-Gas (total weight, including the weight of the LP-Gas and cylinders) can be transported in the vehicle as stated in 69.6.1.1.1. Where the LP-Gas exceeds 1000 lb (454 kg), the requirements of 69.6.1.1.10 and the DOT would apply to the vehicle.

2. **What are the provisions for a cylinder transported in a closed-body vehicle?**

   In this case, a maximum of 90 lb (41 kg) of propane can be transported in the passenger or cargo space of the vehicle. This requirement allows up to four typical grill cylinders [20 lb (9.1 kg) propane capacity], up to three 30 lb (13.6 kg) cylinders, or up to two 40 lb (18 kg) cylinders to be transported.

Note that the 90 lb (41 kg) limit in closed-body vehicles effectively prohibits the transportation of a 100 lb (45 kg) LP-Gas cylinder in passenger cars, vans, sport utility vehicles, and station wagons. Also, see 69.6.1.1.9 for requirements on cylinder orientation when being transported.

These rules apply to all transportation of cylinders, whether by propane company employees delivering cylinders to residences, by exchange cabinets, or by forklift operators or private citizens taking grill cylinders in for filling or exchange. These rules apply in much the same way as building codes apply to the modifications citizens make to their homes. In the case of building codes (and this varies with location), citizens are responsible for obtaining a building permit, for having construction done to meet the applicable code(s), and for getting an inspection by a building code official during construction and/or after the work is complete.

NFPA 58's requirements are less well known to consumers than building codes are, which is why some jurisdictions consider it the responsibility of the propane company employees to ensure that cylinders transported by customers are properly placed and secured in their vehicles when they leave the dispensing site.

69.6.1.1.6 Cylinders and their appurtenances shall be determined to be leak-free before being loaded into vehicles. [**58:**9.3.2.6]

69.6.1.1.7 Cylinders shall be loaded into vehicles with flat floors or equipped with racks for holding cylinders. [**58:**9.3.2.7]

69.6.1.1.8 Cylinders shall be fastened in position to minimize the possibility of movement, tipping, and physical damage. [**58:**9.3.2.8]

TABLE 69.6.1.1.9 Orientation of Cylinders on Vehicles

Propane Capacity of Cylinder		Open Vehicles	Enclosed Spaces of Vehicles
lb	kg		
≤45	≤20	Any position	
>45	>20	Relief valve in communication with the vapor space	
≤4.2	≤1.9		Any position
>4.2	>1.9		Relief valve in communication with the vapor space

[**58:**Table 9.3.2.9]

69.6.1.1.9 Cylinders being transported by vehicles shall be positioned in accordance with Table 69.6.1.1.9. [**58:**9.3.2.9]

Racks that hold cylinders in a horizontal position are commonly used for the delivery of industrial truck cylinders in open-body vehicles. The safety experience with this type of transportation has been good and is the reason that LP-Gas cylinders with a maximum propane capacity of 45 lb (20 kg) can be transported with the relief valve in contact with the liquid space of the container. That size is the maximum portable cylinder generally used in industrial trucks. Larger containers must be transported in a position such that the pressure relief valve is in communication with the vapor space of the container.

In closed-body vehicles, the requirements are much more stringent. Only cylinders less than or equal to 4.2 lb (0.016 m^3) propane capacity can be transported in any position, thereby resulting in the relief valve being in communication with liquid. As a result of this provision, nominal 20 lb (9.1 kg) cylinders (gas grill cylinders) cannot be transported on their sides inside a vehicle.

69.6.1.1.10 Vehicles transporting cylinders where the total weight is more than 1000 lb (454 kg), including the weight of the LP-Gas and the cylinders, shall be placarded as required by DOT regulations or state law. [**58:**9.3.2.10]

69.6.1.2 Fire Extinguishers.

Δ **69.6.1.2.1** Each truck or trailer transporting portable containers in accordance with 69.6.1.1 or 69.6.1.2 shall be equipped with at least one portable fire extinguisher in accordance with Section 4.7 of NFPA 58 having a minimum capacity of 18 lb (8.2 kg) dry chemical. [**58:**9.3.5.1]

•

69.6.2 Parking and Garaging Vehicles Used to Carry LP-Gas Cargo.

The regulations for parking cargo tank vehicles and cylinder delivery trucks cover the following:

- Outdoor parking
- Parking in public buildings
- Parking in buildings owned by the vehicle's operator
- Parking in buildings used to repair vehicles

To facilitate easier understanding of 69.6.2, see the flow charts in Exhibit 69.43 and Exhibit 69.44.

69.6.2.1 Application. Subsection 69.6.2 applies to the parking and garaging of vehicles used for the transportation of LP-Gas. [**58:**9.7.1]

69.6.2.2 Parking Outdoors.

Δ **69.6.2.2.1** Vehicles shall not be left unattended on any street, highway, avenue, or alley, except for necessary absences from the vehicle associated with drivers' normal duties, including stops for meals and rest stops during the day or night, except as follows:

(1) This requirement shall not apply in an emergency.
(2) This requirement shall not apply to vehicles parked in accordance with 69.6.2.2.3 and 69.6.2.2.4.

[**58:**9.7.2.1]

69.6.2.2.2* Vehicles shall not be parked in congested areas. [**58:**9.7.2.2]

A.69.6.2.2.2 The term "congested area" is intended to describe situations where access to the vehicle during an emergency would be impeded or where moving the vehicle away from an emergency would be prevented. [**58:**A.9.7.2.2]

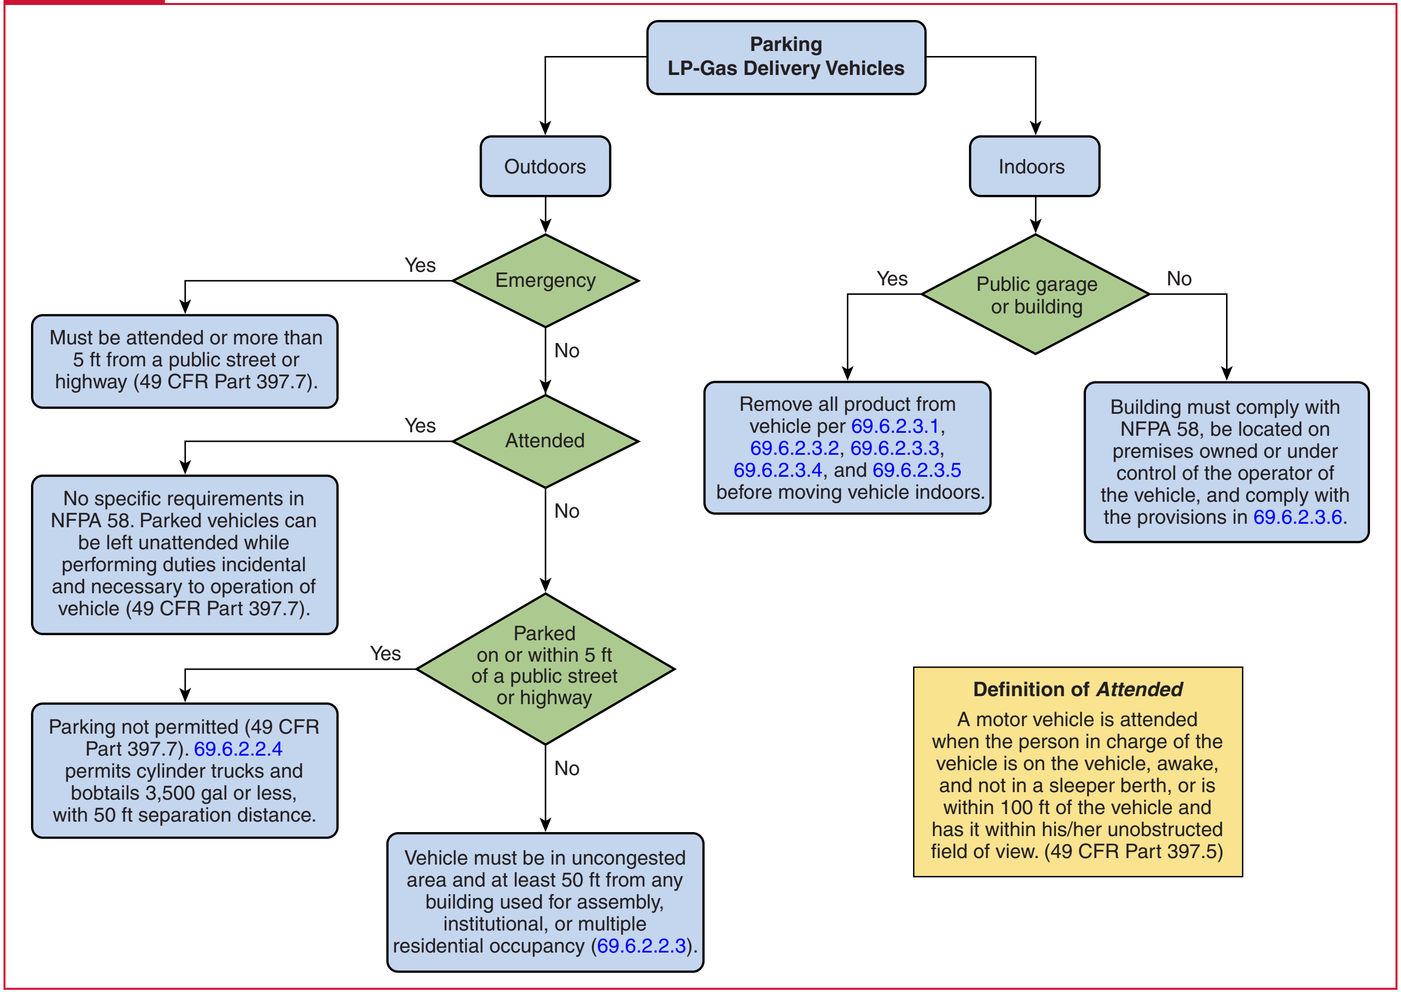
69.6.2.2.3 Where vehicles are parked off the street in uncongested areas, they shall be at least 50 ft (15 m) from any building used for assembly, institutional, or multiple residential occupancy. [**58:**9.7.2.3]

69.6.2.2.4 Where vehicles carrying portable containers or cargo tank vehicles of 3500 gal (13 m^3) water capacity or less are parked on streets adjacent to the driver's residence in uncongested residential areas, the parking locations shall be at least 50 ft (15 m) from a building used for assembly, institutional, or multiple residential occupancy. [**58:**9.7.2.4]

In remote areas, the driver's residence may be a considerable distance from bulk plant facilities, and customers may be located a considerable distance from the bulk plant yet near the driver's residence. In these cases, the retail bulk delivery tank truck or cylinder delivery truck is permitted to be parked near the driver's home.

Local regulations may prohibit parking commercial vehicles in residential neighborhoods; such regulations often supersede NFPA 58.

Exhibit 69.43



Parking of LP-Gas delivery vehicles flow chart. (Courtesy of National Propane Gas Association

69.6.2.3 Parking Indoors.

Δ **69.6.2.3.1** Cargo tank vehicles parked in any public garage or building shall have LP-Gas liquid removed from the following:

(1) Cargo tank
(2) Piping
(3) Pump
(4) Meter
(5) Hose
(6) Related equipment

[**58:**9.7.3.1]

69.6.2.3.2 Vehicles used to carry portable containers shall not be moved into any public garage or building for parking until all portable containers have been removed from the vehicle. [**58:**9.7.3.2]

69.6.2.3.3 The pressure in the delivery hose and related equipment shall be reduced to approximately atmospheric. [**58:**9.7.3.3]

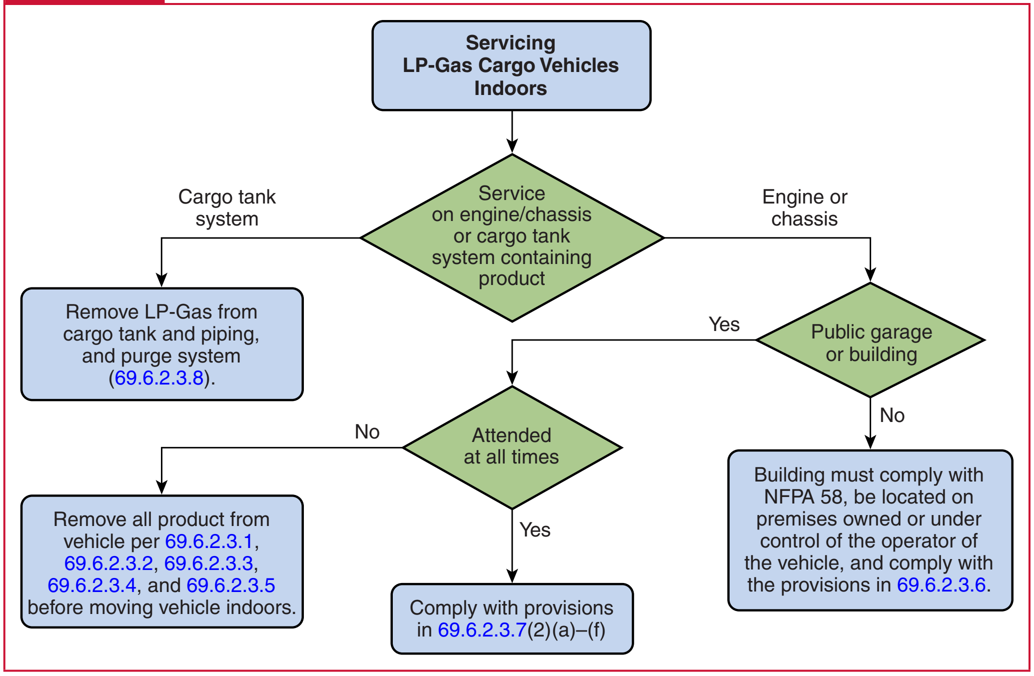
69.6.2.3.4 All valves shall be closed before the vehicle is moved indoors. [**58:**9.7.3.4]

69.6.2.3.5 Delivery hose or valve outlets shall be plugged or capped before the vehicle is moved indoors. [**58:**9.7.3.5]

69.6.2.3.6 Vehicles carrying or containing LP-Gas shall only be parked in buildings complying with Chapter 10 of NFPA 58 and located on premises owned or under the control of the operator of such vehicles where the following provisions are met:

(1) The public shall be excluded from such buildings.
(2) Floor level ventilation shall be provided in all parts of the building where such vehicles are parked.
(3) Leaks in the vehicle LP-Gas systems shall be repaired before the vehicle is moved indoors.
(4) Primary shutoff valves on cargo tanks and other LP-Gas containers on the vehicle (except propulsion engine fuel containers)

Exhibit 69.44



Servicing LP-Gas cargo vehicles indoors flow chart. (Courtesy of National Propane Gas Association)

shall be closed and delivery hose outlets plugged or capped to contain system pressure before the vehicle is moved indoors.

(5) Primary shutoff valves on LP-Gas propulsion engine fuel containers shall be closed while the vehicle is parked.

(6) No LP-Gas container shall be located near a source of heat or within the direct path of hot air being blown from a blower-type heater.

(7) LP-Gas containers shall be gauged or weighed to determine that they are not filled beyond the maximum filling limit according to Section 7.4 of NFPA 58.

[**58:**9.7.3.6]

If it is necessary to park cargo tank vehicles in public buildings, all liquid LP-Gas must be removed from the cargo tank. Cylinder trucks parked in public buildings must have all cylinders removed. In addition, the building in which the vehicle is parked must be constructed to comply with Chapter 10 of NFPA 58.

69.6.2.3.7 Where vehicles are serviced or repaired indoors, the following shall apply:

(1) When it is necessary to move a vehicle into any building located on premises owned or operated by the operator of such vehicle for service on engine or chassis, the provisions of 69.6.2.3.6 shall apply.

(2) When it is necessary to move a vehicle carrying or containing LP-Gas into any public garage or repair facility for service on the engine or chassis, the provisions of 69.6.2.3.1 shall apply, or the driver or a qualified representative of an LP-Gas operator shall be in attendance at all times while the vehicle is indoors, and the following shall apply:

(a) Leaks in the vehicle LP-Gas systems shall be repaired before the vehicle is moved indoors.

(b) Primary shutoff valves on cargo tanks, portable containers, and other LP-Gas containers installed on the vehicle (other than propulsion engine fuel containers) shall be closed.

(c) LP-Gas liquid shall be removed from the piping, pump, meter, delivery hose, and related equipment and the pressure therein reduced to approximately atmospheric before the vehicle is moved inside.

(d) Delivery hose or valve outlets shall be plugged or capped before the vehicle is moved indoors.

(e) No container shall be located near a source of heat or within the direct path of hot air blown from a blower or from a blower-type heater.

(f) LP-Gas containers shall be gauged or weighed to determine that they are not filled beyond the maximum filling capacity in accordance with Section 7.4 of NFPA 58.

[**58:**9.7.3.7]

If it is necessary to service cargo tank vehicles in garages, the following options are provided in 69.6.2.3.7:

1. If the garage is owned or operated by the vehicle operator, the requirements of 69.6.2.3.6 for parking of vehicles in public garages apply.

2. If the garage is a public garage, either the vehicle must be emptied of LP-Gas as required by 69.6.2.3.1 or the vehicle operator must be at the vehicle at all times it is in the garage, and the vehicle must meet the criteria in 69.6.2.3.7(2).

69.6.2.3.8 If repair work or servicing is to be performed on a cargo tank vehicle system, all LP-Gas shall be removed from the cargo tank and piping, and the system shall be thoroughly purged before the vehicle is moved indoors. [**58:**9.7.3.8]

It is extremely important to remove all LP-Gas from the cargo tank and piping and to purge any residual vapor from the system. Even though the repair work may not be intended to open the piping or tank, it may occur.

Δ 69.7 LP-Gases at Utility Plants

The design, construction, location, installation, and operation of refrigerated and nonrefrigerated liquefied petroleum gas systems at utility gas plants shall be in accordance with NFPA 59.

Δ 69.8 Liquefied Natural Gas (LNG) Facilities

The design, location, construction, and operation of liquified natural gas facilities shall be in accordance with NFPA 59A.

70

Oxidizer Solids and Liquids

Oxidizer, as defined in 3.3.201 of this *Code*, is any solid or liquid material that readily yields oxygen or other oxidizing gas or that readily reacts to promote or initiate combustion of combustible materials and that can, under some circumstances, undergo a vigorous self-sustained decomposition due to contamination or heat exposure. Special precautions should be taken where oxidizers and organic peroxide formulations are present in retail outlets, since the potential for contact with incompatible materials is greater in such locations. For requirements pertaining to the storage, use, and handling of oxidizer solids and liquids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, oxidizer solids and liquids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code,* as well as the provisions for display and storage of Class 1 through Class 3 oxidizer solids and liquids in mercantile, storage, or industrial occupancies where the general public has access to the material for sale and the storage of these materials in those occupancies that are not accessible to the public. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

70.1 General

70.1.1 The storage, use, and handling of oxidizer solids and liquids shall comply with the requirements of Chapter 60.

Δ **70.1.2** The storage, use, and handling of oxidizer solids and liquids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

Δ **70.1.3** The display and storage of Class 1 through Class 3 oxidizer solids and liquids in mercantile, storage, or industrial occupancies where the general public has access to the material for sale, and to the storage of oxidizing solid and liquid materials in such occupancies in areas that are not accessible to the public, shall comply with the requirements of NFPA 400.

NFPA 400, *Hazardous Materials Code,* 2016 edition.

71 Pyrophoric Solids and Liquids

Pyrophoric material is defined in 3.3.180.13 as a chemical with an autoignition temperature in air at or below 130°F (54.4°C). For requirements pertaining to the storage, use, and handling of pyrophoric solids and liquids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, pyrophoric solids and liquids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

71.1 General

71.1.1 The storage, use, and handling of pyrophoric solids and liquids shall comply with the requirements of Chapter 60.

Δ **71.1.2** The storage, use, and handling of pyrophoric solids and liquids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

NFPA 400, *Hazardous Materials Code,* 2016 edition.

72

Unstable (Reactive) Solids and Liquids

Unstable (reactive) material is defined in 3.3.180.15 as a material that, in the pure state or as commercially produced, will vigorously polymerize, decompose or condense, become self-reactive, or otherwise undergo a violent chemical change under conditions of shock, pressure, or temperature. For requirements pertaining to the storage, use, and handling of unstable (reactive) solids and liquids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, unstable (reactive) solids and liquids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

72.1 General

72.1.1 The storage, use, and handling of unstable (reactive) solids and liquids shall comply with the requirements of Chapter 60.

Δ **72.1.2** The storage, use, and handling of unstable (reactive) solids and liquids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

Water-Reactive Solids and Liquids

73

Water-reactive material is defined in 3.3.180.16 as materials that explode; violently react; produce flammable, toxic, or other hazardous gases; or evolve enough heat to cause self-ignition or ignition of nearby combustibles upon exposure to water or moisture. For requirements pertaining to the storage, use, and handling of water-reactive solids and liquids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, water-reactive solids and liquids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2013 edition of the document is referenced throughout this edition of NFPA 1, *Fire Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

73.1 General

73.1.1 The storage, use, and handling of water-reactive solids and liquids shall comply with the requirements of Chapter 60.

Δ **73.1.2** The storage, use, and handling of water-reactive solids and liquids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

74 Ammonium Nitrate

Like other inorganic nitrates, ammonium nitrate is an oxidizing agent and will increase the intensity of a fire. The oxidizing gas it gives off is nitrous oxide, rather than oxygen. Chemical- and fertilizer-grade ammonium nitrate must not be confused with certain ammonium nitrate combustible material mixtures used as explosives. All grades of ammonium nitrate can be detonated if they are in the proper crystalline form, if the initiating source is sufficiently large, or if heated under sufficient confinement (the purest material needing the greatest confinement). For requirements pertaining to the storage, use, and handling of ammonium nitrate, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, the storage of ammonium nitrate in the form of crystals, flakes, grains, or prills, including fertilizer grade, dynamic grade, nitrous oxide grade, technical grade, and other mixtures containing 60 percent or more by weight of ammonium nitrate, must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

74.1 General

74.1.1 The storage, use, and handling of ammonium nitrate (solid oxidizer) shall comply with Chapter 60.

Δ **74.1.2** The storage of ammonium nitrate in the form of crystals, flakes, grains, or prills including fertilizer grade, dynamite grade, nitrous oxide grade, technical grade, and other mixtures containing 60 percent or more by weight of ammonium nitrate shall comply with NFPA 400.

Organic Peroxide Solids and Liquids

75

Organic peroxide is defined in 3.3.198 as any organic compound having a double oxygen or peroxy (-O-O-) group in its chemical structure. All organic peroxides are combustible, and many organic peroxides can be decomposed by heat, shock, or friction. Some organic peroxide materials may even be detonatable. Organic peroxides can be liquid or solid and are often dissolved in flammable or combustible solvents. The peroxides are often found wet with water or diluted with stable liquids. With solutions, sensitive crystals can be formed by freezing. For requirements pertaining to the storage, use, and handling of organic peroxide solids and liquids, users are directed to Chapter 60 on hazardous materials. Chapter 60 also contains provisions that must be followed when the storage, use, or handling of a hazardous material exceeds the maximum allowable quantity (MAQ) per control area as set forth in that chapter.

In addition to complying with Chapter 60, organic peroxide solids and liquids exceeding the MAQ must also comply with any additional provisions set forth in NFPA 400, *Hazardous Materials Code*. The first edition of NFPA 400 was published in 2010, and the 2016 edition of the document is referenced throughout this edition of the *Code*. NFPA 400 combined NFPA hazardous materials documents into a single code. Rather than repeating the provisions, many of the chapters of this *Code* related to hazardous materials now reference NFPA 400.

75.1 General

75.1.1 The storage, use, and handling of organic peroxide solids and liquids shall comply with the requirements of Chapter 60.

Δ **75.1.2** The storage, use, and handling of organic peroxide solids and liquids in amounts exceeding the maximum allowable quantity permitted in control areas as set forth in Chapter 60 shall also comply with the requirements of NFPA 400.

Explanatory Material

A

The material contained in Annex A of the 2018 edition of NFPA 1, *Fire Code,* is not a part of the requirements of the *Code* but is included with the *Code* for informational purposes only. For the convenience of readers, in this handbook, the Annex A material follows the text to which it applies in Chapters 1 through 75 and, therefore, is not repeated here.

Hazardous Materials Classifications

B

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Scope

Annex B provides information, explanations, and examples to illustrate and clarify the hazard categories contained in Chapter 60. The hazard categories are based upon Title 29 of the Code of Federal Regulations. Where numerical classifications are included, they are in accordance with nationally recognized standards. Annex B should not be used as the sole means of hazardous materials classification.

B.2 Hazard Categories

B.2.1 Physical Hazards.

B.2.1.1 Explosives and Blasting Agents.

B.2.1.1.1 High Explosives. Can be detonated by means of blasting cap when unconfined. Examples: dynamite, TNT, nitroglycerine, C-3, and C-4.

B.2.1.1.2 Low Explosives. Can be deflagrated when confined. Examples: black powder, smokeless powder, propellant explosives, and display fireworks.

B.2.1.1.3 Blasting Agents. Oxidizer and liquid fuel slurry mixtures. Example: ammonium nitrate combined with fuel oil.

B.2.1.2 Compressed Gases.

B.2.1.2.1 Flammable. Examples: acetylene, carbon monoxide, ethane, ethylene, hydrogen, and methane.

B.2.1.2.2 Oxidizing. Examples: oxygen, ozone, oxides of nitrogen, chlorine, and fluorine. Chlorine and fluorine do not contain oxygen but reaction with flammables is similar to that of oxygen.

B.2.1.2.3 Corrosive. Examples: ammonia, hydrogen chloride, and fluorine.

B.2.1.2.4 Highly Toxic. Examples: arsine, cyanogen, fluorine, germane, hydrogen cyanide, hydrogen selenide, nitric oxide, phosphine, and stibene.

B.2.1.2.5 Toxic. Examples: chlorine, hydrogen fluoride, hydrogen sulfide, silicon tetrafluoride, and phosgene.

B.2.1.2.6 Inert (Chemically Unreactive). Examples: argon, helium, krypton, neon, nitrogen, and xenon.

B.2.1.2.7 Pyrophoric. Examples: diborane, dichloroborane, phosphine, and silane.

B.2.1.2.8 Unstable (Reactive). Examples: butadiene (unstabilized), ethylene oxide, and vinyl chloride.

B.2.1.3 Flammable and Combustible Liquids.

B.2.1.3.1 Flammable Liquids.

B.2.1.3.1.1 Class I-A liquids include those having flash points below 73°F (22.8°C) and having a boiling point below 100°F (37.8°C).

B.2.1.3.1.2 Class I-B liquids include those having flash points below 73°F (22.8°C) and having a boiling point at or above 100°F (37.8°C).

B.2.1.3.1.3 Class I-C liquids include those having flash points at or above 73°F (22.8°C) and below 100°F (37.8°C).

B.2.1.3.2 Combustible Liquids.

B.2.1.3.2.1 Class II liquids include those having flash points at or above 100°F (37.8°C) and below 140°F (60°C).

B.2.1.3.2.2 Class III-A liquids include those having flash points at or above 140°F (60°C) and below 200°F (93.3°C).

B.2.1.3.2.3 Class III-B liquids include those liquids having flash points at or above 200°F (93.3°C).

B.2.1.4 Flammable Solids.

B.2.1.4.1 Organic Solids. Examples: camphor, cellulose nitrate, and naphthalene.

B.2.1.4.2 Inorganic Solids. Examples: decaborane, lithium amide, phosphorous heptasulfide, phosphorous sesquisulfide, potassium sulfide, anhydrous sodium sulfide, and sulfur.

B.2.1.4.3 Combustible Metals (Except Dusts and Powders). Examples: cesium, magnesium, and zirconium.

B.2.1.4.4 Combustible Dusts and Powders (Including Metals). Examples: wood sawdust, plastics, coal, flour, and powdered metals (few exceptions).

B.2.1.5 Oxidizers.

B.2.1.5.1 Gases. Examples: oxygen, ozone, oxides of nitrogen, fluorine, and chlorine (reaction with flammables is similar to that of oxygen).

B.2.1.5.2 Liquids. Examples: bromine, hydrogen peroxide, nitric acid, perchloric acid, and sulfuric acid.

B.2.1.5.3 Solids. Examples: chlorates, chromates, chromic acid, iodine, nitrates, perchlorates, and peroxides.

B.2.1.5.4 Examples of Liquid and Solid Oxidizers According to Hazard.

B.2.1.5.4.1 Class 4. Examples: ammonium perchlorate (particle size greater than 15 microns), ammonium permanganate, guanidine nitrate, hydrogen peroxide solutions (greater than 91 percent), and tetranitromethane.

B.2.1.5.4.2 Class 3. Examples: ammonium dichromate, calcium hypochlorite (over 50 percent by weight), chloric acid (10 percent maximum concentration), hydrogen peroxide solutions (greater than 52 percent up to 91 percent), mono-(trichloro)-tetra-(monopotassium dichloro)-penta-s-triazinetrione, nitric acid, fuming (more than 86 percent concentration), perchloric acid solutions (60 percent to 72 percent by weight), potassium bromate, potassium chlorate, potassium dichloro-s-triazinetrione (potassium dichloroisocyanurate), sodium bromate, sodium chlorate, sodium chlorite (over 40 percent by weight), and sodium dichloro-s-triazinetrione (sodium dichloroisocyanurate).

B.2.1.5.4.3 Class 2. Examples: barium bromate, barium chlorate, barium hypochlorite, barium perchlorate, barium permanganate, 1-bromo-3-chloro-5, 5-dimethylhydantoin, calcium chlorate, calcium chlorite, calcium hypochlorite (50 percent or less by weight), calcium perchlorate, calcium permanganate, chromium trioxide (chromic acid), copper chlorate, halane (1,3-dichloro-5, 5-dimethylhydantoin), hydrogen peroxide (greater than 27.5 percent up to 52 percent), lead perchlorate, lithium chlorate, lithium hypochlorite (more than 39 percent available chlorine), lithium perchlorate, magnesium bromate, magnesium chlorate, magnesium perchlorate, mercurous chlorate, nitric acid (more than 40 percent but less than 86 percent), perchloric acid solutions (more than 50 percent but less than 60 percent), potassium perchlorate, potassium permanganate, potassium peroxide, potassium superoxide, silver peroxide, sodium chlorite (40 percent or less by weight), sodium perchlorate, sodium perchlorate monohydrate, sodium permanganate, sodium peroxide, strontium chlorate, strontium perchlorate, thallium chlorate, trichloro-s-triazinetrione (trichloroisocyanuric acid), urea hydrogen peroxide, zinc bromate, zinc chlorate, and zinc permanganate.

B.2.1.5.4.4 Class 1. Examples: all inorganic nitrates (unless otherwise classified), all inorganic nitrites (unless otherwise classified), ammonium persulfate, barium peroxide, calcium peroxide, hydrogen peroxide solutions (greater than 8 percent up to 27.5 percent), lead dioxide, lithium hypochlorite (39 percent or less available chlorine), lithium peroxide, magnesium peroxide, manganese dioxide, nitric acid (40 percent concentration or less), perchloric acid solutions (less than 50 percent by weight), potassium dichromate, potassium percarbonate, potassium persulfate, sodium carbonate peroxide, sodium dichloro-s-triazinetrione dihydrate, sodium dichromate, sodium perborate (anhydrous), sodium perborate monohydrate, sodium perborate tetrahydrate, sodium percarbonate, sodium persulfate, strontium peroxide, and zinc peroxide.

B.2.1.6 Organic Peroxides. Examples of organic peroxides according to hazard: Unclassified. Unclassified organic peroxides are capable of detonation and are regulated in accordance with Chapter 75.

B.2.1.6.1 Class I. Examples: acetyl cyclohexane sulfonyl 60-65 percent concentration by weight, fulfonyl peroxide, benzoyl peroxide over 98 percent concentration, *t*-butyl hydroperoxide 90 percent, *t*-butyl peroxyacetate 75 percent, *t*-butyl peroxyisopropylcarbonate 92 percent, diisopropyl peroxydicarbonate 100 percent, di-n-propyl peroxydicarbonate 98 percent, and di-n-propyl peroxydi-carbonate 85 percent.

B.2.1.6.2 Class II. Examples: acetyl peroxide 25 percent, *t*-butyl hydroperoxide 70 percent, *t*-butyl peroxybenzoate 98 percent, *t*-butyl peroxy-2-ethylhex-anoate 97 percent, *t*-butyl peroxyisobutyrate 75 percent, *t*-butyl peroxyisopropyl-carbonate 75 percent, *t*-butyl peroxypivalate 75 percent, dybenz-oyl peroxydicarbonate 85 percent, di-sec-butyl peroxydicarbonate 98 percent, di-sec-butyl peroxydicarbonate 75 percent, 1,1-di-(*t*-butylperoxy)-3,5,5-trimethyecyclohexane 95 percent, di-(2-ethythexyl) peroxydicarbonate 97 percent, 2,5-dymethyl-2-5 di (benzoylperoxy) hexane 92 percent, and peroxyacetic acid 43 percent.

B.2.1.6.3 Class III. Examples: acetyl cyclohexane sulfonal peroxide 29 percent, benzoyl peroxide 78 percent, benzoyl peroxide paste 55 percent, benzoyl peroxide paste 50 percent peroxide/50 percent butylbenzylphthalate diluent, cumene hydroperoxide 86 percent, di-(4-butylcyclohexyl) peroxydicarbonate 98 percent, *t*-butyl peroxy-2-ethytehexanoate 97 percent, *t*-butyl peroxyneodecanoate 75 percent, decanoyl peroxide 98.5 percent, di-*t*-butyl peroxide 99 percent, 1,1-di-(*t*-butylperoxy)-3,5,5-trimethylcyclohexane 75 percent, 2,4-dichlorobenzoyl peroxide 50 percent, diisopropyl peroxydi-carbonate 30 percent, 2,-5-dimethyl-2,5-di-(2-ethylhexanolyperoxy)-hexane 90 percent, 2,5-dimethyl-2,5-di-(*t*-butylperoxy) hexane 90 percent, and methyl ethyl ketone peroxide 9 percent active oxygen diluted in dimethyl phthalate.

B.2.1.6.4 Class IV. Examples: benzoyl peroxide 70 percent, benzoyl peroxide paste 50 percent peroxide/15 percent water/35 percent butylphthalate diluent, benzoyl peroxide slurry 40 percent, benzoyl peroxide powder 35 percent, *t*-butyl hydroperoxide 70 percent, *t*-butyl peroxy-2-ethylhexanoate 50 percent, decumyl peroxide 98 percent, di-(2-ethylhexal) peroxydicarbonate 40 percent, laurel peroxide 98 percent, p-methane hydroperoxide 52.5 percent, methyl ethyl ketone peroxide 5.5 percent active oxygen and methyl ethyl ketone peroxide 9 percent active oxygen diluted in water and glycols.

B.2.1.6.5 Class V. Examples: benzoyl peroxide 35 percent, 1,1-di-*t*-butyl peroxy 3,5,5-trimethylcyclohexane 40 percent, 2,5-di-(*t*-butyl peroxy) hexane 47 percent, and 2,4-pentanedione peroxide 4 percent active oxygen.

B.2.1.7 Pyrophoric Materials.

B.2.1.7.1 Gases. Examples: diborane, phosphine, and silane.

B.2.1.7.2 Liquids. Examples: diethyl aluminum chloride, diethyl beryllium, diethyl phosphine, diethyl zinc, dimethyl arsine, triethyl aluminum etherate, thriethyl bismuthine, thriethyl boron, trimethyl aluminum, and trimethyl gallium.

B.2.1.7.3 Solids. Examples: cesium, hafnium, lithium, white or yellow phosphorus, plutonium, potassium, rubidium, sodium, and thorium.

B.2.1.8 Examples of Unstable (Reactive) Materials According to Hazard. Classification by degree of hazard must be in accordance with Chapter 71.

B.2.1.8.1 Class 4. Examples: acetyl peroxide, dibutyl peroxide, dinitrobenzene, ethyl nitrate, peroxyacetic acid, and picric acid (dry) trinitrobenzene.

B.2.1.8.2 Class 3. Examples: hydrogen peroxide (greater than 52 percent), hydroxylamine, nitromethane, paranitroaniline, perchloric acid, and tetrafluoroethylene monomer.

B.2.1.8.3 Class 2. Examples: acrolein, acrylic acid, hydrazine, methacrylic acid, sodium perchlorate, styrene, and vinyl acetate.

B.2.1.8.4 Class 1. Examples: acetic acid, hydrogen peroxide 35 percent to 52 percent, paraldehyde, and tetrahydrofuran.

B.2.1.9 Examples of Water-Reactive Materials According to Hazard. Classification by degree of hazard must be in accordance with Chapter 73.

B.2.1.9.1 Class 3. Examples: aluminum alkyls such as triethylaluminum, isobutylaluminum, and trimethylaluminum; bromine pentafluoride, bromine trifluoride, chlorodiethylaluminium, and diethylzinc.

B.2.1.9.2 Class 2. Examples: calcium carbide, calcium metal, cyanogen bromide, lithium hydride, methyldichlorosilane, potassium metal, potassium peroxide, sodium metal, sodium peroxide, sulfuric acid, and trichlorosilane.

B.2.1.9.3 Class 1. Examples: acetic anhydride, sodium hydroxide, sulfur monochloride, and titanium tetrachloride.

B.2.1.10 Cryogenic Fluids. All of the cryogenics listed will exist as compressed gases when they are stored at ambient temperatures.

B.2.1.10.1 Flammable. Examples: carbon monoxide, deuterium (heavy hydrogen), ethylene, hydrogen, and methane.

B.2.1.10.2 Oxidizing. Examples: fluorine, nitric oxide, and oxygen.

B.2.1.10.3 Corrosive. Examples: fluorine and nitric oxide.

B.2.1.10.4 Inert (Chemically Unreactive). Examples: argon, helium, krypton, neon, nitrogen, and xenon.

B.2.1.10.5 Highly Toxic. Examples: fluorine and nitric oxide.

B.2.2 Health Hazards.

B.2.2.1 Highly Toxic and Toxic Materials.

B.2.2.1.1 Highly Toxic Materials.

B.2.2.1.1.1 Gases. Examples: arsine, chlorine trifluoride, cyanogen, diborane, fluorine, germane, hydrogen cyanide, nitric oxide, nitrogen dioxide, ozone, phosphine, hydrogen selenide, and stibene.

B.2.2.1.1.2 Liquids. Examples: acrolein, acrylic acid, 2-chloroethanol (ethylene chlorohydrin), hydazine, hydrocyanic acid, 2-methylaziridine (propylenimine), 2-methyllactonitrile (acetone cyanohydrin), methyl ester isocyanic acid (methyl isocyanate), nicotine, tetranitromethane, and tetraethylstannane (tetraethyl tin).

B.2.2.1.1.3 Solids. Examples: (acetato) phenylmercury (phenyl mercuric acetate), 4-aminopyridine, arsenic pentoxide, arsenic trioxide, calcium cyanide, 2-choloroacetophenone, aflatoxin B, decaborane (14), mercury (II) bromide (mercuric bromide), mercury (II) chloride (corrosive mercury chloride), pentachlorophenol, methyl parathion, phosphorus (white), and sodium azide.

B.2.2.1.2 Toxic Materials.

B.2.2.1.2.1 Gases. Examples: boron trichloride, boron trifluoride, chlorine, hydrogen fluoride, hydrogen sulfide, phosgene, and silicon tetrafluoride.

B.2.2.1.2.2 Liquids. Examples: acrylonitrile, allyl alcohol, alpha-chlorotoluene, aniline, 1-chloro-2, 3-epoxypropane, chloroformic acid (allyl ester), 3-chloropropene (allyl chloride), o-cresol, crotonaldehyde, dibromomethane, diisopropylamine, diethyl ester sulfuric acid, dimethyl ester sulfuric acid, 2-furaldehyde (furfural), furfuryl alcohol, phosphorus chloride, phosphoryl chloride (phosphorus oxychloride), and thionyl chloride.

B.2.2.1.2.3 Solids. Examples: acrylamide, barium chloride, barium (II) nitrate, benzidine, p-benzoquinone, beryllium chloride, cadmium chloride, cadmium oxide, chloroacetic acid, chlorophenylmercury (phenyl mercuric chloride), chromium (VI) oxide (chromic acid, solid), 2,4-dinitrotoluene, hydroquinone, mercury chloride (calomel), mercury (II) sulfate (mercuric sulfate), osmium tetroxide, oxalic acid, phenol, P-phenylenediamine, phenylhydrazine, 4-phenylmorpholine, phosphorus sulfide, potassium fluoride, potassium hydroxide, selenium (IV) disulfide, and sodium fluoride.

B.2.2.2 Radioactive Materials. (Reserved)

B.2.2.3 Corrosives.

B.2.2.3.1 Acids. Examples: chromic, formic, hydrochloric (muriatic greater than 15 percent), hydrofluoric, nitric (greater than 6 percent), perchloric, and sulfuric (4 percent or more).

B.2.2.3.2 Bases (Alkalis). Examples: hydroxides — ammonium (greater than 10 percent), calcium, potassium (greater than 1 percent), sodium (greater than 1 percent), and certain carbonates — potassium.

B.2.2.3.3 Other Corrosives. Examples: bromine, chlorine, fluorine, iodine, and ammonia.

Note: Corrosives that are oxidizers, e.g., nitric acid, chlorine, fluorine; or are compressed gases, e.g., ammonia, chlorine, fluorine; or are water-reactive, e.g., concentrated sulfuric acid, sodium hydroxide, are physical hazards in addition to being health hazards.

B.2.2.4 Carcinogens, Irritants, Sensitizers, and Other Health Hazard Materials. (Reserved)

B.3 Evaluation of Hazards

B.3.1 Degree of Hazard. The degree of hazard present depends upon many variables that should be considered individually and in combination. Some of the variables are as follows in B.3.1.1 through B.3.1.3.

B.3.1.1 Chemical Properties of the Material. Chemical properties of the material determine self-reactions and reactions that can occur with other materials. Generally, materials within subdivisions of hazard categories exhibit similar chemical properties. However, materials with similar chemical properties can present very different hazards. Each individual material should be researched to determine its hazardous properties and then considered in relation to other materials that it could contact and the surrounding environment.

B.3.1.2 Physical Properties of the Material. Physical properties, such as whether a material is a solid, liquid, or gas at ordinary temperatures and pressures, considered along with chemical properties determines requirements for containment of the material. Specific gravity (weight of a liquid compared to water) and vapor density (weight of a gas compared to air) are both physical properties that are important in evaluating the hazards of a material.

B.3.1.3 Amount and Concentration of the Material.

B.3.1.3.1 General. The amount of material present and its concentration must be considered along with physical and chemical properties to determine the magnitude of the hazard. Hydrogen peroxide, for example, is used as an antiseptic and a hair bleach in low concentrations (approximately 8 percent in water solution). Over 8 percent, hydrogen peroxide is classed as an oxidizer and is toxic. Above 90 percent, it is a Class 4 oxidizer "that can undergo an explosive reaction when catalyzed or exposed to heat, shock, or friction," a definition that incidentally also places hydrogen peroxide over 90 percent concentration in the unstable (reactive) category. Small amounts at high concentrations can present a greater hazard than large amounts at low concentrations.

B.3.1.3.2 Mixtures. Gases — toxic and highly toxic gases include those gases that have an LC_{50} of 2000 parts per million (ppm) or less when rats are exposed for a period of 1 hour or less. To maintain consistency with the definitions for these materials, exposure data for periods other than 1 hour must be normalized to 1 hour. To classify mixtures of compressed gases that contain one or more toxic or highly toxic components, the LC_{50} of the mixture must be determined. Mixtures that contain only two components are binary mixtures. Those that contain more than two components are multicomponent mixtures. When two or more hazardous substances (components) having an LC_{50} below 2000 ppm are present in a mixture, their combined effect, rather than that of the individual substances (components), must be considered. In the absence of information to the contrary, the effects of the hazards present must be considered as additive. Exceptions to the above rule can be made when there is a good reason to believe that the principal effects of the different harmful substances (components) are not additive.

For binary mixtures where the hazardous component is diluted with a nontoxic gas such as an inert gas, the LC_{50} of the mixture is estimated by use of the following formula:

$$LC_{50m} = \frac{1}{\left(\frac{C_i}{LC_{50i}}\right)} \quad \textbf{[B.3.1.3.2a]}$$

For multicomponent mixtures where more than one component has a listed LC_{50}, the LC_{50} of the mixture is estimated by use of the following formula:

$$LC_{50m} = \frac{1}{\left(\frac{C_{i1}}{LC_{50i1}}\right) + \left(\frac{C_{i2}}{LC_{50i2}}\right) + \left(\frac{C_{in}}{LC_{50\varepsilon}}\right)} \quad \textbf{[B.3.1.3.2b]}$$

where:

LC_{50m} = LC_{50} of the mixture in parts per million (ppm).

C = concentration of component (i) in decimal percent. The concentration of the individual components in a mixture of gases is to be expressed in terms of percent by volume.

LC_{50i} = LC_{50} of component (i). The LC_{50} of the component is based on a 1-hour exposure. LC_{50} data that are for other than 1-hour exposures must be normalized to 1 hour by multiplying the LC_{50} for the time determined by the factor indicated in Table B.3.1.3.2. The preferred mammalian species for LC_{50} data is the rat, as specified in the definitions of toxic and highly toxic in Chapter 3. If data for rats are unavailable, and in the absence of information to the contrary, data for other species can be utilized. The data must be taken in the following order of preference: rat, mouse, rabbit, guinea pig, cat, dog, and monkey.

i_n = component 1, component 2, and so on to the nth component.

Examples:

A. What is the LC_{50} of a mixture of 15 percent chlorine, 85 percent nitrogen? The 1-hour (rat) LC_{50} of pure chlorine is 293 ppm.

LC_{50m} = 1 / (0.15 / 293) or 1953 ppm. Therefore the mixture is toxic.

B. What is the LC_{50} of a mixture of 15 percent chlorine, 15 percent fluorine, and 70 percent nitrogen? The 1-hour (rat) LC_{50} of chlorine is 293 ppm. The 1-hour (rat) LC_{50} of fluorine is 185 ppm.

LC_{50m} = 1 / (0.15 / 293) + (0.15 / 185) or 755 ppm. Therefore the mixture is toxic.

TABLE B.3.1.3.2 Normalization Factor

Time (hours)	Multiply By
0.5	0.7
1.0	1.0
1.5	1.2
2.0	1.4
3.0	1.7
4.0	2.0
5.0	2.2
6.0	2.4
7.0	2.6
8.0	2.8

C. Is the mixture of 1 percent phosphine in argon toxic or highly toxic? The 4-hour (rat) LC_{50} is 11 ppm.

LC_{50m} = 1 / [0.01 / (11 × 2)] or 2200 ppm. Therefore the mixture is neither toxic nor highly toxic. Note that the 4-hour LC_{50} of 11 ppm was normalized to 1 hour by use of Table B.3.1.3.2.

B.3.1.3.3 Actual Use, Activity, or Process Involving the Material. The definition of handling, storage, and use in closed systems refers to materials in packages or containers. Dispensing and use in open containers or systems describes situations where a material is exposed to ambient conditions or vapors are liberated to the atmosphere. Dispensing and use in open systems, then, are generally more hazardous situations than handling, storage, or use in closed systems. The actual use or process can include heating, electric or other sparks, catalytic or reactive materials, and many other factors that could affect the hazard and must therefore be thoroughly analyzed.

B.3.1.3.4 Surrounding Conditions. Conditions such as other materials or processes in the area, type of construction of the structure, fire protection features (e.g., fire walls, sprinkler systems, alarms, etc.), occupancy (use) of adjoining areas, normal temperatures, exposure to weather, etc., must be taken into account in evaluating the hazard.

B.3.2 Evaluation Questions. The following are sample evaluation questions:

(1) What is the material? Correct identification is important; exact spelling is vital. Check labels, MSDS, ask responsible persons, etc.
(2) What are the concentration and strength?
(3) What is the physical form of the material? Liquids, gases, and finely divided solids have differing requirements for spill and leak control and containment.
(4) How much material is present? Consider in relation to permit amounts, exempt amounts (from Group H Occupancy requirements), amounts that require detached storage, and overall magnitude of the hazard.
(5) What other materials (including furniture, equipment, and building components) are close enough to interact with the material?
(6) What are the likely reactions?
(7) What is the activity involving the material?
(8) How does the activity impact the hazardous characteristics of the material? Consider vapors released or hazards otherwise exposed.
(9) What must the material be protected from? Consider other materials, temperature, shock, pressure, etc.
(10) What effects of the material must people and the environment be protected from?
(11) How can protection be accomplished? Consider the following:
  (a) Proper containers and equipment
  (b) Separation by distance or construction
  (c) Enclosure in cabinets or rooms
  (d) Spill control, drainage, and containment
  (e) Control systems — ventilation, special electrical, detection and alarm, extinguishment, explosion venting, limit controls, exhaust scrubbers, and excess flow control
  (f) Administrative (operational) controls — signs, ignition source control, security, personnel training, established procedures, storage plans, and emergency action plans

Evaluation of the hazard is a strongly subjective process; therefore, the person charged with this responsibility must gather as much relevant data as possible so that the decision is objective and within the limits prescribed in laws, policies, and standards.

It could be necessary to cause the responsible persons in charge to have tests made by qualified persons or testing laboratories to support contentions that a particular material or process is or is not hazardous. See 1.4.2.

B.5 Oxidizers and Organic Peroxides

B.5.1 General. This annex provides information, explanations, and examples to illustrate and clarify the hazard categories contained in Chapter 70 and Chapter 75 of this *Code*. The hazard categories are based on 29 CFR. Where numerical classifications are included, they are in accordance with nationally recognized standards.

B.5.2 Oxidizers.

B.5.2.1 General. The oxidizers on the following lists are typical for their class. Each oxidizer is undiluted unless a concentration is specified.

Unless concentration is specified, undiluted material is referenced. The following lists of oxidizers are provided to clarify how the NFPA Hazardous Chemicals Committee has classified typical oxidizers. The lists are not all-inclusive and are amended to reflect typical oxidizers used.

B.5.2.2 Class 1 Oxidizers. The following are typical Class 1 oxidizers:

(1) All inorganic nitrates (unless otherwise classified)
(2) All inorganic nitrites (unless otherwise classified)
(3) Ammonium persulfate
(4) Barium peroxide
(5) Calcium hypochlorite (nominal 80 percent, maximum 81 percent) blended with magnesium sulfate heptahydrate (nominal 20 percent, minimum 19 percent) having an available chlorine of less than or equal to 66 percent and a total water content of at least 17 percent.
(6) Calcium peroxide
(7) Hydrogen peroxide solutions (greater than 8 percent up to 27.5 percent)
(8) Lead dioxide
(9) Lithium hypochlorite (39 percent or less available chlorine)
(10) Lithium peroxide
(11) Magnesium peroxide
(12) Manganese dioxide
(13) Nitric acid (40 percent concentration or less)
(14) Perchloric acid solutions (less than 50 percent by weight)
(15) Potassium dichromate
(16) Potassium percarbonate
(17) Potassium persulfate
(18) Sodium carbonate peroxide
(19) Sodium dichloro-s-triazinetrione dihydrate (sodium dichloroisocyanurate dihydrate)
(20) Sodium dichromate
(21) Sodium perborate (anhydrous)
(22) Sodium perborate monohydrate
(23) Sodium perborate tetrahydrate
(24) Sodium percarbonate
(25) Sodium persulfate
(26) Strontium peroxide
(27) Trichloro-s-triazinetrione [trichloroisocyanuric acid (TCCA; trichlor), all physical forms]
(28) Zinc peroxide [**400:** G.3.2]

B.5.2.3 Class 2 Oxidizers. The following are typical Class 2 oxidizers:

(1) Barium bromate
(2) Barium chlorate
(3) Barium hypochlorite
(4) Barium perchlorate
(5) Barium permanganate
(6) 1-Bromo-3-chloro-5,5-dimethylhydantoin (BCDMH)
(7) Calcium chlorate
(8) Calcium chlorite
(9) Calcium hypochlorite (50 percent or less by weight unless covered by other formulations in Section G.3 of NFPA 400)
(10) Calcium perchlorate
(11) Calcium permanganate
(12) Chromium trioxide (chromic acid)
(13) Copper chlorate
(14) Halane (1,3-dichloro-5,5-dimethylhydantoin)
(15) Hydrogen peroxide (greater than 27.5 percent up to 52 percent)
(16) Lead perchlorate
(17) Lithium chlorate
(18) Lithium hypochlorite (more than 39 percent available chlorine)
(19) Lithium perchlorate
(20) Magnesium bromate
(21) Magnesium chlorate
(22) Magnesium perchlorate
(23) Mercurous chlorate
(24) Nitric acid (more than 40 percent but less than 86 percent)
(25) Nitrogen tetroxide
(26) Perchloric acid solutions (more than 50 percent but less than 60 percent)
(27) Potassium perchlorate
(28) Potassium permanganate
(29) Potassium peroxide
(30) Potassium superoxide
(31) Silver peroxide
(32) Sodium chlorite (40 percent or less by weight)
(33) Sodium perchlorate
(34) Sodium perchlorate monohydrate
(35) Sodium permanganate
(36) Sodium peroxide
(37) Strontium chlorate
(38) Strontium perchlorate
(39) Thallium chlorate
(40) Urea hydrogen peroxide
(41) Zinc bromate
(42) Zinc chlorate
(43) Zinc permanganate [**400:** G.3.3]

B.5.2.4 Class 3 Oxidizers. The following are typical Class 3 oxidizers:

(1) Ammonium dichromate
(2) Calcium hypochlorite (over 50 percent by weight unless covered in other formulations in B.5.2)
(3) Calcium hypochlorite (over 50 percent by weight)
(4) Chloric acid (10 percent maximum concentration)
(5) Hydrogen peroxide solutions (greater than 52 percent up to 91 percent)
(6) Mono-(trichloro)-tetra-(monopotassium dichloro)-penta-s-triazinetrione
(7) Nitric acid, fuming (more than 86 percent concentration)
(8) Perchloric acid solutions (60 percent to 72 percent by weight)
(9) Potassium bromate
(10) Potassium chlorate
(11) Potassium dichloro-s-triazinetrione (potassium dichloroisocyanurate)
(12) Sodium bromate
(13) Sodium chlorate
(14) Sodium chlorite (over 40 percent by weight)

[**400:** G.3.4]

B.5.2.5 Class 4 Oxidizers. The following are typical Class 4 oxidizers:

(1) Ammonium perchlorate (particle size greater than 15 microns)
(2) Ammonium permanganate
(3) Guanidine nitrate
(4) Hydrogen peroxide solutions (greater than 91 percent)
(5) Tetranitromethane

Ammonium perchlorate less than 15 microns is classified as an explosive and, as such, is not covered by NFPA 400. *(See NFPA 495.)* [**400:** G.3.5]

B.5.3 Typical Organic Peroxide Formulations.

Δ **B.5.3.1 General.** The assignment of the organic peroxide formulation classifications shown in the tables in this annex are based on the container sizes shown. A change in the container size could affect the classification. The information in this annex was collected from the Organic Peroxides Producers (Society of the Plastics Industry-Organic Peroxide Producers Safety Division).

For an alphabetical listing of typical organic peroxide formulations, see Table B.5.3.1. [**400:** F.1]

**Depending on package used for tests.

[a]These columns refer to temperatures in the Department of Transportation (DOT) Organic Peroxides Table. (See 49 CFR 173.225 for more information.)

[b]The column refers to NFPA 704 hazard ratings for health, flammability, and instability. *(See NFPA 704 for more information.)*

[c]Diluents Type A — are organic liquids which are compatible with the organic peroxide and which have a boiling point of not less than 150°C. Type A diluents may be used for desensitizing all organic peroxides.

Diluents Type B — are organic liquids which are compatible with the organic peroxide and which have a boiling point of less than 150°C but not less than 60°C and a flash point of not less than 5°C. Type B diluents may be used for desensitizing of all organic peroxides providing that the boiling point is at least 60°C higher than the SADT in a 50 kg package.

[d]See Table F.7 of NFPA 400.

[e]See NFPA 30 for additional storage requirements.

T[f] — Temperature control should be considered to reduce fire hazard depending on packaging size and recommendations in manufacturers' literature.

[**400:**Table F.1]

B.5.3.2 Class I Formulations.

B.5.3.2.1 Fire Hazard Characteristics. Class I formulations present a deflagration hazard through easily initiated, rapid explosive decomposition. Large-scale burn rates ≥300 kg/min can be expected. Class I includes some formulations that are relatively safe only under closely controlled temperatures. Either excessively high or low temperatures can increase the potential for severe explosive decomposition and/or rapid burning. [**400:** F.2.1]

B.5.3.2.2 Fire-Fighting Information. The immediate area should be evacuated and the fire should be fought from a remote location. Some damage to structures from overpressure can be expected should a deflagration occur. [**400:** F.2.2]

Δ **B.5.3.2.3 Typical Class I Formulations.** See Table B.5.3.2.3. [**400:** F.2.3]

[**400:**Table F.2.3]

B.5.3.3 Class II Formulations.

B.5.3.3.1 Fire Hazard Characteristics. Class II formulations present a severe fire hazard similar to Class I flammable liquids. The decomposition is not as rapid or violent as that produced by Class I organic peroxide formulations. As with Class I formulations, this class includes some formulations that are relatively safe when under controlled temperatures or when diluted. Many of the formulations in this class might require controlled temperature or might contain diluents to maintain their safety and stability. [**400:**F.3.1]

B.5.3.3.2 Fire-Fighting Information. Fires should be fought from a safe distance, because a hazard exists from rupturing containers. [**400:** F.3.2]

△ **B.5.3.3.3 Typical Class II Formulations.** See Table B.5.3.3.3. [**400:** F.3.3]

[a]These columns refer to temperatures in the Department of Transportation (DOT) Organic Peroxides Table. *(See 49 CFR 173.225 for more information.)*

[b]The column refers to NFPA 704 hazard ratings for health, flammability, and instability. *(See NFPA 704 for more information.)*

[c]See Table F.7 of NFPA 400.

[d]See NFPA 30 for additional storage requirements.

[e]T — Temperature control should be considered to reduce fire hazard depending on packaging size and recommendations in manufacturers' literature.

[**400:**Table F.3.3]

B.5.3.4 Class III Formulations.

B.5.3.4.1 Fire Hazard Characteristics. Class III formulations present a fire hazard similar to Class II combustible liquids. They are characterized by rapid burning and high heat liberation due to decomposition. Large-scale burn rates of <60 kg/min but ≥10 kg/min are expected for these organic peroxide formulations. These organic peroxides are typically less reactive or contain much higher levels of diluent than the Class I and Class II formulations. [**400:**F.4.1]

B.5.3.4.2 Fire-Fighting Information. Caution should be observed due to possible unexpected increases in fire intensity. [**400:** F.4.2]

Δ **B.5.3.4.3 Typical Class III Formulations.** See Table B.5.3.4.3. [**400:** F.4.3]

B.5.3.5 Class IV Formulations.

B.5.3.5.1 Fire Hazard Characteristics. Class IV formulations present fire hazards that are easily controlled. Reactivity has little effect on fire intensity. Large-scale burn rates of these organic peroxide formulations are <10 kg/min. [**400:** F.5.1]

B.5.3.5.2 Fire-Fighting Information. Normal fire-fighting procedures can be used. [**400:** F.5.2]

Δ **B.5.3.5.3 Typical Class IV Formulations.** See Table B.5.3.5.3. [**400:** F.5.3]

B.5.3.6 Class V Formulations.

B.5.3.6.1 Fire Hazard Characteristics. Class V formulations do not present severe fire hazards. Those that do burn do so with less intensity than ordinary combustibles. [**400:** F.6.1]

B.5.3.6.2 Fire-Fighting Information. Fire-fighting procedures need primarily consider the combustibility of containers. [**400:** F.6.2]

Δ **B.5.3.6.3 Typical Class V Formulations.** See Table B.5.3.6.3. [**400:** F.6.3]

[**400:**Table F.6.3]

Sample Ordinance Adopting the NFPA 1, *Fire Code*

C

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

C.1

The following sample ordinance is provided to assist a jurisdiction in the adoption of this *Code* and is not part of this *Code*.

ORDINANCE NO. ____________________

An ordinance of the *[jurisdiction]* adopting the *[year]* edition of NFPA 1, *Fire Code*, 2015 edition; and documents listed in Chapter 2 of that *Code*; prescribing regulations governing conditions hazardous to life and property from fire or explosion; providing for the issuance of permits and collection of fees; repealing Ordinance No. _______ of the [jurisdiction] and all other ordinances and parts of ordinances in conflict therewith; providing a penalty; providing a severability clause; and providing for publication; and providing an effective date.

BE IT ORDAINED BY THE *[governing body]* **OF THE** *[jurisdiction]*:

SECTION 1 That the NFPA 1, *Fire Code*, 2015 edition, and documents adopted by Chapter 2, three (3) copies of which are on file and are open to inspection by the public in the office of the *[jurisdiction's keeper of records]* of the *[jurisdiction]*, are hereby adopted and incorporated into this ordinance as fully as if set out at length herein, and from the date on which this ordinance shall take effect, the provisions thereof shall be controlling within the limits of the *[jurisdiction]*. The same are hereby adopted as the *Code* of the *[jurisdiction]* for the purpose of prescribing regulations governing conditions hazardous to life and property from fire or explosion and providing for issuance of permits and collection of fees.

SECTION 2 Any person who shall violate any provision of this code or standard hereby adopted or fail to comply therewith; or who shall violate or fail to comply with any order made thereunder; or who shall build in violation of any detailed statement of specifications or plans submitted and approved thereunder; or fail to operate in accordance with any certificate or permit issued thereunder; and from which no appeal has been taken; or who shall fail to comply with such an order as affirmed or modified by a court of competent jurisdiction, within the time fixed herein, shall severally for each and every such violation and noncompliance, respectively, be guilty of a misdemeanor, punishable by a fine of not less than $ _____ nor more than $_____ or by imprisonment for not less than ______ days nor more than ______ days or by both such fine and imprisonment. The imposition of one penalty for any violation shall not excuse the violation or permit it to continue; and all such persons shall be required to correct or remedy such violations or defects within a reasonable time; and when not otherwise specified the application of the above penalty shall not be held to prevent the enforced removal of prohibited conditions. Each day that prohibited conditions are maintained shall constitute a separate offense.

SECTION 3 Additions, insertions, and changes — that the [year] edition of NFPA 1, *Fire Code*, 2015 edition, is amended and changed in the following respects:

[List Amendments]

SECTION 4 That ordinance No. _________ of *[jurisdiction]* entitled *[fill in the title of the ordinance or ordinances in effect at the present time]* and all other ordinances or parts of ordinances in conflict herewith are hereby repealed.

SECTION 5 That if any section, subsection, sentence, clause, or phrase of this ordinance is, for any reason, held to be invalid or unconstitutional, such decision shall not affect the validity or constitutionality of the remaining portions of this ordinance. The *[governing body]* hereby declares that it would have passed this ordinance, and each section, subsection, clause, or phrase hereof, irrespective of the fact that any one or more sections, subsections, sentences, clauses, and phrases be declared unconstitutional.

SECTION 6 That the *[jurisdiction's keeper of records]* is hereby ordered and directed to cause this ordinance to be published.

[NOTE: An additional provision may be required to direct the number of times the ordinance is to be published and to specify that it is to be in a newspaper in general circulation. Posting may also be required.]

SECTION 7 That this ordinance and the rules, regulations, provisions, requirements, orders, and matters established and adopted hereby shall take effect and be in full force and effect *[time period]* from and after the date of its final passage and adoption.

Hazardous Materials Management Plans and Hazardous Materials Inventory Statements

D

This annex is not a part of the requirements of this NFPA document unless specifically adopted by the AHJ.

D.1 Scope

Hazardous materials inventory statements (HMIS) and hazardous materials management plans (HMMP), which are required by the AHJ pursuant to Chapter 60, shall be provided for hazardous materials in accordance with Annex D.

Exception No. 1: Materials that have been satisfactorily demonstrated not to present a potential danger to public health, safety, or welfare, based upon the quantity or condition of storage, when approved.

Exception No. 2: Chromium, copper, lead, nickel, and silver need not be considered hazardous materials for the purposes of this annex unless they are stored in a friable, powdered, or finely divided state. Proprietary and trade secret information shall be protected under the laws of the state or AHJ.

A hazardous materials inventory statement (HMIS) and a hazardous materials management plan (HMMP) are optional tools for the authority having jurisdiction (AHJ). An operator or user of hazardous materials should contact the AHJ to determine whether and when an HMIS and an HMMP are needed. Requirements for the proper use of an HMMP and provisions that are found in a typical HMMP are located in 60.1.6 and Section 60.5. Annex D provides information and a number of sample forms for an HMMP of a typical facility.

Any modification to the forms, time frames, or thresholds found in this annex should be documented before the HMIS or HMMP is prepared. The AHJ should provide the needed information on how to submit the information, to whom it is to be submitted, and what approval form will be provided to the user to confirm that the HMIS or HMMP was accepted by the AHJ.

D.2 Hazardous Materials Inventory Statements (HMIS)

The purpose of an HMIS is to provide the AHJ with comprehensive documentation of the hazardous materials present in a facility. The HMIS allows emergency personnel to respond to an incident appropriately, based on the types and quantities of hazardous materials involved.

D.2.1 When Required. A separate HMIS shall be provided for each building, including its appurtenant structures, and each exterior facility in which hazardous materials are stored. The hazardous materials inventory statement shall list by hazard class all hazardous materials stored. The hazardous materials inventory statement shall include the following information for each hazardous material listed:

(1) Hazard class.
(2) Common or trade name.
(3) Chemical name, major constituents, and concentrations if a mixture. If a waste, the waste category.
(4) Chemical Abstract Service number (CAS number) found in 29 Code of Federal Regulations (CFR).
(5) Whether the material is pure or a mixture, and whether the material is a solid, liquid, or gas.
(6) Maximum aggregate quantity stored at any one time.
(7) Storage conditions related to the storage type, temperature, and pressure.

D.2.2 Changes to HMIS. An amended HMIS shall be provided within 30 days of the storage of any hazardous materials that changes or adds a hazard class or that is sufficient in quantity to cause an increase in the quantity that exceeds 5 percent for any hazard class.

If an HMIS has been developed, both the facility and the AHJ must be prepared to revisit and update the HMIS and HMMP whenever changes are identified that would impact either or both. The ongoing review should include the amount, type, use, or storage of hazardous materials, but the review is not limited simply to quantities for those purposes. If, for example, modifications in facility operating schedules have occurred, such as changing staffing at the facility from a 24-hour, 7-day operation to an 8 a.m. to 5 p.m. operation, 5 days a week, a different warning protection feature might be needed, and the plan would need to reflect other related items that might be affected.

D.3 Hazardous Materials Management Plan (HMMP)

The purpose of an HMMP is to provide specific information on hazardous materials and to specify uses and storage arrangements, as well as incident responses within the facility. The HMMP serves as a key component of the pre-plan for the site. When an HMMP is provided, it must be reviewed, and input should be provided from all impacted parties that would be requested to respond to an incident at the facility. The impacted parties should review their roles in responding to an incident. Training programs and site information should be reviewed and updated as modifications occur or if changes in key participants are modified.

The AHJ has the discretion to decide whether an HMMP is required. Many AHJs use the permit threshold to determine if an HMMP is required. See 1.12.8 for permit thresholds. Others might use an HMMP when the maximum allowable quantities (MAQs) are exceeded. Both of these conditions for imposing an HMMP are local issues and should be reviewed with an understanding of the capabilities of the local emergency responders and resources of the community. Some communities use the type of facility and not the amount of hazardous material (storage quantities only versus use and storage quantities) as a trigger for the HMMP. Annex D was designed to provide information on how to complete an HMMP, not when to invoke the requirement for an HMMP.

D.3.1 General. Applications for a permit to store hazardous materials shall include an HMMP standard form or short form in accordance with Section D.3 and shall provide a narrative description of the operations and processes taking place at the facility. *(See Figure D.3.1.)*

D.3.2 Information Required. The HMMP standard form shall include the information in D.3.2.1 through D.3.2.9.

D.3.2.1 General Information. General information, including business name and address, emergency contacts, business activity, business owner or operator, SIC code, number of employees and hours, Dunn and Bradstreet number, and signature of owner, operator, or designated representative.

D.3.2.2 General Site Plan. A general site plan drawn at a legible scale that shall include, but not be limited to, the location of buildings, exterior storage facilities, permanent access ways, evacuation routes, parking lots, internal roads, chemical loading areas, equipment cleaning areas, storm and sanitary sewer accesses, emergency equipment, and adjacent property uses. The exterior storage areas shall be identified with the hazard class and the maximum quantities per hazard class of hazardous materials stored. When required by the AHJ, information regarding the location of wells, flood plains, earthquake faults, surface water bodies, and general land uses within 1 mile (1.6 km) of the facility boundaries shall be included.

D.3.2.3 Building Floor Plan. A building floor plan drawn to a legible scale that shall include, but not be limited to, hazardous materials storage areas within the building and shall indicate rooms, doorways, corridors, means of egress, and evacuation routes. Each hazardous materials storage facility shall be identified by a map key that lists the individual hazardous materials, their hazard class, and quantity present for each area.

D.3.2.4 Hazardous Materials Handling. Information showing that activities involving the handling of hazardous materials between the storage areas and manufacturing processes on site are conducted in a manner to prevent the accidental release of such materials.

D.3.2.5 Chemical Compatibility and Separation. Information showing procedures, controls, signs, or other methods used to ensure separation and protection of stored materials from factors that could cause accidental ignition or reaction of ignitable, reactive, or incompatible materials in each area.

D.3.2.6 Monitoring Program. Information including, but not limited to, the location, type, manufacturer's specifications, if applicable, and suitability of monitoring methods for each storage facility when required.

D.3.2.7 Inspection and Record Keeping. Schedules and procedures for inspecting safety and monitoring and emergency equipment. The permittee shall develop and follow a written inspection procedure acceptable to the AHJ for inspecting the facility for events or practices that could lead to unauthorized discharges of hazardous materials. Inspections shall be conducted at a frequency appropriate to detect problems prior to a discharge. An inspection check sheet shall be developed to be used in conjunction with routine inspections. The check sheet shall provide for the date, time, and location of inspection; note problems and dates and times of corrective actions taken; and include the name of the inspector and the countersignature of the designated safety manager for the facility.

D.3.2.8 Employee Training. A training program appropriate to the types and quantities of materials stored or used shall be conducted to prepare employees to safely handle hazardous materials on a daily basis and during emergencies. The training program shall include the following:

(1) Instruction in safe storage and handling of hazardous materials, including maintenance of monitoring records
(2) Instruction in emergency procedures for leaks, spills, fires, or explosions, including shutdown of operations and evacuation procedures
(3) Record-keeping procedures for documenting training given to employees

D.3.2.9 Emergency Response. A description of facility emergency procedures is to be provided.

D.3.3 HMMP Short Form — Minimal Storage Site. A facility shall qualify as a minimal storage site if the quantity of each hazardous material stored in one or more facilities in an aggregate quantity for the facility is 500 lb (227 kg) or less for solids, 55 gal (208.2 L) or less for liquids, or 200 ft^3 (5.7 m^3) or less at NTP for

SAMPLE FORMAT
HAZARDOUS MATERIALS MANAGEMENT PLAN (HMMP) INSTRUCTIONS

SECTION I — FACILITY DESCRIPTION

1.1 Part A

1. Fill out Items 1 through 11 and sign the declaration.
2. Only Part A of this section is required to be updated and submitted annually, or within 30 days of a change.

1.2 Part B—General Facility Description (Site Plan)

1. Provide a site plan on 8½ in. by 11 in. (215 mm by 279 mm) paper, using letters on the top and bottom margins and numbers on the right and left side margins, showing the location of all buildings, structures, chemical loading areas, parking lots, internal roads, storm and sanitary sewers, wells, and adjacent property uses. Indicate the approximate scale, northern direction and date the drawing was completed.
2. List all special land uses within 1 mile (1.609 km).

1.3 Part C—Facility Storage Map (Confidential Information)

1. Provide a floor plan of each building on 8½ in. by 11 in. (215 mm by 279 mm) paper, using letters on the top and bottom margins and numbers on the right and left side margins, with approximate scale and northern direction, showing the location of each storage area. Mark map clearly "Confidential — Do Not Disclose" for trade-secret information as specified by federal, state, and local laws.
2. Identify each storage area with an identification number, letter, name, or symbol.
3. Show the following:
   - (a) Accesses to each storage area.
   - (b) Location of emergency equipment.
   - (c) The general purpose of other areas within the facility.
   - (d) Location of all aboveground and underground tanks to include sumps, vaults, belowgrade treatment systems, piping, etc.
4. **Map key.** Provide the following on the map or in a map key or legend for each storage area:
   - (a) A list of hazardous materials, including wastes.
   - (b) Hazard class of each hazardous waste.
   - (c) The maximum quantity for hazardous materials.
   - (d) Include the contents and capacity limit of all tanks at each area and indicate whether they are above or below ground.
   - (e) List separately any radioactives, cryogens, and compressed gases for each facility.
   - (f) Trade-secret information shall be listed as specified by federal, state, and local laws.

SECTION II — HAZARDOUS MATERIALS INVENTORY STATEMENT (HMIS)

2.1 Part A—Declaration

Fill out all appropriate information.

2.2 Part B—Inventory Statement

1. You must complete a separate inventory statement for all waste and nonwaste hazardous materials. List all hazardous materials in alphabetical order by hazard class.
2. Inventory Statement Instructions.

Column	Information Required
1	Provide hazard class for each material.
2	**Nonwaste.** Provide the common or trade name of the regulated material. **Waste.** In lieu of trade names, you may provide the waste category.
3	Provide the chemical name and major constituents and concentrations, if a mixture.
4	Enter the chemical abstract service number (CAS number) found in 29 CFR. For mixtures, enter the CAS number of the mixture as a whole if it has been assigned a number distinct from its constituents. For a mixture that has no CAS number, leave this item blank or report the CAS numbers of as many constituent chemicals as possible.
5	Enter the following descriptive codes as they apply to each material. You may list more than one code, if applicable. P = Pure M = Mixture S = Solid L = Liquid G = Gas
6	Provide the maximum aggregate quantity of each material handled at any one time by the business. For underground tanks, list the maximum volume [in gallons (liters)] of the tank. Enter the estimated average daily amount on site during the past year.
7	Enter the units used in Column 6 as: Lb = Pounds Ga = Gallons Cf = Cubic Feet
8	Enter the number of days that the material was present on site (during the last year).

 NFPA 1 (p. 1 of 8)

Δ ***FIGURE D.3.1*** *Sample Format of Hazardous Materials Management Plan (HMMP) Instructions.*

Column	Information Required
9	Enter the storage codes below for type, temperature, and pressure:

Type

A = Aboveground Tank
B = Belowground Tank
C = Tank Inside Building
D = Steel Drum
E = Plastic or Nonmetallic Drum
F = Can
G = Carboy
H = Silo
I = Fiber Drum
J = Bag
K = Box
L = Cylinder
M = Glass Bottle or Jug
N = Plastic Bottles or Jugs
O = Tote Bin
P = Tank Wagon
Q = Rail Car
R = Other

Temperature

4 = Ambient
5 = Greater than Ambient
6 = Less than Ambient, but not Cryogenic [less than –150°F (–101.1°C)]
7 = Cryogenic conditions [less than –150°F (–101.1°C)]

Pressure

1 = Ambient (Atmospheric)
2 = Greater than Ambient (Atmospheric)
3 = Less than Ambient (Atmospheric)

10 For each material listed, provide the SARA Title III hazard class as listed below. You may list more than one class. These categories are defined in 40 CFR 370.3.

Physical Hazard

F = Fire
P = Sudden Release of Pressure
R = Reactivity

Health Hazard

I = Immediate (Acute)
D = Delayed (Chronic)

11 **Waste Only.** For each waste, provide the total estimated amount of hazardous waste handled throughout the course of the year.

SECTION III — SEPARATION AND MONITORING

3.1 Part A — Aboveground

Fill out Items 1 through 6, or provide similar information for each storage area shown on the facility map. Use additional sheets as necessary.

3.2 Part B — Underground

1. Complete a separate page for each underground tank, sump, vault, belowgrade treatment system, etc.
2. Check the type of tank and method(s) that applies to your tank(s) and piping, and answer the appropriate questions. Provide any additional information in the space provided or on a separate sheet.

SECTION IV — WASTE DISPOSAL

Check all that apply and list the associated wastes for each method checked.

SECTION V — RECORD KEEPING

Include a brief description of your inspection procedures. You are also required to keep an inspection log and recordable discharge log, which are designed to be used in conjunction with routine inspections for all storage facilities or areas. Place a check in each box that describes your forms. If you do not use the sample forms, provide copies of your forms for review and approval.

SECTION VI — EMERGENCY RESPONSE PLAN

1. This plan should describe the personnel, procedures, and equipment available for responding to a release or threatened release of hazardous materials that are stored, handled, or used on site.
2. A check or a response under each item indicates that a specific procedure is followed at the facility, or that the equipment specified is maintained on site.
3. If the facility maintains a more detailed emergency response plan on site, indicate this in Item 5. This plan shall be made available for review by the inspecting jurisdiction.

SECTION VII — EMERGENCY RESPONSE TRAINING PLAN

1. This plan should describe the basic training plan used at the facility.
2. A check in the appropriate box indicates the training is provided or the records are maintained.
3. If the facility maintains a more detailed emergency response training plan, indicate this in Item 4. This plan shall be made available for review by the inspecting jurisdiction.

SECTION VII: EMERGENCY RESPONSE TRAINING PLAN

1. Person responsible for the emergency response training plan:

Name	Title	Phone
______________	______________	______________

2. Training Requirements:
   A. All employees trained in the following as indicated:
      ______ Procedures for internal alarm/notification
      ______ Procedures for notification of external emergency response organizations
      ______ Location and content of the emergency response plan
   B. Chemical handlers are trained in the following as indicated:
      ______ Safe methods for handling and storage of hazardous materials
      ______ Proper use of personal protective equipment
      ______ Locations and proper use of fire- and spill-control equipment
      ______ Specific hazards of each chemical to which they may be exposed
   C. Emergency response team members are trained in the following:
      ______ Procedures for shutdown of operations
      ______ Procedures for using, maintaining, and replacing facility emergency and monitoring equipment

3. The following records are maintained for all employees:
   ______ Verification that training was completed by the employee
   ______ Description of the type and amount of introductory and continuing training
   ______ Documentation on and description of emergency response drills conducted at the facility

4. A more comprehensive and detailed emergency response training plan is maintained on site.
   Location: ______________________________
   Responsible Person: ______________________________
   Phone: ______________________________

 NFPA 1 (p. 8 of 8)

Δ ***FIGURE D.3.1*** *Continued*

compressed gases and does not exceed the threshold planning quantity as listed in 40 CFR 355 Sections 302 and 304. The applicant for a permit for a facility that qualifies as a minimal storage site shall be permitted to file the short form HMMP. Such plan shall include the following components:

(1) General facility information
(2) A simple line drawing of the facility showing the location of storage facilities and indicating the hazard class or classes and physical state of the hazardous materials being stored
(3) Information describing that the hazardous materials will be stored and handled in a safe manner and will be appropriately contained, separated, and monitored
(4) Assurance that security precautions have been taken, employees have been appropriately trained to handle the hazardous materials and react to emergency situations, adequate labeling and warning signs are posted, adequate emergency equipment is maintained, and the disposal of hazardous materials will be in an appropriate manner

Subsection D.3.3 provides a short version of the HMMP so that if the local AHJ requires only limited information, this tool can be used without overburdening the facility. The thresholds listed are provided as guidelines for the use of the form but can be modified when adopted by the local AHJ.

D.4 Maintenance of Records

Hazardous materials inventory statements and hazardous materials management plans shall be maintained by the permittee for a period of not less than 3 years after submittal of updated or revised versions. Such records shall be made available to the AHJ upon request.

Fire Fighter Safety Building Marking System

E

This annex is not a part of the requirements of this NFPA document unless specifically adopted by the AHJ.

E.1 Fire Fighter Safety Building Marking System (FFSBMS)

The fire fighter safety building marking system (FFSBMS) was designed by fire service members as a tool to help responding fire fighters quickly determine certain information about a building and its occupants. Information about the building construction, sprinkler systems and standpipe systems, hazards of contents, occupants, and special hazards is placed on a single, easy-to-read sign. Note that this system does not take the place of fire department pre-fire planning.

To be adopted as part of a jurisdiction's fire code, Annex E must be specifically named in the adopting ordinance.

E.1.1 General.

E.1.1.1 The fire fighter safety building marking system provides basic building information for fire fighters responding to the building or structure.

E.1.1.2 Where required by the AHJ, buildings and structures shall have the fire fighter safety building marking system sign installed.

E.1.2 Sign.

E.1.2.1 The approved fire fighter safety building marking system sign shall be placed in a position to be plainly legible and visible from the street or road fronting the property or as approved by the fire department.

The FFSBMS sign must be placed in a location where responding fire fighters can easily see it. The authority having jurisdiction (AHJ) should consult with the fire department to determine where the sign is to be located. The fire department might require more than one sign based on its response plan for the location. At least one sign should be located near the access box to help ensure that fire fighters see it.

E.1.2.2 The fire fighter safety building marking system sign shall consist of the following:

(1) White reflective background with black letters
(2) Durable material
(3) Arabic numerals or alphabet letters
(4) Permanently affixed to the building or structure in an approved manner

The FFSBMS sign must be designed to be visible in all lighting conditions. The sign is to be permanently installed and affixed to the building. Paper or other nonpermanent signs should not be permitted.

E.1.2.3 The fire fighter safety building marking system shall be a Maltese cross as shown in Figure E.1.2.3.

E.1.2.4 The minimum size of the fire fighter safety building marking system sign and lettering shown in Figure E.1.2.4 shall

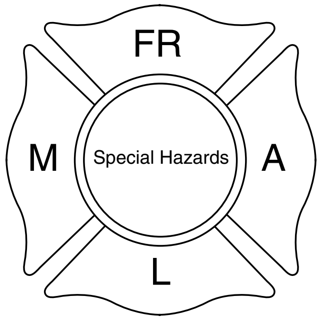

FIGURE E.1.2.3 *Sample Sign for Fire Fighter Safety Building Marking System.*

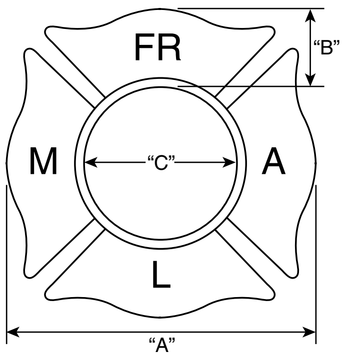

FIGURE E.1.2.4 *Dimensions for Fire Fighter Safety Building Marking System Signs.*

be in accordance with the following or as approved by the fire department:

(1) *A* shall be 5 in. × 5 in.
(2) *B* shall be 1¼ in.
(3) *C* shall be 2½ in.
(4) Letters shall be 1 in. height with a stroke of ¼ in.

The minimum sign size required by E.1.2.4 is 5 in. by 5 in. (127 mm by 127 mm). If the NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response,* marking system is to be included in the center of the sign, then the NFPA 704 sign must meet the size requirements outlined in NFPA 704. See the commentary following E.1.3.6.

E.1.3 Ratings.

E.1.3.1 Ratings shall be determined by the construction type, hazards of contents, automatic fire sprinkler systems and standpipe systems, occupancy/life safety, and special hazards in accordance with this section.

E.1.3.1.1 Where multiple ratings occur within a classification category, a determination shall be made by the AHJ of the rating that shall be based on the greatest potential risk for the specific category. *(See Note 1 in E.2.1.)*

Many buildings have numerous occupancies, construction types, or other ratings that could affect the FFSBMS. The AHJ should be consulted as to which rating to place in the appropriate hazard placeholder. An example of the greatest potential risk for construction type is where fire-resistive (FR) and noncombustible (NC) construction types are present. In that case, the suggested ranking for the FFSBMS is NC, because the risk of structural failure due to fire is greater with noncombustible construction compared to that associated with fire-resistive construction.

E.1.3.2 Construction Type. The construction type shall be designated by assigning the appropriate lettering to the top of the Maltese cross as follows:

(1) FR — Fire-resistive construction
(2) NC — Noncombustible construction
(3) ORD — Ordinary construction
(4) HT — Heavy timber construction
(5) C — Combustible construction

The construction types identified in E.1.3.2 are those used in fire fighter training programs. If the fire department prefers to use the construction types used by the building code adopted in its jurisdiction, it can easily change the designation. For a cross reference of building construction types, see Table A.12.2.

E.1.3.3 Hazards of Contents. The hazards of contents shall be rated by determining its hazard and assigning the appropriate rating to the left of the Maltese cross as follows *(see Note 2 in E.2.2)*:

L — Low hazard. Low hazard contents shall be classified as those of such low combustibility that no self-propagating fire therein can occur.

M — Moderate hazard. Moderate hazard contents shall be classified as those that are likely to burn with moderate rapidity or to give off a considerable volume of smoke.

H — High hazard. High hazard contents *(see Note 3 in E.2.3)* shall be classified as those that are likely to burn with extreme rapidity or from which explosions are likely.

The hazards of content ratings that are identified in E.1.3.3 are based on 6.2.2 NFPA *101*®, *Life Safety Code*®, as follows:

> **Low Hazard Contents.** Low hazard contents are classified as those of such low combustibility that no self-propagating fire therein can occur. Storage occupancies recognize storage of noncombustible materials as low hazard. In other occupancies, it is assumed that, even where the actual contents hazard is normally low, there is sufficient likelihood that some combustible materials or hazardous operations will be introduced in connection with building repair or maintenance, or some psychological factor might create conditions conducive to panic, so that the egress facilities cannot safely be reduced below those specified for ordinary hazard contents.
>
> **Ordinary Hazard Contents.** Ordinary hazard contents are classified as those that are likely to burn with moderate rapidity or to give off a considerable volume of smoke. Ordinary hazard classification represents the conditions found in most buildings and is the basis for the general requirements of this *Code*.
>
> The fear of poisonous fumes or explosions is necessarily a relative matter to be determined on a judgment basis. All smoke contains some toxic fire gases but, under conditions of ordinary hazard, there should be no unduly dangerous exposure during the period necessary to escape from the fire area, assuming there are proper exits.
>
> **High Hazard Contents.** High hazard contents are classified as those that are likely to burn with extreme rapidity or from which explosions are likely. High hazard contents include occupancies where flammable liquids are handled or used or are stored under conditions involving possible release of flammable vapors; where grain dust, wood flour or plastic dust, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where materials are processed or handled under conditions producing flammable flyings; and other situations of similar hazard.

E.1.3.4 Automatic Fire Sprinkler and Standpipe System. The automatic fire sprinkler system and standpipe system shall be rated by determining its level of protection and assigning the appropriate rating to the right of the Maltese cross. If multiple systems are provided, all systems shall be included in the Maltese cross as follows:

(1) A — Automatic fire sprinkler system installed throughout
(2) P — Partial automatic fire sprinkler system or other suppression system installed
(3) S — Standpipe system installed
(4) N — None

E.1.3.5 Occupancy/Life Safety Issues. The occupancy/life safety type shall be rated by determining the level of difficulty in evacuating occupants from the building and the occupancy type by assigning the appropriate rating to the bottom of the Maltese cross as follows:

(1) L — Business, industrial, mercantile, residential, and storage occupancies
(2) M — Ambulatory health care, assembly, educational, and day care occupancies
(3) H — Detention and correction facilities, health care, and board and care occupancies

The occupancy ratings identified in E.1.3.5 are based on the number of occupants in a facility and whether the occupants are ambulatory or nonambulatory, or otherwise incapable of self-preservation, such as occupants in a detention and correctional occupancy. The rating will be higher where relatively large numbers of occupants, nonambulatory occupants, or occupants who are incapable of self-preservation are present.

E.1.3.6 Special Designations. The special hazards can be assigned to the center of the Maltese cross *(see Note 4 in E.2.4)*.

The center of the FFSBMS sign is left empty to provide space for additional information at the discretion of the local jurisdiction. The NFPA 704 marking system can be incorporated into the center of the FFSBMS sign if all the applicable provisions of NFPA 704 are met, such as lettering size.

E.1.4 Installation and Maintenance.

E.1.4.1 Fire departments that implement the fire fighter safety building marking system (FFSBMS) shall provide written instructions to the owner/operator of a facility equipped with a fire fighter safety building marking system sign regarding the information to be included on the sign, and the fire department shall perform annual inspections to verify continued compliance with the information shown on the sign *(see Note 5 in E.2.5)*.

The intent of E.1.4.1 is to verify on a regular basis that the information on the FFSBMS sign is correct. Fire departments responding to facilities equipped with an FFSBMS sign should verify signage and pre-plans annually. Other means of verifying the information on the sign could include mailings, use of outside consultants, and community service programs.

E.1.4.2 Installation and maintenance of the sign shall be the responsibility of the owner/operator.

E.1.4.3 The fire department shall enact procedures to identify changes of occupancy that could establish a need to update information on the sign and shall notify the owner/operator when changes are necessary.

The fire department should provide written procedures to building owners that establish when ratings on the FFSBMS need to be changed, such as in the case of a change of occupancy classification, which requires review by the AHJ in accordance with 1.7.12.5.

E.1.5 Training.

E.1.5.1 Training shall be provided to all fire department personnel responding to buildings using the FFSBMS sign.

E.2 Notes

The following notes are explanatory and are not part of the mandatory text for Annex E.

E.2.1 Note 1. An example of the greatest potential risk for construction type where an FR and an NC are present, the ranking on the FFSBMS sign would be NC.

E.2.2 Note 2. Hazard of contents are described as follows:

Low hazard recognizes storage of noncombustible materials as low hazard. In other occupancies it is assumed that, even where the actual contents hazard is normally low, there is sufficient likelihood that some combustible materials or hazardous operations will be introduced in connection with building repair or maintenance, or some psychological factor might create conditions conducive to panic, so that the egress facilities cannot safely be reduced below those specified for ordinary hazard contents.

Moderate hazard classification represents the conditions found in most buildings and is the basis for the general requirements of this *Code*.

The fear of poisonous fumes or explosions is necessarily a relative matter to be determined on a judgment basis. All smoke contains some toxic fire gases but, under conditions of moderate hazard, there should be no unduly dangerous exposure during the period necessary to escape from the fire area, assuming there are proper exits.

E.2.3 Note 3. High hazard contents include occupancies where flammable liquids are handled or used or are stored under conditions involving possible release of flammable vapors; where grain dust, wood flour or plastic dust, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where cotton or other combustible fibers are processed or handled under conditions producing flammable flyings; and other situations of similar hazard.

E.2.4 Note 4. The center of the fire fighter safety building marking system sign has been left empty to permit the local jurisdiction space to provide for additional information that they may wish to add. The NFPA 704 marking system can be incorporated into the center of the fire fighter safety building marking system sign if all the applicable provisions of NFPA 704 are met including lettering size and so forth.

E.2.5 Note 5. The intent of this provision is to verify that the information on the FFSBMS sign is correct on a regular basis. Fire departments responding to facilities equipped with a FFSBMS sign should verify signage and preplans annually. Other means of verifying the information on the FFSBMS sign could include mailings, outside consultants, and community service programs.

F

Fire Fighter Breathing-Air Replenishment Systems

N *This annex is not a part of the requirements of this NFPA document unless specifically adopted by the AHJ.*

N F.1 General

Where required by the AHJ, fire fighter breathing-air replenishment systems shall comply with Appendix F of the *Uniform Plumbing Code*.

Annex F is new to the 2018 edition of the *Code*. It provides the necessary guidance for those jurisdictions using fire fighter air replenishment systems. It should be noted that these systems are not mandated by the *Code* and that this annex is included solely to provide assistance to those authorities having jurisdiction (AHJs) that need to enforce fire fighter breathing-air replenishment system regulations in their jurisdictions.

IMPORTANT NOTICES AND DISCLAIMERS CONCERNING NFPA® STANDARDS

NOTICE AND DISCLAIMER OF LIABILITY CONCERNING THE USE OF NFPA STANDARDS

NFPA® codes, standards, recommended practices, and guides ("NFPA Standards"), of which the document contained herein is one, are developed through a consensus standards development process approved by the American National Standards Institute. This process brings together volunteers representing varied viewpoints and interests to achieve consensus on fire and other safety issues. While the NFPA administers the process and establishes rules to promote fairness in the development of consensus, it does not independently test, evaluate, or verify the accuracy of any information or the soundness of any judgments contained in NFPA Standards.

The NFPA disclaims liability for any personal injury, property or other damages of any nature whatsoever, whether special, indirect, consequential or compensatory, directly or indirectly resulting from the publication, use of, or reliance on NFPA Standards. The NFPA also makes no guaranty or warranty as to the accuracy or completeness of any information published herein.

In issuing and making NFPA Standards available, the NFPA is not undertaking to render professional or other services for or on behalf of any person or entity. Nor is the NFPA undertaking to perform any duty owed by any person or entity to someone else. Anyone using this document should rely on his or her own independent judgment or, as appropriate, seek the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

The NFPA has no power, nor does it undertake, to police or enforce compliance with the contents of NFPA Standards. Nor does the NFPA list, certify, test, or inspect products, designs, or installations for compliance with this document. Any certification or other statement of compliance with the requirements of this document shall not be attributable to the NFPA and is solely the responsibility of the certifier or maker of the statement.

ADDITIONAL NOTICES AND DISCLAIMERS

Updating of NFPA Standards

Users of NFPA codes, standards, recommended practices, and guides ("NFPA Standards") should be aware that these documents may be superseded at any time by the issuance of new editions or may be amended from time to time through the issuance of Tentative Interim Amendments or corrected by Errata. An official NFPA Standard at any point in time consists of the current edition of the document together with any Tentative Interim Amendments and any Errata then in effect. In order to determine whether a given document is the current edition and whether it has been amended through the issuance of Tentative Interim Amendments or corrected through the issuance of Errata, consult appropriate NFPA publications such as the National Fire Codes® Subscription Service, visit the NFPA website at www.nfpa.org, or contact the NFPA at the address listed below.

Interpretations of NFPA Standards

A statement, written or oral, that is not processed in accordance with Section 6 of the Regulations Governing the Development of NFPA Standards shall not be considered the official position of NFPA or any of its Committees and shall not be considered to be, nor be relied upon as, a Formal Interpretation.

Patents

The NFPA does not take any position with respect to the validity of any patent rights referenced in, related to, or asserted in connection with an NFPA Standard. The users of NFPA Standards bear the sole responsibility for determining the validity of any such patent rights, as well as the risk of infringement of such rights, and the NFPA disclaims liability for the infringement of any patent resulting from the use of or reliance on NFPA Standards.

NFPA adheres to the policy of the American National Standards Institute (ANSI) regarding the inclusion of patents in American National Standards ("the ANSI Patent Policy"), and hereby gives the following notice pursuant to that policy:

> **NOTICE:** The user's attention is called to the possibility that compliance with an NFPA Standard may require use of an invention covered by patent rights. NFPA takes no position as to the validity of any such patent rights or as to whether such patent rights constitute or include essential patent claims under the ANSI Patent Policy. If, in connection with the ANSI Patent Policy, a patent holder has filed a statement of willingness to grant licenses under these rights on reasonable and nondiscriminatory terms and conditions to applicants desiring to obtain such a license, copies of such filed statements can be obtained, on request, from NFPA. For further information, contact the NFPA at the address listed below.

Law and Regulations

Users of NFPA Standards should consult applicable federal, state, and local laws and regulations. NFPA does not, by the publication of its codes, standards, recommended practices, and guides, intend to urge action that is not in compliance with applicable laws, and these documents may not be construed as doing so.

Copyrights

NFPA Standards are copyrighted. They are made available for a wide variety of both public and private uses. These include both use, by reference, in laws and regulations, and use in private self-regulation, standardization, and the promotion of safe practices and methods. By making these documents available for use and adoption by public authorities and private users, the NFPA does not waive any rights in copyright to these documents.

Use of NFPA Standards for regulatory purposes should be accomplished through adoption by reference. The term "adoption by reference" means the citing of title, edition, and publishing information only. Any deletions, additions, and changes desired by the adopting authority should be noted separately in the adopting instrument. In order to assist NFPA in following the uses made of its documents, adopting authorities are requested to notify the NFPA (Attention: Secretary, Standards Council) in writing of such use. For technical assistance and questions concerning adoption of NFPA Standards, contact NFPA at the address below.

For Further Information

All questions or other communications relating to NFPA Standards and all requests for information on NFPA procedures governing its codes and standards development process, including information on the procedures for requesting Formal Interpretations, for proposing Tentative Interim Amendments, and for proposing revisions to NFPA standards during regular revision cycles, should be sent to NFPA headquarters, addressed to the attention of the Secretary, Standards Council, NFPA, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101; email: stds_admin@nfpa.org

For more information about NFPA, visit the NFPA website at www.nfpa.org. All NFPA codes and standards can be viewed at no cost at www.nfpa.org/docinfo.
